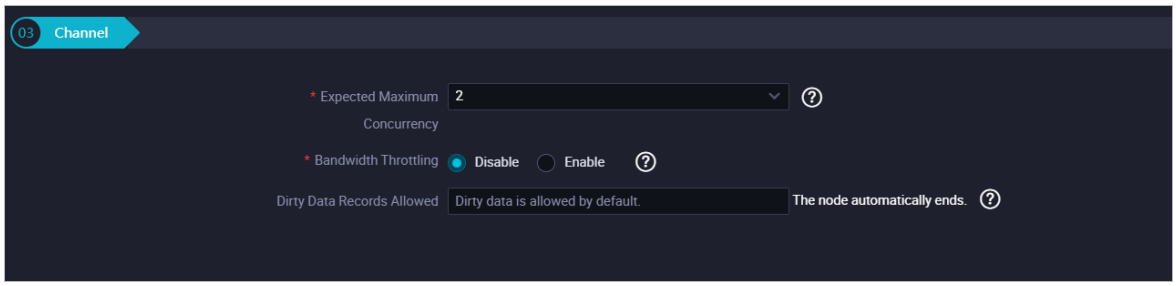
Table	This parameter corresponds to the table parameter that is described in the preceding section.
Statement Run Before Writing	This parameter corresponds to the preSql parameter that is described in the preceding section. Enter the SQL statement that you want to execute before the synchronization node is run.
Statement Run After Writing	This parameter corresponds to the postSql parameter that is described in the preceding table. Enter the SQL statement that you want to execute after the synchronization node is run.
Solution to Primary Key Violation	This parameter corresponds to the writeMode parameter that is described in the preceding section. You can select the desired write mode.

2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in the preceding section. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that are established.

Operation	Description
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on specific rules.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure MySQL Writer by using the code editor

In the following code, a synchronization node is configured to write data to MySQL. For more information about the parameters, see the preceding parameter description.

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"mysql",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement that you want to execute after the synchronization
node is run.
                "datasource":"",// The name of the data source.
                "column":[// The names of the columns to which you want to write data.
                    "id",
                    "value"
                ],
                "writeMode":"insert",// The write mode.
                "batchSize":1024,// The number of data records to write at a time.
                "table":"",// The name of the table to which you want to write data.
                "preSql":[]// The SQL statement that you want to execute before the synchronization
node is run.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{// The maximum number of dirty data records allowed.
            "record":"0"
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling.
            "concurrent":1// The number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.13. Oracle Writer

This topic describes the data types and parameters that are supported by Oracle Writer and how to configure Oracle Writer by using the codeless user interface (UI) and code editor.

Oracle Writer writes data to tables stored in primary Oracle databases. Oracle Writer connects to a remote Oracle database by using Java Database Connectivity (JDBC) and executes the `INSERT INTO` statement to write data to the Oracle database.

> **Note** Before you configure Oracle Writer, you must configure an Oracle data source. For more information, see Configure an Oracle connection.

Oracle Writer is designed for extract, transform, load (ETL) developers to import data from data warehouses to Oracle databases. Oracle Writer can also be used as a data migration tool by users such as database administrators.

Oracle Writer obtains data from a Data Integration reader, connects to a remote Oracle database by using JDBC, and then executes an SQL statement to write data to the Oracle database.

Data types

Oracle Writer supports most Oracle data types. Make sure that the data types of your database are supported.

The following table lists the data types that are supported by Oracle Writer.

Category	Oracle data type
Integer	NUMBER, ROWID, INTEGER, INT, and SMALLINT
Floating point	NUMERIC, DECIMAL, FLOAT, DOUBLE PRECISION, and REAL
String	LONG, CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR2, CLOB, NCLOB, CHARACTER, CHARACTER VARYING, CHAR VARYING, NATIONAL CHARACTER, NATIONAL CHAR, NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING, and NCHAR VARYING
Date and time	TIMESTAMP and DATE
Boolean	BIT and BOOLEAN
Binary	BLOB, BFILE, RAW, and LONG RAW

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
table	If the table uses the default schema for the destination database, set this parameter to the name of the table to which you want to write data. If the table does not use the default schema for the destination database, specify this parameter in the Schema name.Name of the table to which you want to write data format.	Yes	No default value

Parameter	Description	Required	Default value
writeMode	The write mode. Valid values: *insert into*, *on duplicate key update*, and *replace into*. • *insert into*: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. • *on duplicate key update*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, specified fields in the original rows are replaced by new rows, and data is written to Oracle. • *replace into*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, the original rows are deleted, and new rows are inserted. This indicates that all fields of the original rows are replaced.	No	*insert*
column	The names of the columns to which you want to write data in the destination table. Separate the names with commas (,), such as `"column": ["id","name","age"]`. If you want to write data to all the columns in the destination table, set this parameter to an asterisk (*), such as `"column":["*"]`.	Yes	No default value
preSql	The SQL statement that you want to execute before the synchronization node is run. For example, you can set this parameter to the SQL statement that is used to delete outdated data. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	No default value
postSql	The SQL statement that you want to execute after the synchronization node is run. For example, you can set this parameter to the SQL statement that is used to add a timestamp. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	No default value
batchSize	The number of data records to write at a time. Set this parameter to an appropriate value based on your business requirements. This greatly reduces the interactions between Data Integration and Oracle and increases throughput. If you set this parameter to an excessively large value, an out of memory (OOM) error may occur during data synchronization.	No	*1,024*

Parameter	Description	Required	Default value

driverVersion	The version of the driver that can be used to access the database. Valid values: ojdbc5, ojdbc6, ojdbc7, ojdbc8, and ojdbc14.
	If you want to use a driver of a specific version that is compatible with the database, add the following configurations by using the code editor:
	`"driverVersion": "ojdbc5" // Driver version of ojdbc5-11.2.0.3.jar`
	`"driverVersion": "ojdbc6" // Driver version of ojdbc6-12.1.1.jar`
	`"driverVersion": "ojdbc7" // Driver version of ojdbc7-12.1.0.2.jar`
	`"driverVersion": "ojdbc8" // Driver version of ojdbc8-12.2.0.1.jar`
	`"driverVersion": "ojdbc14" // Driver version of ojdbc14-10.2.0.3.0.jar`
		No	No default value

Configure Oracle Writer by using the codeless UI

1. Configure data sources.

   Log on to the DataWorks console. The **DataStudio** page appears. On the DataStudio page, move the pointer over the icon and choose **Data Integration > Batch Synchronization**. In the **Create Node** dialog box, configure the parameters to create a batch synchronization node.

   Configure **Source** and **Target** for the synchronization node.

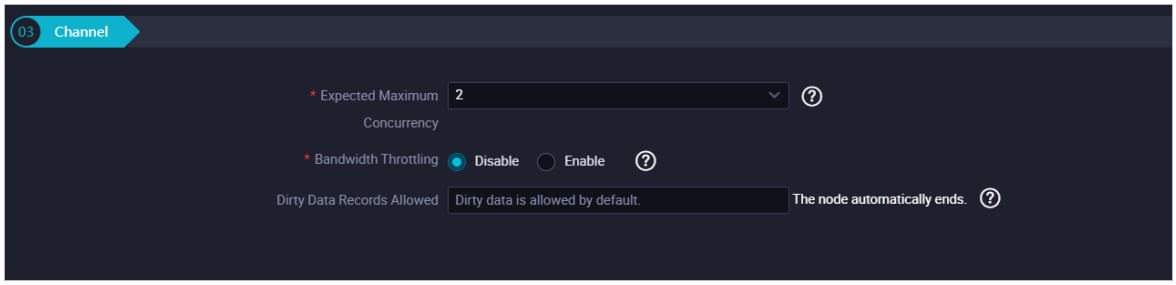
Parameter	Description
Connection	The name of the data source to which you want to write data. This parameter corresponds to the datasource parameter that is described in the preceding section.
Table	The name of the table to which you want to write data. This parameter corresponds to the table parameter that is described in the preceding section.
Statement Run Before Writing	The SQL statement that you want to execute before the synchronization node is run. This parameter corresponds to the preSql parameter that is described in the preceding section.
Statement Run After Writing	The SQL statement that you want to execute after the synchronization node is run. This parameter corresponds to the postSql parameter that is described in the preceding section.

2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in

the preceding section. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove the mappings that are established.
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on specific rules.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure Oracle Writer by using the code editor

In the following code, a synchronization node is configured to write data to Oracle:

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"oracle",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement that you want to execute after the synchronization node is run.
                "datasource":"",
                "session":[],// The settings of the session to the database.
                "column":[// The names of the columns to which you want to write data.
                    "id",
                    "name"
                ],
                "encoding":"UTF-8",// The encoding format.
                "batchSize":1024,// The number of data records to write at a time.
                "table":"",// The name of the table to which you want to write data.
                "preSql":[]// The SQL statement that you want to execute before the synchronization node is run.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. The value false indicates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttling is enabled. The mbps parameter takes effect only when the throttle parameter is set to true.
            "concurrent":1 // The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.14. Configure OSS Writer

This topic describes the data types and parameters supported by OSS Writer and how to configure it by using the codeless user interface (UI) and code editor.

OSS Writer writes one or more CSV-like files to Object Storage Service (OSS).

> **Note** Before you configure OSS Writer, you must configure an OSS data source.

OSS Writer can write files that store logical two-dimensional tables, such as CSV files that store text data, to OSS.

OSS Writer converts the data obtained from a Data Integration reader to files and write the files to OSS. OSS stores only unstructured data. OSS Writer supports the following features:

- Writes only files that store text data. The text data must be logical two-dimensional tables.
- Writes data stored in CSV-like files with custom delimiters.
- Uses parallel threads to write multiple files. Each thread is used to write one file.
- Supports object rotation. OSS Writer can write the excess data in a file to another object when the size of the file or the number of rows in the file exceeds a specific value.

OSS Writer does not support the following features:

- Uses parallel threads to write a single file.
- Distinguishes between data types. OSS does not distinguish between data types. Therefore, OSS Writer writes all data as strings to OSS.

The following table lists the data types supported by OSS Writer.

Category	OSS data type
Integer	Long
Floating point	Double
String	String
Boolean	Bool
Date and time	Date

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
object	The prefix for the names of the files that you want to write to OSS. OSS simulates the directory effect by adding delimiters to object names. You can set the object parameter based on the following rules: • `"object": "datax"`: The names of the objects start with datax, which is followed by a random string as the suffix. • `"object": "cdo/datax"`: The names of the objects start with `/cdo/datax`, which is followed by a random string as the suffix. OSS uses forward slashes (/) in object names to simulate the directory effect. If you do not want to add a random universally unique identifier (UUID) as the suffix, we recommend that you set `"writeSingleObject": "true"`. For more information, see writeSingleObject.	Yes	No default value

Parameter	Description	Required	Default value
writeMode	The mode in which OSS Writer writes the files. Valid values: • *truncate*: OSS Writer deletes all existing objects with the specified object name prefix before files are written to OSS. For example, you set the object parameter to `abc`. In this case, OSS Writer deletes all the objects whose names start with abc. • *append*: OSS Writer writes all files and ensures that the actual file names do not conflict with the names of existing objects by suffixing the file names with random UUIDs. For example, you set the object parameter to DI. In this case, the actual names of the files written to OSS are in the following format: DI_****_****_****. • *nonConflict*: OSS Writer returns an error message if an object whose name contains the specified prefix exists. For example, you set the `object` parameter to abc, and the object named abc123 exists. In this case, OSS Writer returns an error message.	Yes	No default value
fileFormat	The format in which the files are written to OSS. Valid values: csv and text. • If a file is written as a CSV file, the file strictly follows CSV specifications. If the data in the file contains column delimiters, the column delimiters are escaped by using double quotation marks ("). • If a file is written as a text file, the data in the file is separated by column delimiters. In this case, the column delimiters are not escaped.	No	*text*
fieldDelimiter	The column delimiter that is used in the files that you want to write to OSS.	No	,
encoding	The encoding format of the files that you want to write to OSS.	No	*utf-8*
nullFormat	The string that represents a null pointer. No standard strings can represent a null pointer in TXT files. Therefore, Data Integration provides the nullFormat parameter to define which string represents a null pointer. For example, you set `nullFormat="null"`. In this case, Data Integration considers null as a null pointer.	No	No default value
header (advanced parameter, available only in the code editor)	The table header in the files to write to OSS, such as ['id','name','age'].	No	No default value
maxFileSize (advanced parameter, available only in the code editor)	The maximum size of a single file that can be written to OSS. Default value: 100000. Unit: MB. File rotation based on this maximum size is similar to log rotation of Log4j. When a file is uploaded to OSS in multiple parts, the minimum size of each part is 10 MB. This size is the minimum granularity for file rotation. This indicates that if you set the maxFileSize parameter to a value that is less than 10 MB, the minimum size of a file is 10 MB. You can call the InitiateMultipartUploadRequest operation to write a maximum of 10,000 parts at a time. If file rotation occurs, suffixes, such as _1, _2, and _3, are appended to the new file names that consist of file name prefixes and random UUIDs.	No	100,000MB

Parameter	Description	Required	Default value
suffix (advanced parameter, available only in the code editor)	The file name extension of the files that you want to write to OSS. For example, you set the suffix parameter to .csv. In this case, the final name of a file written to OSS is in the fileName****.csv format.	No	No default value

Configure OSS Writer by using the codeless UI

1. Configure data sources.

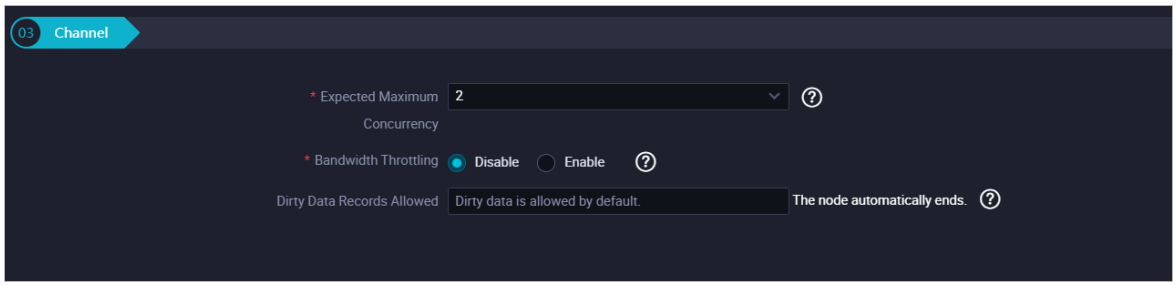
   Configure **Source** and **Target** for the synchronization node.

Parameter	Description
Connection	This parameter corresponds to the datasource parameter that is described in the preceding section. Select the name of a data source that you configured.
Object Name Prefix	This parameter corresponds to the object parameter that is described in the preceding section. Enter the path of the directory that stores the files. Do not include the name of the OSS bucket in the path.
File Type	This parameter corresponds to the fileFormat parameter that is described in the preceding section. Valid values: *csv* and *text*.
Field Delimiter	This parameter corresponds to the fieldDelimiter parameter that is described in the preceding section. The default delimiter is commas (,).
Encoding	This parameter corresponds to the encoding parameter that is described in the preceding section. The default encoding format is *UTF-8*.
Null String	This parameter corresponds to the nullFormat parameter that is described in the preceding section. Enter a string that represents a null pointer. If the source contains the string, the string is replaced with a null pointer.
Time format	The format in which data of the DATE type is serialized in an object, such as `"dateFormat": "yyyy-MM-dd"`.
Solution to Duplicate Prefixes	The solution to take when a prefix conflict occurs. If an object with the specified name prefix exists, the system can replace the object with the new object, insert the new object, or return an error message.

2. Configure field mappings. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that are established.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure OSS Writer by using the code editor

In the following code, a synchronization node is configured to write data to OSS. For more information about the parameters, see the preceding parameter description.

```
{
    "type":"job",
    "version":"2.0",
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"oss",// The writer type.
            "parameter":{
                "nullFormat":"",//The string that represents a null pointer.
                "dateFormat":"",// The format in which data of the DATE type is serialized in an obj
ect.
                "datasource":"",// The name of the data source.
                "writeMode":"",// The write mode.
                "encoding":"",// The encoding format.
                "fieldDelimiter":","// The column delimiter.
                "fileFormat":"",// The format in which files are written to OSS.
                "object":""// The prefix for the names of the files that you want to write to OSS.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. The value false in
dicates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttlin
g is enabled. The mbps parameter takes effect only when the throttle parameter is set to true.
            "concurrent":1// The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.15. Configure PostgreSQL Writer

This topic describes the data types and parameters supported by PostgreSQL Writer and how to configure it by using the codeless user interface (UI) and code editor.

PostgreSQL Writer can write data to PostgreSQL. PostgreSQL Writer connects to a remote PostgreSQL database by using Java Database Connectivity (JDBC), and executes an SQL statement to write data to the PostgreSQL database.

> **Note** Before you configure PostgreSQL Writer, you must configure a PostgreSQL data source.

PostgreSQL Writer connects to a remote PostgreSQL database by using JDBC, generates a SELECT statement based on your configurations, and then executes the SQL statement to write data to the PostgreSQL database. Then, PostgreSQL Writer assembles the returned result into abstract datasets of CDP custom data types and sends the datasets to a writer.

- PostgreSQL Writer generates the SQL statement based on the table, column, and where parameters that you specified, and sends the generated SQL statement to the PostgreSQL database.
- If you specify the querySql parameter, PostgreSQL Writer directly sends the value of this parameter to the PostgreSQL database.

Data types

PostgreSQL Writer supports most PostgreSQL data types. Make sure that your data types are supported.

The following table lists the data types supported by PostgreSQL Writer.

Data Integration data type	PostgreSQL data type
LONG	BIGINT, BIGSERIAL, INTEGER, SMALLINT, and SERIAL
DOUBLE	DOUBLE, PRECISION, MONEY, NUMERIC, and REAL
STRING	VARCHAR, CHAR, TEXT, BIT, and INET
DATE	DATE, TIME, and TIMESTAMP
BOOLEAN	BOOLEAN
BYTES	BYTEA

> **Note**
> - PostgreSQL Writer supports only the data types that are listed in the preceding table.
> - You can convert the MONEY, INET, and BIT data types by using syntax such as `a_inet::varchar`.

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
table	The name of the table to which you want to write data.	Yes	No default value

Parameter	Description	Required	Default value
writeMode	The write mode. Valid values: • *insert*: executes the `INSERT INTO...VALUES...` statement to write data to PostgreSQL. If a primary key conflict or unique index conflict occurs, data cannot be written to PostgreSQL and is regarded as dirty data. We recommend that you us the insert mode. • *copy*: copies data between tables and the standard input or output file. Data Integration supports the `COPY FROM` command, which allows you to copy data from files to tables. We recommend that you use this mode when performance issues occur.	No	*insert*
column	The names of the columns to which you want to write data in the destination table. Separate the names with commas (,), such as `"column":["id","name","age"]`. To write data to all the columns in the destination table, set the value to `["*"]`.	Yes	No default value
preSql	The SQL statement that you want to execute before the synchronization node is run. For example, you can set this parameter to the SQL statement that is used to delete outdated data. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	No default value
postSql	The SQL statement that you want to execute after the synchronization node is run. For example, you can set this parameter to the SQL statement that is used to add a timestamp. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	No default value
batchSize	The number of data records to write at a time. Set this parameter to an appropriate value based on your business requirements. This greatly reduces the interactions between Data Integration and PostgreSQL on the network and increases throughput. If you set this parameter to an excessively large value, an out of memory (OOM) error may occur during data synchronization.	No	*1,024*

Parameter	Description	Required	Default value
pgType	The PostgreSQL configuration for converting data types. Valid values: bigint[], double[], text[], jsonb, and json. The following code provides a configuration example: `{ "job": { "content": [{ "reader": {...}, "writer": { "parameter": { "column": [// The names of the columns to which you want to write data in the destination table. "bigint_arr", "double_arr", "text_arr", "jsonb_obj", "json_obj"], "pgType": { // The configuration that is specific for PostgreSQL to convert data types. In each key-value pair, the key specifies the name of a field in the destination table, and the value specifies the data type of the field. "bigint_arr": "bigint[]", "double_arr": "double[]", "text_arr": "text[]", "jsonb_obj": "jsonb", "json_obj": "json" }] } } }] } }`	No	No default value

Configure PostgreSQL Writer by using the codeless UI

1. Configure data sources.

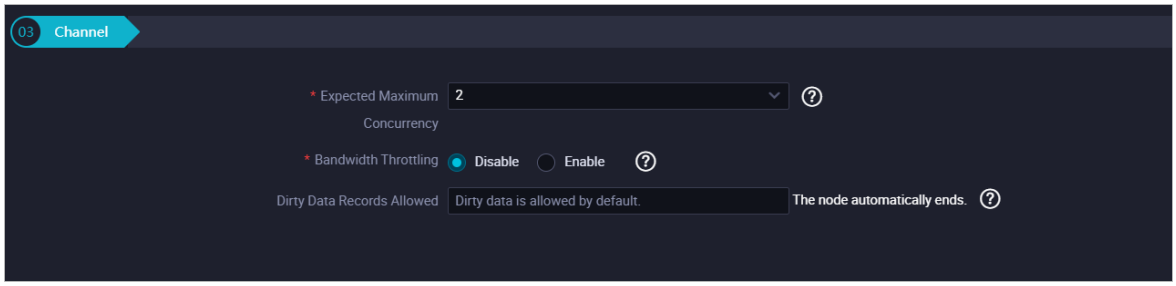
   Configure **Source** and **Target** for the synchronization node.

Parameter	Description
Connection	This parameter corresponds to the datasource parameter that is described in the preceding section. Select the name of a data source that you configured.
Table	This parameter corresponds to the table parameter that is described in the preceding section.
Statement Run Before Writing	This parameter corresponds to the preSql parameter that is described in the preceding section. Enter the SQL statement that you want to execute before the synchronization node is run.
Statement Run After Writing	This parameter corresponds to the postSql parameter that is described in the preceding section. Enter the SQL statement that you want to execute after the synchronization node is run.
Write Method	This parameter corresponds to the writeMode parameter that is described in the preceding section. Valid values: *insert* and *copy*.

2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in the preceding section. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that are established.
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on specified rules.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.

Parameter	Description
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure PostgreSQL Writer by using the code editor

In the following code, a synchronization node is configured to write data to PostgreSQL. For more information about the parameters, see the preceding parameter description.

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"postgresql",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement that you want to execute after the synchronization
node is run.
                "datasource":"// The name of the data source.
                    "col1",
                    "col2"
                ],
                "table":"",// The name of table to which you want to write data.
                "preSql":[]// The SQL statement that you want to execute before the synchronization
node is run.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false// Specifies whether to enable bandwidth throttling. The value false ind
icates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttling
is enabled. The mbps parameter takes effect only when the throttle parameter is set to true.
            "concurrent":1// The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.16. Configure Redis Writer

Redis Writer is a writer that is developed based on the Data Integration framework. It can be used to import data from data stores such as data warehouses to Redis databases.

Redis is a network-enabled key-value storage system that is either in-memory or permanent. It supports logs and delivers high performance. It can be used as a database, cache, and message broker. Redis supports diverse data types for values, including STRING, LIST, SET, ZSET (sorted set), and HASH.

Redis Writer interacts with a Redis server by using Jedis. As a preferred Java client development kit provided by Redis, Jedis supports almost all the features of Redis.

> **Note**
> - You must configure a connection before you configure Redis Writer.
> - If you write values of the LIST type to Redis by using Redis Writer, the result of rerunning a sync node is not idempotent. If the data type of the values is LIST, you must manually clear the corresponding data on Redis when you rerun a sync node.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
keyIndexes	The columns used as the key. The index of the first column is 0. For example, if you want to set the first and second columns of the source data as the key, set the keyIndexes parameter to [0,1]. **Note** After you specify the keyIndexes parameter, Redis Writer specifies the remaining columns as the value. If you do not want to synchronize all the columns, filter columns when you configure the reader.	Yes	None
keyFieldDelimiter	The delimiter used to separate keys when data is written to Redis. Example: key=key1\u0001id. If multiple keys need to be concatenated, this parameter is required. If only one key exists, this parameter is not required.	No	*\u0001*
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Redis database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,000*
expireTime	The expiration time of the values to be cached in Redis. Unit: seconds. The data is valid permanently if you do not specify this parameter. • *seconds*: the relative time in seconds starting from the current time point. It specifies the time range during which data is valid. • *unixtime*: the UNIX timestamp, indicating that data is invalid at a specific time point in the future. The UNIX timestamp represents the number of seconds that have elapsed since 00:00:00 on January 1, 1970. **Note** If the specified expiration time is larger than 30 days, the server identifies the time as the UNIX timestamp.	No	*0*, indicating that the values never expire
timeout	The timeout period to connect to Redis when data is written to Redis. Unit: milliseconds.	No	*30,000*

Parameter	Description	Required	Default value
dateFormat	The format in which the data of the DATE type is written to Redis. Set the value to yyyy-MM-dd HH:mm:ss.	No	None
writeMode	The write mode. Redis supports diverse data types for values, including STRING, LIST, SET, ZSET (sorted set), and HASH. Redis Writer allows you to write values of the preceding types to Redis. The value of the writeMode parameter varies based on the specified data type of the values. **Note** When you configure Redis Writer, you can choose only one of the five data types described in the following table. If you do not specify a data type, the data type is STRING by default.	No	*string*

The following table lists the data types supported by Redis Writer.

Type	Parameter	Description	Required
String `"writeMode":{ "type": "string", "mode": "set", "valueFieldDelimiter": "\u0001" }`	type	The data type of the values is STRING.	Yes
	mode	The mode in which data of the STRING type is written to Redis.	Yes. Valid value: set (overwrites the existing data).
	valueFieldDelimiter	This parameter is required if two or more columns are specified as the values. This parameter is not required if only one column is specified as the values. The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: \u0001.
LIST `"writeMode":{ "type": "list", "mode": "lpush|rpush", "valueFieldDelimiter": "\u0001" }`	type	The data type of the values is LIST.	Yes
	mode	The mode in which data of the LIST type is written to Redis.	Yes. Valid values: lpush (stores the data at the leftmost of the list) and rpush (stores the data at the rightmost of the list).
	valueFieldDelimiter	The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: *\u0001*.

Type	Parameter	Description	Required
SET `"writeMode":{ "type": "set", "mode": "sadd", "valueFieldDelimiter": "\u0001" }`	type	The data type of the values is SET.	Yes
	mode	The mode in which data of the SET type is written to Redis.	Yes. Valid value: sadd (stores the data to a set, or overwrites the existing data).
	valueFieldDelimiter	The delimiter used to separate values if the data is of the STRING type. Example: value1\u0001value2\u0001value3.	No. Default value: *\u0001*.
ZSET (sorted set) `"writeMode":{ "type": "zset", "mode": "zadd" }`	type	The data type of the values is ZSET. **Note** If the data type of the values is ZSET, each data record must follow the following standard: Except for the key, a data record can contain only one score and one value. The score must be placed before the value. In this way, Redis Writer can identify which column is the score and which column is the value.	Yes
	mode	The mode in which data of the ZSET type is written to Redis.	Yes. Valid value: zadd (stores data to a sorted set, or overwrites the existing data).

Type	Parameter	Description	Required
HASH `"writeMode":{ "type": "hash", "mode": "hset" }`	type	The data type of the values is HASH. **Note** If the data type of the values is HASH, each data record must follow the following standards: Except for the key, a data record can contain only one attribute and one value. The attribute must be placed before the value. In this way, Redis Writer can identify which column is the attribute and which column is the value.	Yes
	mode	The mode in which data of the HASH type is written to Redis.	Yes. Valid value: hmset (stores data to a hash sorted set, or overwrites the existing data). If you do not specify a data type, the data type is STRING by default.

Configure Redis Writer by using the codeless UI

The codeless UI is not supported for Redis Reader.

Configure Redis Writer by using the code editor

In the following code, a node is configured to write data to Redis. For more information about parameters, see the preceding parameter description.

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"redis",// The writer type.
            "parameter":{
                "expireTime":{// The expiration time of the values to be cached in Redis.
                    "seconds":"1000"
                },
                "keyFieldDelimiter":"u0001",// The delimiter used to separate keys when data is writ
ten to Redis.
```

```
                "dateFormat":"yyyy-MM-dd HH:mm:ss",// The format in which the data of the DATE type
is written to Redis.
                "datasource":"",// The connection name.
                "writeMode":{// The write mode.
                    "mode":"",// The write mode used to write data of a specified data type.
                    "valueFieldDelimiter":"",// The delimiter used to separate values.
                    "type":""// The data type of the values.
                },
                "keyIndexes":[// The columns used as the key.
                    0,
                    1
                ],
                "batchSize":"1000"// The number of data records to write at a time.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false i
ndicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is thrott
led. The maximum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1 // The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}Writer"
            }
        ]
    }
}
```

2.1.4.5.4.17. Configure SQL Server Writer

This topic describes the data types and parameters supported by SQL Server Writer and how to configure it by using the codeless user interface (UI) and code editor.

SQL Server Writer writes data to tables stored in primary SQL Server databases. Specifically, SQL Server Writer connects to a remote SQL Server database by using Java Database Connectivity (JDBC), and executes an `INSERT INTO` statement to write data to the SQL Server database. Internally, data is submitted to the database in batches.

SQL Server Writer is designed for extract, transform, load (ETL) developers to import data from data warehouses to SQL Server. SQL Server Writer can also be used as a data migration tool by users such as database administrators.

SQL Server Writer obtains data from a Data Integration reader and generates the `INSERT INTO` statement. If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows. To improve performance, SQL Server Writer performs batch updates by using the `PreparedStatement` method and the setting of `rewriteBatchedStatements=true`. This way, SQL Server Writer buffers data and submits a write request when the amount of data in the buffer reaches a specific threshold.

> **Note**
>
> - Data can be written to tables stored only in primary SQL Server databases.
> - A synchronization node that uses SQL Server Writer must have at least the permissions to execute the INSERT INTO statement. Whether other permissions are required depends on the SQL statements that you specify in the preSql and postSql parameters when you configure the node.

Data types

SQL Server Writer supports most SQL Server data types. Make sure that your data types are supported.

The following table lists the data types supported by SQL Server Writer.

Category	SQL Server data type
Integer	BIGINT, INT, SMALLINT, and TINYINT
Floating point	FLOAT, DECIMAL, REAL, and NUMERIC
String	CHAR, NCHAR, NTEXT, NVARCHAR, TEXT, VARCHAR, NVARCHAR (MAX), and VARCHAR (MAX)
Date and time	DATE, TIME, and DATETIME
Boolean	BIT
Binary	BINARY, VARBINARY, VARBINARY (MAX), and TIMESTAMP

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
table	The name of the table to which you want to write data.	Yes	No default value
column	The names of the columns to which you want to write data in the destination table. Separate the names with commas (,), such as `"column":["id","name","age"]`. To write data to all the columns in the destination table, set the value to `["*"]`.	Yes	No default value
preSql	The SQL statement that you want to execute before the synchronization node is run. For example, you can set this parameter to the SQL statement that is used to delete outdated data. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	No default value

Parameter	Description	Required	Default value
postSql	The SQL statement that you want to execute after the synchronization node is run. For example, you can set this parameter to the SQL statement that is used to add a timestamp. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor.	No	No default value
writeMode	The write mode. Valid value: *insert*. When a data record violates the primary key constraint or unique index constraint, Data Integration considers it dirty and retains the original data.	No	*insert*
batchSize	The number of data records to write at a time. Set this parameter to an appropriate value based on your business requirements. This greatly reduces the interactions between Data Integration and SQL Server on the network and increases throughput. If you set this parameter to an excessively large value, an out of memory (OOM) error may occur during data synchronization.	No	*1,024*

Configure SQL Server Writer by using the codeless UI

1. Configure data sources.

   Configure **Source** and **Target** for the synchronization node.

Parameter	Description
Connection	This parameter corresponds to the datasource parameter that is described in the preceding section. Select the name of a data source that you configured.
Table	This parameter corresponds to the table parameter that is described in the preceding section.
Statement Run Before Writing	This parameter corresponds to the preSql parameter that is described in the preceding section. Enter the SQL statement that you want to execute before the synchronization node is run.
Statement Run After Writing	This parameter corresponds to the postSql parameter that is described in the preceding section. Enter the SQL statement that you want to execute after the synchronization node is run.
Solution to Primary Key Violation	This parameter corresponds to the writeMode parameter that is described in the preceding section. You can select the desired write mode.

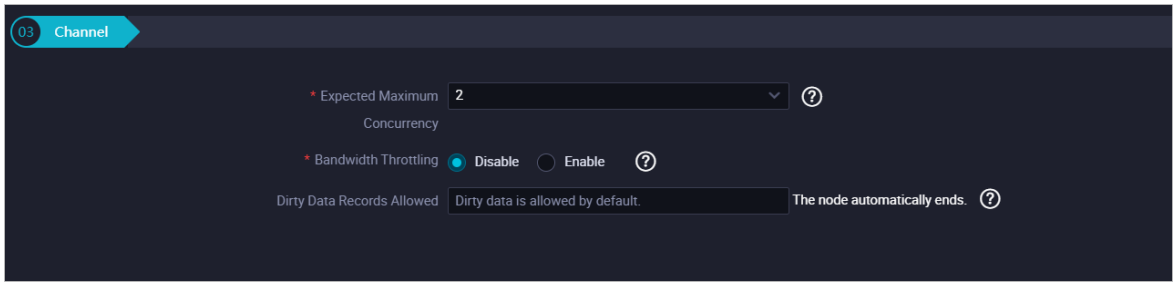
2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in the preceding section.

   Fields in the source on the left have a one-to-one mapping with fields in the destination on the right. You can click **Add** to add a field, or move the pointer over a field and click the **Delete** icon to delete the field.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove mappings that are established.

Operation	Description
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on specified rules.
Change Fields	Click the Change Fields icon. In the Change Fields dialog box, you can manually edit the fields in the source table. Each field occupies a row. The first and the last blank rows are included, whereas other blank rows are ignored.
Add	○ Click Add to add a field. You can enter constants. Each constant must be enclosed in single quotation marks ('), such as 'abc' and '123'. ○ You can use scheduling parameters such as ${bizdate}. ○ You can enter functions supported by relational databases, such as now() and count(1). ○ Fields that cannot be parsed are indicated as Unidentified.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure SQL Server Writer by using the code editor

In the following code, a synchronization node is configured to write data to SQL Server. For more information about the parameters, see the preceding parameter description.

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"sqlserver",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement that you want to execute after the synchronization node is run.
                "datasource":"",// The name of the data source.
                "column":[// The names of the columns to which you want to write data.
                    "id",
                    "name"
                ],
                "table":"",// The name of the table to which you want to write data.
                "preSql":[]// The SQL statement that you want to execute before the synchronization node is run.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. The value false indicates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttling is enabled. The mbps parameter takes effect only when the throttle parameter is set to true.
            "concurrent":1,// The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.18. Configure Elasticsearch Writer

This topic describes the data types and parameters supported by Elasticsearch Writer and how to configure it by using the code editor.

Elasticsearch is an open-source product that complies with the Apache open standards. It is the mainstream search engine for enterprise data. Elasticsearch is a Lucene-based data search and analysis tool that provides distributed services. The mappings between Elasticsearch core concepts and database core concepts are as follows:

```
Relational database (instance) -> database -> table -> row -> column
Elasticsearch -> index -> type -> document -> field
```

Elasticsearch can contain multiple indexes (databases). Each index can contain multiple types (tables). Each type can contain multiple documents (rows). Each document can contain multiple fields (columns). Elasticsearch Writer uses the RESTful API of Elasticsearch to write multiple data records retrieved by a reader to Elasticsearch at a time.

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint for accessing Elasticsearch, in the format of `http://xxxx.com:9999`.	No	None
accessId	The AccessKey ID for accessing Elasticsearch, which is used for authorization when a connection with Elasticsearch is established. **Note** The accessId and accessKey parameters are required. If you do not set the parameters, an error is returned. If you use on-premises Elasticsearch for which basic authentication is not configured, the AccessKey ID and AccessKey secret are not required. In this case, you can set the accessId and accessKey parameters to random values.	No	None
accessKey	The AccessKey secret for accessing Elasticsearch.	No	None
index	The index name in Elasticsearch.	No	None
indexType	The type name in the index of Elasticsearch.	No	*Elasticsearch*
cleanup	Specifies whether to clear existing data in the index. The method used to clear the data is to delete and rebuild the corresponding index. The default value false indicates that the existing data in the index is retained.	No	*false*
batchSize	The number of data records to write at a time.	No	*1000*
trySize	The number of retries after a failure.	No	*30*
timeout	The connection timeout of the client. Unit: milliseconds.	No	*600000*
discovery	Specifies whether to enable Node Discovery. When Node Discovery is enabled, the server list in the client is polled and regularly updated.	No	*false*
compression	Specifies whether to enable compression for an HTTP request.	No	*true*

Parameter	Description	Required	Default value
multiThread	Specifies whether to use multiple threads for an HTTP request.	No	*true*
ignoreWriteError	Specifies whether to ignore write errors and proceed with writing without retries.	No	*false*
ignoreParseError	Specifies whether to ignore format parsing errors and proceed with writing.	No	*true*
alias	The alias of the index. The alias feature of Elasticsearch is similar to the view feature of a traditional database. For example, if you create an alias named my_index_alias for the index my_index, the operations on my_index_alias also take effect on my_index. Configuring alias means that after the data import is completed, an alias is created for the specified index.	No	None
aliasMode	The mode in which an alias is added after the data is imported. Valid values: *append* and *exclusive*.	No	append
settings	The delimiter (-,-) for splitting the source data if you are inserting an array to Elasticsearch. Example: The source column stores data `a-,-b-,-c-,-d` of the String type. Elasticsearch Writer uses the delimiter (-,-) to split the source data and obtains the array `["a", "b", "c", "d"]`. Then, Elasticsearch Writer writes the array to the corresponding field in Elasticsearch.	No	-,-
	The fields of the document. The parameters for each field include basic parameters such as name and type and advanced parameters such as analyzer, format, and array. The field types supported by Elasticsearch are as follows:		

Parameter	Description	Required	Default value

column	- id // The id type corresponds to the _id type in Elasticsearch, and can be considered as the unique primary key. Data with the same ID will be overwritten and not indexed.
	- string
	- text
	- keyword
	- long
	- integer
	- short
	- byte
	- double
	- float
	- date
	- boolean
	- binary
	- integer_range
	- float_range
	- long_range
	- double_range
	- date_range
	- geo_point
	- geo_shape
	- ip
	- token_count
	- array
	- object
	- nested
	
	• When the field type is Text, you can specify the analyzer, norms, and index_options parameters. Example:
	`{ "name": "col_text", "type": "text", "analyzer": "ik_max_word" }`
	• When the field type is date, you can specify the format and timezone parameters, indicating the date serialization format and the time zone, respectively. Example:
	`{ "name": "col_date", "type": "date", "format": "yyyy-MM-dd HH:mm:ss", "timezone": "UTC" }`
	• When the field type is ge_shape, you can specify the tree (geohash or quadtree) and precision parameters. Example:
		Yes	None

Parameter	Description	Required	Default value

	<pre>{
	"name": "col_geo_shape",
	"type": "geo_shape",
	"tree": "quadtree",
	"precision": "10m"
	}</pre>
	If you specify the array parameter for a field and set the array parameter to *true*, the field is an array column. Elasticsearch Writer uses the delimiter specified by the splitter to split the source data, converts the data to an array of strings, and writes the array to the destination. Only one delimiter is supported for one node. Example:
	<pre>{
	"name": "col_integer_array",
	"type": "integer",
	"array": true
	}</pre>		

dynamic	Specifies whether to use the mapping configuration of Elasticsearch. A value of *true* indicates that the mapping configuration of Elasticsearch, instead of the mapping configuration of Data Integration, is used.	No	*false*
actionType	The type of the action for writing data to Elasticsearch. Currently, Data Integration supports only the following action types: *index* and *update*. Default value: *index*. • *index*: Data Integration uses Index.Builder of the Elasticsearch SDK to construct a request for writing multiple data records at a time. In *index* mode, Elasticsearch first checks whether an ID is specified for the document to be inserted. ◦ If the ID is not specified, Elasticsearch generates a unique ID by default. In this case, the document is directly inserted to Elasticsearch. ◦ If the ID is specified, Elasticsearch replaces the existing document with the document to be inserted. **Note** In this case, you cannot modify specific fields in the document. • *update*: Data Integration uses Update.Builder of the Elasticsearch SDK to construct a request for writing multiple data records at a time. In *update* mode, Elasticsearch calls the get method of InternalEngine to obtain the information of the original document for each update. In this way, you can modify specific fields. In update mode, you must obtain the information of the original document for each update, which greatly affects the performance. However, you can modify specific fields in this mode. If the original document does not exist, the new document is directly inserted.	No	*index*

Configure Elasticsearch Writer by using the code editor

In the following code, a node is configured to write data to Elasticsearch. For more information about the parameters, see the preceding parameter description.

```
{
    "order": {
        "hops": [
            {
                "from": "Reader",
                "to": "Writer"
            }
        ]
    },
    "setting": {
        "errorLimit": {
            "record": "0"
        },
        "speed": {
            "concurrent": 1,
            "throttle": false
        }
    },
    "steps": [
        {
            "category": "reader",
            "name": "Reader",
            "parameter": {
            },
            "stepType": "stream"
        },
        {
            "category": "writer",
            "name": "Writer",
            "parameter": {
                "endpoint": "http://xxxx.com:9999",
                "accessId": "xxxx",
                "accessKey": "yyyy",
                "index": "test-1",

                    },
                    {
```

```
                        "name": "col_long",
                        "type": "long"
                    },
                    {
                        "name": "col_integer",
                        "type": "integer"
                    },
                    {
                        "name": "col_keyword",
                        "type": "keyword"
                    },
                    {
                        "name": "col_text",
                        "type": "text",
                        "analyzer": "ik_max_word"
                    },
                    {
                        "name": "col_geo_point",
                        "type": "geo_point"
                    },
                    {
                        "name": "col_date",
                        "type": "date",
                        "format": "yyyy-MM-dd HH:mm:ss"
                    },
                    {
                        "name": "col_nested1",
                        "type": "nested"
                    },
                    {
                        "name": "col_nested2",
                        "type": "nested"
                    },
                    {
                        "name": "col_object1",
                        "type": "object"
                    },
                    {
                        "name": "col_object2",
                        "type": "object"
                    },
                    {
                        "name": "col_integer_array",
                        "type": "integer",
                        "array": true
                    },
                    {
                        "name": "col_geo_shape",
                        "type": "geo_shape",
                        "tree": "quadtree",
                        "precision": "10m"
                    }
                ]
            },
            "stepType": "elasticsearch"
        }
    ],
    "type": "job",
    "version": "2.0"
```

```
}
```

> **Note** Currently, Elasticsearch that is deployed in a Virtual Private Cloud (VPC) supports only custom resource groups. A sync node that is run on the default resource group may fail to connect to Elasticsearch.

2.1.4.5.4.19. Configure LogHub Writer

This topic describes the data types and parameters supported by LogHub Writer and how to configure it by using the code editor.

LogHub Writer allows you to transfer data from a Data Integration reader to LogHub through Log Service Java SDK.

> **Note** LogHub does not guarantee idempotence. Rerunning a node after the node fails may result in redundant data.

LogHub Writer obtains data from a Data Integration reader and converts the data types supported by Data Integration to String. When the number of the data records reaches the value specified for the batchSize parameter, LogHub Writer sends the data records to LogHub at a time through Log Service Java SDK. LogHub Writer sends 1,024 data records at a time by default. The batchSize parameter can be set to 4096 at most.

Data types

The following table lists the data types supported by LogHub Writer.

Data Integration data type	LogHub data type
LONG	STRING
DOUBLE	STRING
STRING	STRING
DATE	STRING
BOOLEAN	STRING
BYTES	STRING

Parameters

Parameter	Description	Required	Default value
endpoint	The endpoint for accessing Log Service.	Yes	None
accessKeyId	The AccessKey ID for accessing Log Service.	Yes	None
accessKeySecret	The AccessKey secret for accessing Log Service.	Yes	None
project	The name of the destination Log Service project.	Yes	None
logstore	The name of the destination Logstore.	Yes	None

Parameter	Description	Required	Default value
topic	The name of the destination topic.	No	Empty string
batchSize	The number of data records to write at a time.	No	*1024*
column	The columns in each data record.	Yes	None

Configure LogHub Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for LogHub Writer.

Configure LogHub Writer by using the code editor

In the following code, a node is configured to write data to LogHub. For more information about the parameters, see the preceding parameter description.

```
{
    "type": "job",
    "version": "2.0",// The version number.
    "steps": [
        { //
            "stepType": "stream",
            "parameter": {},
            "name": "Reader",
            "category": "reader"
        },
        {
            "stepType": "loghub",// The writer type.
            "parameter": {
                "datasource": "",// The connection name.
                "column": [// The columns in each data record.
                    "col0",
                    "col1",
                    "col2",
                    "col3",
                    "col4",
                    "col5"
                ],
                "topic": "",// The name of the destination topic.
                "batchSize": "1024",// The number of data records to write at a time.
                "logstore": ""// The name of the destination Logstore.
            },
            "name": "Writer",
            "category": "writer"
        }
    ],
    "setting": {
        "errorLimit": {
            "record": ""// The maximum number of dirty data records allowed.
        },
        "speed": {
            "concurrent": 3,// The maximum number of concurrent threads.
            "throttle": false,// Specifies whether to enable bandwidth throttling. A value of false
indicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is throt
tled. The maximum transmission rate takes effect only if you set this parameter to true.
        }
    },
    "order": {
        "hops": [
            {
                "from": "Reader",
                "to": "Writer"
            }
        ]
    }
}
```

2.1.4.5.4.20. Configure Open Search Writer

This topic describes the data types and parameters supported by Open Search Writer and how to configure it by using the code editor.

How it works

Open Search Writer allows you to insert data into or update data in Open Search. Open Search Writer is designed to import data to Open Search so that the data can be searched.

Specifically, Open Search Writer uses the search API provided by Open Search to import data.

> **Note**
>
> - Open Search V3 uses internal dependent databases, with POM of `com.aliyun.opensearch aliyun-sdk-opensearch 2.1.3`.
> - To use Open Search Writer, you must install JDK 1.6-32 or later. You can run the `java -version` command to view the JDK version.

Features

The columns in Open Search are unordered. Open Search Writer writes data in strict accordance with the order of the specified columns. If the number of specified columns is less than that in Open Search, redundant columns in Open Search are set to the default value or null.

For example, an Open Search table contains columns a, b, and c, and you only need to write data to columns b and c. You can set the column parameter to ["c","b"]. In this case, Open Search Writer imports the first and second columns of the source data that is obtained from a reader to columns c and b in the Open Search table respectively. Column a in the Open Search table is set to the default value or null.

Additional instructions:

- Handling of column configuration errors

  To avoid losing the data of redundant columns and ensure high data reliability, Open Search Writer returns an error message if the number of columns to be written is more than that in the destination Open Search table. For example, an Open Search table contains columns a, b, and c. Open Search Writer returns an error if more than three columns are to be written to the table.

- Table configuration

  Open Search Writer can write data to only one table at a time.

- Node rerunning

  After a node is rerun, data is overwritten based on IDs. Therefore, the data written to Open Search must contain an ID column. An ID is a unique identifier of a row in Open Search. The existing data with the same ID as the new data will be overwritten.

Data types

Open Search Writer supports most Open Search data types. Make sure that your data types are supported.

The following table lists the data types supported by Open Search Writer.

Category	Open Search data type
Integer	INT
Floating point	DOUBLE and FLOAT
String	TEXT, LITERAL, and SHORT_TEXT
Date and time	INT
Boolean	LITERAL

Parameters

Parameter	Description	Required	Default value
accessId	The AccessKey ID of the account that is used to access Open Search.	Yes	None
accessKey	The AccessKey secret that corresponds to the AccessKey ID. The AccessKey secret is equivalent to a logon password.	Yes	None
host	The endpoint of Open Search. You can view the endpoint in the Apsara Uni-manager Management Console.	Yes	None
indexName	The name of the Open Search project.	Yes	None
table	The name of the table to which data is written. You can specify only one table name because Data Integration does not allow you to import data to multiple tables at a time.	Yes	None
column	The columns in the destination table to which data is written. To write data to all the columns in the destination table, set this parameter to an asterisk (*), such as `"column":["*"]`. If you want to write data only to specific columns in the destination table, set this parameter to the columns. Separate the columns with commas (,), such as `"column":["id","name"]`. Open Search Writer can filter columns and change the order of columns. For example, an Open Search table has three columns: a, b, and c. If you want to write data only to columns c and b, you can set the column parameter in the format of `"column":["c","b"]`. During data synchronization, column a is automatically set to null.	Yes	None
batchSize	The number of data records to write at a time. Multiple data records are written to Open Search at a time. The advantage of Open Search is data query. The transactions per second (TPS) of Open Search is generally not high. Set this parameter based on the resources available for the account that is used to access Open Search. Generally, the size of a data record must be less than 1 MB, and the size of the data records to write at a time must be less than 2 MB.	Required only for writing data to a partitioned table	*300*
writeMode	The write mode. To ensure the idempotence of write operations, set this parameter to add/update. • add: deletes the existing data record and inserts the new data record to Open Search, which is an atomic operation. • update: updates the existing data record based on the new data record, which is an atomic operation. **Note** Writing multiple data records to Open Search at a time is not an atomic operation. Part of the data may fail to be written. Exercise caution when you set the writeMode parameter. Open Search V3 does not support the update mode.	Yes	None

Parameter	Description	Required	Default value
ignoreWriteError	Specifies whether to ignore failed write operations. Example: `"ignoreWriteError":true`. If multiple data records are written to Open Search at a time, this parameter specifies whether to ignore failed write operations in the current batch. If you set this parameter to true, Open Search Writer continues to perform other write operations. If you set this parameter to false, the synchronization node ends, and an error message is returned. We recommend that you use the default value.	No	*false*
version	The version of Open Search, such as `"version":"v3"`. We recommend that you use Open Search V3 because the push operation faces many constraints in Open Search V2.	No	*v2*

Configure Open Search Writer by using the code editor

In the following code, a synchronization node is configured to write data to Open Search.

```
{
    "type": "job",
    "version": "1.0",
    "configuration": {
        "reader": {},
        "writer": {
            "plugin": "opensearch",
            "parameter": {
                "accessId": "*********",
                "accessKey": "********",
                "host": "http://yyyy.aliyuncs.com",
                "indexName": "datax_xxx",
                "table": "datax_yyy",
                "column": [
                "appkey",
                "id",
                "title",
                "gmt_create",
                "pic_default"
                ],
                "batchSize": 500,
                "writeMode": add,
                "version":"v2",
                "ignoreWriteError": false
            }
        }
    }
}
```

2.1.4.5.4.21. Tablestore Writer

This topic describes the data types and parameters that are supported by Tablestore Writer and how to configure Tablestore Writer by using the codeless user interface (UI) and code editor.

Tablestore is a NoSQL database service that is built on the Apsara distributed operating system. The service allows you to store and access large volumes of structured data in real time. Tablestore organizes data into instances and tables. It uses data sharding and load balancing technologies to seamlessly expand the data scale.

Tablestore Writer connects to the Tablestore server by using Tablestore SDK for Java and writes data to the server by using the SDK. Tablestore Writer greatly optimizes the write process, including retry after write timeouts, retry after exceptions, and batch submission.

Tablestore Writer writes data to Tablestore in one of the following modes:

- PutRow: the PutRow API operation for Tablestore, which is used to insert data to a specific row. If the specified row does not exist, a new row is added. Otherwise, the original row is overwritten.
- UpdateRow: the UpdateRow API operation for Tablestore, which is used to update the data of a specific row. If the specified row does not exist, a new row is added. Otherwise, the values of the specified columns are added, modified, or removed as requested.

Tablestore Writer supports all Tablestore data types. The following table lists the data types that are supported by Tablestore Writer.

Category	Tablestore data type
Integer	INTEGER
Floating point	DOUBLE
String	STRING
Boolean	BOOLEAN
Binary	BINARY

Note To write INTEGER-type data, set the data type to INT in the code editor. Then, DataWorks converts the INT type into the INTEGER type. If you directly set the data type to INTEGER, an error is reported in the log, and the node fails.

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
endPoint	The endpoint of the Tablestore server.	Yes	No default value
accessId	The AccessKey ID of the account that is used to access Tablestore.	Yes	No default value
accessKey	The AccessKey secret of the account that is used to access Tablestore.	Yes	No default value

Parameter	Description	Required	Default value
instanceName	The name of the Tablestore instance. The instance is an entity for you to use and manage Tablestore. After you activate the Tablestore service, you must create an instance in the Tablestore console before you can create and manage tables. Instances are the basic units that you can use to manage Tablestore resources. Access control and resource measurement for applications are implemented at the instance level.	Yes	No default value
table	The name of the table to which you want to write data. You can specify only one table. Multi-table synchronization is not required for Tablestore.	Yes	No default value
primaryKey	The primary key of the destination table. Specify the primary keys in a JSON array. Tablestore is a NoSQL database service. You must specify the primary key of the destination table for Tablestore Writer to write data. **Note** The primary keys in Tablestore must be of the STRING or INT type. Therefore, you must set the data type of a primary key to STRING or INT in the code editor. Data Integration supports data type conversion. Tablestore Writer can convert data that is not of the STRING or INT type to the STRING or INT type. The following code provides a configuration example: `"primaryKey" : [ {"name":"pk1", "type":"string"}, null ],`	Yes	No default value
column	The names of the columns to which you want to write data. Specify the columns in a JSON array. Specify this parameter in the following format: `{"name":"col2", "type":"INT"},` The name parameter specifies the name of the column to which data is written. The type parameter specifies the data type of the column. Data types supported by Tablestore include STRING, INT, DOUBLE, BOOLEAN, and BINARY.	Yes	No default value

Parameter	Description	Required	Default value
writeMode	The write mode. Constants, functions, or custom statements are not supported during the write process. The following three modes are supported: • PutRow: the PutRow API operation for Tablestore, which is used to insert data to a specific row. If the specified row does not exist, a new row is added. Otherwise, the original row is overwritten. • UpdateRow: the UpdateRow API operation for Tablestore, which is used to update the data of a specific row. If the specified row does not exist, a new row is added. Otherwise, the values of the specified columns are added, modified, or removed as requested. • DeleteRow: deletes a row.	Yes	No default value

Configure Tablestore Writer by using the codeless UI

This method is not supported.

Configure Tablestore Writer by using the code editor

In the following code, a synchronization node is configured to write data to Tablestore:

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"ots",// The writer type.
            "parameter":{
                "datasource":"",// The name of the data source.
                "column":[// The names of the columns to which you want to write data.
                    {
                        "name":"columnName1",// The name of the column.
                        "type":"INT"// The data type of the column.
                    },
                    {
                        "name":"columnName2",
                        "type":"STRING"
                    },
                    {
                        "name":"columnName3",
                        "type":"DOUBLE"
                    },
                    {
                        "name":"columnName4",
                        "type":"BOOLEAN"
                    },
                    {
                        "name":"columnName5",
                        "type":"BINARY"
```

```
                    }
                ],
                "writeMode":"",// The write mode.
                "table":"",// The name of the table to which you want to write data.
                "primaryKey":[// The primary key of the destination table.
                    {
                        "name":"pk1",
                        "type":"STRING"
                    },
                    {
                        "name":"pk2",
                        "type":"INT"
                    }
                ]
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. The value false in
dicates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttlin
g is enabled. The mbps parameter takes effect only when the throttle parameter is set to true.
            "concurrent":1,// The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.22. Configure RDBMS Writer

This topic describes the data types and parameters supported by RDBMS Writer and how to configure it by using the code editor.

RDBMS Writer allows you to write data to tables stored in primary relational database management system (RDBMS) databases. Specifically, RDBMS Writer obtains data from a Data Integration reader, connects to a remote RDBMS database through Java Database Connectivity (JDBC), and then runs an `INSERT INTO` statement to write data to the RDBMS database. RDBMS Writer is a common writer for relational databases. To enable RDBMS Writer to support a new relational database, register the driver for the relational database.

RDBMS Writer is designed for extract-transform-load (ETL) developers to import data from data warehouses to RDBMS databases. RDBMS Writer can also be used as a data migration tool by users such as database administrators (DBAs).

Data types

RDBMS Writer supports most data types in relational databases, such as numbers and characters. Make sure that your data types are supported.

Parameters

Parameter	Description	Required	Default value
jdbcUrl	The JDBC URL for connecting to the database. The format must be in accordance with official specifications. You can also specify the information of the attachment facility. The format varies with the database type. Data Integration selects an appropriate driver for data reading based on the format. • Format for DM databases: `jdbc:dm://ip:port/database` • Format for Db2 databases: `jdbc:db2://ip:port/database` • Format for PPAS databases: `jdbc:edb://ip:port/database`	Yes	None
username	The username for connecting to the database.	Yes	None
password	The password for connecting to the database.	Yes	None
table	The name of the destination table.	Yes	None
column	The columns in the destination table to which data is written. Separate the columns with a comma (,). **Note** We recommend that you do not use the default setting.	Yes	None
preSql	The SQL statement to run before the sync node is run. For example, you can clear outdated data before data synchronization. Currently, you can run only one SQL statement. **Note** If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None

Parameter	Description	Required	Default value
postSql	The SQL statement to run after the sync node is run. For example, you can add a timestamp after data synchronization. Currently, you can run only one SQL statement. **Note** If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the RDBMS database over the network, and increase the throughput. However, an excessively large value may lead to the out of memory (OOM) error during the data synchronization process.	No	1024

Configure RDBMS Writer by using the code editor

In the following code, a node is configured to write data to an RDBMS database.

```
{
    "job": {
        "setting": {
            "speed": {
                "channel": 1
            }
        },
        "content": [
            {
                "reader": {
                    "name": "streamreader",
                    "parameter": {
                        "column": [
                            {
                                "value": "DataX",
                                "type": "string"
                            },
                            {
                                "value": 19880808,
                                "type": "long"
                            },
                            {
                                "value": "1988-08-08 08:08:08",
                                "type": "date"
                            },
                            {
                                "value": true,
                                "type": "bool"
                            },
                            {
                                "value": "test",
```

```
                                "type": "bytes"
                            }
                        ],
                        "sliceRecordCount": 1000
                    }
                },
                "writer": {
                    "name": "RDBMS Writer",
                    "parameter": {
                        "connection": [
                            {
                                "jdbcUrl": "jdbc:dm://ip:port/database",
                                "table": [
                                    "table"
                                ]
                            }
                        ],
                        "username": "username",
                        "password": "password",
                        "table": "table",
                        "column": [
                            "*"
                        ],
                        "preSql": [
                            "delete from XXX;"
                        ]
                    }
                }
            }
        ]
    }
}
```

You can enable RDBMS Writer to support a new database as follows:

1. Go to the directory of RDBMS Writer, *${DATAX_HOME}/plugin/writer/RDBMS Writer*. In the preceding directory, ${DATAX_HOME} indicates the main directory of Data Integration.
2. Add the driver of your database to the drivers array in the *plugin.json* file in the RDBMS Writer directory. RDBMS Writer automatically selects an appropriate driver for connecting to a database.

```
{
    "name": "RDBMS Writer",
    "class": "com.alibaba.datax.plugin.reader.RDBMS Writer.RDBMS Writer",
    "description": "useScene: prod. mechanism: Jdbc connection using the database, execute selec
t sql, retrieve data from the ResultSet. warn: The more you know about the database, the less pr
oblems you encounter.",
    "developer": "alibaba",
    "drivers": [
        "dm.jdbc.driver.DmDriver",
        "com.ibm.db2.jcc.DB2Driver",
        "com.sybase.jdbc3.jdbc.SybDriver",
        "com.edb.Driver"
    ]
}
```

3. Add the package of the driver to the libs directory in the RDBMS Writer directory.

```
$tree
.
|-- libs
|   |-- Dm7JdbcDriver16.jar
|   |-- commons-collections-3.0.jar
|   |-- commons-io-2.4.jar
|   |-- commons-lang3-3.3.2.jar
|   |-- commons-math3-3.1.1.jar
|   |-- datax-common-0.0.1-SNAPSHOT.jar
|   |-- datax-service-face-1.0.23-20160120.024328-1.jar
|   |-- db2jcc4.jar
|   |-- druid-1.0.15.jar
|   |-- edb-jdbc16.jar
|   |-- fastjson-1.1.46.sec01.jar
|   |-- guava-r05.jar
|   |-- hamcrest-core-1.3.jar
|   |-- jconn3-1.0.0-SNAPSHOT.jar
|   |-- logback-classic-1.0.13.jar
|   |-- logback-core-1.0.13.jar

```

2.1.4.5.4.23. Configure Stream Writer

This topic describes the data types and parameters supported by Stream Writer and how to configure it by using the code editor.

Stream Writer allows you to display the data obtained from a Data Integration reader on the screen or discard the data. Stream Writer is mainly applicable to performance testing for data synchronization and basic functional testing.

Parameters

print

- Description: specifies whether to display the data obtained from the reader on the screen.
- Required: No
- Default value: true

Configure Stream Writer by using the codeless UI

Currently, the codeless user interface (UI) is not supported for Stream Writer.

Configure Stream Writer by using the code editor

In the following code, a node is configured to display the data obtained from a Data Integration reader on the screen.

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"stream",// The writer type.
            "parameter":{
                "print": false, // Specifies whether to display data on the screen.
                "fieldDelimiter":","// The column delimiter.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false i
ndicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is thrott
led. The maximum transmission rate takes effect only if you set this parameter to true.
            "concurrent":1,// The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.24. Hive Writer

Hive Writer writes data to the Hadoop distributed file system (HDFS) and loads the data to Hive. This topic describes how Hive Writer works, the parameters that are supported by Hive Writer, and how to configure Hive Writer by using the codeless user interface (UI) and code editor.

Background information

Hive is a Hadoop-based data warehouse tool that is used to process large amounts of structured logs. Hive maps structured data files to a table and allows you to execute SQL statements to query data in the table.

Essentially, Hive converts Hive Query Language (HQL) or SQL statements to MapReduce programs.

- Hive stores processed data in HDFS.
- Hive uses MapReduce programs to analyze data at the underlying layer.
- Hive runs MapReduce programs on Yarn.

How it works

Hive Writer connects to a Hive metastore and obtains the storage path, format, and column delimiter of the HDFS file to which you want to write data. Then, Hive Writer writes data to the HDFS file and loads data in the HDFS file to the destination Hive table by using Java Database Connectivity (JDBC).

The underlying logic of Hive Writer is the same as that of HDFS Writer. You can configure parameters for HDFS Writer in the parameters of Hive Writer. Data Integration transparently transmits the configured parameters to HDFS Writer.

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source.	Yes	No default value
column	The names of the columns to which you want to write data, such as `"column": ["id", "name"]`. • You can select specific columns to write. • The column parameter must explicitly specify all the columns to which you want to write data. The parameter cannot be left empty. • The column order cannot be changed.	Yes	No default value
table	The name of the Hive table to which you want to write data. **Note** The name is case-sensitive.	Yes	No default value
partition	The partition in the Hive table. This parameter is required for partitioned Hive tables. After you specify this parameter, Hive Writer writes data to the partition that is specified by this parameter.	No	No default value

Parameter	Description	Required	Default value
writeMode	The mode in which Hive Writer loads data to the Hive table. After data is written to an HDFS file, Hive Writer executes the `LOAD DATA INPATH (overwrite) INTO TABLE` statement to load data to the Hive table. The writeMode parameter specifies the mode in which Hive Writer loads data from the HDFS file to the Hive table. Valid values: • *truncate*: Hive Writer deletes existing data before it loads data to the Hive table. • *append*: Hive Writer retains the existing data and appends data to the Hive table. • Other: Hive Writer writes data to the HDFS file but does not load the data to the Hive table. **Note** Setting the writeMode parameter is a high-risk operation. Pay attention to the destination directory and the value of this parameter to prevent data from being incorrectly deleted. This parameter must be used together with the hiveConfig parameter.	Yes	No default value

Parameter	Description	Required	Default value

parquet schema	The schema of the destination files. This parameter is available only when the FileType parameter is set to *Parquet*.
	
	The parquet schema parameter is specified in the following format:
	
	`message MessageTypeName {`
	`required, dataType, columnName;`
	`.....;`
	`}`
	
	• MessageTypeName: the name of the MessageType object. You can customize the name.
	• dataType: the data type. Valid values: BOOLEAN, INT32, INT64, INT96, FLOAT, DOUBLE, BINARY, and FIXED_LEN_BYTE_ARRAY.
	
	Note Each line, including the last line, must end with a semicolon (;).
	
	Example:
	
	`message m {`
	`optional int64 id;`
	`optional int64 date_id;`
	`optional binary datetimestring;`
	`optional int32 dspId;`
	`optional int32 advertiserId;`
	`optional int32 status;`
	`optional int64 bidding_req_num;`
	`optional int64 imp;`
	`optional int64 click_num;`
	`}`
		Specifies whether the desired columns are required in the parquet schema parameter. Valid values:
		• required
		• optional
		
		Note We recommend that you use optional for the desired columns.
			No default value

Parameter	Description	Required	Default value
hiveConfig	The extended parameters for Hive, including hiveCommand, jdbcUrl, username, and password. • hiveCommand: the full path of the Hive client. After you run the `hive -e` command, execute the `LOAD DATA INPATH` statement to load data based on the mode that is specified by the writeMode parameter. The client that is specified by the hiveCommand parameter provides access information about Hive. • jdbcUrl, username, and password: the information that is required to connect to Hive by using JDBC. After Hive Writer connects to Hive by using JDBC, Hive Writer executes the `LOAD DATA INPATH` statement to load data based on the mode that is specified by the writeMode parameter. `"hiveConfig": { "hiveCommand": "", "jdbcUrl": "", "username": "", "password": "" }` • Hive Writer uses an HDFS client to write data to HDFS files. You can use the hiveConfig parameter to specify advanced settings for the HDFS client.	Yes	No default value

Configure Hive Writer by using the codeless UI

Log on to the DataWorks console. The **DataStudio** page appears. On the **DataStudio** page, double-click the desired synchronization node and configure the node.

Perform the following steps on the configuration tab of the node:

1. Configure data sources.

   Configure **Source** and **Target** for the synchronization node.

Parameter	Description
Connection	The name of the data source to which you want to write data. This parameter corresponds to the datasource parameter that is described in the preceding section.
Table	The name of the table to which you want to write data. This parameter corresponds to the table parameter that is described in the preceding section.
Partition info	The partition to which you want to write data. You must specify the last-level partition. Hive Writer can write data only to a single partition.
Write mode	The write mode. This parameter corresponds to the writeMode parameter that is described in the preceding section.

2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in the preceding section. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove the mappings that are established.
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on specific rules.

3. Configure channel control policies.

Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure Hive Writer by using the code editor

In the following code, a synchronization node is configured to write data to Hive in the JSON format:

```
{
    "type": "job",
    "steps": [
        {
            "stepType": "hive",
            "parameter": {
            },
            "name": "Reader",
            "category": "reader"
        },
        {
            "stepType": "hive",
            "parameter": {
                "partition": "year=a,month=b,day=c", // The partition to which you want to write dat
a.
                "datasource": "hive_ha_shanghai", // The name of the data source.
                "table": "partitiontable2", // The name of the table to which you want to write data
.
                "column": [ // The names of the columns to which you want to write data.
                    "id",
                    "name",
                    "age"
                ],
                "writeMode": "append" // The write mode.
            },
            "name": "Writer",
            "category": "writer"
        }
    ],
    "version": "2.0",
    "order": {
        "hops": [
            {
                "from": "Reader",
                "to": "Writer"
            }
        ]
    },
    "setting": {
        "errorLimit": {
            "record": ""
        },
        "speed": {
            "throttle": false,
            "concurrent": 2
        }
    }
}
```

2.1.4.5.4.25. Configure Vertica Writer

Vertica is a column-oriented database using the MPP architecture. Vertica Writer allows you to write data to tables stored in Vertica databases. This topic describes how Vertica Writer works, its parameters, and how to configure it by using the code editor.

How it works

Vertica Writer connects to a remote Vertica database by using JDBC, and executes an `INSERT INTO` statement to write data to the Vertica database. Internally, data is submitted to the Vertica database in batches.

Vertica Writer is designed for ETL developers to import data from data warehouses to Vertica databases. Vertica Writer can also be used as a data migration tool by users such as DBAs.

Vertica Writer obtains data from a Data Integration reader, and generates the INSERT INTO statement based on your configurations.

- `INSERT INTO` : If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows.
- Data can be written only to tables stored in the primary Vertica database.

  > **Note** A sync node that uses Vertica Writer must have at least the permission to execute the `INSERT INTO` statement. Whether other permissions are required depends on the SQL statements specified in the preSql and postSql parameters when you configure the node.

- Vertica Writer does not support the writeMode parameter.
- Vertica Writer accesses a Vertica database by using the Vertica database driver. Confirm the compatibility between the driver version and your Vertica database. Vertica Writer uses the following version of the Vertica database driver:

```
<dependency>
    <groupId>com.vertica</groupId>
    <artifactId>vertica-jdbc</artifactId>
    <version>7.1.2</version>
</dependency>
```

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be the same as the name of the added connection. You can add connections in the code editor.	Yes	None
jdbcUrl	The JDBC URL for connecting to the Vertica database. You do not need to set this parameter because the system automatically obtains the value from the connection parameter. • You can configure only one JDBC URL for a database. Vertica Writer cannot write data to a database with multiple primary databases. • The format must be in accordance with Vertica official specifications. You can also specify the information of the attachment facility. Example: `jdbc:vertica://127.0.0.1:3306/database` .	Yes	None
username	The username that you can use to connect to the database.	Yes	None
password	The password that you can use to connect to the database.	Yes	None
table	The names of the destination tables, which are described in a JSON array. **Note** You do not need to set this parameter because the system automatically obtains the value from the connection parameter.	Yes	None

Parameter	Description	Required	Default value
column	The columns in the destination table to which data is written. Separate the columns with a comma (,), for example, `"column": ["id","name","age"]`.	Yes	None
preSql	The SQL statement to execute before the sync node is run. Use `@table` to specify the name of the destination table in the SQL statement. When you execute this SQL statement, DataWorks replaces @table with the name of the destination table.	No	None
postSql	The SQL statement to execute after the sync node is run.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Vertica database over the network, and increase the throughput. However, an excessively large value may lead to the OOM error during the data synchronization process.	No	*1,024*

Configure Vertica Writer by using the codeless UI

The codeless UI is not supported for Vertica Writer.

Configure Vertica Writer by using the code editor

In the following code, a node is configured to write data to a Vertica database.

```
{
    "type":"job",
    "version":"2.0",// The version number.
     "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"vertica",// The writer type.
             "parameter":{
                "datasource": "The connection name.",
                "username": "",
                "password": "",
                "column": [// The columns to which data is written.
                     "id",
                    "name"
                ],
                "connection": [
                    {
                        "table": [// The name of the destination table.
                             "vertica_table"
                        ],
                        "jdbcUrl": "jdbc:vertica://ip:port/database"
                    }
                ],
                "preSql": [ // The SQL statement to execute before the sync node is run.
                     "delete from @table where db_id = -1"
                ],
```

```
                "postSql": [// The SQL statement to execute after the sync node is run.
                     "update @table set db_modify_time = now() where db_id = 1"
                ]
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{
            "record":"0"// The maximum number of dirty data records allowed.
         },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. A value of false i
ndicates that the bandwidth is not throttled. A value of true indicates that the bandwidth is thrott
led. The maximum transmission rate takes effect only if you set this parameter to true.
             "concurrent":1 // The maximum number of concurrent threads.
         }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.26. Configure Gbase8a Writer

This topic describes the implementation principle and parameter configurations of Gbase8a Writer.

Gbase8a Writer allows you to write data to tables stored in Gbase8a databases. At the underlying implementation level, Gbase8a Writer connects to a remote Gbase8a database through the JDBC Driver and runs the relevant SQL statements to write data to the Gbase8a database.

> **Note** You must configure a connection before configuring Gbase8a Writer.

Parameters

Parameter	Description	Required	Default value
datasource	The connection name. It must be identical to the name of the added connection. You can add connections in the code editor.	Yes	None
table	The name of the table to be synchronized.	Yes	None

Parameter	Description	Required	Default value
writeMode	The write mode. Valid values: *insert into*, *on duplicate key update*, and *replace into*. • *insert into*: If a primary key conflict or unique index conflict occurs, data cannot be written to the conflicting rows and is regarded as dirty data. • *on duplicate key update*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, specified fields in original rows are updated. • *replace into*: If no primary key conflict or unique index conflict occurs, the action is the same as that of `insert into`. If a conflict occurs, original rows are deleted and new rows are inserted. That is, all fields of original rows are replaced.	No	*insert*
column	The columns in the destination table to which data is written. Separate the columns with a comma (,). Example: `"column": ["id", "name", "age"]`. Set the value to an asterisk (*) if data is written to all the columns in the destination table. That is, set the column parameter as follows: `"column":["*"]`.	Yes	None
preSql	The SQL statement to run before the sync node is run. For example, you can clear outdated data before data synchronization. Currently, you can run only one SQL statement on the codeless user interface (UI), and multiple SQL statements in the code editor. **Note** If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None
postSql	The SQL statement to run after the sync node is run. For example, you can add a timestamp after data synchronization. Currently, you can run only one SQL statement on the codeless UI, and multiple SQL statements in the code editor. **Note** If you specify multiple SQL statements in the code editor, the system does not guarantee that they are run in the same transaction.	No	None
batchSize	The number of data records to write at a time. Setting this parameter can greatly reduce the interactions between Data Integration and the Gbase8a database over the network, and increase the throughput. However, an excessively large value may lead to the out of memory (OOM) error during the data synchronization process.	No	*1024*

Configure Gbase8a Writer by using the codeless UI

Currently, the codeless UI is not supported for Gbase8a Writer.

Configure Gbase8a Writer by using the code editor

In the following code, a node is configured to write data to the Gbase8a database. For more information about the parameters, see the preceding parameter description.

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"gbase8a",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement to run after the sync node is run.
                "datasource":"",// The connection name.
                "column":[// The columns to be synchronized.
                    "id",
                    "value"
                ],
                "writeMode":"insert",// The write mode.
                "batchSize":1024,// The number of data records to write at a time.
                "table":"",// The name of the table to be synchronized.
                "preSql":[]// The SQL statement to run before the sync node is run.
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{// The maximum number of dirty data records allowed.
            "record":"0"
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling.
            "concurrent":1,// The maximum number of concurrent threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.27. KingbaseES Writer

This topic describes the parameters that are supported by KingbaseES Writer and how to configure KingbaseES Writer by using the codeless user interface (UI) and code editor.

Context

KingbaseES Writer writes data to tables stored in KingbaseES databases. KingbaseES Writer connects to a remote KingbaseES database by using Java Database Connectivity (JDBC) and executes the `INSERT INTO` or `REPLACE INTO` statement to write data to the database. KingbaseES uses the InnoDB engine so that data is written to the database in batches.

KingbaseES Writer can also be used as a data migration tool by users such as database administrators. KingbaseES Writer obtains protocol data from a Data Integration reader, and writes the data to the destination database based on the value of the writeMode parameter.

> **Note** A synchronization node that uses kingbaseES Writer must have at least the permissions to execute the `INSERT INTO` or `REPLACE INTO` statement. Whether other permissions are required depends on the SQL statements that you specify in the preSql and postSql parameters when you configure the node.

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
table	The name of the table to which you want to write data.	Yes	No default value
column	The names of the columns to which you want to write data. Separate the names with commas (,), such as `"column": ["id", "name", "age"]`. If you want to write data to all the columns in the destination table, set this parameter to an asterisk (*), such as `"column":["*"]`.	Yes	No default value
preSql	The SQL statement that you want to execute before the synchronization node is run. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor. For example, you can set this parameter to the following statement to delete outdated data before the synchronization node is run: `truncate table tablename` **Note** If you specify multiple SQL statements, they may not be executed in the same transaction.	No	No default value
postSql	The SQL statement that you want to execute after the synchronization node is run. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor. For example, you can set this parameter to `alter table tablenameadd colname timestamp DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP` to add a timestamp after the synchronization node is run.	No	No default value

Parameter	Description	Required	Default value
batchSize	The number of data records to write at a time. Set this parameter to an appropriate value based on your business requirements. This greatly reduces the interactions between Data Integration and the database and increases throughput. If you set this parameter to an excessively large value, an out of memory (OOM) error may occur during data synchronization.	No	*2048*

Configure KingbaseES Writer by using the codeless UI

1. Configure data sources.

   Log on to the DataWorks console. The **DataStudio** page appears. On the DataStudio page, move the pointer over the icon and choose **Data Integration > Batch Synchronization**. In the **Create Node** dialog box, configure the parameters to create a batch synchronization node.

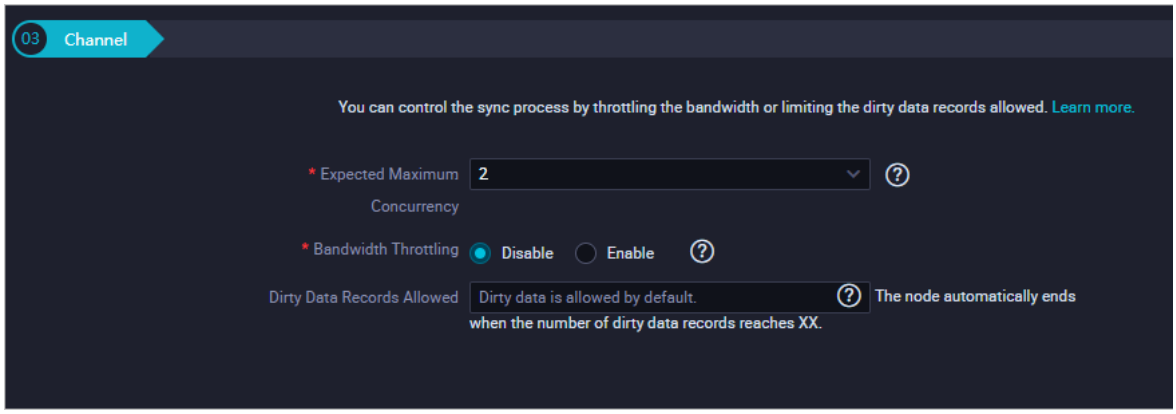
   On the configuration tab of the batch synchronization node, configure Source and **Target** for the node.

Parameter	Description
Connection	The name of the data source to which you want to write data. This parameter corresponds to the datasource parameter that is described in the preceding section. Select the name of a data source that you configured.
Table	The name of the table to which you want to write data. This parameter corresponds to the table parameter that is described in the preceding section.
Pre sql	The SQL statement that you want to execute before the synchronization node is run. This parameter corresponds to the preSql parameter that is described in the preceding section. Enter the SQL statement that you want to execute before the synchronization node is run.
Post sql	The SQL statement that you want to execute after the synchronization node is run. This parameter corresponds to the postSql parameter that is described in the preceding table. Enter the SQL statement that you want to execute after the synchronization node is run.
Data Records Per Write	The number of data records to write at a time. This parameter corresponds to the batchSize parameter that is described in the preceding section. Valid values: *2048*. You can specify this parameter based on your business requirements.

2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in the preceding section. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove the mappings that are established.
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on the specified rules.
Add	Click **Add** to add a field. Take note of the following rules when you add a field: ○ You can enter constants. Each constant must be enclosed in single quotation marks ('), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions that are supported by relational databases, such as now() and count(1). ○ If the value that you entered cannot be parsed, the value of Type for the field is Unidentified.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure KingbaseES Writer by using the code editor

In the following code, a synchronization node is configured to write data to KingbaseES:

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"kingbasees",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement that you want to execute after the synchronization
node is run.
                "datasource":"",// The name of the data source.
                "column":[// The names of the columns to which you want to write data.
                    "id",
                    "value"
                ],
                "batchSize":2048,// The number of data records to write at a time.
                "table":"",// The name of the table to which you want to write data.
                "preSql":[
                     "delete from XXX;"// The SQL statement that you want to execute before the sync
hronization node is run.
                   ]
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{// The maximum number of dirty data records allowed.
            "record":"0"
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling.
            "concurrent":1// The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.4.28. SAP HANA Writer

This topic describes the parameters that are supported by SAP HANA Writer and how to configure SAP HANA Writer by using the codeless user interface (UI) and code editor.

Context

SAP HANA Writer writes data to tables stored in SAP HANA databases. SAP HANA Writer connects to a remote SAP HANA database by using Java Database Connectivity (JDBC) and executes the `INSERT INTO` or `REPLACE INTO` statement to write data to the SAP HANA database. SAP HANA uses the InnoDB engine so that data is written to the database in batches.

SAP HANA Writer can also be used as a data migration tool by users such as database administrators.

> **Note** A synchronization node that uses SAP HANA Writer must have at least the permissions to execute the `INSERT INTO` or `REPLACE INTO` statement. Whether other permissions are required depends on the SQL statements that you specify in the preSql and postSql parameters when you configure the node.

Parameters

Parameter	Description	Required	Default value
datasource	The name of the data source. It must be the same as the name of the added data source. You can add data sources by using the code editor.	Yes	No default value
table	The name of the table to which you want to write data.	Yes	No default value
column	The names of the columns to which you want to write data. Separate the names with commas (,), such as `"column": ["id", "name", "age"]`. If you want to write data to all the columns in the destination table, set this parameter to an asterisk (*), such as `"column":["*"]`.	Yes	No default value
preSql	The SQL statement that you want to execute before the synchronization node is run. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor. For example, you can set this parameter to the following SQL statement that is used to delete outdated data: `truncate table tablename` **Note** If you specify multiple SQL statements in the code editor, the SQL statements cannot be executed in the same transaction.	No	No default value
postSql	The SQL statement that you want to execute after the synchronization node is run. You can execute only one SQL statement on the codeless UI and multiple SQL statements in the code editor. For example, you can set this parameter to `alter table tablenameadd colname timestamp DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP` that is used to add a timestamp.	No	No default value

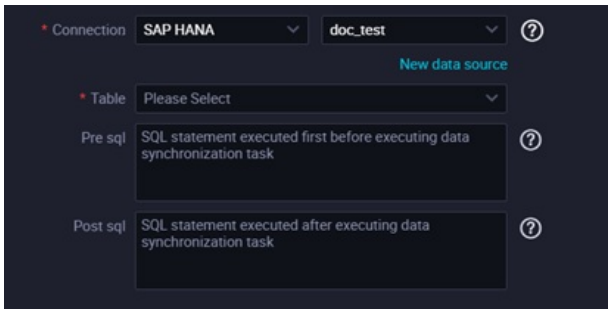
Parameter	Description	Required	Default value
batchSize	The number of data records to write at a time. Set this parameter to an appropriate value based on your business requirements. This greatly reduces the interactions between Data Integration and SAP HANA and increases throughput. If you set this parameter to an excessively large value, an out of memory (OOM) error may occur during data synchronization.	No	*2048*

Configure SAP HANA Writer by using the codeless UI

1. Configure data sources.

   Log on to the DataWorks console. The **DataStudio** page appears. On the DataStudio page, move the pointer over the icon and choose **Data Integration > Batch Synchronization**. In the **Create Node** dialog box, configure the parameters to create a batch synchronization node.

   Configure Source and **Target** for the synchronization node.

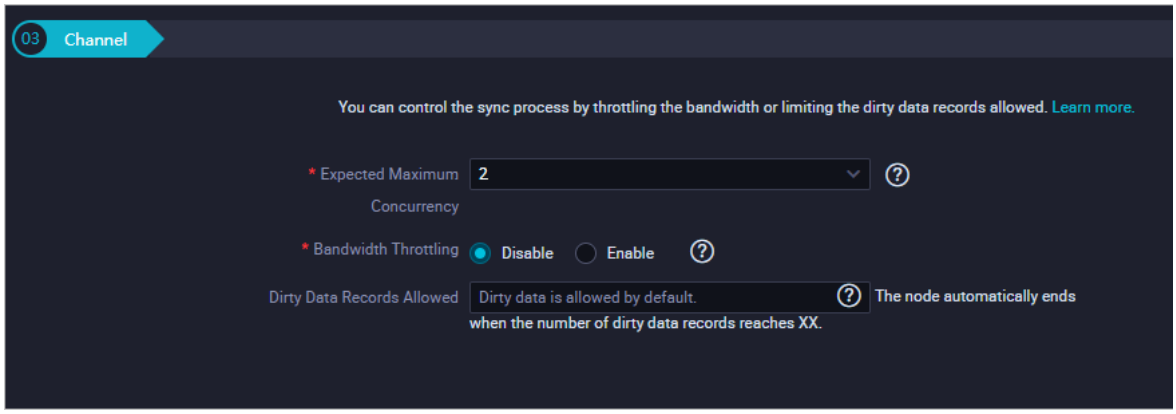
   


Parameter	Description
Connection	The name of the data source to which you want to write data. This parameter corresponds to the datasource parameter that is described in the preceding section.
Table	The name of the table to which you want to write data. This parameter corresponds to the table parameter that is described in the preceding section.
Pre sql	The SQL statement that you want to execute before the synchronization node is run. This parameter corresponds to the preSql parameter that is described in the preceding section.
Post sql	The SQL statement that you want to execute after the synchronization node is run. This parameter corresponds to the postSql parameter that is described in the preceding section.

2. Configure field mappings. This operation is equivalent to setting the column parameter that is described in the preceding section. Fields in the source on the left have a one-to-one mapping with fields in the destination on the right.

Operation	Description
Map Fields with the Same Name	Click **Map Fields with the Same Name** to establish mappings between fields with the same name. The data types of the fields must match.
Map Fields in the Same Line	Click **Map Fields in the Same Line** to establish mappings between fields in the same row. The data types of the fields must match.
Delete All Mappings	Click **Delete All Mappings** to remove the mappings that are established.
Auto Layout	Click Auto Layout. Then, the system automatically sorts the fields based on specific rules.
Add	Click **Add** to add a field. Take note of the following rules when you add a field: ○ You can enter constants. Each constant must be enclosed in single quotation marks ('), such as 'abc' and '123'. ○ You can use scheduling parameters, such as ${bizdate}. ○ You can enter functions that are supported by relational databases, such as now() and count(1). ○ If the field that you entered cannot be parsed, the value of Type for the field is Unidentified.

3. Configure channel control policies.



Parameter	Description
Expected Maximum Concurrency	The maximum number of parallel threads that the synchronization node uses to read data from the source or write data to the destination. You can configure the parallelism for the synchronization node on the codeless UI.

Parameter	Description
Bandwidth Throttling	Specifies whether to enable bandwidth throttling. You can enable bandwidth throttling and set a maximum transmission rate to avoid heavy read workloads on the source. We recommend that you enable bandwidth throttling and set the maximum transmission rate to an appropriate value based on the configurations of the source.
Dirty Data Records Allowed	The maximum number of dirty data records allowed.

Configure SAP HANA Writer by using the code editor

In the following code, a synchronization node is configured to write data to SAP HANA:

```
{
    "type":"job",
    "version":"2.0",// The version number.
    "steps":[
        {
            "stepType":"stream",
            "parameter":{},
            "name":"Reader",
            "category":"reader"
        },
        {
            "stepType":"saphana",// The writer type.
            "parameter":{
                "postSql":[],// The SQL statement that you want to execute after the synchronization
node is run.
                "datasource":"",// The name of the data source.
                "column":[// The names of the columns to which you want to write data.
                    "id",
                    "value"
                ],
                "batchSize":1024,// The number of data records to write at a time.
                "table":"",// The name of the table to which you want to write data.
                "preSql":[
                     "delete from XXX;" // The SQL statement that you want to execute before the syn
chronization node is run.
                   ]
            },
            "name":"Writer",
            "category":"writer"
        }
    ],
    "setting":{
        "errorLimit":{// The maximum number of dirty data records allowed.
            "record":"0"
        },
        "speed":{
            "throttle":false,// Specifies whether to enable bandwidth throttling. The value false in
dicates that bandwidth throttling is disabled, and the value true indicates that bandwidth throttlin
g is enabled. The mbps parameter takes effect only when the throttle parameter is set to true.
            "concurrent":1 // The maximum number of parallel threads.
        }
    },
    "order":{
        "hops":[
            {
                "from":"Reader",
                "to":"Writer"
            }
        ]
    }
}
```

2.1.4.5.5. Optimize synchronization performance

This topic describes how to maximize the synchronization speed by adjusting the concurrency configuration, the difference between nodes that are configured with bandwidth throttling and those that are not, and precautions for custom resource groups.

Data Integration is a one-stop platform that supports real-time and offline data synchronization between any connections in any location and in any network environment. You can synchronize 10 TB of data between various types of cloud storage and local storage each day.

DataWorks provides excellent data transmission performance and supports data exchanges between more than 400 pairs of disparate connections. These features allow you to focus on the key issues on constructing big data solutions.

Factors affecting the speed of data synchronization

The factors that affect the speed of data synchronization are listed as follows:

- Source
  - Database performance: the performance of the CPU, memory module, SSD, network, and hard disk.
  - Concurrency: A high concurrency results in a heavy database workload.
  - Network: the bandwidth (throughput) and speed of the network. Generally, a database with better performance can support more concurrent nodes and a larger concurrency value can be set for sync nodes.
- Sync node
  - Synchronization speed: whether an upper limit is set for the synchronization speed.
  - Concurrency: a maximum number of concurrent threads to read data from the source and write data to destination data storage within a single sync node.
  - Nodes that are waiting for resources.
  - Bandwidth throttling: The bandwidth of a single thread is 1,048,576 bit/s. Timeout occurs when the business is sensitive to the network speed. We recommend that you set a smaller value.
  - Whether to create an index for query statements.
- Destination
  - Performance: the performance of the CPU, memory module, SSD, network, and hard disk.
  - Load: Excessive load in the destination database affects the write efficiency within the sync nodes.
  - Network: the bandwidth (throughput) and speed of the network.

You need to monitor and optimize the performance, load, and network of the source and destination databases. The following describes the optimal settings of a sync node.

Concurrency

You can configure the concurrency for a node on the codeless user interface (UI). The following is an example of how to configure the concurrency in the code editor:

```
"setting": {
      "speed": {
        "concurrent": 10
      }
    }   }
```

Bandwidth throttling

By default, bandwidth throttling is disabled. In a sync node, data is synchronized at the maximum speed given the concurrency configured for the node. Considering that excessively fast synchronization may overstress the database and thus affect the production, Data Integration allows you to limit the synchronization speed and optimize the configuration as required. If bandwidth throttling is enabled, we recommend that you limit the maximum speed to 30 Mbit/s. The following is an example for configuring an upper limit for synchronization speed in the code editor, in which the transmission bandwidth is 1 Mbit/s:

```
"setting": {
      "speed": {
         "throttle": true // The bandwidth throttling is enabled.
        "mbps": 1, // The synchronization speed.
      }
    }
```

Note

- When the throttle parameter is set to false, throttling is disabled, and you do not need to configure the mbps parameter.
- The bandwidth value is a Data Integration metric and does not represent the actual network interface card (NIC) traffic. Generally, the NIC traffic is two to three times of the channel traffic, which depends on the serialization of the data storage system.
- A semi-structured file does not have shard keys. If multiple files exist, you can set the maximum job speed to increase the synchronization speed. However, the maximum job speed is limited by the number of files. For example, the maximum job speed limit is set to n Mbit/s for n files. If you set the limit to n+1 Mbit/s, the synchronization speed remains at n Mbit/s. If you set the limit to n-1 Mbit/s, the synchronization is performed at n-1 Mbit/s.
- A table can be partitioned according to the preset maximum job speed only when a maximum job speed and a shard key are configured for a relational database. Relational databases only support numeric shard keys, while Oracle databases support both numeric and string shard keys.

Scenarios of slow data synchronization

- Scenario 1: Resolve the issue that sync nodes to be run on the default resource group remain waiting for resources.
  - Example

    When you test a sync node in DataWorks, the node remains waiting for resources and an internal system error occurs.

    For example, a sync node is configured to synchronize data from RDS to MaxCompute. The node has waited for about 800 seconds before it is run successfully. However, the log shows that the node runs for only 18 seconds and then stops. The sync node uses the default resource group. When you run other sync nodes, they also remain in the waiting state.

    The log is displayed as follows:

    ```
    2017-01-03 07:16:54 : State: 2(WAIT) | Total: 0R 0B | Speed: 0R/s 0B/s | Error: 0R 0B | Stage: 0
    .0%
    ```

  - Solution

    The default resource group is not exclusively used by a single user. It is used by many projects concurrently, not just two or three nodes for a single user. If such resources are insufficient after you start to run a node, the node needs to wait for resources. In this case, the node is completed 800 seconds after you start running the node, but it only takes 10 seconds for the node to be executed.

    To improve the synchronization speed and reduce the waiting time, we recommend that you run sync nodes during off-peak hours. Typically, most sync nodes are run between 00:00 and 03:00.

- Scenario 2:

  Accelerate nodes that synchronize data from multiple source tables to the same destination table.

- Example

  To synchronize data from tables of multiple data stores to a table, you configure multiple sync nodes to run in sequence. However, the synchronization takes a long time.

- Solution

  To launch multiple concurrent nodes that write data to the same destination database, pay attention to the following points:

  - Ensure that the destination database can support the execution of all the concurrent nodes.
  - You can configure a sync node that synchronizes multiple source tables to the same destination table. Alternatively, you can configure multiple nodes to run concurrently in the same workflow.
  - If resources are insufficient, you can configure sync nodes to run during off-peak hours.

- Scenario 3:

  If no index is added when the WHERE clause is used, a full table scan slows down the data synchronization.

  - Example

    SQL statement:

    ```
    select bid,inviter,uid,createTime from `relatives` where createTime>='2016-10-23 00:00:00'and re
    ateTime<'2016-10-24 00:00:00';
    ```

    Assume that the sync node started to run the preceding statement at 2016-10-25 11:01:24 and started to return results from 2016-10-25 11:11:05. It took a long time to finish the sync node.

  - Cause

    When the WHERE clause is used for a query, the createTime column is not indexed, resulting in a full table scan.

  - Solution

    We recommend that you use an indexed column or add an index to the column that you want to scan if you use the WHERE clause.

2.1.4.6. Synchronize data in real time

2.1.4.6.1. Overview

This topic describes the definition, highlights, supported data sources, and architecture of the real-time synchronization feature. This topic also describes how to use this feature.

Definition

The real-time synchronization feature allows you to synchronize the data changes in a source database to a destination database in real time. For example, after you add, modify, or delete the data in a source database, the real-time synchronization feature synchronizes these changes to a destination database in real time. If a real-time synchronization is performed during a batch synchronization for full historical data, all the data in your source database is synchronized to your destination database. The real-time synchronization feature helps ensure that the data in your destination database is updated in real time and consistent with that in your source database.

Highlights

- Diverse data sources
  - Star-shaped combination is supported. Each supported source can be combined with a supported destination to synchronize data.

  - The feature will soon allow you to synchronize data from a single source to multiple destinations at the same time.
- Comprehensive synchronization solutions
  - You can configure a synchronization solution to synchronize the full data or incremental data from a database to MaxCompute or Hologres.
  - The feature synchronizes full data first and then continuously synchronizes incremental data to the destination database based on the synchronization solution that you configure.
- Real-time data extraction

  The feature can extract data from the table shards, a single table, and multiple tables in a database, and extract the data definition language (DDL) statements of tables.
- Data processing

  The feature can filter data and replace strings during synchronization.
- Monitoring and alerting
  - The feature monitors the service latency, failovers, dirty data, heartbeats, and failures during synchronization.
  - Alert notifications can be sent by email, phone call, and DingTalk message.
- Small impact on the source

  The feature is optimized to have a small impact on the source.
- Graphical development
  - You can develop real-time synchronization nodes in a graphical user interface (GUI) without the need to write code.
  - The feature is easy to use even for beginners.

Supported data sources

- Source: MySQL Binlog, Oracle CDC, Kafka, DataHub, LogHub, and PolarDB.
- Destination: MaxCompute, Hologres, Kafka, and DataHub.
- The feature can filter data and replace strings during synchronization.

How to use the feature

You can use the real-time synchronization feature to create real-time synchronization solutions or synchronization nodes.

- For more information about how to create a real-time synchronization node, see Create a real-time synchronization node.
- For more information about how to create a synchronization solution, see Go to the Sync Solutions page.

2.1.4.6.2. Data sources supported by real-time synchronization

Real-time synchronization supports reader, writer, and conversion plug-ins. The following table lists the plug-ins.

Category	Plug-in	References
	MySQL Binlog Reader	Configure MySQL Binlog Reader
	Oracle Change Data Capture (CDC) Reader	Configure Oracle CDC Reader

Category	Plug-in	References
Reader	DataHub Reader	Configure DataHub Reader
	LogHub Reader	Configure LogHub Reader
	Kafka Reader	Configure Kafka Reader
Writer	Hologres Writer	Configure Hologres Writer
	DataHub Writer	Configure DataHub Writer
	Kafka Writer	Configure Kafka Writer
	MaxCompute Writer	Configure MaxCompute Writer
Conversion	Data filtering	Configure data filtering
	String replacement	Configure string replacement

Note A real-time synchronization node cannot be directly run on the node configuration tab. Instead, you must save and commit the node before the real-time synchronization node is run in the production environment.

Basic configuration

After you configure the reader, writer, and conversion plug-ins, you can click the **Basic configuration** panel in the right-side navigation pane to configure the synchronization node.

Parameter	Description
Description	The description of the real-time synchronization node.
JVM parameters	The Java virtual machine (JVM) memory allocated for the real-time synchronization node. If this parameter is not specified, Data Integration automatically allocates JVM memory based on your node configurations.

2.1.4.6.3. Create, configure, commit, and manage real-time synchronization nodes

DataWorks allows you to synchronize data in real time. This topic describes how to create, configure, commit, and manage real-time synchronization nodes.

Create a real-time synchronization node

1. Log on to the DataWorks console.
2. On the DataStudio page, move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can find the required workflow, right-click the workflow name, and then choose **Create > Data Integration > Real-time synchronization**.
3. In the **Create Node** dialog box, configure the parameters.

Parameter	Description
Node Type	The type of the node. Default value: **Real-time synchronization**.
Sync Method	The method used to synchronize data. Valid values: ○ **End-to-end ETL**: synchronizes data in one table to one or more tables. Data type conversion is supported during the synchronization. ○ **Migration to Hologres**: synchronizes all or some tables in a database to Hologres. Destination tables can be automatically created in Hologres. ○ **Migration to MaxCompute**: synchronizes all or some tables in a database to MaxCompute. ○ **Migration to DataHub**: synchronizes all or some tables in a database to DataHub.
Node Name	The name of the node. The name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
Location	The directory in which the real-time synchronization node is stored.

4. Click **Commit**.

Configure the real-time synchronization node

The operations that you can perform on the configuration tab of the real-time synchronization node vary based on the synchronization method that you selected.

- To configure the real-time synchronization node for which **Sync Method** is set to **End-to-end ETL**, perform the following steps:
  i. Click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.

No.	Description
1	The left-side navigation tree, which consists of the **Input**, **Output**, and **Conversion** sections.
2	The configuration canvas of the real-time synchronization node. You can drag a component from the navigation tree to the canvas and configure the component.
3	The property configuration panel of the real-time synchronization node. This panel appears after you click **Basic configuration** in the right-side navigation pane.

  ii. Drag components from the navigation tree to the canvas, and draw lines to connect the components. This way, the components synchronize data based on the connections.
  iii. Click each component on the canvas. In the panel that appears, configure the parameters.
  iv. Click the icon in the top toolbar.

- To configure the real-time synchronization node for which **Sync Method** is set to **Migration to Hologres**, perform the following steps:
  i. Click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.

> **Notice** You must select a **resource group** before you commit the node. Otherwise, the system returns an error when you commit the node.

ii. In the **Data source** section, specify **Type** and **Data source**.

iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click the > icon to move the tables to the **Selected Source table** list.

The SOURCE Table list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

> **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

iv. (Optional)In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables.

Supported options include **Table name conversion rules** and **Target table name rule**.

- **Table name conversion rules**: the rule for converting the names of source tables to those of destination tables.
- **Target table name rule**: the rule for adding a prefix and suffix to the converted names of destination tables.

v. Click **Next Step**.

vi. In the **Set target table** step, specify **Target Hologres data source** and **Schema**.

vii. Click **Reload source table and Hologres Table mapping** to configure the mappings between the source tables and destination Hologres tables.

viii. View the mapping progress, source tables, and mapped destination tables, and click **Next Step**.

You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the **Hologres Table name** column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
- If you set Table creation method to **Use existing Table**, you must select a table from the drop-down list in the **Hologres Table name** column.

ix. In the **Run resource settings** step, specify **Maximum number of connections supported by source read** and **Number of concurrent writes on the target side**. Then, click the icon in the top toolbar.

- To configure the real-time synchronization node for which **Sync Method** is set to **Migration to MaxCompute**, perform the following steps:

i. Click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.

ii. In the **Data source** section, specify **Type** and **Data source**.

iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click the > icon to move the tables to the **Selected Source table** list.

The SOURCE Table list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

> **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

iv. In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables.

Supported options include **Table name conversion rules** and **Target table name rule**.

- **Table name conversion rules**: the rule for converting the names of source tables to those of destination tables.
- **Target table name rule**: the rule for adding a prefix and suffix to the converted names of destination tables.

v. Click **Next Step**.

vi. In the **Set target table** step, select a data source from the **Target MaxCompute data source** drop-down list and click the icon next to **MaxCompute time automatic partition settings**. In the **Edit** dialog box, set the partition interval of tables in MaxCompute to day or hour.

vii. Click **Reload source table and MaxCompute Table mapping** to configure the mappings between the source tables and destination MaxCompute tables.

viii. View the mapping progress, source tables, and destination tables. Then, click **Next Step**.

You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the **MaxCompute Table name** column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
- If you set **Table creation method** to **Use existing Table**, you must select a table name from the drop-down list in the MaxCompute Table name column.

ix. In the **Run resource settings** step, specify **Maximum number of connections supported by source read** and **Number of concurrent writes on the target side**. Then, click the icon in the top toolbar.

- To configure the real-time synchronization node for which **Sync Method** is set to **Migration to DataHub**, perform the following steps:

i. On the node configuration tab that appears, click **Basic configuration** in the right-side navigation pane. In the Basic configuration panel, select the required resource group from the **Resource Group** drop-down list.

ii. In the **Data source** section, specify **Type** and **Data source**.

iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click the icon to move the tables to the **Selected Source table** list.

The SOURCE Table list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

> **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

iv. In the **Set synchronization rules** section, click **Add rule** and then select an option to configure naming rules for destination DataHub topics.

Supported options include **SOURCE table name and Topic conversion rules** and **Target Topic rules**.

v. Click **Next Step**.

vi. In the **Set target table** step, select a data source from the **Target DataHub data source** drop-down list and then click **Reload source table and DataHub Topic mapping** to configure the mappings between the source tables and destination DataHub topics.

vii. View the mapping progress, source tables, and destination topics. Then, click **Next Step**.

You can view the mapping progress between the source tables and destination topics. The mapping may take a long period of time if you want to synchronize a large number of tables.

You can set Topic creation method to **Create tables automatically** or **Use existing Topic** . The message that appears in the **DataHub Topic** column varies based on the setting of Topic creation method.

- If you set Topic creation method to **Create tables automatically**, the **Create tables automatically** dialog box appears after you click **Next Step**. Click **Start table building** in the dialog box, and then click **Close** after the topic is created.
- If you set Topic creation method to **Use existing Topic**, you must select a topic from the drop-down list in the **DataHub Topic** column.

viii. In the **Run resource settings** step, specify **Maximum number of connections supported by source read** and **Number of concurrent writes on the target side**. Then, click the icon in the top toolbar.

Commit the real-time synchronization node

1. On the configuration tab of the real-time synchronization node, click the icon in the top toolbar.
2. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
3. Click **OK**.

   If the workspace that you use is in standard mode, you must click **Deploy** in the upper-right corner after you commit the real-time synchronization node.

Manage the real-time synchronization node

1. After you commit or deploy the real-time synchronization node, click **Operation Center** in the upper-right corner of the DataStudio page to manage the node on the **Real Time DI** page.
2. On the **Real Time DI** page, find the real-time synchronization node, click the node name, and then view the O&M details about the node.

   On the Real Time DI page, you can start, stop, undeploy, or configure alert settings for the real-time synchronization node.

   - To start a node that is not running, perform the following steps:
     a. Find the node and click **Start** in the Operation column.

b. In the **Start** dialog box, configure the parameters.

Parameter	Description
Whether to reset the site	Specifies whether to set the time point for the next startup. If you select Reset site, the **Start time point** and **Time zone** parameters are required.
Start time point	The date and time for starting the real-time synchronization node.
Time zone	The time zone where the source resides. Select a time zone from the **Time zone** drop-down list.
Failover	■ The condition for automatically terminating the real-time synchronization node. You can specify the maximum number of dirty data records allowed. If you set this parameter to 0, no dirty data records are allowed. If this parameter is not specified, the node continues to run no matter whether dirty data records exist. ■ You can also specify the maximum number of failover times. If you do not specify the times, the node is automatically terminated if the node fails 100 times within 5 minutes. This prevents resource occupation caused by frequent startups.

c. Click **OK**.

- To stop a running node, perform the following steps:
  a. Find the node and click **Stop** in the Operation column.
  b. In the message that appears, click **Stop**.
- To undeploy a node that is not running, perform the following steps:
  a. Find the node and click **Offline** in the Operation column.
  b. In the message that appears, click **Offline**.
- Find the node and click **Alarm settings** in the Operation column. Then, you can view alert event information and alert rules on the **Alert event** and **Alarm rules** tabs.
- To configure alert settings for a node, perform the following steps:
  a. Select the node and click **New Alarm** in the lower part of the page.

b. In the **New rule** dialog box, configure the parameters.

Parameter	Description
Name	Required. The name of the rule that you want to create.
Description	The description of the rule.
Indicators	The metrics in the rule that you want to create. Valid values: **Task Status**, **Business latency**, **Failover**, **Dirty Data**, and **DDL error**.
Threshold	The threshold for reporting an alert. The default value is 5 minutes for both **WARNING** and **CRITICAL** alerts.
Alarm interval	The interval at which an alert is reported. The default value is 5 minutes.
WARNING	The method used to send alert notifications. The value of this parameter can be only **Mail**.
CRITICAL	
Recipient	The alert recipient. Select a recipient from the **Receiver** drop-down list.

c. Click **OK**.

- To modify alert settings for a node, perform the following steps:
  a. Select the node whose alarm settings you want to modify and click **Operation alarm** in the lower part of the page.
  b. In the **Operation alarm** dialog box, specify **Operation type** and **Alarm indicators**.

     DataWorks automatically modifies all the rules for the selected alert types at a time.
  c. Click **OK**.

2.1.4.6.4. Reader

2.1.4.6.4.1. Configure MySQL Binlog Reader

MySQL Binlog Reader reads data from tables in your MySQL database in real time after you subscribe to real-time binary logs.

Context

MySQL Binlog Reader supports the following versions of ApsaraDB RDS for MySQL: V5.1, V5.5, V5.6, V5.7, and V8.0.

If the binary log write feature is enabled for a read-only database and the binlog-format parameter is set to ROW, MySQL Binlog Reader can read data from this read-only database.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

> **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **MySQL Binlog** in the **Input** section to the canvas on the right.
6. Click the **MySQL Binlog** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The MySQL Binlog data source that you have added. You can select only a MySQL Binlog data source. If no data source is available, click **New data source** to add one on the **Data Source** page.
Table	The name of the table from which you want to read data. You can click **Data preview** on the right to preview the selected table. In the case of sharding, MySQL Binlog Reader can read data from multiple tables and databases in real time. **Notice** To prevent errors, the tables must use the same schema.
Output field	The fields that you want to synchronize. Valid values: ○ **Manage fields**: additional fields that are automatically added when the fields in the source tables are synchronized to the destination. These fields facilitate data management, sorting, and deduplication. ○ **Data Field**: the fields in the original tables that you want to synchronize.

MySQL Binlog Reader supports sharding. You can click **Add a database and table data source** and select the required **data source** and **table** from the Data source drop-down list. This way, multiple data sources are added, and data in these data sources is synchronized at the same time.

> **Notice** To prevent errors, the tables must use the same schema.

7. Click the icon in the toolbar.

2.1.4.6.4.2. Configure Oracle CDC Reader

Oracle Change Data Capture (CDC) Reader synchronizes data by using the triggers created in Oracle databases. You must activate the Oracle CDC service before you use Oracle CDC Reader.

Context

Oracle CDC Reader V11g is supported.

Configure Oracle CDC Reader

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create >**

Real-time synchronization.

3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Oracle CDC** in the **Input** section to the canvas on the right.
6. Click the **Oracle CDC** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The Oracle CDC data source that you have added. You can select only an Oracle CDC data source. If no data source is available, click **New data source** to add one on the **Data Source** page.
Table	The name of the table from which you want to read data. You can click **Data preview** on the right to preview the selected table.
Output field	The fields from which you want to read data.

7. Click the icon in the toolbar.

Create and authorize an Oracle subscriber

Common users have no permissions to read data from the production environment. If you want the system to run a real-time synchronization node to read data from the production environment, you must create an Oracle subscriber and grant the user the minimum permissions.

1. Execute the following statement to create an Oracle subscriber:

```
create user cdc_pubuser identified by cdc_pubuserpwd default tablespace ts_cdcpub QUOTA UNLIMITE
D ON ts_cdcpub;
```

2. Execute the following statements to grant permissions to the Oracle subscriber:

```
grant create session to cdc_pubuser;
grant create table to cdc_pubuser;
grant select_catalog_role to cdc_pubuser;
grant execute_catalog_role to cdc_pubuser;
grant connect,resource to cdc_pubuser;
# You can grant the Oracle subscriber the permissions to synchronize specific tables or all tabl
es in real time based on your business requirements.
grant select on schema.tableName to cdc_pubuser;
```

2.1.4.6.4.3. Configure DataHub Reader

DataHub Reader reads data from DataHub in real time by using the DataHub SDK.

Context

DataHub Reader keeps running after it is started and reads data from DataHub when new data is stored to DataHub. DataHub Reader provides the following features:

- Reads data in real time.

- Reads data in parallel based on the number of shards in DataHub.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **DataHub** in the **Input** section to the canvas on the right.
6. Click the **DataHub** node. In the configuration panel that appears, set the parameters.

Parameter	Description
Data source	The configured DataHub data source. In this example, you can select only a DataHub data source. If no data source is available, click **New data source** on the right to add one on the **Data Source** page.
Topic	The name of the DataHub topic from which you want to read data. You can click **Data preview** on the right to preview the selected topic.
Output field	The fields from which you want to read data.

7. Click the icon in the toolbar.

2.1.4.6.4.4. Configure LogHub Reader

LogHub Reader reads data from LogHub topics in real time by using the LogHub SDK and supports shard merge and split. After shards are merged or split, duplicate data records may exist but no data is lost.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Loghub** in the **Input** section to the canvas on the right.

6. Click the **LogHub** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The LogHub data source that you have configured. You can select only a LogHub data source. If no data source is available, click **New data source** on the right to add one on the **Data Source** page.
Logstore	The name of the Logstore from which you want to read data. You can click **Data preview** on the right to preview the selected Logstore.
Advanced Configuration	Specifies whether to split data in the Logstore. If you select **Split** for Split tasks, you must specify **Split rules**.
Output field	The fields that you want to synchronize.

7. Click the icon in the toolbar.

2.1.4.6.4.5. Configure Kafka Reader

Kafka Reader reads data from Kafka in real time by using a Kafka SDK.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   Notice The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Kafka** in the **Input** section to the canvas on the right.
6. Click the **Kafka** node. In the panel that appears, configure the parameters.

Parameter	Description
server	The broker server address of Kafka, in the format of `ip:port`.
topic	The name of the Kafka topic from which you want to read data. Kafka maintains the feeds of messages in categories called topics. Each message published to a Kafka cluster is assigned to a topic. Each topic contains a group of messages. **Note** Kafka Reader can read data from only one topic for each synchronization node.

Parameter	Description
keyType	The type of the key in Kafka.
valueType	The type of the value in Kafka.
Initiation Site	The start time of data synchronization.
Configuration parameters	The extended parameters specified when KafkaConsumer is created, such as bootstrap.servers, auto.commit.interval.ms, and session.timeout.ms. You can control the data consumption behaviors of KafkaConsumer by setting parameters in KafkaConfig.

Parameter	Description
Output field	The output fields, which can be customized. ○ Click **Add more fields**. In the line that appears, enter a field name and select a data type to customize the field. **Note** The output fields of Kafka are in the JSON format by default. You do not need to specify the **Value Method** parameter. To use the entire value of a Kafka field, you can customize the output field __value__. You can use the .Sub-fieldor [Element in the data array] syntax to obtain the data in the complex JSON format. The following code shows data in a Kafka message: `{ "a": { "a1": "hello" }, "b": "world", "c":[ "xxxxxxx", "yyyyyyy" ], "d":[ { "AA":"this", "BB":"is_data" }, { "AA":"that", "BB":"is_also_data" } ] }` You can set the Output field parameter to the following values based on the preceding code: ■ To synchronize all the data in the Kafka message, set this parameter to __value__. ■ To synchronize "hello" in the a1 field, set this parameter to a.a1. ■ To synchronize "world in the b field, set this parameter to b. ■ To synchronize "yyyyyyy" in the c field, set this parameter to c[1]. ■ To synchronize "this" in the AA field, set this parameter to d[0].AA. ○ To delete a field, move the pointer over the field and click the icon.

7. Click the icon in the toolbar.

2.1.4.6.4.6. Configure PolarDB Reader

PolarDB Reader can read data only from PolarDB for MySQL databases. It cannot read data from PolarDB for PostgreSQL databases.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **PolarDB** in the **Input** section to the canvas on the right.
6. Click the **PolarDB** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The PolarDB for MySQL data source that you have added. You can select only a PolarDB for MySQL data source. If no data source is available, click **New data source** to add one on the **Data Source** page.
Table	The name of the table from which you want to read data. You can click **Data preview** on the right to preview the selected table.
Output field	The fields from which you want to read data.

7. Click the icon in the toolbar.

2.1.4.6.5. Writer

2.1.4.6.5.1. Configure MaxCompute Writer

MaxCompute offers a comprehensive data import solution to support fast computing for large amounts of data.

Prerequisites

A reader or conversion node is configured.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **MaxCompute** in the **Output** section to the canvas on the right. Connect the MaxCompute node to the configured reader or conversion node.
6. Click the **MaxCompute** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The MaxCompute data source that you have configured. You can select only a MaxCompute data source. If no data source is available, click **New data source** on the right to add one on the **Data Source** page.
Table	The name of the MaxCompute table to which you want to write data. You can click **One-Click table creation** on the right to create a table, or click **Data preview** to preview the selected table. **Notice** Before you create a table, connect the MaxCompute node to a reader node, and make sure that the output field parameters are specified for the reader node.
Partition message	The information about the partitioned MaxCompute table.
Field Mapping	The field mappings between the source and destination. Click **Field Mapping** and configure field mappings. The synchronization node synchronizes data based on the field mappings.

If you want to create a table, click **One-Click table creation** next to Table. In the **New data table** dialog box, configure the parameters.

Parameter	Description
Table name	The name of the MaxCompute table.
Life cycle	The lifecycle of the MaxCompute table.
Data field structure	The field structure of the MaxCompute table. To add a field, click **Add**.
Partition settings	The partitions of the MaxCompute table. **Notice** You must configure at least two levels of partitions, which are yearly and monthly partitions. You can configure a maximum of five levels of partitions, which are yearly, monthly, daily, hourly, and minutely partitions.

7. Click the icon in the toolbar.

2.1.4.6.5.2. Configure Hologres Writer

You can build a real-time data warehouse by using the real-time write capability of Hologres.

Prerequisites

A reader or conversion node is configured.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Hologres** in the **Output** section to the canvas on the right. Then, draw a line to connect it to the configured reader or conversion node.
6. Click the **Hologres** node. In the panel that appears, configure the parameters.

Parameter	Description
Data source	The Hologres data source that you configured. You can select only a Hologres data source. If no data source is available, click **New data source** to add one on the **Data Source** page.
Table	The name of the Hologres table to which you want to write data. You can click **One-Click table creation** on the right to create a table, or click **Data preview** to preview the selected table.
Dynamic Time Partition	If the Hologres table is a partitioned table, you must specify a dynamic time-based partition. The dynamic time-based partition parses the value of a source field in the yyyymmdddhhmmss format. After the value is parsed, you can use the dynamic partition whose name is a string of variables in the destination table. The destination partition varies based on the value of the source field. For example, the value of the source field is 20200816, and the name of the destination partition is in the {yyyy}-{mm}-{dd} format. In this case, the value is written to the 2020-08-16 partition.
Job type	The type of the data write operation. Valid values: **Replay (replay operation log to restore data)** and **Insert (direct archive save)**. ○ **Replay (replay operation log to restore data)**: indicates that Hologres Writer performs the same operation on the Hologres destination as that performed on the source. For example, if the `INSERT` statement is executed to add a record to the source, Hologres Writer executes the `INSERT` statement to add the same record to the Hologres destination. If the `UPDATE` or `DELETE` statement is executed in the source, Hologres Writer executes the `UPDATE` or `DELETE` statement in the Hologres destination. ○ **Insert (direct archive save)**: indicates that Hologres Writer uses the Hologres destination as streaming data storage. Data is synchronized from the source to the Hologres destination by using the `INSERT` statement.

Parameter	Description
Writer conflict policy	The solution to data write conflicts. Valid values: ○ **Cover (Overwrite)**: indicates that Hologres Writer uses the new data synchronized from the source to overwrite the existing data in the Hologres destination. ○ **Ignore (Ignore)**: indicates that Hologres Writer ignores the new data synchronized from the source and retains the existing data in the Hologres destination.
Field Mapping	The field mappings between the source and destination. Click **Field Mapping** and configure field mappings between the source and destination. The synchronization node synchronizes data based on the field mappings.

7. Click the icon in the toolbar.

2.1.4.6.5.3. Configure DataHub Writer

DataHub is a platform that is designed to process streaming data. You can publish and subscribe to streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data.

Prerequisites

A reader or conversion node is configured.

Context

DataHub Writer writes data to DataHub by using DataHub SDK for Java. The following code provides an example of DataHub SDK for Java:

```
<dependency>
    <groupId>com.aliyun.datahub</groupId>
    <artifactId>aliyun-sdk-datahub</artifactId>
    <version>2.5.1</version>
</dependency>
```

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   Notice The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **DataHub** in the **Output** section to the canvas on the right. Connect the new node to the configured reader or conversion node.
6. Click the new **DataHub** node. In the configuration panel that appears, set the parameters.

Parameter	Description
Data source	The configured DataHub data source. In this example, you can select only a DataHub data source. If no data source is available, click **New data source** on the right to add one on the **Data Source** page.
Topic	The name of the DataHub topic to which you want to write data. You can click **Data preview** on the right to preview the selected topic.
Batch number	The number of records to write at a time.
Field Mapping	The mappings between fields in the source and destination. DataWorks synchronizes data based on the field mappings.

7. Click the icon in the toolbar.

2.1.4.6.5.4. Configure Kafka Writer

To configure Kafka Writer, select a table and configure field mappings.

Prerequisites

A reader or conversion node is configured.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Kafka** in the **Output** section to the canvas on the right. Connect the new node to the configured reader or conversion node.
6. Click the new **Kafka** node. In the configuration panel that appears, set the parameters.

Parameter	Description
server	The broker server address of Kafka, in the format of `ip:port`.
topic	The name of the Kafka topic to which you want to write data. Kafka maintains feeds of messages in categories called topics. Each message that is published to a Kafka cluster is assigned to a topic. Each topic contains a group of messages.
keyColumn	The column that is specified as the key.

Parameter	Description
valueColumn	The column that is specified as the value. If this parameter is not specified, all columns are concatenated by the delimiter that is specified by the fieldDelimiter parameter to form the value.
keyType	The type of the key in Kafka.
valueType	The type of the value in Kafka.
batchSize	The number of data records to write at a time. Default value: *1024*.
Configuration parameters	The extended parameters specified when KafkaConsumer is created, such as bootstrap.servers, auto.commit.interval.ms, and session.timeout.ms. You can set parameters in kafkaConfig to control the data consumption behavior of KafkaConsumer.

7. Click the icon in the toolbar.

2.1.4.6.6. Transform

2.1.4.6.6.1. Configure data filtering

The Data Filtering plug-in is used to filter data based on specific rules, such as the field size. Only data that meets the rules is retained.

Prerequisites

A reader node is configured.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **Data Filtering** in the **Conversion** section to the canvas on the right. Connect the Data Filtering node to the configured reader node.
6. Click the new **Data Filtering** node. In the configuration panel that appears, set the parameters.
   - **Node configuration**

     Rules: the rules for filtering data in data sources. Only data that meets the rules is retained.
   - **Output field**

     The names and types of output fields after filtering.
7. Click the icon in the toolbar.

2.1.4.6.6.2. Configure string replacement

The String Replace plug-in is used to replace the field values of the STRING type.

Prerequisites

A reader node is configured.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Real-time synchronization**.

   Alternatively, you can click the required workflow, right-click **Data Integration**, and then choose **Create > Real-time synchronization**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Notice** The node name must be 1 to 128 characters in length. It can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the configuration tab of the real-time synchronization node, drag **String Replace** in the **Conversion** section to the canvas on the right. Connect the String Replace node to the configured reader node.
6. Click the **String Replace** node. In the configuration panel that appears, set the parameters.

Parameter	Description
Rules	The rules that are used to replace the field values of the STRING type. Each rule is defined by the following parameters: ○ **Field**: the field of the parent node that you want to use as the input field. ○ **Regular matching**: specifies whether a regular expression is used to search for the original string. ○ **Original string**: the original string to search. ○ **New string**: the new string that is used to replace the original string. ○ **Case Sensitive**: specifies whether the value is case-sensitive during the search.
Add condition	Click this button to add more string replacement rules.
Output field	The output fields after string replacement.

7. Click the icon in the toolbar.

2.1.4.7. Data synchronization solutions

2.1.4.7.1. Go to the Sync Solutions page

The Data Integration service of DataWorks allows you to create and configure a synchronization solution to synchronize data from a source to a destination in real time. You can use a synchronization solution to synchronize multiple tables at a time or synchronize both full and incremental data. If you want to synchronize both full and incremental data, you can synchronize the incremental data after the full data is synchronized.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
3. In the left-side navigation pane, click **Sync Solutions**. The **Solution Task list** page appears.

   You can create synchronization solutions and view the details and statuses of the created synchronization solutions on this page. A synchronization solution has the following states:

   - **Not running**: The synchronization solution is not run. You can click **Start execution** in the Operation column that corresponds to the synchronization solution to run the synchronization solution.

     > **Note** You can click **Task configuration** in the Operation column that corresponds to a synchronization solution in the **Not running** state to edit the synchronization solution. If you click Task configuration in the Operation column that corresponds to a synchronization solution in another state, you can only view the information about the synchronization solution.

   - **Running**: The synchronization solution is running and cannot be terminated. You must wait until the synchronization solution is completed.
   - **Exception**: An error occurred during the running of the synchronization solution. You can click **Execution details** in the Operation column that corresponds to the synchronization solution to troubleshoot the error.
   - **Success**: The synchronization solution is completed. You can click **Execution details** in the Operation column that corresponds to the synchronization solution to view the running results of the synchronization solution.

2.1.4.7.2. Synchronize data to Hologres in real time

You can create and configure a data synchronization solution to synchronize data in a specified data source to Hologres in real time. This topic describes how to synchronize data to Hologres in real time.

Procedure

1. Go to the **Solution Task list** page.
   i. Log on to the DataWorks console.
   ii. Click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. In the left-side navigation pane, click **Sync Solutions**.
2. On the **Solution Task list** page, click **New Task** in the upper-right corner.
3. In the **New resolution task** dialog box, click **One-click real-time synchronization to Hologres**.
4. In the **Set synchronization sources and rules** step, configure the parameters.

i. In the **Basic configuration** section, configure the relevant parameters.

Parameter	Description
Scheme name	The name of the synchronization solution. The name can be a maximum of 50 characters in length.
Description	The description of the synchronization solution. The description can be a maximum of 50 characters in length.
Destination task storage location	If you select Automatically establish workflow, DataWorks automatically creates a workflow named in the format of clone_database_Source name+to+Destination name in the **Data Integration** directory. All synchronization nodes generated by the synchronization solution are placed in the directory of this workflow. If you do not select **Automatically establish workflow**, you must select a directory from the **Select Location** drop-down list. All synchronization nodes generated by the synchronization solution are placed in the specified directory.

ii. In the **Data source** section, specify **Type** and **Data source**.

iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click **>** to move the tables to the **Selected Source table** list.

The SOURCE Table list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

> **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

iv. In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables.

Supported options include **Table name conversion rules** and **Target table name rule**.

- **Table name conversion rules**: the rule for converting the names of source tables to those of destination tables.
- **Target table name rule**: the rule for adding a prefix and suffix to the converted names of destination tables.

v. Click **Next Step**.

5. In the **Set target table** step, configure the parameters.

i. Specify **Target Hologres data source** and **Schema**. **Write Hologres policy** is set to **Replay (replay operation log to restore data)** by default and cannot be changed.

ii. Click **Reload source table and Hologres Table mapping** to configure the mappings between the source tables and destination Hologres tables.

iii. View the mapping progress, source tables, and mapped destination tables.

You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the **Hologres Table name** column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
- If you set **Table creation method** to **Use existing Table**, you must select a table from the drop-down list in the Hologres Table name column.

iv. Click **Next Step**.

6. In the **Run resource settings** step, configure the parameters.

Parameter	Description
Realtime task resource group	The resource group used for running the batch synchronization node and real-time synchronization nodes generated by the synchronization solution.
Offline task resource group	
Select scheduling Resource Group	The resource group for scheduling used for running the nodes generated by the synchronization solution.
Maximum number of connections supported by source read	The maximum number of Java Database Connectivity (JDBC) connections that are allowed for the source. Specify an appropriate number based on the resources of the source.
Offline task name rules	The name of the batch synchronization node that is used to synchronize the full data of the source. After a synchronization solution is created, a batch synchronization node is generated first to synchronize full data, and then real-time synchronization nodes are generated to synchronize incremental data.

7. Click **Complete configuration**.
8. On the **Solution Task list** page, find the newly created synchronization solution and click **Start execution** in the Operation column.

After the running of the synchronization solution is successful, you can perform the following operations on the synchronization solution:

- Click **Task configuration** in the Operation column to view the information about or edit the synchronization solution.

> **Note** You can click **Task configuration** in the Operation column that corresponds to the data synchronization solution in the **Not running** state to edit the data synchronization solution. If you click Task configuration in the Operation column of a synchronization solution in another state, you can only view information about the synchronization solution.

- Click **Execution details** in the Operation column to view the points in time at which the synchronization solution was started and ended and the status of each node.
- Click **Delete** in the Operation column to delete the synchronization solution. In the **Delete** message, click

Confirm.

> **Note** After you click Confirm, only the configuration record of the data synchronization solution is deleted. The generated synchronization nodes and tables are not affected.

2.1.4.7.3. Synchronize data to MaxCompute in real time

You can create a synchronization solution to synchronize data from a specified data source to MaxCompute in real time.

Procedure

1. Go to the **Solution Task list** page.
   i. Log on to the DataWorks console.
   ii. Click the ☰ icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. In the left-side navigation pane, click **Sync Solutions**.
2. On the **Solution Task list** page, click **New Task** in the upper-right corner.
3. In the **New resolution task** dialog box, click **One-click real-time synchronization to MaxCompute**.
4. In the **Set synchronization sources and rules** step, configure the parameters.
   i. In the **Basic configuration** section, configure the relevant parameters.

Parameter	Description
Scheme name	The name of the synchronization solution. The name can be a maximum of 50 characters in length.
Description	The description of the synchronization solution. The description can be a maximum of 50 characters in length.
Destination task storage location	If you select Automatically establish workflow, DataWorks automatically creates a workflow named in the format of clone_database_Source name+to+Destination name in the **Data Integration** directory. All synchronization nodes generated by the synchronization solution are placed in the directory of this workflow. If you do not select **Automatically establish workflow**, you must select a directory from the **Select Location** drop-down list. All synchronization nodes generated by the synchronization solution are placed in the specified directory.

   ii. In the **Data source** section, specify **Type** and **Data source**.
   iii. In the **Select the source table for synchronization** section, select the tables that you want to synchronize in the **SOURCE Table** list and click **>** to move the tables to the **Selected Source table** list.

   The SOURCE Table list displays all the tables in the source. You can select all or some tables to synchronize them at a time.

> **Notice** If a selected table does not have a primary key, the table cannot be synchronized in real time.

iv. In the **Set synchronization rules** section, click **Add rule** and select an option to configure naming rules for destination tables.

Supported options include **Table name conversion rules** and **Target table name rule**.

- **Table name conversion rules**: the rule for converting the names of source tables to those of destination tables.
- **Target table name rule**: the rule for adding a prefix and suffix to the converted names of destination tables.

v. Click **Next Step**.

5. In the **Set target table** step, configure the parameters.

i. Select a data source from the **Target MaxCompute data source** drop-down list and specify **Write mode**.

ii. Click next to **MaxCompute time automatic partition settings**. In the **Edit** dialog box, modify the partition settings for the destination tables. You can configure daily and hourly partitions.

iii. Click **Reload source table and MaxCompute Table mapping** to configure the mappings between the source tables and destination MaxCompute tables.

iv. View the mapping progress, source tables, and mapped destination tables.

You can view the mapping progress between the source tables and destination tables. The mapping may take a long period of time if you want to synchronize a large number of tables.

An error message appears if the selected source table does not have a primary key. The synchronization can be performed if one of the selected source tables has a primary key. Source tables without primary keys are ignored during the synchronization.

You can set Table creation method to **Create tables automatically** or **Use existing Table**. The name of the destination table that appears in the MaxCompute Table name column varies based on the setting of Table creation method.

- If you set **Table creation method** to **Create tables automatically**, the name of the destination table that is automatically created appears. You can click the table name to view and modify the table creation statements.
- If you set **Table creation method** to **Use existing Table**, you must select a table name from the drop-down list in the MaxCompute Table name column.

v. Click **Next Step**.

6. In the **Run resource settings** step, configure the parameters.

Parameter	Description
Synchronization engine	Default value: **Default embedded engine**.
Realtime task resource group	The resource group that is used to run the nodes generated by the real-time synchronization solution.
Real-time synchronization task name	The name of the real-time synchronization solution.
Select scheduling Resource Group	The resource group that is used to run the real-time synchronization nodes and batch synchronization node generated by the synchronization solution. Synchronization solutions can run on shared resource groups and custom resource groups for Data Integration.
Offline task resource group	

Parameter	Description
Maximum number of connections supported by source read	The maximum number of Java Database Connectivity (JDBC) connections that are allowed for the source database. Specify an appropriate number based on the resources of the source database.
Offline task name rules	The name of the batch synchronization node that is used to synchronize the full data of the source database. After a data synchronization solution is created, DataWorks first generates a batch synchronization node to synchronize full data, and then generates real-time synchronization nodes to synchronize incremental data.

7. Click **Complete configuration**.
8. On the **Solution Task list** page, find the newly created synchronization solution and click **Start execution** in the Operation column.

   After the synchronization solution is run, you can perform the following operations on the synchronization solution:

   - Click **Task configuration** in the Operation column to view information about or configure the synchronization solution.

     > **Note** You can configure a synchronization solution only when it is in the **Not running** state. If you click Task configuration in the Operation column of a synchronization solution that is in another state, you can only view information about the synchronization solution.

   - Click **Execution details** in the Operation column to view the time at which the synchronization solution was started and ended and the status of each node.
   - Click **Delete** in the Operation column to delete the synchronization solution. In the **Delete** message, click **Confirm**.

     > **Note** After you click Confirm, only the configuration record of the data synchronization solution is deleted. The generated synchronization nodes and tables are not affected.

2.1.4.8. Resource groups

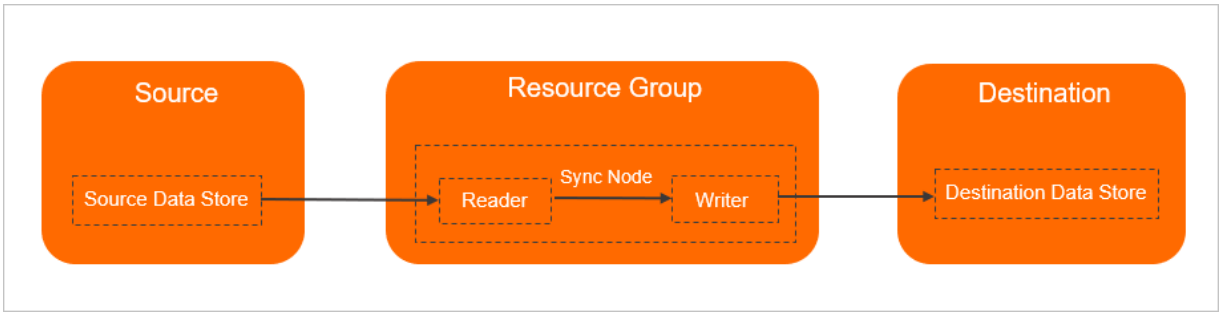
2.1.4.8.1. Overview

This topic introduces the definition of resource groups. It also describes how the connectivity and performance of resource groups affect data synchronization.

Definition

A resource group is a collection of computing resources on which synchronization nodes of Data Integration are run. In most cases, a resource group is one or more servers that consist of CPU, memory, and network resources.

In the process of running a synchronization node, the resource group pulls data from the source and pushes the data to the destination.



Connectivity and performance

When you use resource groups, you must pay attention to their connectivity and performance.

- Connectivity

  To ensure that data can be synchronized, a resource group must be connected to the source and destination. Connectivity is the most important factor that affects data synchronization.

  Data Integration cannot build networks. Before you use Data Integration to synchronize data, you must make sure that the resource group is connected to the data sources. If the resource group is disconnected from the data sources, synchronization nodes cannot be run.

- Performance

  Synchronization nodes consume the CPU, memory, and network resources on the servers where the nodes are run. Insufficient resources may lead to various issues. For example, the nodes fail to be started, wait for resources for a long period of time after startup, transmit data at a low rate, or fail to generate data. To ensure the smooth running of synchronization nodes, you must allocate adequate resources for them.

2.1.4.8.2. Shared resource groups

Data Integration of DataWorks provides shared resource groups for you to create and run synchronization nodes.

Shared resource groups for Data Integration are created and maintained by Data Integration. Shared resource groups compose a public resource pool. Nodes that use resources in the public resource pool may not be run as scheduled due to insufficient resources. We recommend that you prepare sufficient resources to ensure the efficient running of synchronization nodes.

> **Note**
>
> - You can run a maximum of 25 parallel nodes on a shared resource group for Data Integration when the shared resource group is not in use.
> - You cannot change the memory size of a shared resource group. Instead, you can change the number of parallel nodes that can be run on the shared resource group.
>
>   The following formula is used to calculate the memory size: Memory size = `Number of parallel nodes × 512 MB`.

2.1.4.8.3. Create a custom resource group for Data Integration

This topic describes how to create a custom resource group for Data Integration and select a resource group for Data Integration to run a batch synchronization node.

Prerequisites

An Elastic Compute Service (ECS) instance is available.

Context

If the shared resource groups of DataWorks do not support your data sources or you want to speed up data transmission, you can create custom resource groups to run your synchronization nodes.

A workspace administrator can create or modify custom resource groups on the **Custom Resource Groups** page of Data Integration.

> **Note**
> - The admin permission is required to access some files on the ECS instance that hosts a custom resource group. For example, the admin permission is required to call shell or Structured Query Language (SQL) files on the ECS instance when you write a shell script for a node.
> - Resource groups for scheduling are used to run nodes. These resource groups have limited resources and are not suitable for computing nodes. Therefore, we recommend that you do not create custom resource groups on the ECS instances of a resource group for scheduling. MaxCompute can process large amounts of data. We recommend that you use MaxCompute for big data computing.

Custom resource groups for Data Integration are subject to the following limits:

- The difference between the time of the ECS instance where a custom resource group for Data Integration resides and the current Internet time must be within 2 minutes. Otherwise, service requests may time out, and nodes may fail to be run on the custom resource group for Data Integration.
- You can add only one custom resource group for Data Integration on an ECS instance. You can select only one network type for each custom resource group for Data Integration.
- Custom resource groups added on the **Custom Resource Groups** page of Data Integration can run synchronization nodes created only in the current workspace.

  Custom resource groups for Data Integration that you added on the Custom Resource Groups page cannot run synchronization nodes in a manually triggered workflow.

If the timeout error message `response code is not 200` exists in the log file of alisatasknode, the custom resource group for Data Integration was not accessible within the specific period in time. The ECS instance that hosts the custom resource group for Data Integration can continue to work if the exception persists for no more than 10 minutes. To find the exception details, view the heartbeat.log file in the `/home/admin/alisatasknode/logs` directory.

Create a custom resource group for Data Integration

1. Go to the **Data Integration** page.
   i. Log on to the DataWorks console.
   ii. Click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
2. In the left-side navigation pane, click **Custom Resource Group**.
3. On the **Custom Resource Groups** page, click **Add Resource Group** in the upper-right corner.

   > **Notice** By default, the Custom Resource Groups page displays only your custom resource groups and does not display your shared resource groups.

4. In the **Add Resource Group** wizard, perform the following steps:

i. In the **Create Resource Group** step, set the **Resource Group Name** parameter.

> **Note** The name can contain letters, digits, and underscores (_) and must start with a letter.

ii. Click **Next**.

iii. In the **Add Server** step, set the parameters.

Parameter	Description
Network Type	The network type. Valid values: **Classic Network** and **VPC**.
Server Name or **ECS UUID**	The hostname or the universally unique identifier (UUID) of the ECS instance that hosts the custom resource group. ■ If you set Network Type to **Classic Network**, you must set the **Server Name** parameter. To obtain the hostname, log on to the ECS instance and run the `hostname` command. ■ If you set Network Type to **VPC**, you must set the **ECS UUID** parameter. To obtain the UUID, log on to the ECS instance and run the `dmidecode | grep UUID` command.
Server IP Address	The private IP address of the ECS instance.
Server CPU (Cores)	The number of CPU cores on the ECS instance. We recommend that you configure at least four CPU cores for an ECS instance that hosts a custom resource group.
Server RAM (GB)	The memory of the ECS instance. We recommend that you configure at least 8 GB RAM and 80 GB disk space for an ECS instance that hosts a custom resource group.

iv. Click **Next**.

v. Perform the steps that are listed in the **Install Agent** step.

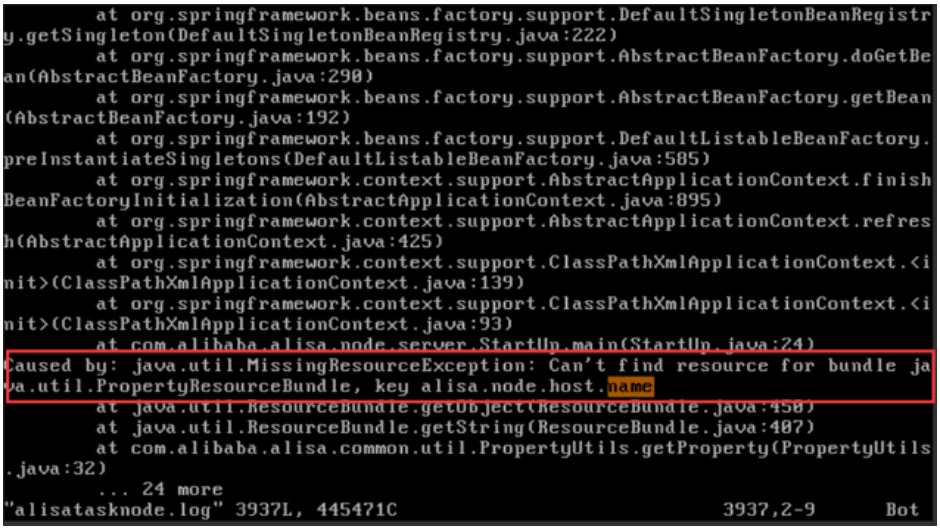
> **Note** If an error occurs when you run the `install.sh` script or you need to run it again, run the `rm -rf install.sh` command in the same directory as the `install.sh` script to delete the generated file. Then, run the `install.sh` script again.
>
> The commands to run during the installation and initialization process differ for each user. Run relevant commands based on the instructions on the initialization interface.

vi. Click **Next**.

vii. In the **Test Connection** step, click **Refresh** and check the status of the instance.

viii. Click **Complete**.

If the instance status remains **Stopped** after the preceding steps, the hostname may not be bound to an IP address, as shown in the following figure.



1. Log on to the ECS instance by using the admin user.
2. Run the `hostname -i` command to view the hostname binding information.
3. Run the `vim/etc/hosts` command to add the binding of the IP address and hostname.
4. Refresh the instance status and check whether the ECS instance is registered.

   If the ECS instance is still in the Stopped state after you refresh the page, perform the following steps to restart alisatasknode:

   i. Log on to the ECS instance by using the admin user.

   ii. Run the following command:

   ```
   /home/admin/alisatasknode/target/alisatasknode/bin/serverctl restart
   ```

   > **Note** You must enter your AccessKey pair when you run this command. Keep your AccessKey secret strictly confidential.

Configure the resource group for Data Integration

1. Click the icon in the upper-left corner of the Data Integration page and choose **All Products > Data Development > DataStudio**.
2. In the upper-left corner of the page that appears, select the workspace where your resource group for Data Integration resides.
3. On the **Data Analytics** tab, expand the workflow where the batch synchronization node you want to configure resides, find the batch synchronization node in the Data Integration folder, and then double-click it.
4. On the configuration tab of the node, click the **Resource Group configuration** tab in the right-side navigation pane.
5. On the **Resource Group configuration** tab, set **Programme** and select a resource group based on your business requirements.
6. On the configuration tab of the node, click the icon in the top toolbar.

2.1.4.9. Full-database migration

2.1.4.9.1. Overview

This section describes the full-database migration feature in terms of its functions and limits.

Full-database migration is an easy-to-use tool that helps you to improve cost-efficiency. It can quickly upload all the tables in a MySQL database to MaxCompute at a time, saving time that is spent on creating batch tasks for initial data migration to the cloud.

For example, if a database contains 100 tables, you must configure 100 data synchronization tasks in a traditional way. With the full-database migration, you can upload all the tables at a time. However, an upload failure might occur due to the issues that involve the principles of designing database tables.

Task generation rules

After the configuration is completed, MaxCompute tables are created and data synchronization tasks are generated based on the selected tables to be synchronized.

The table names, field names, and field types of the MaxCompute tables are generated according to the advanced settings. If no advanced settings are configured, the structure of MaxCompute tables is identical to that of MySQL tables. The partition of these tables is pt, and its format is yyyymmdd.

The generated data synchronization tasks are daily scheduled tasks and run automatically on the early morning of the next day. The typical transmission rate is 1 Mbit/s, but it varies depending on the synchronization method and concurrency configurations. **To customize a data synchronization task, locate the task by choosing clone_database > Data Source Name > mysql2odps_table name,** and then specify its settings.

> **Note** We recommend that you perform smoke testing on a data synchronization task on the day when it is generated.**To perform smoke testing, choose Administration Center > Task Management > project_etl_start > Upload Database > Data Source Name**, find the synchronization task, right-click the task, and then test the task.

Limits

Full-database migration has the following limits due to the issues that involve the principles of designing database tables.

- Currently, only the full-database migration from a MySQL data source to MaxCompute is supported. We are working on support for full-database migration from a Hadoop or Hive data source to Oracle.
- Only the daily incremental and daily full upload modes are available.

  If you want to synchronize historical data at a time, this feature cannot meet your needs. We recommend that:

  - You configure daily tasks instead of synchronizing historical data at a time. You trace the historical data with the provided retrospective data import feature. This eliminates the need to run temporary SQL tasks to split data after all the historical data is synchronized.
  - To synchronize historical data at a time, configure a task on the task development page and click **Run**. Then, data is converted by using SQL statements. They are both one-time operations.

  If your daily incremental upload task uses a special business logic and cannot be identified by a date field, this feature cannot meet your needs. We provide the following suggestions:

  - The incremental data upload can be achieved by using two methods: binlog provided by the DTS product and the date field for data changes provided by databases.

    Currently, Data Integration supports the second method. Therefore, your database must contain the date field for data changes. The system determines whether your data is changed on the same day as the business date by using this field. If yes, all the changed data is synchronized.
  - To facilitate the incremental data uploading, we recommend that you include the gmt_create and gmt_modify fields when creating any database tables. Additionally, you can set the id field as the primary key to improve efficiency.

- Full-database migration supports batch upload and full upload modes.

  Batch upload is configured with time intervals. Currently, the connection pool protection feature for data sources is not supported, but will be available later.

  - To prevent overloads on the database, the full-database migration feature provides the batch upload mode. This mode enables you to upload tables in batches at a specified time interval and prevents compromised service functionality. We provide the following suggestions:
    - If you have master and slave databases, we recommend that you synchronize the data of the slave database.
    - In a batch upload task, each table has a database connection with a maximum transmission rate of 1 Mbit/s. For example, if you run a synchronization task for 100 tables at a time, 100 database connections are established. We recommend that you specify proper concurrency settings based on your business needs.
  - If you have special requirements for transmission efficiency, this feature cannot meet your needs. The maximum transmission of each generated tasks is 1 Mbit/s.

- Only the mapping of all table names, field names, and field types are supported.

  During the full-database migration process, MaxCompute tables are created automatically, where the partition field is pt, the field type is string, and the format is yyyymmdd.

  > **Note** When you select tables for synchronization, all fields must be synchronized and none of these fields can be edited.

2.1.4.9.2. Migrate a MySQL database

This topic describes how to migrate a MySQL database to MaxCompute.

The database migration feature improves efficiency and reduces costs. It can quickly upload all tables in a MySQL database to MaxCompute. For more information, see Overview.

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, click **Add Connection**.
4. In the **Add Connection** dialog box that appears, select **MySQL**.
5. Add a MySQL connection named clone_database for database migration.
6. Click **Test Connection** and verify that the database can be accessed. Click **Complete**.
7. The added MySQL connection named clone_database appears in the connection list. Find the added connection and click **Migrate Database** in the Actions column.

   The database migration settings page consists of three functional modules.

Functional module	Description
Tables to migrate	This module lists all the tables in the MySQL connection named clone_database. Selected tables will be migrated.
Advanced Settings	You can configure the rules for converting the table name, column names, and data types.

Functional module	Description
Basic settings	You can select whether to synchronize full or incremental data, whether to upload data in one or more batches, and the synchronization efficiency. You can also view the migration progress and results.

8. Click **Advanced Settings** and configure conversion rules based on your needs. For example, you can add an ods_ prefix to the name of each MaxCompute table.
9. Specify basic settings. Set Sync Method to Synchronize Incremental Data Daily, and configure the incremental data to be determined based on the gmt_modified column. Data Integration will generate WHERE clauses based on the specified column and DataWorks scheduling parameters such as ${bdp.system.bizdate}.

   Data Integration reads data from MySQL tables by connecting to a remote MySQL database over JDBC and running SELECT statements. Data Integration uses standard SQL statements, and therefore you can configure WHERE clauses to filter data. The WHERE clause used in this example is provided as follows:

   ```
   STR_TO_DATE('${bdp.system.bizdate}', '%Y%m%d') <= gmt_modified AND gmt_modified < DATE_ADD(STR_T
   O_DATE('${bdp.system.bizdate}', '%Y%m%d'), interval 1 day)
   ```

   Select data upload in batches to protect the MySQL database from being overloaded. Let Data Integration start data synchronization for three tables every one hour from 00:00 each day.

   Click **Commit**. Then, you can view the migration progress and results of each table.
10. Find table a1 and click View Node to view the migration results.

You have configured a node for migrating a MySQL connection named clone_database to MaxCompute. This node is run based on the specified schedule, daily by default. You can also create retroactive node instances to transmit historical data. The database migration feature of **Data Integration** significantly simplifies the initial configurations for migrating your data to the cloud and reduces data migration costs.

You can view the migration success logs of table a1.

2.1.4.9.3. Migrate Oracle databases

This topic describes how to migrate an Oracle database to MaxCompute.

The database migration feature improves efficiency and reduces costs. It can quickly upload all tables in an Oracle database to MaxCompute. For more information, see Overview.

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page.
3. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, click **Add Connection** in the upper-right corner.
4. In the **Add Connection** dialog box that appears, select **Oracle**.
5. Add an Oracle connection named clone_databae for database migration.
6. Click **Test Connection** and verify that the database can be accessed. Click **Complete**.
7. The added Oracle connection named clone_databae appears in the connection list. Find the added connection and click **Migrate Database** in the Actions column.

   The database migration settings page consists of three functional modules.

Functional module	Description
Tables to migrate	This module lists all the tables in the Oracle connection named clone_databae. Selected tables will be migrated.
Advanced Settings	You can configure the rules for converting the table name, column names, and data types.
Basic settings	You can select whether to synchronize full or incremental data, whether to upload data in one or more batches, and the synchronization efficiency. You can also view the migration progress and results.

8. Click **Advanced Settings** and configure conversion rules based on your needs.
9. Set Sync Method to Synchronize All Data Daily.

   > **Note** If a date column exists in your table, you can select incremental migration and configure the incremental data to be determined based on the date column. Data Integration will generate WHERE clauses based on the specified column and DataWorks scheduling parameters such as ${bdp.system.bizdate}.

   Select data upload in batches to protect the Oracle database from being overloaded. Let Data Integration start data synchronization for three tables every one hour from 00:00 each day.

   Click **Commit**. Then, you can view the migration progress and results of each table.
10. Find a related table and click **View Node** to view the node details.

    You have configured a node for migrating an Oracle connection named clone_databae to MaxCompute. This node is run based on the specified schedule, daily by default. You can also create retroactive node instances to transmit historical data. The database migration feature of **Data Integration** significantly simplifies the initial configurations for migrating your data to the cloud and reduces data migration costs.

2.1.5. Data Analytics

2.1.5.1. Solution

The data analytics mode of DataWorks is upgraded so that you can group multiple workflows in a solution of a workspace.

Overview

DataWorks upgrades the data analytics mode to organize various types of nodes based on the business category. You can organize workflows to analyze data by business.

By using the data analytics mode that involves the **workspace**, **solution**, and **workflow**, DataWorks defines a new development process and improves user experience.

- A workspace is the basic organizational unit that manages the development and O&M permissions of users. The code of all nodes in a workspace can be collaboratively developed and managed by workspace members.
- A solution contains one or more workflows. It has the following advantages:
  - A solution can contain multiple workflows.
  - A workflow can be added to multiple solutions.
  - All solutions in a workspace can be collaboratively developed and managed by workspace members.
- A workflow is an abstract entity of business that enables you to develop data analytics code from a business perspective. A workflow can be added to multiple solutions. It has the following advantages:

- Workflows facilitate business-oriented code development. Nodes in a workflow are organized by type. A hierarchical directory structure is supported. We recommend that you create a maximum of four levels of sub-directories. To create a sub-directory, right-click the target node type and select **Create Folder**.
- You can view and optimize each workflow from a business perspective.
- You can view each workflow on a dashboard to develop code with improved efficiency.
- You can deploy and manage each workflow as a whole.

Develop a solution

If you double-click a solution in the left-side navigation pane, the left-side navigation pane only displays workflows in the solution. This prevents the development process from being affected by the code that is not related to the current solution in the workspace. To develop a solution, perform the following steps:

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over and select **Solution**.
3. In the **Create Solution** dialog box, set **Solution Name** and **Description**, select a workflow from the **Workflows** drop-down list, and then click **Create**.
4. In the solution list, right-click the created solution and select **Solution Kanban**. On the solution dashboard that appears, you can view the selected workflows or modify the solution.
5. Move the pointer over the solution name. The and icons appear.

   - Click the icon. The **Deploy** page appears. You can view the nodes to be deployed in the current solution.

     
     > **Note** This icon is available only when the workspace is in standard mode.

   - Click the icon to go to the **Cycle Instance** page under **Cycle Task Maintenance** in **Operation Center**. You can view recurring instances of all nodes in the current solution.

   In the left-side navigation pane, double-click the created solution. All the created workflows in the solution appear. You can click a workflow name to show the created nodes in it and perform operations on the nodes and the workflow.

   A workflow can be added to multiple solutions. After you develop a solution and add a workflow to the solution, other users can edit the workflow you referenced in their solutions for collaborative development.

2.1.5.2. Guidelines and specifications of SQL coding

This topic describes the basic guidelines and detailed specifications of SQL coding.

SQL coding guidelines

When you write SQL code, take note of the following guidelines:

- The code is comprehensive.
- Code lines are clear, neat, well-organized, and structured.
- The optimal execution speed is considered during SQL coding.

- Comments need to be added if necessary to enhance the readability of your code.
- The guidelines impose non-mandatory constraints on the coding behavior of developers. In practice, understandable deviations are allowed when developers obey general rules.
- All SQL keywords and reserved words must be all uppercase or lowercase, such as select/SELECT, from/FROM, where/WHERE, and/AND, or/OR, union/UNION, insert/INSERT, delete/DELETE, group/GROUP, having/HAVING, and count/COUNT. Do not use mixed-case letters, such as Select or seLECT.
- A unit of indentation contains four spaces. All indentations must be the integral multiple of an indentation unit. The code is aligned based on its hierarchy.
- You cannot use an `asterisk (*)` to specify a column name. The column name must be specified for all statements.
- Matching opening and closing parentheses must be placed in the same column.

SQL coding specifications

When you write SQL code, take note of the following specifications:

- Code header

  The code header contains information such as the subject, description, author, and date. Reserve a line for change log and a title line so that users can add change records in the future. Each line can contain a maximum of 80 characters. The following code provides an example template:

```
-- MaxCompute(ODPS) SQL
--********************************************************************
-- ** Subject: Transaction
-- ** Description: Transaction refund analysis
-- ** Author: Youma
-- ** Created on: 20170616
-- ** Change log:
-- ** Modified on  Modified by  Content
-- yyyymmdd name comment
-- 20170831  Wuma  Add a comment on the biz_type=1234 transaction
--********************************************************************
```

- Field arrangement
  - Use a line for each field that is selected for the SELECT statement.
  - Reserve one unit of indentation between the word SELECT and the first selected field.
  - Start each of the other field names in a new line with two units of indentation and a comma (,).
  - Place the comma (,) between two fields right before the second field.
  - Place the AS statement in the same line as its matching field and keep AS statements of multiple fields in the same column.

```
select  channel_id            as channel_id
       ,trade_channel_desc    as trade_channel_desc
       ,trade_channel_edesc   as trade_channel_edesc
       ,inst_date             as inst_date
       ,trade_iswap           as trade_iswap
       ,channel_type          as channel_type
       ,channel_second_desc   as channel_second_desc
from   (
```

- Clause arrangement for an INSERT statement

  Arrange the clauses of an INSERT statement in the same line.

- Clause arrangement for a SELECT statement

The clauses such as FROM, WHERE, GROUP BY, HAVING, ORDER BY, JOIN, and UNION in a SELECT statement must be arranged in compliance with the following requirements:

- Use a line for each clause.
- The clauses are left aligned with the SELECT statement.
- Reserve two units of indentation between the first word of a clause and its content.
- Keep the logical operators such as AND and OR in a WHERE clause left aligned with the word WHERE.
- If the length of a clause name exceeds two units of indentation such as ORDER BY and GROUP BY, add a space between the clause name and its content.

```
select    trim(channel) channel
          ,min(id)      id
from      ods_trd_trade_base_dd
where     channel is not null
and       dt = ${tmp_uuuummdd}
and       trim(channel) <> ''
group by  trim(channel)
order by  trim(channel)
```

- Spacing before and after operators

  Reserve one space before and after each arithmetic operator and logical operator. Keep all the operators in the same line unless the length of the code exceeds 80 characters.

```
select      trim(channel) channel
            ,min(id)      id
from        ods_trd_trade_base_dd
where       channel is not null
and         dt = ${tmp_uuuummdd}
and         trim(channel) <> ''
group by    trim(channel)
order by    trim(channel)
```

- Arrangement for a SELECT CASE statement

  The SELECT CASE statement is used to evaluate the value of a variable. Take note of the following specifications on SELECT CASE statements:

  - Write the WHEN clause one unit of indentation after the CASE statement in the same line.
  - Use a line for each WHEN clause. Wrap a line if the clause is excessively long.

```
,case   when p1.trade_from = '3008' and p1.trade_email is null then 2
        when p1.trade_from = '4000' and p1.trade_email is null then 1
        when p9.trade_from_id is not null then p9.trade_from_id
 end                                 as trade_from_id
,p1.trade_email                      as partner_id
```

  - The CASE statement must contain the ELSE clause. The ELSE clause must be aligned with the WHEN clause.

- Nested query

Nested queries are often used to implement the extract, transform, and load (ETL) process of data warehouse systems. The following figure shows an example of arranging nested queries.

```
select      p.channel
            ,rownumber()  order_id
from        (
                select    s1.channel
                          ,s1.id
                from      (
                                select  trim(channel)       as channel
                                        ,min(id)            as id
                                from    ods_trd_trade_base_dd
                                where   channel is not null
                                and     dt = ${tmp_yyyymmdd}
                                and     trim(channel) <> ''
                                group by trim(channel)
                          ) s1
                left outer join
                        dim_trade_channel s2
                on      s1.channel = s2.trade_channel_edesc
                where   s2.trade_channel_edesc is null
                order by id
            ) p
;
```

- Table alias
  - If an alias is defined for a table in a SELECT statement, you must use the alias whenever you reference the table in the statement. Specify an alias for each table in the SELECT statement.
  - We recommend that you define the table aliases by using letters in alphabetical order.
  - In the nested query, levels 1 to 4 of SQL statements are named part, segment, unit, and detail, which are abbreviated as P, S, U, and D. You can also use a, b, c, and d to represent levels 1 to 4.

    To differentiate multiple clauses at the same level, add numbers such as 1, 2, 3, and 4after the letter that represents the level.

```
select      p.channel
            ,rownumber()  order_id
from        (
                select    s1.channel
                          ,s1.id
                from      (
                                select  trim(channel)       as channel
                                        ,min(id)            as id
                                from    ods_trd_trade_base_dd
                                where   channel is not null
                                and     dt = ${tmp_yyyymmdd}
                                and     trim(channel) <> ''
                                group by trim(channel)
                          ) s1
                left outer join
                        dim_trade_channel s2
                on      s1.channel = s2.trade_channel_edesc
                where   s2.trade_channel_edesc is null
                order by id
            ) p
;
```

- SQL comments

- Add a comment for each SQL statement.
- Use a separate line for the comment of each SQL statement and place the comment in front of the SQL statement.
- Place the comment of a field right after the field.
- Add comments to clauses that are difficult to understand.
- Add a comment to important code.
- If a statement is long, we recommend that you add comments based on the purposes of each segment.
- The description for a constant or variable is required. The comment on the valid value range is optional.

2.1.5.3. GUI elements

2.1.5.3.1. Overview

This topic describes the graphical user interface (GUI) elements on the DataStudio page and the configuration tab of an ODPS SQL node.

Log on to the DataWorks console. The **Data Analytics** page appears. You can double-click a created node to perform operations on the node configuration tab.

The following table describes the GUI elements.

No.	GUI element	Description
1	**Show My Nodes Only icon**	Click the icon to view your own nodes.
2	**Search Code icon**	Click the icon to search for a node or a code segment.
3	**Create icon**	Click the icon to create a solution, workflow, folder, node, table, resource, or function.
4	**Refresh icon**	Click the icon to refresh the directory tree in the left-side navigation pane.
5	**Locate icon**	Click the icon to find the current node in the left-side navigation pane.
6	**Import icon**	Click the icon to import local data to an online table. You must specify the encoding format. **Note** In a workspace of the standard mode, the local data is imported to a table in the development environment.
7	**Filter icon**	Click the icon to query nodes based on the specified filter conditions.
8	**Save icon**	Click the icon to save the code of the current node.
9	**Save as Ad-Hoc Query Node icon**	Click the icon to save the code of the current node in an ad-hoc query node. You can find the node on the Ad-Hoc Query tab.
10	**Commit icon**	Click the icon to commit the current node.
11	**Commit and Unlock icon**	Click the icon to commit and unlock the current node for editing.
12	**Steal Lock icon**	Click the icon to steal the lock of the current node and then edit it if you are not the owner of the node.

No.	GUI element	Description
13	**Run icon**	Click the icon to run the code of the current node. You only need to assign values to variables in SQL statements once. The initial values are retained even if the node code changes.
14	**Run with Arguments icon**	Click the icon to run the code of the current node with the configured parameters. You must manually assign values to variables in SQL statements each time you click this icon. The initial values are passed to the **Run with Arguments** feature, which replaces the initial values with the assigned values. For example, if the run date of a node is set to April 2, the node always runs on April 2 when you click the Run icon. After you click Run with Arguments icon and change the run date to April 3, the run date is updated. When you click the Run icon again, the node is run on April 3.
15	**Stop icon**	Click the icon to stop running the code of the current node.
16	**Reload icon**	Click the icon to reload the code of the current node. The code will be restored to the version last saved. Unsaved changes will be lost.
17	**Run Smoke Test icon**	Click the icon to test the code of the current node. A smoke test allows you to replace the values of scheduling parameters in the specified data timestamp with your simulated ones. This feature tests the effect of value changes for scheduling parameters. **Note** Each time after you modify the values of scheduling parameters, you must save and commit the modification before running the smoke test. Otherwise, the new values of scheduling parameters do not take effect.
18	**View Smoke Test Log icon**	Click the icon to view the runtime logs of the current script template.
19	**Format Code icon**	Click the icon to format the code to avoid excessively long code in a single line.
20	**Operation Center button**	Click the icon to go to Operation Center.
21	**Properties tab**	Click the tab to configure the properties such as the scheduling properties, parameters, and resource group for the current node.
22	**Lineage tab**	Click the tab to view the relationships between the current node and other nodes.
23	**Versions tab**	Click the tab to view the committed and deployed versions of the current node.
24	**Code Structure tab**	Click the tab to view the code structure of the current node. If the code is excessively long, you can quickly find a code segment based on the key information in the structure.

2.1.5.3.2. Workflow Parameters

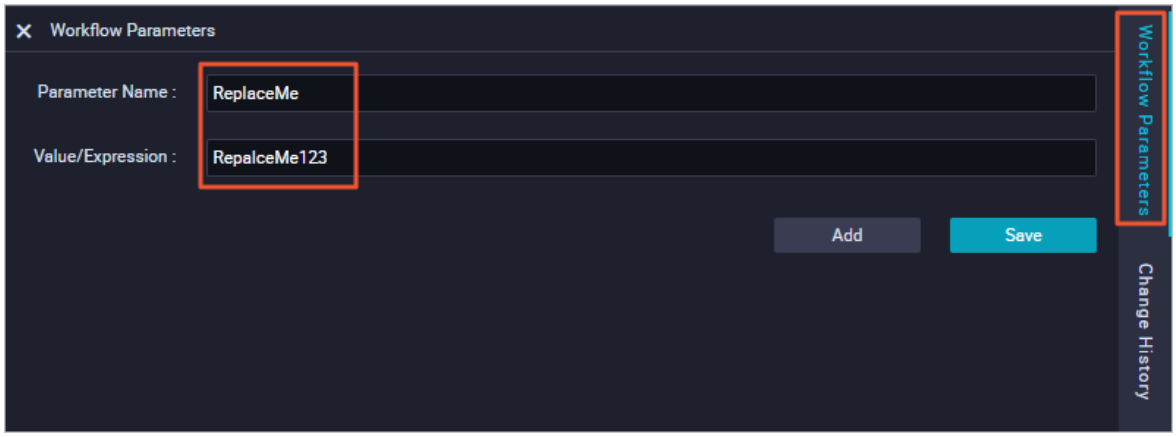
On the Workflow Parameters tab, you can assign a value to a variable or replace the value of a parameter for all nodes in the current workflow. This topic describes how to configure a workflow parameter by assuming that you want to replace the value of the ReplaceMe parameter with ReplaceMe123 in a manually triggered workflow.

Limits

- In manually triggered workflows, ODPS SQL nodes, Shell nodes, and sync nodes support global parameters. The format for specifying a global parameter varies based on the node type. For example, a global workflow parameter is specified as x=y1.
  - To configure the workflow parameter for an ODPS SQL node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter x=aaa in the Arguments field. When the node is run, x=aaa specified in the Arguments field is replaced with x=y1. You can use $x to reference the workflow parameter in the code.
  - To configure the workflow parameter for a Shell node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter $x in the Arguments field. When the node is run, x=aaa specified in the Arguments field is replaced with y1. You can use $1 to reference the workflow parameter in the code.
  - To configure the workflow parameter for a sync node, double-click the target node and click the **General** tab in the right-side navigation pane. On the **General** tab, enter -p"-Dx=aaa" in the Arguments field. When the node is run, x=aaa specified in the Arguments field is replaced with -p"-Dx=y1. You can use $x to reference the workflow parameter in the code.
- In auto triggered workflows, only ODPS SQL nodes support global parameters.
- Parameter names and values are case-sensitive.

Configure a workflow parameter

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Manually Triggered Workflows**.
3. Double-click the target workflow to go to the workflow configuration tab.
4. In the right-side navigation pane, click the **Workflow Parameters** tab. In the Workflow Parameters pane, enter ReplaceMe in the **Parameter Name** field and ReplaceMe123 in the **Value/Expression** field.

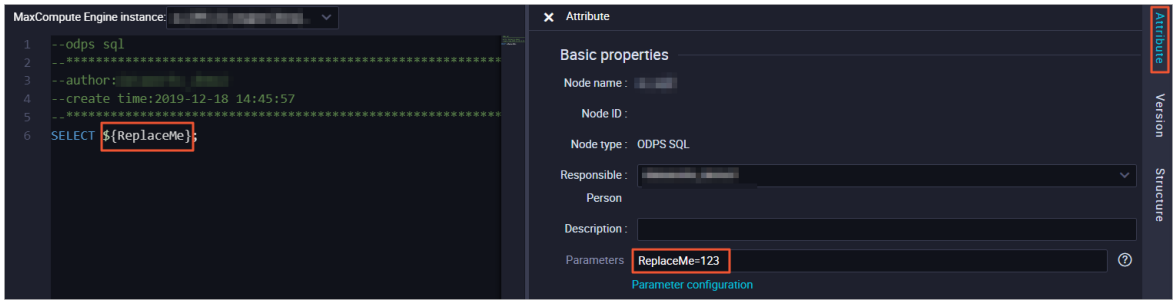


5. Click in the toolbar.

Configure the workflow parameter for an ODPS SQL node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and choose **MaxCompute > Data Analytics** to show all the existing data analytics nodes. Double-click the target ODPS SQL node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter ReplaceMe=123 in the

Arguments field.



The workflow parameter is specified as ReplaceMe=ReplaceMe123. Therefore, the workflow parameter ReplaceMe is assigned the value ReplaceMe123 for this node when the workflow is run.

4. Click in the toolbar.

Configure the workflow parameter for a Shell node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and click **General** to show all the existing data analytics nodes. Double-click the target Shell node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter ${ReplaceMe} in the **Arguments** field.

> **Note** Make sure that you enter the parameter in the correct format.

4. Click in the toolbar.

Configure the workflow parameter for a sync node

1. On the **DataStudio** page, click **Manually Triggered Workflows** in the left-side navigation pane.
2. Find the target workflow and click **Data Integration** to show all the existing data integration nodes. Double-click the target sync node to go to the node configuration tab.
3. In the right-side navigation pane, click the **General** tab. In the General pane, enter -p"ReplaceMe=abc" in the **Arguments** field.

> **Note** Make sure that you enter the parameter in the correct format, namely, -p"-DParameter name=Parameter value".

4. Click in the toolbar.

Run the workflow to view the result

On the configuration tab of the workflow, click in the toolbar. In the Warning dialog box, click Settings. In the **Runtime Parameters** dialog box, set Arguments to ReplaceMe. The value of the workflow parameter is replaced when the workflow is run.

You can use the following methods to view the value assigned to the workflow parameter for different types of nodes:

- Right-click the ODPS SQL node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the ODPS SQL node.
- Right-click the Shell node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the Shell node.
- Right-click the sync node and select **View Log**. Then, you can view the value assigned to the workflow parameter for the sync node.

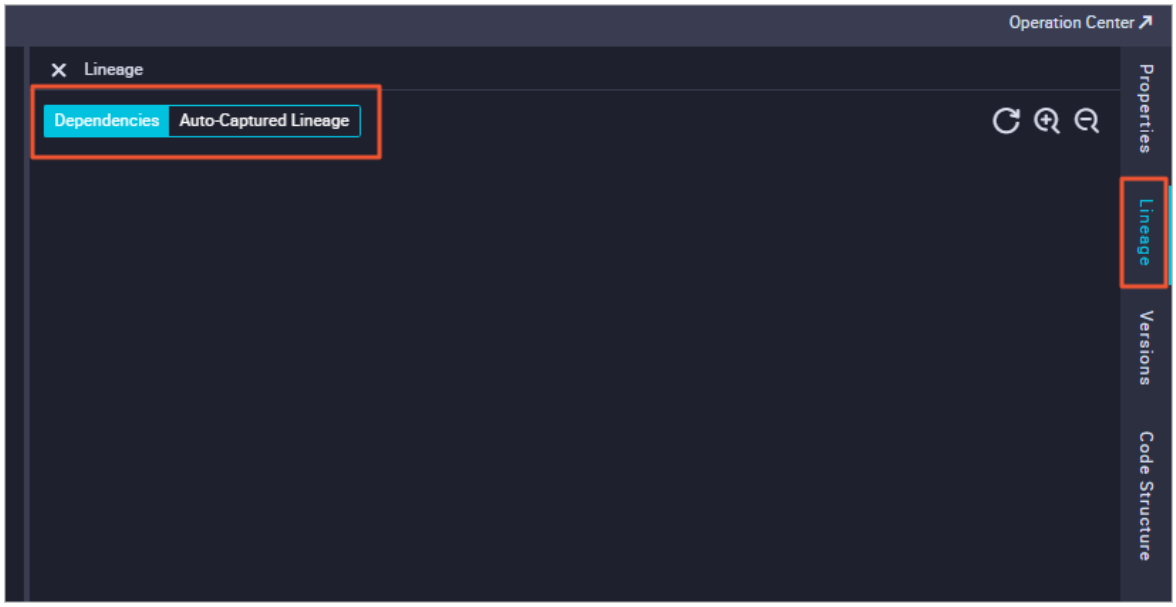
If you have not assigned a value to a workflow parameter on the **Workflow Parameters** tab for a manually triggered workflow, you must assign a value to the workflow parameter every time you run the workflow in the production environment.

2.1.5.3.3. Lineage

The Lineage tab displays the relationships between a node and other nodes. You can view the node dependencies and the lineage parsed from the code of the node.

Go to the Lineage tab

1. Log on to the DataWorks console.
2. Double-click the target node. For more information about how to create a node, see Create an ODPS SQL node.
3. On the node configuration tab that appears, click the **Lineage** tab in the right-side navigation pane.



On the **Lineage** tab, you can click **Dependencies** to view the dependencies or click **Auto-Captured Lineage** to view the lineage.

View the dependencies

You can check the node dependencies presented based on the current configuration. If the node dependencies fail to meet your expectations, you can reconfigure the node dependencies on the Properties tab.

View the auto-captured lineage

The lineage is parsed based on the code of the current node. For example, an ODPS SQL node contains the following SQL statements:

```
INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
SELECT COALESCE(a.uid, b.uid) AS uid
  , b.gender
  , b.age_range
  , b.zodiac
  , a.region
  , a.device
  , a.identity
  , a.method
  , a.url
  , a.referer
  , a.time
FROM (
  SELECT *
  FROM ods_log_info_d
  WHERE dt = ${bdp.system.bizdate}
) a
LEFT OUTER JOIN (
  SELECT *
  FROM ods_user_info_d
  WHERE dt = ${bdp.system.bizdate}
) b
ON a.uid = b.uid;
```

The following figure shows the lineage parsed from the preceding SQL statements. The results queried from the ods_log_info_d and ods_user_info_d tables are joined and then inserted into the dw_user_info_all_d table.

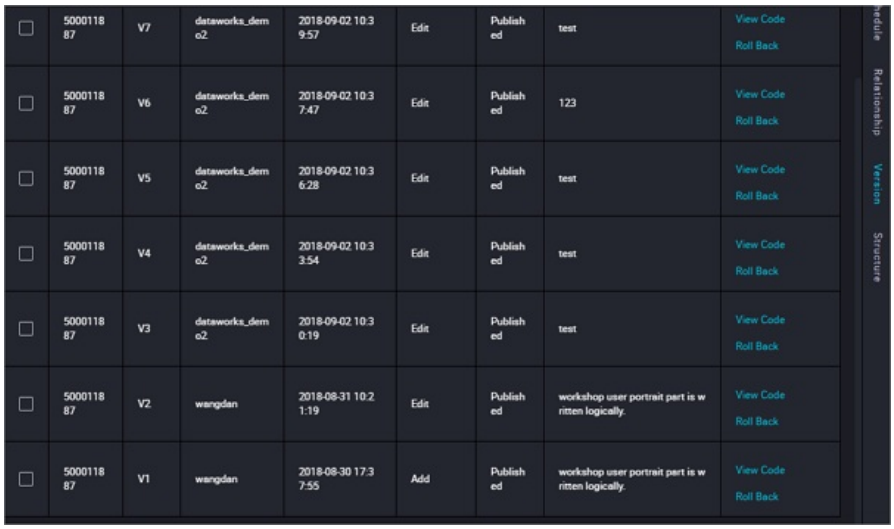
2.1.5.3.4. Versions

The Versions tab displays all committed and deployed versions of a node. You can view the historical versions and information about each version, including the user who committed the version, time when the version was committed, change type, status, and description.

> **Note** Only a committed node has the version information. Every time a node is committed, a version is generated and added to the **Versions** tab.

1. Log on to the DataWorks console.

2. On the **DataStudio** page, double-click the target node.
3. On the node configuration tab that appears, click the **Versions** tab in the right-side navigation pane. In the Versions pane, view the committed and deployed versions of the current node.



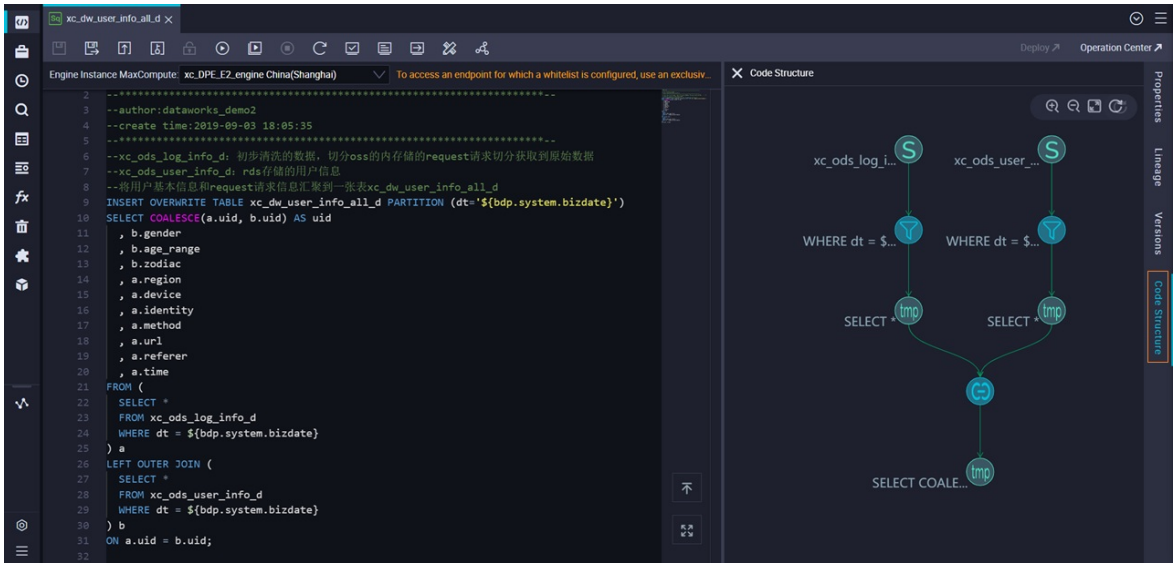
GUI element	Description
File ID	The ID of the node.
Versions	The version of the node. A version is generated each time the node is committed and deployed. V1 indicates version 1 and V2 indicates version 2. The version number is incremented by 1 each time.
Committed By	The user who committed the version.
Committed At	The time when the version was committed. If a version is committed and then deployed at a later time point, the value of this parameter is updated to the time when the version is deployed. By default, this column records the time when the version is last operated.
Change Type	The operation on the node. The value of this parameter is Create if the node is committed and deployed for the first time or Change if the node is modified, committed, and then deployed.
Status	The status of the version. Valid values: ○ **Yes**: The version is committed to the development environment but the related deployment task has not been created. The version has not been deployed in the production environment. ○ **Not Deployed**: The version is committed to the development environment and the deployment task is created. The version is pending for deployment. ○ **Deployed**: The version is committed to the development environment and deployed in the production environment.
Description	The change description of the version when it is committed. This description helps other users find the relevant version when they manage the node.

GUI element	Description
Actions	The actions that you can perform on the version. Two actions are available: **View Code** and **Roll Back**. ○ **View Code**: Click the button to view the code of the current version. ○ **Roll Back**: Click the button to roll back the node from the current version to the required version. After you roll back a node, you must commit and deploy it again.
Compare	Click the button to compare the code and properties between two selected versions.  Click **View Details**. On the details page that appears, you can view the changes in code and properties. **Note** You can only compare two versions and cannot compare one or more than two versions at a time.

2.1.5.3.5. Code Structure

The Code Structure tab displays the SQL code structure parsed from the code of a node. The code structure helps you view and modify the code.

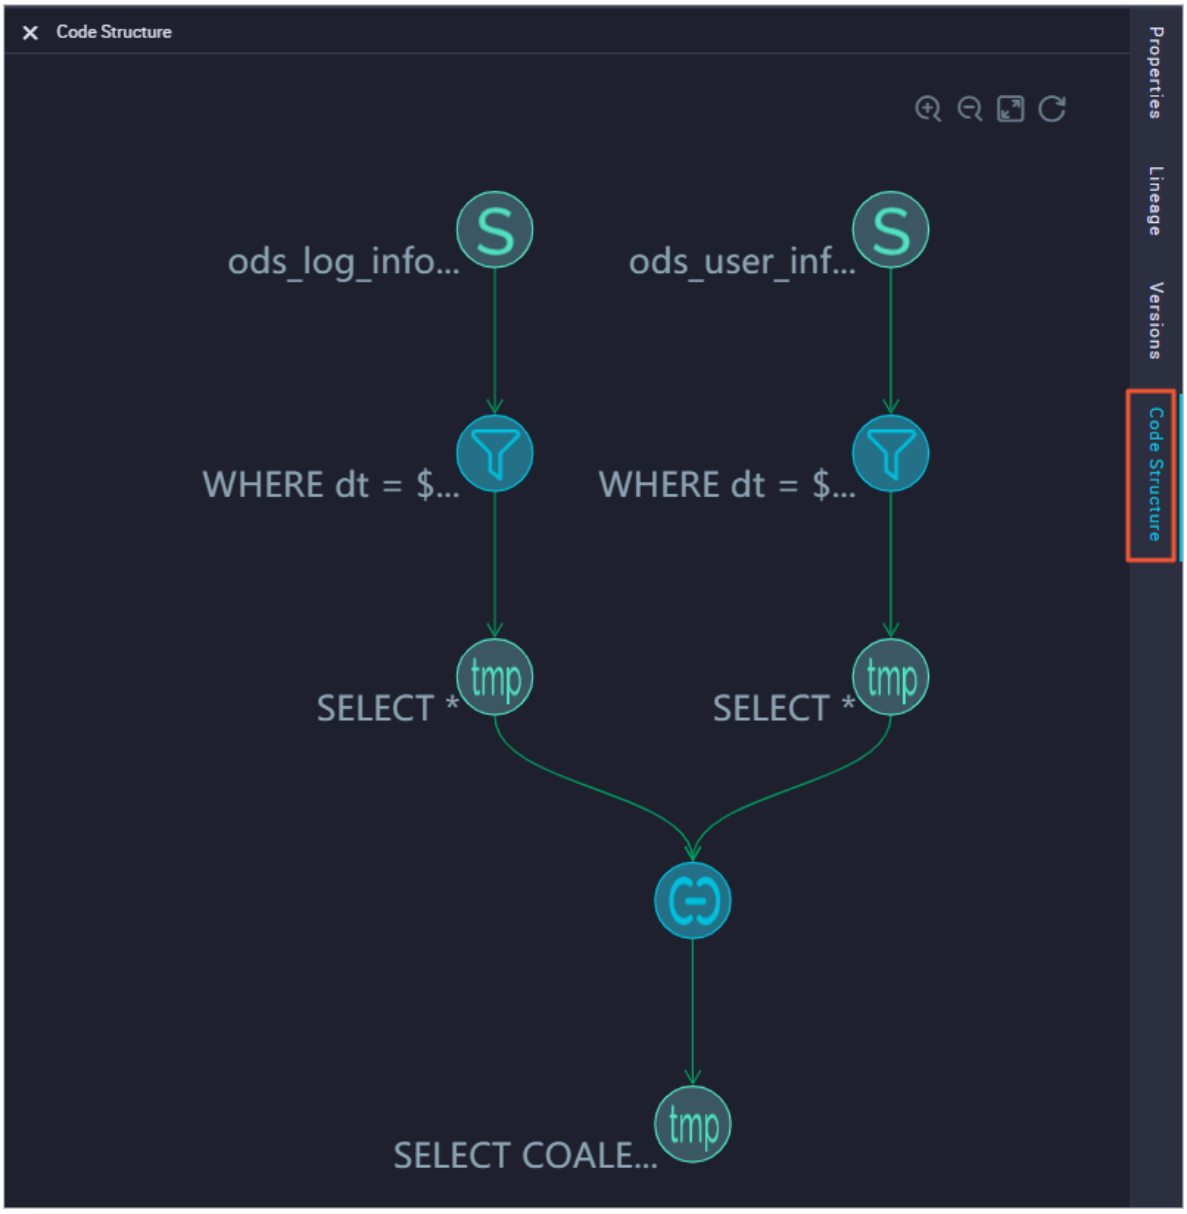
1. Log on to the DataWorks console.
2. Double-click the ODPS SQL node whose code structure you want to view. For more information about how to create a node, see Create an ODPS SQL node.
3. On the node configuration tab that appears, click the **Code Structure** tab in the right-side navigation pane.



In this example, the ODPS SQL node contains the following SQL statement:

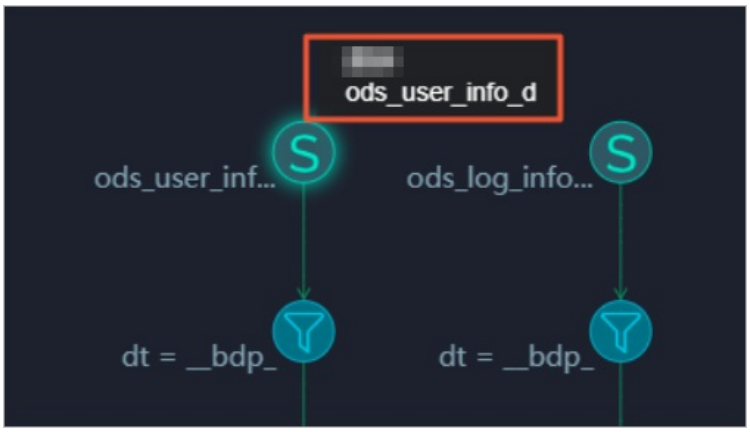
```
INSERT OVERWRITE TABLE dw_user_info_all_d PARTITION (dt='${bdp.system.bizdate}')
SELECT COALESCE(a.uid, b.uid) AS uid
  , b.gender
  , b.age_range
  , b.zodiac
  , a.region
  , a.device
  , a.identity
  , a.method
  , a.url
  , a.referer
  , a.time
FROM (
  SELECT *
  FROM ods_log_info_d
  WHERE dt = ${bdp.system.bizdate}
) a
LEFT OUTER JOIN (
  SELECT *
  FROM ods_user_info_d
  WHERE dt = ${bdp.system.bizdate}
) b
ON a.uid = b.uid;
```

The following figure shows the code structure parsed from the preceding SQL statement.

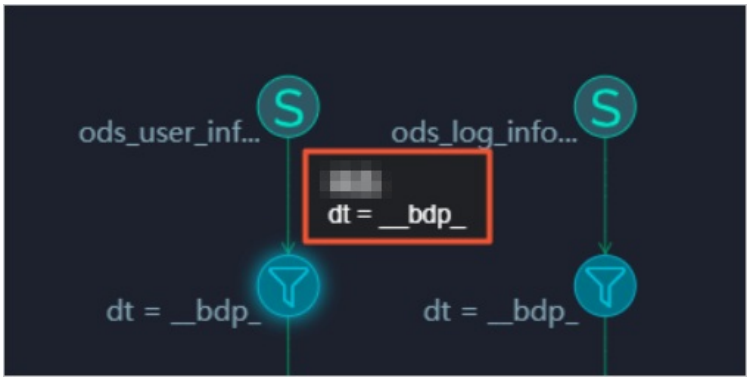


Move the pointer over a circle to view the description.

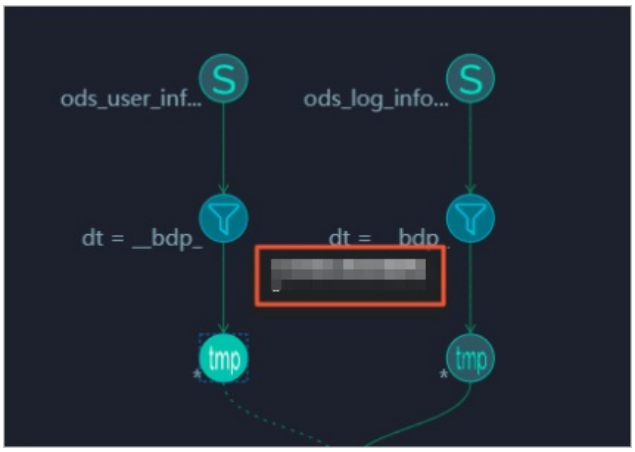
- **Source table**: the table to be queried.



- **Filter**: the condition for filtering the partitions in the table to be queried.

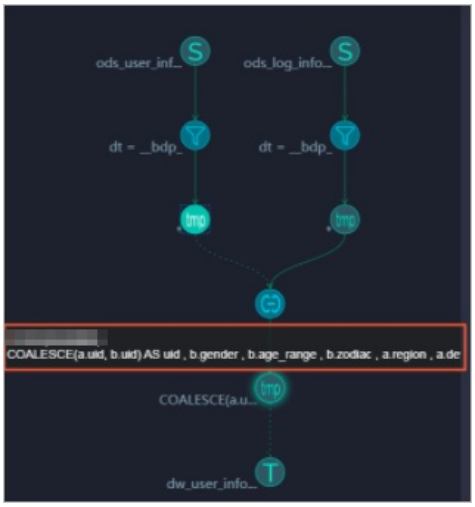


- **First intermediate table (view)**: the temporary table that stores the query results.

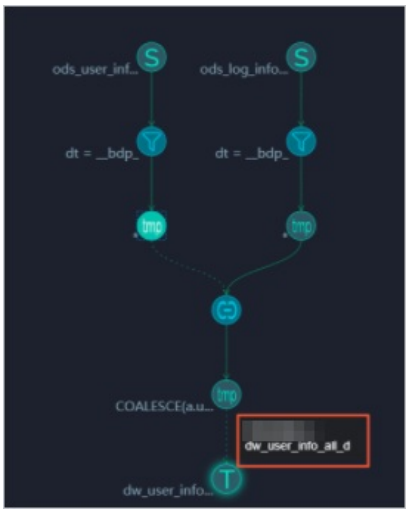


- **Join**: the operation for joining the query results.

- **Second intermediate table (view)**: the temporary table that stores the results of the JOIN operation. This temporary table can be stored for three days. After three days, this table is automatically deleted.



- **Destination table (insert)**: the destination table to which the query results are inserted by using an **INSERT OVERWRITE** statement.



2.1.5.4. Business flows

2.1.5.4.1. Overview

DataWorks organizes different types of nodes in a workflow by business category. This allows you to develop code by business.

DataWorks provides dashboards for different types of nodes in each workflow and provides tools for you to optimize and manage nodes in each workflow. This implements easy, intelligent development and management.

Workflow structure

A workspace supports multiple types of compute engines and multiple workflows. A workflow is a collection of various types of nodes that are closely associated with each other. DataWorks automatically generates a directed acyclic graph (DAG) for the workflow so that you can view the workflow. A workflow supports the following types of nodes: data integration, data analytics, table, resource, function, and algorithm.

Each type of node has an independent folder. You can also create subfolders in each folder. To facilitate management, we recommend that you create a maximum of four levels of subfolders. If more than four subfolder levels are required, your workflow is excessively complex. We recommend that you split the workflow into two or more workflows and add the workflows to one solution.

Create a workflow

1. Log on to the DataWorks console.
2. In the left-side navigation pane, click **Data Analytics**.
3. On the **Data Analytics** tab, right-click **Business Flow** and select **Create Workflow**.
4. In the **Create Workflow** dialog box, set **Workflow Name** and **Description**.

   > **Notice** The name of the workflow can be a maximum of 128 characters in length.

5. Click **Create**.

Nodes in a workflow

A workflow consists of the following types of nodes:

- **Data integration**

  Click **Data Integration** in a workflow to view all the data integration nodes in the workflow.

- **MaxCompute**

  The MaxCompute compute engine supports various data analytics nodes, such as MaxCompute SQL, SQL Snippet, MaxCompute Spark, PyODPS, MaxCompute Script, and MaxCompute MR nodes. You can also view and create tables, resources, and functions.

  - **Data analytics**

    Right-click **MaxCompute** in a workflow to create a data analytics node.

  - **Table**

    Right-click **MaxCompute** in a workflow and choose **Create > Table** to create a table. You can also view all the tables that are created in the current MaxCompute project.

  - **Resource**

    Right-click **MaxCompute** in a workflow, choose **Create > Resource**, and then select a specific resource type to create a resource. You can also view all the resources that are created in the current MaxCompute project.

  - **Function**

    Right-click **MaxCompute** in a workflow and choose **Create > Function** to create a function. You can also view all the functions that are created in the current MaxCompute project.

- **AnalyticDB for PostgreSQL**

  You can create AnalyticDB for PostgreSQL nodes and tables.

  > **Note** The AnalyticDB for PostgreSQL folder is displayed on the DataStudio page only after you associate an AnalyticDB for PostgreSQL instance with the current workspace on the **Project Management** page.

- **EMR**

  The E-MapReduce (EMR) compute engine supports various data analytics nodes, such as EMR Hive, EMR MR, EMR Spark, and EMR Spark SQL nodes. You can also view and create EMR resources.

  > **Note** The **EMR** folder is displayed only after you associate an EMR compute engine instance with the current workspace on the **Project Management** page.

- **Data analytics**

  Right-click **Data Analytics** in the **EMR** folder in a workflow and select Create to create a data analytics node of a specific type.

- **Resource**

  Right-click **Resource** in the **EMR** folder in a workflow and select Create to create a resource of a specific type. You can also view all the resources that are created in the current EMR compute engine instance.

- **Algorithm**

  Right-click **Algorithm** in a workflow and choose **Create > PAI Experiment** to create a PAI Experiment node. You can also view all the PAI Experiment nodes that are created in the current workflow.

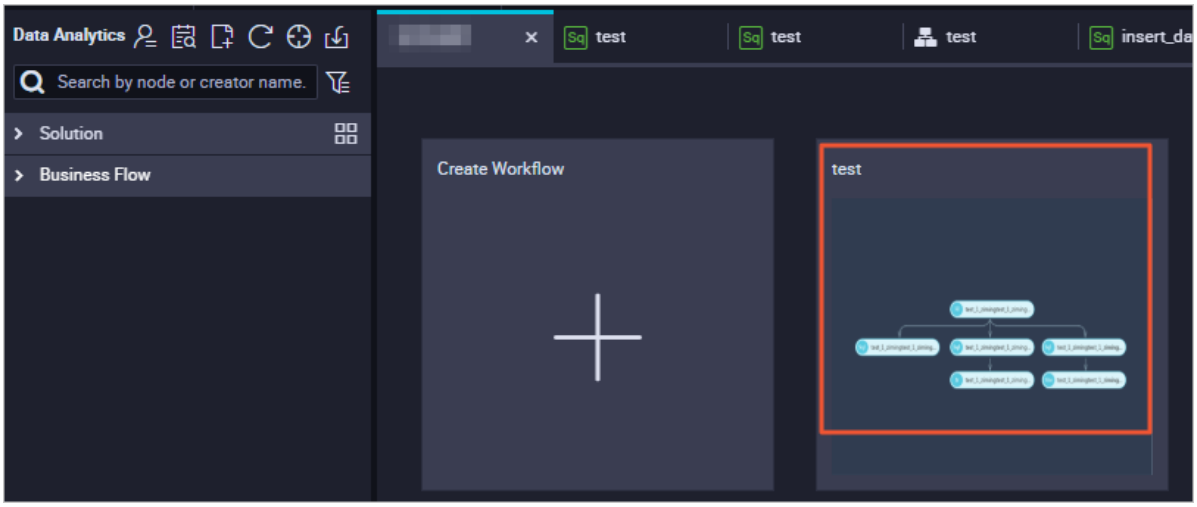
- **General**

  Right-click **General** in a workflow and select Create to create a node of a specific type.

View all workflows

On the **Data Analytics** tab, right-click **Business Flow** and select **All Workflows** to view all the workflows that are created in the current workspace.

Click a workflow. The dashboard of the workflow appears.



View the dashboard for each type of node

DataWorks provides a dashboard for each type of node in a workflow. On the dashboard, each node is presented by a card that offers operation and optimization suggestions. This way, you can intelligently manage nodes.

For example, the card of each data analytics node provides two indicators to show whether baseline-based monitoring and event notification are enabled for the node. This allows you to understand the status of each node.

You can double-click a folder in a workflow to view the dashboard of the selected node type.

Commit a workflow

1. Go to the dashboard of a workflow and click the icon in the top toolbar.
2. In the **Commit** dialog box, select the nodes that you want to commit, set **Change description**, and then select **Ignore I/O Inconsistency Alerts**.
3. Click **Commit**.

> **Note** A committed node whose code is not modified cannot be selected again. In this case, you can enter your comments on the node and click **Commit**. The property changes of the node are automatically committed.

2.1.5.4.2. Create and reference a node group

This topic describes how to create and reference a node group.

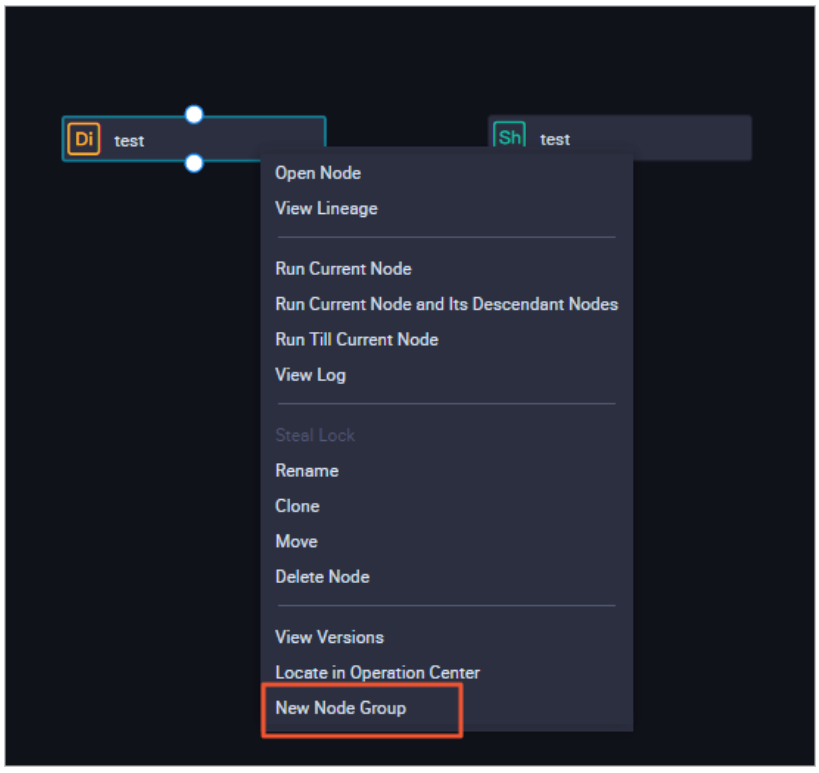
Context

You can group several nodes that are frequently reused together as a node group. The configuration of each node remains unchanged after the nodes are added to a node group. Later, you can directly reference the node group to reuse these nodes.

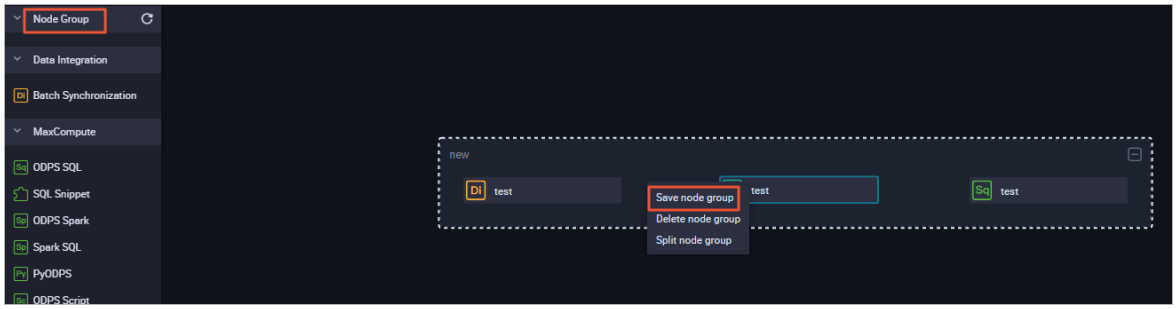
Create a node group

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, create a workflow. For more information, see Create a workflow.
3. Go to the dashboard of the created workflow. Click in the upper-right corner and drag a box to select the target nodes to be included in a node group.

4. Right-click any node among the selected nodes and select **New Node Group**.



5. In the **New Node Group** dialog box, enter a name in the **Name** field and click **OK**.
6. Right-click the node group and select **Save node group**. In the dialog box that appears, click OK. Then, you can view the created node group in the **Node Group** section.



Menu item	Description
Save node group	Save the node group. The node group that you have created appears in the Node Group section only after you click **Save node group**. A node group that is not saved cannot be referenced in other workflows.
Delete node group	Delete the node group. Click **Delete node group** to delete all nodes in the selected node group.
Split node group	Dismiss the node group. After the node group is dismissed, the selected nodes no longer form a node group in the workflow. However, the node group still exists in the Node Group section.

> **Note** If the created node group contains a PAI Experiment node, create a PAI experiment in another workflow to reference the node group. If the created node group contains a branch node, add digits to the value in the **Associated Node Output** parameter.

Reference a node group

You can directly drag a node group to another workflow to reference the node group in the workflow. The dependencies among the nodes in the node group remain unchanged.

You can run the workflow or commit and deploy the workflow. Then, go to **Operation Center** to view the running result.

2.1.5.5. Node types

2.1.5.5.1. Data Integration

2.1.5.5.1.1. Create a batch synchronization node

Batch synchronization nodes support various types of data sources, such as MaxCompute, MySQL, PolarDB-X, SQL Server, PostgreSQL, Oracle, MongoDB, Db2, Tablestore, Object Storage Service (OSS), FTP, HBase, LogHub, HDFS, and Stream.

Context

When you enter a table name, a drop-down list appears, displaying all matching tables. Only exact matches are supported. Therefore, you must enter a complete table name. Tables are labeled as unsupported if they are not supported by batch synchronization nodes.

If you move the pointer over a table in the list, the details of the table are displayed, such as the database, IP address, and owner of the table. The details help you select the correct table. After you select and click a table, the column information is automatically entered. You can add, move, or remove columns.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Data Integration > Batch Synchronization**.

   Alternatively, you can click the desired workflow in the Business Flow section, right-click **Data Integration**, and then choose **Create > Batch Synchronization**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. Configure the batch synchronization node. For more information, see Overview.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

   > **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

   i. Click the icon in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.2. MaxCompute

2.1.5.5.2.1. Create an ODPS SQL node

Using the SQL-like syntax, ODPS SQL nodes can process terabytes of data in distributed processing scenarios that do not require real-time processing.

Context

Generally, it takes a long time from preparing to committing a job. You can use ODPS SQL nodes to process thousands to tens of thousands of transactions. ODPS SQL nodes are online analytical processing (OLAP) applications designed to deal with large amounts of data.

Limits

- You cannot use SET statements, USE statements, or SQL alias statements independently in the code of an ODPS SQL node. They must be executed together with other SQL statements. For example, you can use a SET statement together with a CREATE TABLE statement.

```
set a=b;
create table name(id string);
```

- You cannot add comments to statements containing keywords, including SET statements, USE statements, and SQL alias statements, in the code of an ODPS SQL node. For example, the following comment is not allowed:

```
create table name(id string);
set a=b; // Comment.
create table name1(id string);
```

- The running of an ODPS SQL node during workflow development and the scheduled running of an ODPS SQL node have the following differences:
  - Running during workflow development: combines all the statements containing keywords, including SET statements, USE statements, and SQL alias statements, in the node code and executes them before executing other SQL statements.
  - Scheduled running: executes all SQL statements in sequence.

```
set a=b;
create table name1(id string);
set c=d;
create table name2(id string);
```

The following table shows the differences between the two running modes for the preceding SQL statements.

SQL statement	Running during workflow development	Scheduled running

First SQL statement	`set a=b;`
	`set c=d;`
	`create table name1(id string);`
		`set a=b;`
		`create table name1(id string);`

Second SQL statement	`set a=b;`
	`set c=d;`
	`create table name2(id string);`
		`set c=d;`
		`create table name2(id string);`

- You must specify a scheduling parameter in the format of key=value. Do not add any spaces before or after the equation mark (=). Examples:

```
time = {yyyymmdd hh:mm:ss} // Incorrect format.
a =b // Incorrect format.
```

- If you use keywords such as bizdate and date as scheduling parameters, you must specify the values in the format of yyyymmdd. If you want to use other time formats, do not use the preceding keywords as scheduling parameters. Example:

```
bizdate=201908 // Incorrect format.
```

- You can only use statements starting with SELECT, READ, or WITH to query the result data for a node during the workflow development. Otherwise, no results are returned.
- Separate multiple SQL statements with semicolons (;) and place them in different lines.

- Incorrect example

```
create table1;create table2
```

- Correct example

```
create table1;
create table2;
```

Create an ODPS SQL node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > ODPS SQL**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS SQL**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Edit the code of the ODPS SQL node.

   Edit the code of the ODPS SQL node. The code must conform to the syntax. The following example creates a table, inserts data to the table, and queries data in the table:

   i. Create a table named test1.

```
CREATE TABLE IF NOT EXISTS test1
( id BIGINT COMMENT '' ,
  name STRING COMMENT '' ,
  age BIGINT COMMENT '' ,
  sex STRING COMMENT '');
```

   ii. Insert data to the table.

```
INSERT INTO test1 VALUES (1,'Zhang San',43,'Male');
INSERT INTO test1 VALUES (1,'Li Si',32,'Male');
INSERT INTO test1 VALUES (1,'Chen Xia',27,'Female');
INSERT INTO test1 VALUES (1,'Wang Wu',24,'Male');
INSERT INTO test1 VALUES (1,'Ma Jing',35,'Female');
INSERT INTO test1 VALUES (1,'Zhao Qian',22,'Female');
INSERT INTO test1 VALUES (1,'Zhou Zhuang',55,'Male');
```

   iii. Query data in the table.

```
select * from test1;
```

iv. After you enter the preceding SQL statements in the code editor, click  in the toolbar. DataWorks executes your SQL statements from top to bottom and displays logs.

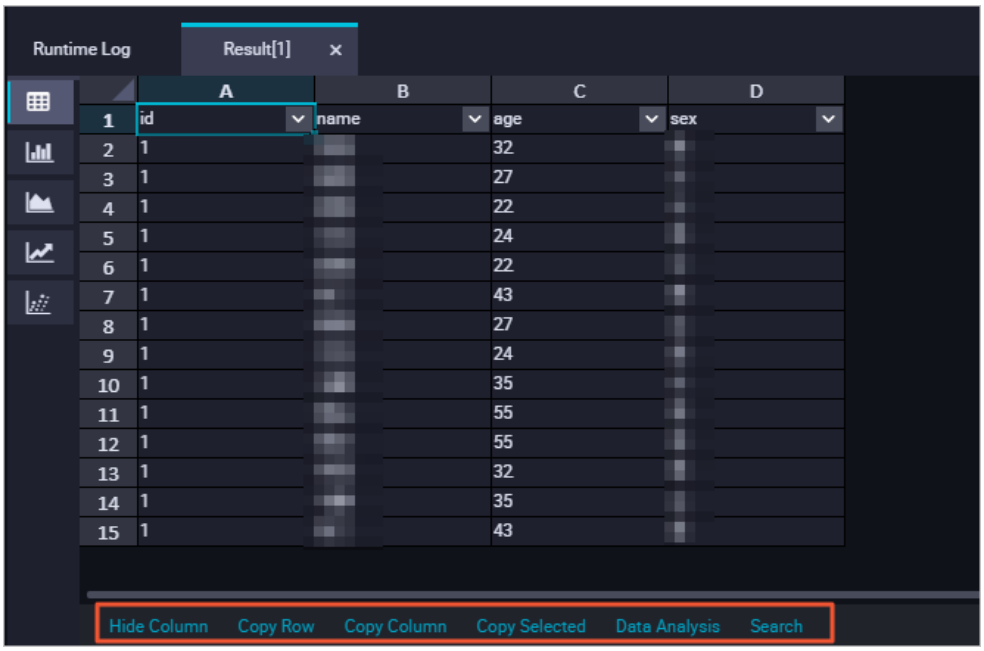
The `INSERT INTO` statement may result in unexpected data duplication. Although DataWorks does not re-execute the `INSERT INTO` statement, it may rerun corresponding nodes. We recommend that you avoid using the `INSERT INTO` statement. When DataWorks executes the INSERT INTO statement, the following information appears in logs:

```
The INSERT INTO statement in SQL may cause repeated data insertion. Although SQL-level retri
es have been revoked for the INSERT INTO statement, task level retries may still happen. We
recommend that you avoid the use of the INSERT INTO statement.
If you continue to use INSERT INTO statements, we deem that you are aware of the associated
risks and are willing to take the consequences of potential data duplication.
```

v. View the query result.

DataWorks displays the query result in a workbook.

You can view or manage the query result in the workbook, or copy the query result to a local Excel file.



Action	Description
Hide Column	Select one or more columns and click **Hide Column** at the bottom to hide the selected columns.
Copy Row	Select one or more rows and click **Copy Row** at the bottom to copy the selected rows.
Copy Column	Select one or more columns and click **Copy Column** at the bottom to copy the selected columns.
Copy Selected	Select one or more cells in the workbook and click **Copy Selected** at the bottom to copy the selected cells.
Data Analysis	Click **Data Analysis** at the bottom to go to the workbook editing page.
Search	Click **Search** at the bottom to search for data in the workbook. After you click the button, a search box appears in the upper-right corner of the Results tab.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

> **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click in the toolbar.

ii. In the **Commit Node** dialog box, ignore the alert on mismatch between the input and output that you set with those detected in code lineage analysis, enter your comments in the **Description** field, and then select **I confirm to proceed with the commission**.

iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the ODPS SQL node. For more information, see Publish nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.2.2. Create an SQL Snippet node

SQL script templates are SQL templates that involve multiple input and output parameters. Each SQL script template involves one or more source tables. You can use an SQL script template to filter, join, or aggregate data in source tables.

Context

When a new version is released for a script template, you can decide whether to upgrade the version of the script template used in your nodes to the latest version.

The script template upgrade mechanism allows developers to continuously upgrade script template versions. This mechanism enhances the process execution efficiency and optimizes the business performance.

For example, User A uses V1.0 of a script template that belongs to User B. Then, User B releases V2.0 for the script template. User A receives a notification of the new version. After User A compares the code of the two versions, User A can decide whether to upgrade the script template to the latest version.

To upgrade an SQL script template, click **Update Code** and check whether the parameter configuration of the SQL script template is valid in the new version. Set parameters for the SQL script template of the new version based on the version description. Then, save the node and commit it for deployment.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > SQL Snippet**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > SQL Snippet**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select a script template from the **Snippet** drop-down list.

   To improve development efficiency, you can create data analytics nodes by using the script templates provided by workspace members and tenants.

   - The script templates provided by members of the current workspace are available on the **Workspace-Specific** tab.
   - The script templates provided by tenants are available on the **Public** tab.

6. Click the **Parameters** tab in the right-side navigation pane and set parameters for the SQL script template.

7. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
8. Commit the node.

   > **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

   i. Click the icon in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.
9. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.2.3. Create an ODPS Spark node

DataWorks supports ODPS Spark nodes. This topic uses the JAR resource type as an example to describe how to create and configure an ODPS Spark node.

Create and upload a resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > Resource > JAR**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > JAR**.

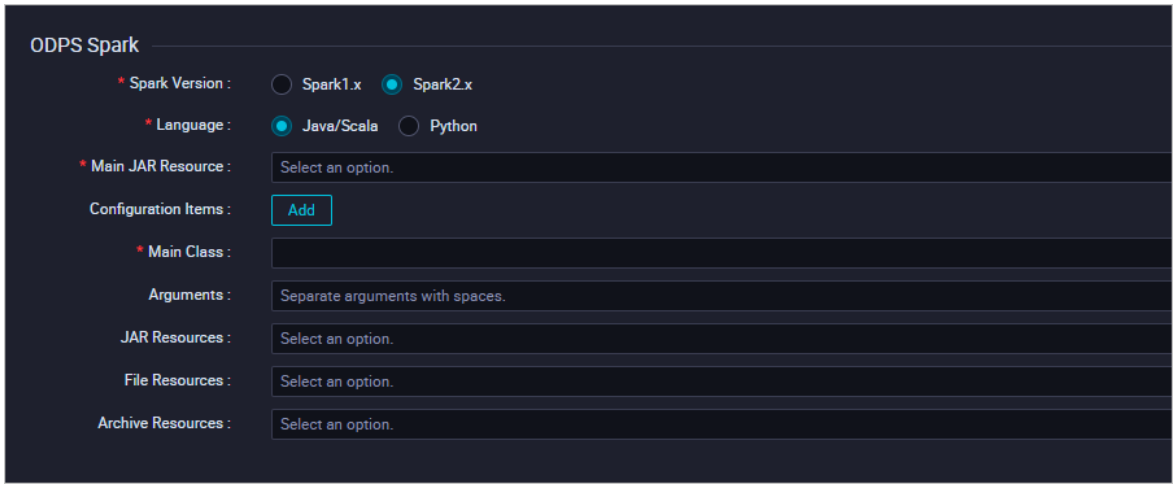
   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.
3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.
4. Click **Upload** and select the target file to upload.
5. Click **OK**.

Create an ODPS Spark node

1. On the **Data Analytics** tab, move the pointer over and choose **MaxCompute > ODPS Spark**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS Spark**.
2. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
3. Click **Commit**.
4. On the node configuration tab, set the parameters.



You can set **Spark Version** and **Language** as needed. The parameters vary with the value of the **Language** parameter. You can set the parameters as prompted.

The following table describes the parameters that appear after you set the Language parameter to **Java/Scala**.

Parameter	Description
Spark Version	The Spark version of the node. Valid values: **Spark1.x** and **Spark2.x**.
Language	The programming language of the node. Valid values: **Java/Scala** and **Python**. Select **Java/Scala**.
Main JAR Resource	The main JAR resource referenced by the node. Select a JAR resource that you uploaded from the drop-down list.
Configuration Items	The configuration items of the node. Click **Add** and set key and value to add a configuration item.
Main Class	The class name of the node.
Arguments	The parameter used to assign a value to a variable in the code during node scheduling. Separate multiple parameters with spaces.
JAR Resources	The JAR resource referenced by the node. Select a JAR resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded JAR resources based on the resource type.
File Resources	The file resource referenced by the node. Select a file resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded file resources based on the resource type.
Archive Resources	The archive resource referenced by the node. Select an archive resource that you uploaded from the drop-down list. The ODPS Spark node automatically finds the uploaded archive resources based on the resource type. Only compressed resources appear.

5. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
6. Commit the node.

> **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

i. Click the icon in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

iii. Click **OK**.

In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.

7. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.2.4. Create a PyODPS 2 node

DataWorks supports PyODPS 2 nodes, which are integrated with Alibaba Cloud MaxCompute SDK for Python. You can edit Python code in PyODPS 2 nodes to process data in MaxCompute.

Context

You can also use MaxCompute SDK for Python to process data in MaxCompute.

> **Note**
> - The Python version of PyODPS 2 nodes is V2.7.
> - Each PyODPS 2 node can process a maximum of 50 MB of data and can occupy a maximum of 1 GB of memory. Otherwise, DataWorks terminates the PyODPS 2 node. Avoid writing excessive data processing code for a PyODPS node.

PyODPS 2 nodes are designed to use MaxCompute SDK for Python. If you want to run pure Python code, you can create a Shell node to run the Python scripts uploaded to DataWorks.

Create a PyODPS 2 node

1. Log on to the DataWorks console.
2. On the DataStudio page, move the pointer over the icon and choose **MaxCompute > PyODPS 2**.

   Alternatively, you can find the required workflow, right-click the workflow name, and then choose **Create > MaxCompute > PyODPS 2**.

   > **Notice** The **MaxCompute** folder is displayed on the DataStudio page only after you associate a **MaxCompute** compute engine instance with the current workspace on the **Workspace Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Configure the PyODPS 2 node on the node configuration tab.

i. Use the MaxCompute entry point.

In DataWorks, each PyODPS 2 node includes the global variable odps or o, which is the MaxCompute entry. Therefore, you do not need to manually specify the MaxCompute entry point.

```
print(odps.exist_table('PyODPS_iris'))
```

ii. Execute SQL statements.

PyODPS 2 nodes allow you to execute MaxCompute SQL statements to query data and obtain query results. If you use the execute_sql or run_sql method, the running instances are returned.

Not all statements that can be executed on the MaxCompute client are supported by PyODPS 2 nodes. To execute statements other than data definition language (DDL) or data manipulation language (DML) statements, you must use alternative methods.

For example, to execute a GRANT or REVOKE statement, use the run_security_query method. To run a Machine Learning Platform for AI (PAI) command, use the run_xflow or execute_xflow method.

```
o.execute_sql('select * from dual') # Execute the statement in synchronous mode. Other nodes
are blocked until the execution of the SQL statement is complete.
instance = o.run_sql('select * from dual') # Execute the statement in asynchronous mode.
print(instance.get_logview_address()) # Obtain the Logview URL of an instance.
instance.wait_for_success() # Block other nodes until the execution of the SQL statement is
complete.
```

iii. Configure runtime parameters.

You can use the hints parameter to configure the runtime parameters. The type of the hints parameter is DICT.

```
o.execute_sql('select * from PyODPS_iris', hints={'odps.sql.mapper.split.size': 16})
```

If you specify the sql.settings parameter for the global configuration, you must configure the runtime parameters each time you run the code.

```
from odps import options
options.sql.settings = {'odps.sql.mapper.split.size': 16}
o.execute_sql('select * from PyODPS_iris') # The hints parameter is automatically configured
based on global configuration.
```

iv. Obtain SQL query results.

You can use the open_reader method to obtain query results in the following scenarios:

- The SQL statement returns structured data.

```
with o.execute_sql('select * from dual').open_reader() as reader:
for record in reader: # Process each record.
```

- SQL statements such as DESC are executed. In this case, you can use the reader.raw property to obtain raw query results.

```
with o.execute_sql('desc dual').open_reader() as reader:
print(reader.raw)
```

> **Note** If you use a custom time variable, you must fix the variable to a time. PyODPS 2 nodes do not support relative time variables.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.

7. Commit the node.

   > **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

   i. Click the icon in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

Built-in services of PyODPS 2 nodes

A PyODPS 2 node contains the following built-in services:

- setuptools
- cython
- psutil
- pytz
- dateutil
- requests
- pyDes
- numpy
- pandas
- scipy
- scikit_learn
- greenlet
- six
- Other built-in services in Python 2.7, such as smtplib

2.1.5.5.2.5. Create an ODPS Script node

You can create an ODPS Script node to develop an SQL script by using the SQL engine provided by MaxCompute V2.0.

Context

The ODPS Script node allows DataWorks to compile the SQL script as a whole, instead of compiling the SQL statements in the script one by one. In this way, the SQL script is committed and run as a whole. This guarantees that an execution plan is only queued and executed once, making full use of MaxCompute computing resources.

Create an ODPS Script node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > ODPS Script**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > ODPS Script**.

> **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

> **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Edit the SQL script of the ODPS Script node as required.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

> **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

   i. Click the icon in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

SQL syntax and limits for ODPS Script nodes

Write SQL statements based on your business logic in a way similar to that of using a common programming language. You do not need to consider how to organize the SQL statements.

```
-- SET statements
set odps.sql.type.system.odps2=true;
[set odps.stage.reducer.num=***;]
[...]
-- DDL statements
create table table1 xxx;
[create table table2 xxx;]
[...]
-- DML statements
@var1 := SELECT [ALL | DISTINCT] select_expr, select_expr, ...
    FROM table3
    [WHERE where_condition];
@var2 := SELECT [ALL | DISTINCT] select_expr, select_expr, ...
    FROM table4
    [WHERE where_condition];
@var3 := SELECT [ALL | DISTINCT] var1.select_expr, var2.select_expr, ...
    FROM @var1 join @var2 on ... ;
INSERT OVERWRITE|INTO TABLE [PARTITION (partcol1=val1, partcol2=val2 ...)]
    SELECT [ALL | DISTINCT] select_expr, select_expr, ...
    FROM @var3;
[@var4 := SELECT [ALL | DISTINCT] var1.select_expr, var.select_expr, ... FROM @var1
    UNION ALL | UNION
    SELECT [ALL | DISTINCT] var1.select_expr, var.select_expr, ... FROM @var2;
CREATE [EXTERNAL] TABLE [IF NOT EXISTS] table_name
    AS
    SELECT [ALL | DISTINCT] select_expr, select_expr, ...
    FROM var4;]
```

SQL syntax and limits for ODPS Script nodes

- ODPS Script nodes support SET statements, DML statements, and some DDL statements. The DDL statements used to return data, such as DESC and SHOW statements, are not supported.
- A complete script consists of SET statements, DDL statements, and DML statements in sequence. You can write one or more statements of each type, or even skip a type without writing any statements of that type. However, you cannot mix different types of statements together. You must strictly follow the sequence of SET statements > DDL statements > DML statements.
- The at signs (@) residing before some statements indicate that these statements are connected by using variables.
- A script supports only one statement that returns data, such as an independent SELECT statement. If multiple such statements are provided, an error occurs. We recommend that you do not use SELECT statements in a script.
- A script supports only one `CREATE TABLE AS` statement, which must be the last statement. We recommend that you put CREATE TABLE statements and INSERT statements in different sections to separate them.
- If one statement in a script fails, the whole script fails.
- A job is generated to process data only after all the input data is prepared for a script.
- If a script writes data to a table and then reads the table, an error occurs. For example, an error occurs for the following statements:

  ```
  insert overwrite table src2 select * from src where key > 0;
  @a := select * from src2;
  select * from @a;
  ```

  To avoid the error, modify the statements to the following:

```
@a := select * from src where key > 0;
insert overwrite table src2 select * from @a;
select * from @a;
```

Sample script:

```
create table if not exists dest(key string , value bigint) partitioned by (d string);
create table if not exists dest2(key string,value bigint ) partitioned by (d string);
@a := select * from src where value >0;
@b := select * from src2 where key is not null;
@c := select * from src3 where value is not null;
@d := select a.key,b.value from @a left outer join @b on a.key=b.key and b.value>0;
@e := select a.key,c.value from @a inner join @c on a.key=c.key;
@f := select * from @d union select * from @e union select * from @a;
insert overwrite table dest partition (d='20171111') select * from @f;
@g := select e.key,c.value  from @e join @c on e.key=c.key;
insert overwrite table dest2 partition (d='20171111') SELECT * from @g;
```

Scenarios of ODPS Script nodes

- You can use an ODPS Script node to rewrite a single statement with nested subqueries, or a script that must be split into multiple statements due to its complexity.
- Data from different data stores may be prepared at different time points, and the time difference may be large. For example, the data from one data store can be prepared at 01:00, whereas that from another data store can be prepared at 07:00. In this case, table variables are not suitable for connecting statements. You can use an ODPS Script node to combine the statements to a script.

2.1.5.5.2.6. Create an ODPS MR node

MaxCompute supports the MapReduce API. You can create and commit ODPS MR nodes that call the Java API operations of MapReduce to develop MapReduce programs for processing data in MaxCompute.

Context

Before you create ODPS MR nodes, you must upload, commit, and then deploy required resources.

Create a resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > Resource > JAR**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > JAR**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.

   > **Note**
   > - The resource name can be different from the name of the uploaded file.
   > - Convention for naming resources: A resource name can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive and must be 1 to 128 characters in length. A JAR resource name must end with .jar. A Python resource name must end with .py.

4. Click **Upload** and select the target file to upload.
5. Click **OK**.
6. Click  in the toolbar to commit the resource to the development environment.

Create an ODPS MR node

1. On the **Data Analytics** tab, find the target workflow, right-click **MaxCompute**, and then choose **Create > ODPS MR**.
2. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

3. Click **Commit**.
4. Edit the ODPS MR node.

```
-- Create an input table.
CREATE TABLE if not exists jingyan_wc_in (key STRING, value STRING);
-- Create an output table.
CREATE TABLE if not exists jingyan_wc_out (key STRING, cnt BIGINT);
    --- Create the dual table.
    drop table if exists dual;
    create table dual(id bigint); -- Create the dual table if no dual table exists in the curren
t workspace and initialize the table.
    --- Initialize the dual table.
    insert overwrite table dual select count(*)from dual;
    --- Insert the sample data to the wc_in table.
    insert overwrite table jingyan_wc_in select * from (
    select 'project','val_pro' from dual
    union all
    select 'problem','val_pro' from dual
    union all
    select 'package','val_a' from dual
    union all
    select 'pad','val_a' from dual
      ) b;
-- Reference the uploaded JAR package. You can find the JAR package in the resource list, right-
click the JAR resource, and select Insert Resource Path.
--@resource_reference{"mapreduce-examples.jar"}
jar -resources mapreduce-examples.jar -classpath ./mapreduce-examples.jar com.aliyun.odps.mapred
.open.example.WordCount jingyan_wc_in jingyan_wc_out
```

Pay attention to the following information when you write the code:

- `--@resource_reference`: references a resource. Find the target resource, right-click it, and then select **Insert Resource Path** to generate the reference statement.
- `-resources`: the name of the referenced JAR resource.
- `-classpath`: the path of the JAR resource. You can enter ./Resource name because the resource has been referenced.
- `com.aliyun.odps.mapred.open.example.WordCount`: the main class in the JAR resource to be called during node running. It must be the same as the main class name in the JAR resource.
- `jingyan_wc_in`: the name of the input table of the ODPS MR node. The input table is created in the preceding code.
- `jingyan_wc_out`: the name of the output table of the ODPS MR node. The output table is created in

the preceding code.

- If you use multiple JAR resources in a single ODPS MR node, separate the resource paths with commas (,), for example, `-classpath ./xxxx1.jar,./xxxx2.jar` .

5. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
6. Commit the node.

   > **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

   i. Click the icon in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.
7. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.2.7. Create a MaxCompute table

This topic describes how to create a MaxCompute table.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **MaxCompute > Table**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Table**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Table** dialog box, set **Table Name** and click **Commit**.

   > **Notice** A table name can be up to 64 characters in length. The table name must start with a letter and cannot contain Chinese or special characters.

4. On the table configuration tab that appears, set the parameters in the **General** section.

Parameter or button	Description
Display Name	The display name of the table.
Level 1 Folder	The name of the level-1 folder where the table resides. **Note** Level-1 and level-2 folders only show the table locations in DataWorks so that you can better manage tables.

Parameter or button	Description
Level 2 Folder	The name of the level-2 folder where the table resides.
Create Folder	Goes to the **Folder Management** tab. On this tab, you can create level-1 and level-2 folders for tables.
Description	The description of the table.

5. Create a table.

   Use one of the following methods to create a table:

   - Create a table by using DDL statements.

     Click **DDL Statement** in the top navigation bar. In the dialog box that appears, enter the statements for creating a table.

     After you finish editing the statements, click **Generate Table Schema**. Information is automatically entered in the General, Physical Model, and Schema sections.

   - Create a table on the graphical user interface (GUI).

     If DDL statements are inappropriate for you to create a table, try to use the GUI. The following table describes the relevant parameters for creating a table on the GUI.

Section	Parameter or button	Description
Physical Model	**Partitioning**	Specifies whether the table is partitioned. Valid values: **Partitioned Table** and **Non-Partitioned Table**.
	Time-to-Live	The time-to-live of data in MaxCompute. If you select this check box, you must enter a number in the **TTL** field. If the table or partition is stored for more than the specified number of days, data that has not been updated is cleared.
	Table Level	The level of the table. Generally, tables are divided into operation data store (ODS), common data model (CDM), and application data service (ADS) levels. You can specify a custom level name.
	Categories	The category of the table. Tables are categorized into basic services, advanced services, and other services. You can specify a custom category name. If you want to create a table category or level, click **Create Level** to go to the **Level Management** tab. **Note** Categories are designed only for your management convenience and do not involve underlying implementation.
	Table Type	The type of the table. Default value: **Internal Table**.
	Field Name	The name of the field. The name can contain letters, digits, and underscores (_).
	Display Name	The display name of the field.

Section	Parameter or button	Description
Schema	**Data Type**	The data type of the field.
	Definition or Maximum Value Length	The maximum value length of a field. You can set a maximum value length only for fields of the DECIMAL, VARCHAR, ARRAY, MAP, and STRUCT types.
	Description	The description of the field.
	Primary Key Field	Specifies whether the field serves as the primary key or part of a composite primary key.
	Create Field	Adds a field to the table.
	Delete Field	Deletes a field from the table. **Note** If you delete a field from an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Move Up	Adjusts the field sequence of the table. If you adjust the sequence of fields in an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Move Down	The description is the same as that of the **Move Up** operation.
	Add	Adds a partition to the table. If you add a partition to an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Delete	Deletes a partition from the table. If you delete a partition from an existing table, DataWorks requests you to delete the table and create another table with the same name. This operation is forbidden in the production environment.
	Actions	Commits a partition or deletes a field.
Partition Field Design	**Add**	Adds a partition field.
	Data Type	The data type of the partition field. We recommend that you use the STRING type for all partition fields.
	Length	The maximum length of the partition field. You can set the maximum length only for fields of the VARCHAR-type.
	Description	The description of the partition field.
	Partition Column Date Format	The format of the date partition. If the partition field is a date, although the data type may be STRING, select or enter a date format, such as *yyyymmmdd* or *yyyy-mm-dd*.

Section	Parameter or button	Description
Note This section is available only when Partitioning under Physical Model is set to Partitioned Table.	**Partition Column Date Granularity**	The granularity of the date partition. The granularities can be second, minute, hour, day, month, quarter, and year. You can enter a partition granularity as required. If you want to specify multiple partition granularities, note that a greater granularity corresponds to a higher partition level. For example, three partitions whose granularities are day, hour, and month, respectively, are available. Multi-level partitions are in the hierarchical order of level-1 partition (month), level-2 partition (day), and level-3 partition (hour).

6. Click **Commit in Development Environment** and **Commit to Production Environment** in sequence.

   If you are using a workspace in basic mode, you only need to click **Commit to Production Environment**.

Button	Description
Load from Development Environment	If the table has been committed to the development environment, the button is clickable. After you click the button, the information about the table you create in the development environment overwrites the table information on the current page. **Note** This feature is supported only for MaxCompute tables.
Commit in Development Environment	Before you click the button, make sure that you have filled in all required parameters on the table configuration tab. Do not click the button if any parameters are not specified.
Load from Production Environment	After you click the button, the information about the table that is committed to the production environment overwrites the table information on the current page. **Note** This feature is supported only for MaxCompute tables.
Commit to Production Environment	After you click the button, the table is created in the workspace of the production environment.

What's next

After the table is created, you can query the table data and modify or delete the table. For more information, see Manage tables.

2.1.5.5.2.8. Create, reference, and download resources

This topic describes how to create, reference, and download JAR and Python resources.

Context

If your code or function requires resource files such as.jar files, you can upload resources to your workspace and reference them.

If the existing built-in functions do not meet your requirements, DataWorks allows you to create user-defined functions (UDFs) and customize processing logic. You can upload the required JAR packages to your workspace so that you can reference them when you create UDFs.

> **Note**
> - You can view built-in functions on the **Built-In Functions** tab. For more information, see View built-in functions.
> - You can view the UDFs that you have committed or deployed on the **MaxCompute Functions** tab.

The resources that you can upload to MaxCompute include text files, MaxCompute tables, Python code, and compressed packages in the .zip, .tgz, .tar.gz, .tar, and .jar formats. You can read or use these resources when you run UDFs or MapReduce.

MaxCompute provides API operations for you to read and use resources. The following types of MaxCompute resources are available:

- **Python**: the Python code you have written. You can use Python code to register Python UDFs.
- **JAR**: the compiled Java JAR packages.
- **Archive**: the compressed files that can be identified by the file name extension. Supported file types include .zip, .tgz, .tar.gz, .tar, and .jar.
- **File**: files in the .zip, .so, or .jar format.

JAR resources and **file** resources have the following differences:

- To create a JAR resource, write Java code in the offline Java environment, compress the code to a JAR package, and upload the package as a JAR resource to DataWorks.
- To create a file resource that is smaller than or equal to 500 KB in size, you can create and edit it in the DataWorks console.
- To create a file resource that is larger than 500 KB in size, select **Large File (more than 500 KB)** and click Upload to upload the file.

> **Note** Each resource file to be uploaded in the DataWorks console cannot exceed 30 MB.

Create a JAR resource

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **MaxCompute > Resource > JAR**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > Python**.

   > **Notice** The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

3. In the **Create Resource** dialog box, set **Resource Name** and **Location**.

   > **Note**
   > - The resource name can be different from the name of the uploaded file.
   > - A resource name can contain letters, digits, underscores (_), and periods (.), and is not case-sensitive. It must be 1 to 128 characters in length. A JAR resource name must end with .jar, and a Python resource name must end with .py.

4. Click **Upload** and select the target file to upload.
5. Click **OK**.
6. Click  in the toolbar to commit the resource to the development environment.

Create a Python resource and register a UDF

1. Create a Python resource.
   i. On the **Data Analytics** tab, move the pointer over and choose **MaxCompute > Resource > Python**.
   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Resource > Python**.
   ii. In the **Create Resource** dialog box, set **Resource Name** and **Location**.
   iii. Click **OK**.
   iv. On the configuration tab that appears, edit the code of the created resource. Sample code:

```
from odps.udf import annotate
@annotate("string->bigint")
class ipint(object):
    def evaluate(self, ip):
        try:
            return reduce(lambda x, y: (x << 8) + y, map(int, ip.split('.')))
        except:
            return 0
```

   v. Click in the toolbar.
2. Register a UDF.
   i. On the **Data Analytics** tab, move the pointer over and choose **MaxCompute > Function**.
   Alternatively, you can click a workflow in the Business Flow section, right-click **MaxCompute**, and then choose **Create > Function**.
   ii. In the **Create Function** dialog box, set **Function Name** and **Location**.
   iii. Click **Commit**.
   iv. In the **Register Function** section of the configuration tab that appears, enter the class name and the name of the Python resource that has been created, and then click in the toolbar. In this example, the class name is `ipint.ipint`.
   v. Check whether the ipint function is valid and meets your expectation. For example, you can create an ODPS SQL node to test the ipint function by running an SQL statement.

Reference and download resources

- For more information about how to reference resources for functions, see Register a UDF.
- For more information about how to reference resources for nodes, see Create an ODPS MR node.

To download a resource, double-click **Resource** under the target workflow. In the resource list that appears, move the pointer over the required resource and click **Download**.

2.1.5.5.2.9. Register a UDF

DataWorks allows you to develop UDFs in Python and Java. This topic describes how to register a UDF.

Prerequisites

Before you register a UDF, you must upload the related resource.

Procedure

1. Log on to the DataWorks console.

2. Create a workflow. For more information, see Create a workflow.
3. Write Java code in the offline Java environment, compress the code to a JAR package, and upload the package as a JAR resource to DataWorks. For more information, see Create a JAR resource.
4. Create a UDF.
   i. Find the target workflow, right-click **MaxCompute**, and then choose **Create > Function**.
   ii. In the **Create Function** dialog box, set **Function Name** and **Location** and click **OK**.
   iii. In the **Register Function** section of the configuration tab that appears, set the parameters.

Parameter	Description
Function Type	The type of the function. Valid values: **Mathematical Function**, **Aggregate Function**, **String Function**, **Date Function**, **Analytic Function**, and **Other**.
Engine Instance MaxCompute	The MaxCompute engine instance bound to the current workspace. By default, you cannot change the engine instance.
Function Name	The name of the function, which is used to reference the function in SQL. The function name must be globally unique and cannot be modified after the function is registered.
Owner	The owner of the function. By default, this parameter is automatically set.
Class Name	Required. The name of the class for implementing the function. **Note** If the resource type is Python, enter the class name in the Python resource name.Class name format. Do not include the .py extension in the resource name.
Resources	Required. The list of resources. You can search for existing resources in the current workspace in fuzzy match mode.
Description	The description of the function.
Expression Syntax	The instructions on how to use the function, for example, `test`.
Parameter Description	The description of supported input and output parameter types.
Return Value	Optional. The value to return. Example: 1.
Example	Optional. An example of the function.

5. Click the save icon in the toolbar.
6. Commit the function.
   i. Click the commit icon in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

2.1.5.5.3. EMR

2.1.5.5.3.1. Modes for associating an EMR cluster with a DataWorks workspace

After you associate an EMR cluster with a DataWorks workspace, you can create nodes such as EMR Hive, EMR MR, EMR Presto, and EMR Spark SQL nodes based on an EMR compute engine and configure EMR workflows. You can also schedule the nodes and manage metadata. This improves your data output.

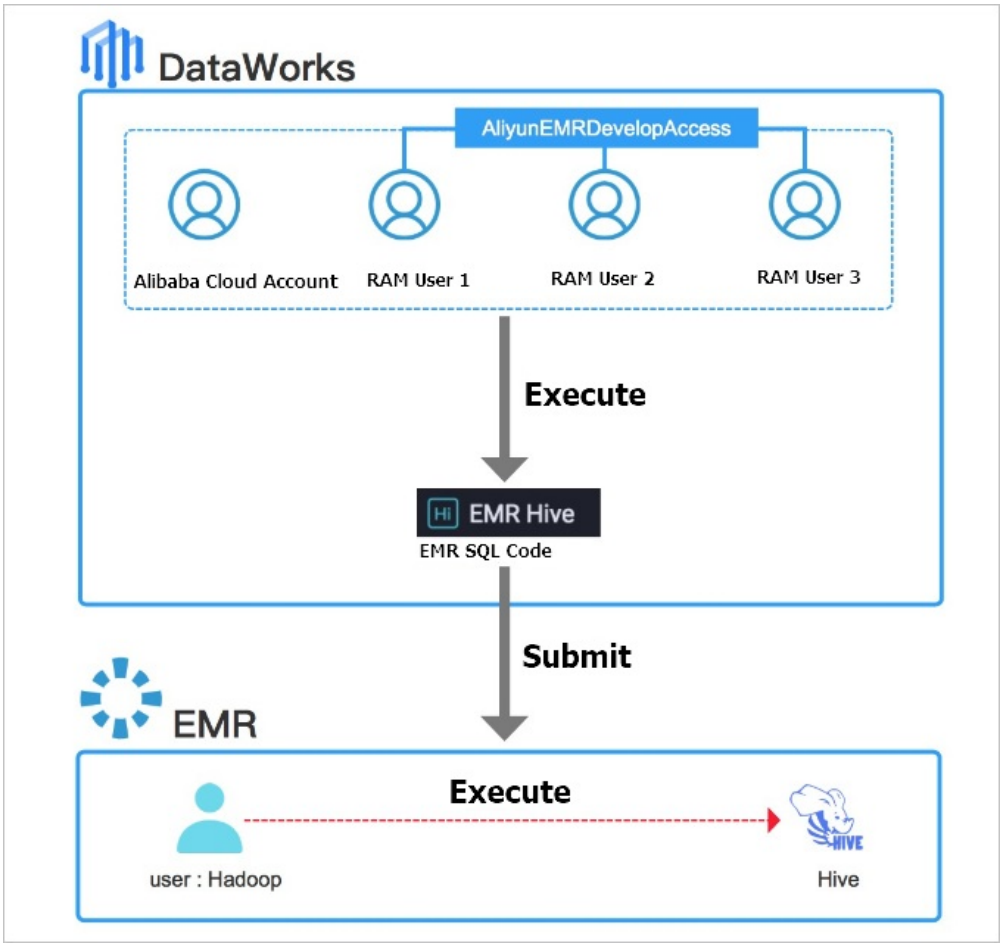
DataWorks provides two modes for you to associate an EMR cluster with a workspace: **Shortcut mode** and **Security mode**. The two modes can meet the security requirements of various enterprises. If you associate an EMR cluster with a workspace by using the **Shortcut mode**, you can create and run EMR nodes to generate data. If you associate an EMR cluster with a workspace by using the **Security mode**, you can create and run EMR nodes to generate data and manage permissions on the data to ensure higher security.

Shortcut mode

In **Shortcut mode**, if you run or schedule EMR nodes in DataWorks by using your Apsara Stack tenant account or as a RAM user, the code is committed to the EMR cluster and run by the Hadoop user of the EMR cluster.

> **Notice**
>
> - The Hadoop user has all the permissions on the EMR cluster. Proceed with caution when you use the Shortcut mode to associate an EMR cluster with a workspace.
> - Before you use the **Shortcut mode** to associate an EMR cluster with a workspace, you must attach the AliyunEMRDevelopAccess policy to workspace roles such as developers and administrators. This way, the roles can be used to create and run EMR nodes in DataStudio.
>   - The AliyunEMRDevelopAccess policy is attached to Apsara Stack tenant accounts by default.
>   - To run EMR nodes as a RAM user, you must attach the AliyunEMRDevelopAccess policy to the RAM user.

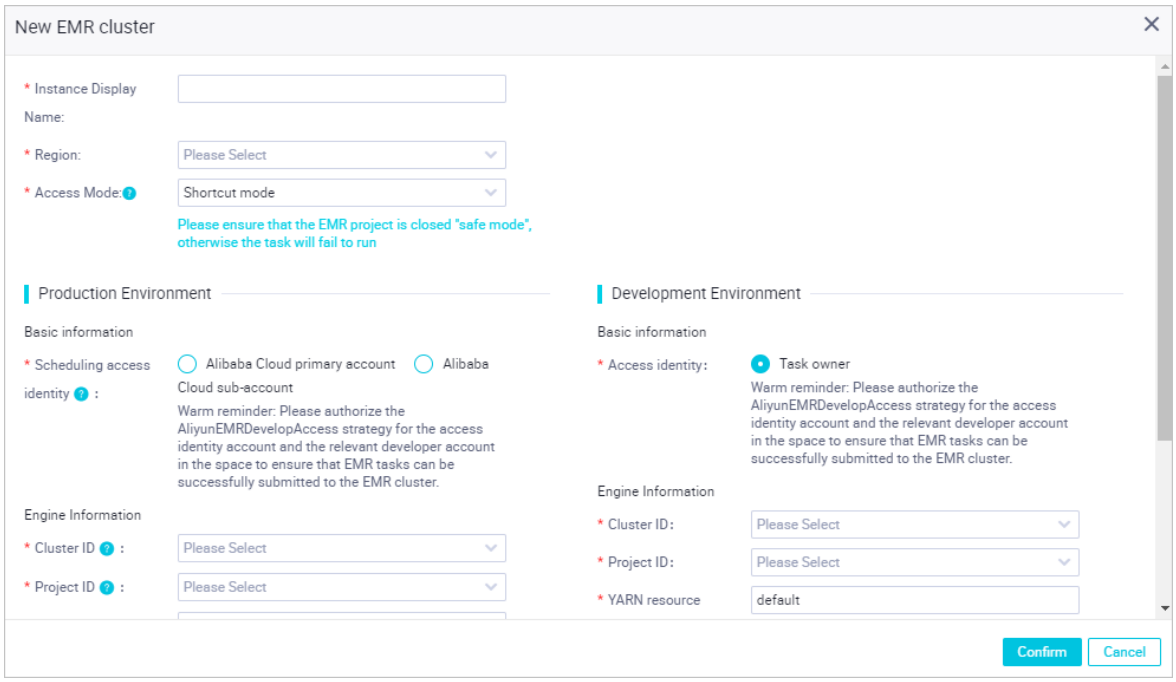
The **Shortcut mode** is suitable for workspaces that do not require strict permission management for users who run nodes.



To associate an EMR cluster with a workspace in **Shortcut mode**, perform the following steps:

1. Log on to the DataWorks console.
2. In the upper-right corner of the page, click the icon to go to the Workspace Management page.
3. In the **Compute Engine Information** section, click the **E-MapReduce** tab.
4. On the **E-MapReduce** tab, click **Add Instance**.
5. In the **New EMR cluster** dialog box, set the parameters.

Parameters in the New EMR cluster dialog box vary based on the mode in which your DataWorks workspace runs. The following table describes the parameters for a DataWorks workspace in standard mode. You must set the parameters for both the production environment and the development environment.



Parameter	Description
Instance Display Name	The display name of the EMR compute engine instance.
Region	The region of the current workspace.
Access Mode	The access mode of the EMR cluster. Select **Shortcut mode** from the drop-down list.

Scheduling access identity	The identity that is used to commit the code of an EMR node to the EMR cluster. The code is committed when the node is committed to the scheduling system of DataWorks in the production environment. Valid values: **Alibaba Cloud primary account** and **Alibaba Cloud sub-account**.
	Note
	- This parameter is available only for the production environment.
	- Before you use the **Shortcut mode** to associate an EMR cluster with a workspace, you must attach the AliyunEMRDevelopAccess policy to workspace roles such as developers and administrators. This way, the roles can be used to create and run EMR nodes in DataStudio.
	  - The AliyunEMRDevelopAccess policy is attached to Apsara Stack tenant accounts by default.
	  - To run EMR nodes as a RAM user, you must attach the AliyunEMRDevelopAccess policy to the RAM user.

Parameter	Description
Access identity	The identity that is used to commit the code of an EMR node in the development environment to the EMR cluster. Default value: **Task owner**. **Note** ◦ This parameter is available only for the development environment of a workspace in standard mode. ◦ **Task owner** can be an Apsara Stack tenant account or a RAM user. Before you use the **Shortcut mode** to associate an EMR cluster with a workspace, you must attach the AliyunEMRDevelopAccess policy to workspace roles such as developers and administrators. This way, the roles can be used to create and run EMR nodes in DataStudio. ■ The AliyunEMRDevelopAccess policy is attached to Apsara Stack tenant accounts by default. ■ To run EMR nodes as a RAM user, you must attach the AliyunEMRDevelopAccess policy to the RAM user.
Cluster ID	The ID of the EMR cluster that you want to associate with the workspace. Select an ID from the drop-down list. The EMR cluster with the selected ID is used as the runtime environment of EMR nodes.
Project ID	The ID of the EMR project that you want to associate with the workspace. Select an ID from the drop-down list. The selected EMR project with the selected ID is used as the runtime environment of EMR nodes. **Note** The IDs of the EMR projects in **Security mode** are not displayed and cannot be selected.
YARN resource queue	The name of the resource queue in the EMR cluster. Unless otherwise specified, set this parameter to *default*.
Endpoint	The endpoint of the EMR cluster. Unless otherwise specified, set this parameter to *default*.

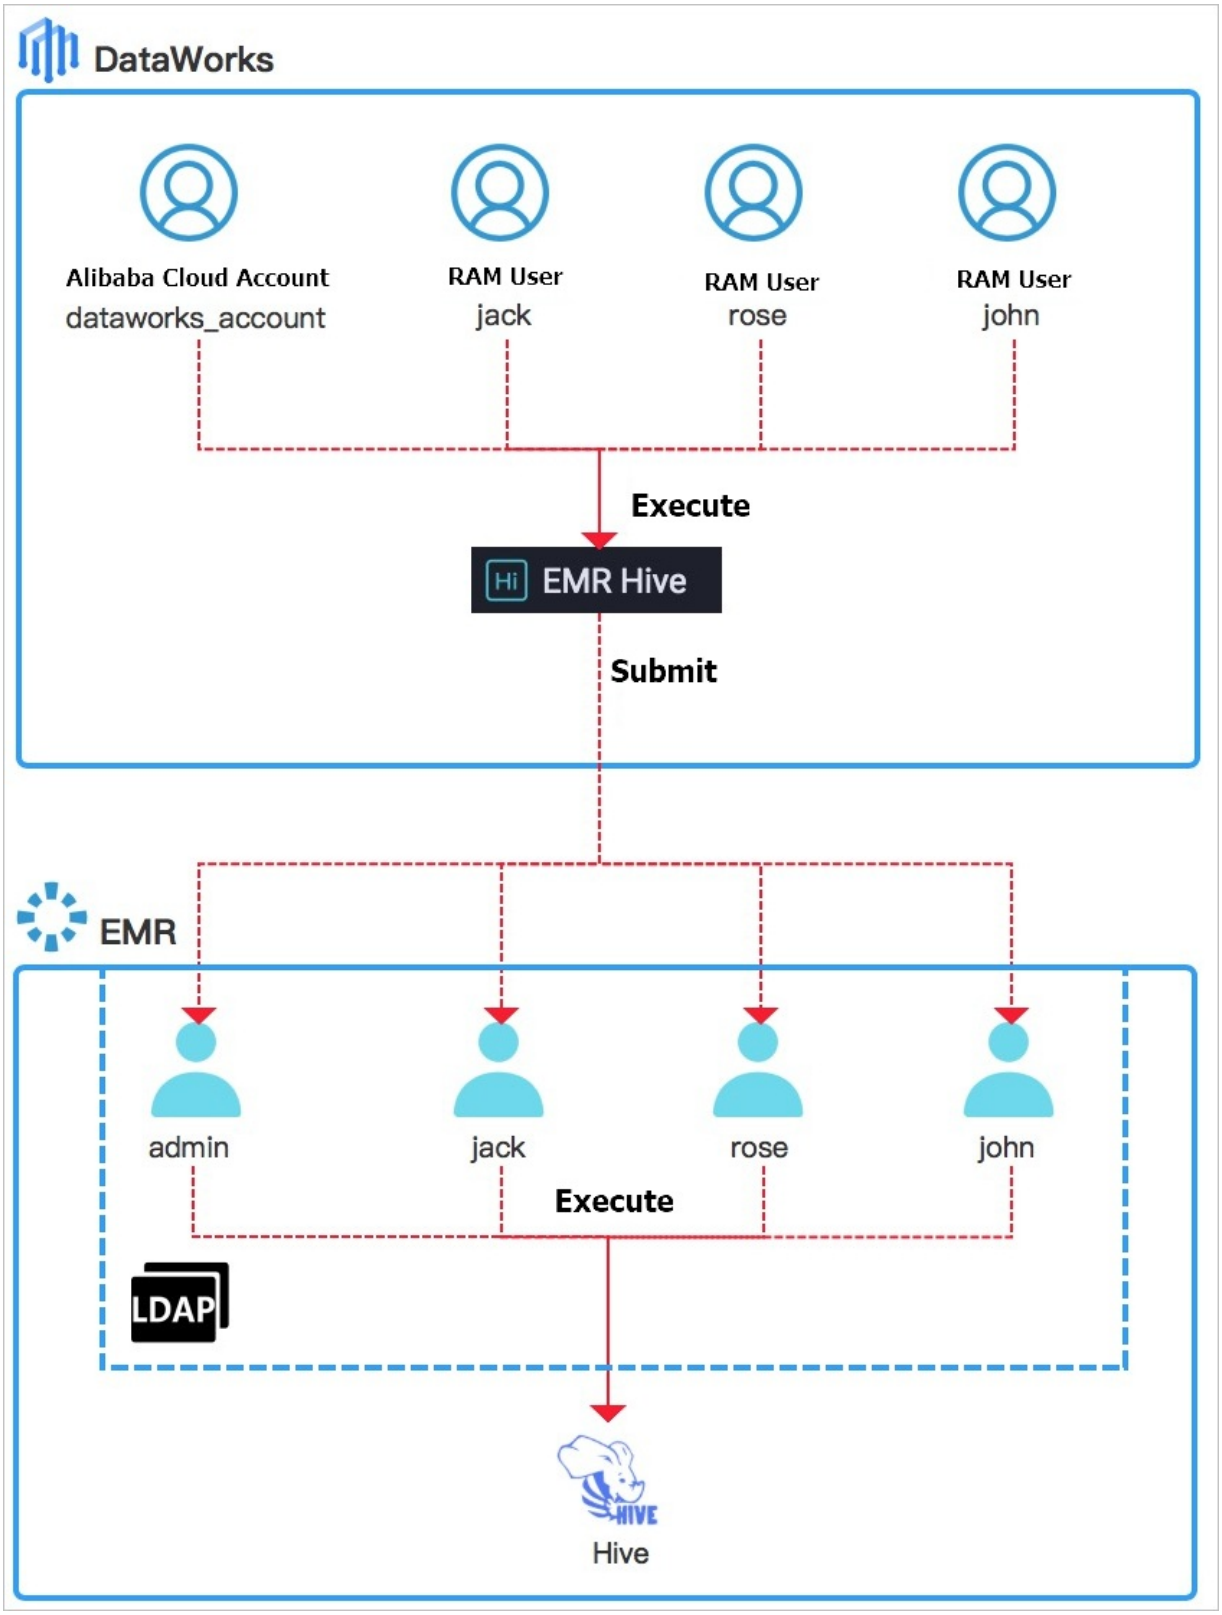
6. Click **Confirm**.

Security mode

In **Security mode**, if you commit the code of EMR nodes by using an Apsara Stack tenant account or as a RAM user to an EMR cluster, the code is run by a user that has the same name as the Apsara Stack tenant account or RAM user. EMR Ranger can be used to manage the permissions of each Hadoop user in the EMR cluster. This ensures that different Apsara Stack tenant accounts, node owners, or RAM users have different data permissions when they run EMR nodes in DataWorks. This provides higher data security.

> **Note**
>
> Before you use the **Security mode** to associate an EMR cluster with a workspace, you must add the credentials of workspace roles such as developers and administrators to the Lightweight Directory Access Protocol (LDAP) directory of the EMR cluster. In addition, you must attach the AliyunEMRDevelopAccess or AliyunEMRFullAccess policy and grant relevant data permissions to the workspace roles. This way, the roles can be used to create and run EMR nodes in DataStudio.
>
> - The credentials of Apsara Stack tenant accounts are in the LDAP directory of the EMR cluster by default. The AliyunEMRDevelopAccess and AliyunEMRFullAccess policies are also attached to Apsara Stack tenant accounts by default.
> - To run EMR nodes as a RAM user, you must add the credential of the RAM user to the LDAP directory of the EMR cluster. For more information, see the *Add the credentials of specific RAM users to the LDAP directory of the EMR cluster* step. In addition, you must attach the AliyunEMRDevelopAccess or AliyunEMRFullAccess policy to the RAM user.

The **Security mode** is suitable for workspaces that require strict management and isolation of data permissions for users who run nodes.



To use the **Security mode** to associate an EMR cluster with a workspace, perform the following steps:

1. Turn on Security Mode for the EMR project.

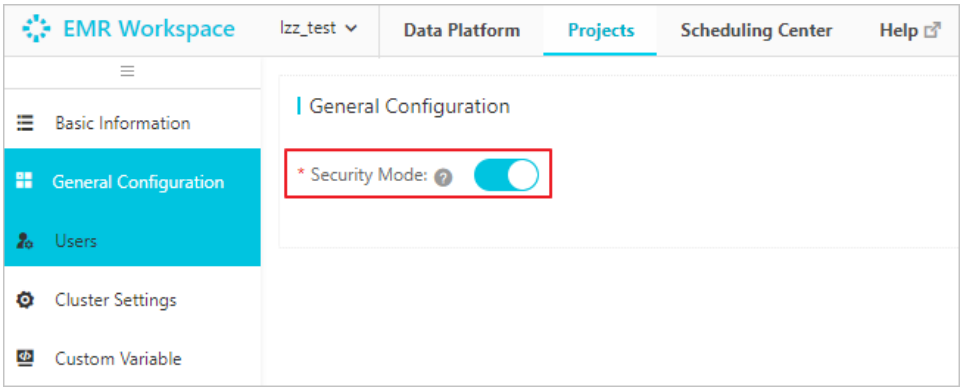
i. Log on to the EMR console.

ii. In the top navigation bar, click **Data Platform**.

iii. In the **Projects** section, find the project for which you want to enable the Security mode and click **Edit Job** in the Actions column.

iv. On the page that appears, click the **Projects** tab in the top navigation bar.

v. In the left-side navigation pane, click **General Configuration**. On the General Configuration page, turn on **Security Mode**.



2. Add the credentials of specific RAM users to the LDAP directory of the EMR cluster.

i. Go back to the homepage of the EMR console. In the top navigation bar, click **Cluster Management**.

ii. Find the cluster that you want to manage and click **Details** in the Actions column.

iii. In the left-side navigation pane, click **Users**.

iv. On the **Users** page, click **Add User**.

v. In the **Add User** dialog box, set the parameters.

We recommend that you add the credentials of the following RAM users to the LDAP directory of the EMR cluster:

- RAM users that create, test, and run EMR nodes in DataStudio
- RAM users that create, commit, and deploy EMR nodes in DataStudio

vi. Click **OK**.

3. Configure EMR Ranger and manage the permissions of the Hadoop users that correspond to your Apsara Stack tenant account and RAM users.

4. Associate the EMR cluster with the current DataWorks workspace.

i. Log on to the DataWorks console.

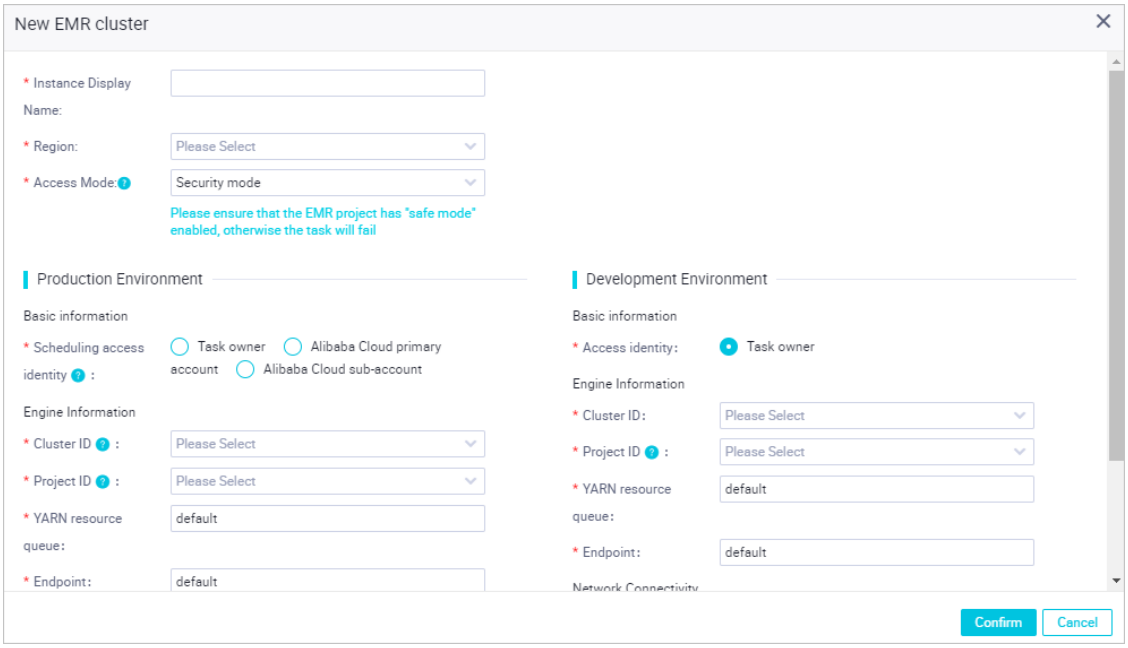
ii. In the upper-right corner of the page, click the icon to go to the Workspace Management page.

iii. In the **Compute Engine Information** section, click the **E-MapReduce** tab.

iv. On the **E-MapReduce** tab, click **Add Instance**.

v. In the **New EMR cluster** dialog box, set the parameters.

Parameters in the New EMR cluster dialog box vary based on the mode in which your DataWorks workspace runs. The following table describes the parameters for a DataWorks workspace in standard mode. You must set the parameters for both the production environment and the development environment.



Parameter	Description
Instance Display Name	The display name of the EMR compute engine instance.
Region	The region of the current workspace.
Access Mode	The access mode of the EMR cluster. Select **Security mode** from the drop-down list and click **Confirm** in the **Please note** message. **Note** You cannot use multiple modes to associate an EMR cluster with a DataWorks workspace at the same time. Proceed with caution when you change the access mode of the EMR cluster because a mode change leads to permission changes.

Parameter	Description
Scheduling access identity	The identity that is used to commit the code of an EMR node to the EMR cluster. The code is committed when the node is committed and deployed to the DataWorks scheduling system in the production environment. The Hadoop user that corresponds to this identity runs the code. Valid values: **Task owner**, **Alibaba Cloud primary account**, and **Alibaba Cloud sub-account**. ■ **Task owner**: commits and runs the code of an EMR node as the node owner. If you select this value, the data permissions of Hadoop users are isolated. **Task owner** can be an Apsara Stack tenant account or a RAM user. ■ **Alibaba Cloud primary account**: commits the code of an EMR node to the EMR cluster by using an Apsara Stack tenant account. ■ **Alibaba Cloud sub-account**: commits the code of an EMR node to the EMR cluster as a RAM user. **Note** ■ This parameter is available only for the production environment. ■ The credentials of Apsara Stack tenant accounts are in the LDAP directory of the EMR cluster by default. The AliyunEMRDevelopAccess and AliyunEMRFullAccess policies are also attached to Apsara Stack tenant accounts by default. ■ To run EMR nodes as a RAM user, you must add the credential of the RAM user to the LDAP directory of the EMR cluster. For more information, see the *Add the credentials of specific RAM users to the LDAP directory of the EMR cluster* step. In addition, you must attach the AliyunEMRDevelopAccess or AliyunEMRFullAccess policy to the RAM user.

Parameter	Description
Access identity	The identity that is used to commit the code of an EMR node in the development environment to the EMR cluster. Default value: **Task owner**. The Hadoop user that corresponds to the user who runs the node runs the code. **Note** ■ This parameter is available only for the development environment of a workspace in standard mode. ■ Make sure that the credential of the user who runs the node is added to the LDAP directory of the EMR cluster. In addition, make sure that the AliyunEMRDevelopAccess or AliyunEMRFulAccess policy is attached to the user and relevant data permissions are granted to the user. This way, the user can run EMR nodes in DataStudio. **Task owner** can be an Apsara Stack tenant account or a RAM user. ■ The credentials of Apsara Stack tenant accounts are in the LDAP directory of the EMR cluster by default. The AliyunEMRDevelopAccess and AliyunEMRFullAccess policies are also attached to Apsara Stack tenant accounts by default. ■ To run EMR nodes as a RAM user, you must add the credential of the RAM user to the LDAP directory of the EMR cluster. For more information, see the *Add the credentials of specific RAM users to the LDAP directory of the EMR cluster* step. In addition, you must attach the AliyunEMRDevelopAccess or AliyunEMRFullAccess policy to the RAM user.
Cluster ID	The ID of the EMR cluster that you want to associate with the workspace. Select an ID from the drop-down list. The EMR cluster with the selected ID is used as the runtime environment of EMR nodes.
Project ID	The ID of the EMR project that you want to associate with the workspace. Select the ID of an EMR project in Security mode from the drop-down list. **Note** The IDs of the EMR projects that are not in **Security mode** are not displayed and cannot be selected.
YARN resource queue	The name of the resource queue in the EMR cluster. Unless otherwise specified, set this parameter to *default*.
Endpoint	The endpoint of the EMR cluster. Unless otherwise specified, set this parameter to *default*.

vi. Click **Confirm**.

2.1.5.5.3.2. Create an EMR MR node

You can create an EMR MR node to compute a large-scale dataset by using multiple Map tasks in a parallel manner.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **EMR > EMR MR**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR MR**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click  in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.3. Create an EMR Spark SQL node

You can create an EMR Spark SQL node to use the distributed SQL query engine to process structured data, improving the task execution efficiency.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **EMR > EMR Spark SQL**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Spark SQL**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

> **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.4. Create an EMR Spark node

You can create an EMR Spark node to perform complex memory analysis and build large and low-latency data analysis applications.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **EMR > EMR Spark**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Spark**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

> **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.5. Create an EMR Hive node

This topic describes how to create an EMR Hive node. This type of node allows you to use SQL-like statements to read data from, write data to, and manage data warehouses with a large amount of data stored in a distributed storage system. By using this type of node, you can efficiently analyze a large amount of log data.

Prerequisites

The EMR folder is available on the DataStudio page only after you bind an E-MapReduce compute engine to the current workspace on the **Project Management** page.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **EMR > EMR Hive**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **EMR**, and then choose **Create > EMR Hive**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. On the node configuration tab, select an E-MapReduce compute engine from the **Engine Instance EMR** drop-down list and edit the code of the node.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.

   i. Click in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.6. Create and use an EMR Shell node

You can create an EMR Shell node and run the node by using the code editor.

Prerequisites

- An EMR cluster is created. An inbound rule that contains the following content is added to the security group to which the EMR cluster belongs:
  - Action: Allow
  - Protocol type: Custom TCP

- Port range: 8898/8898
- Authorization object: 100.104.0.0/16

- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only after you associate an EMR compute engine instance with the workspace on the Workspace Management page. For more information, see Associate an EMR cluster with a workspace.
- If you integrate Hive with Ranger in EMR, you must modify whitelist configurations and restart Hive before you develop EMR nodes in DataWorks. Otherwise, the error message **Cannot modify spark.yarn.queue at runtime** or **Cannot modify SKYNET_BIZDATE at runtime** is returned when you run EMR nodes.
  i. You can modify the whitelist configurations by using custom parameters in EMR. You can append key-value pairs to the value of a custom parameter. In this example, the custom parameter for Hive components is used. The following code provides an example:

  ```
  hive.security.authorization.sqlstd.confwhitelist.append=tez.*|spark.*|mapred.*|mapreduce.*|ALISA.*|SKYNET.*
  ```

  > **Note** In the code, `ALISA.*` and `SKYNET.*` are configurations in DataWorks.

  ii. After the whitelist configurations are modified, restart the Hive service to make the configurations take effect.

Create an EMR Shell node and use the node to develop data

1. Log on to the DataWorks console.
2. Create an **EMR Shell** node.
   i. On the DataStudio page, move the pointer over the icon and choose **EMR > EMR Shell**.

   You can also find the workflow in which you want to create the EMR Shell node, right-click the workflow name, and then choose **Create > EMR > EMR Shell**.

   ii. In the **Create Node** dialog box, set the **Node Name**, **Node Type**, and **Location** parameters.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

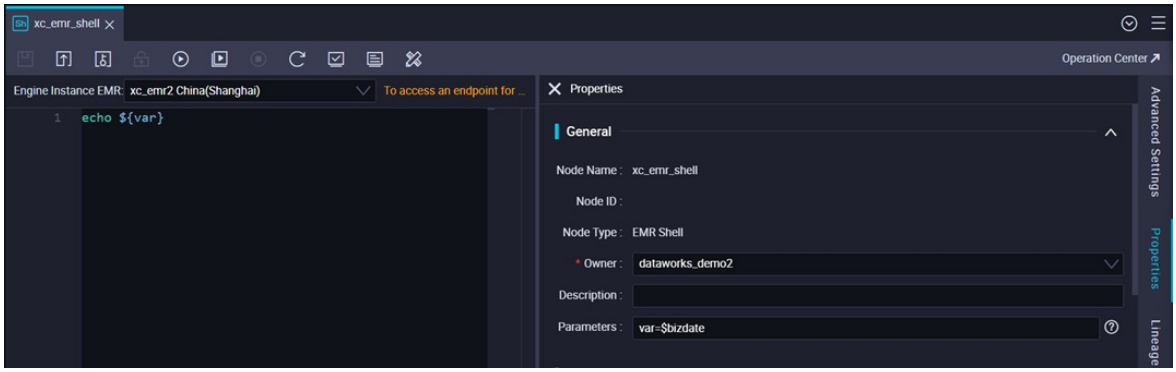
   iii. Click **Commit**. Then, the configuration tab of the **EMR Shell** node appears.
3. Use the **EMR Shell** node to develop data.

   The following code provides an example:

   ```
   DD=`date`;
   echo "hello world, $DD"
   ## Scheduling parameters are supported.
   echo ${var};
   ```

   For more information about the scheduling parameters, see Scheduling parameters.

   If you want to change the values that are assigned to the parameters in the code, click the Run with Parameters icon in the top toolbar.



4. Click the **Advanced Settings** tab in the right-side navigation pane. In the Advanced Settings panel, change the values of the parameters.
   - "USE_GATEWAY":true: If you set this parameter to true, the EMR Shell node is automatically committed to the master node of an EMR gateway cluster.
   - "SPARK_CONF": "--conf spark.driver.memory=2g --conf xxx=xxx": the parameters that are required to run Spark jobs. You can configure multiple parameters in the --conf xxx=xxx format.
   - "queue": the scheduling queue to which jobs are committed. Default value: default.
   - "vcores": the number of CPU cores. Default value:1.
   - "memory": the memory that is allocated to the launcher. Unit: MB. Default value: 2048.
   - "priority": the priority. Default value: 1.
   - "FLOW_SKIP_SQL_ANALYZE": specifies how SQL statements are executed. A value of false indicates that only one SQL statement is executed at a time. A value of true indicates that multiple SQL statements are executed at a time.
5. Configure scheduling properties for the EMR Shell node.

   If you want the system to periodically run the EMR Shell node, you can click the **Properties** tab in the right-side navigation pane to configure scheduling properties for the node based on your business requirements.
6. Commit and deploy the EMR Shell node.
   i. Click the icon in the top toolbar to save the node.
   ii. Click the icon in the top toolbar to commit the node.
   iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
   iv. Click **OK**.
7. View the EMR Shell node.
   i. On the configuration tab of the EMR Shell node, click **Operation Center** in the upper-right corner to go to Operation Center.
   ii. View the scheduled EMR Shell node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.7. Create and use an EMR Spark Shell node

You can create an EMR Spark Shell node and run the node by using the code editor.

Prerequisites

- An EMR cluster is created. An inbound rule that contains the following content is added to the security group to which the EMR cluster belongs:
  - Action: Allow
  - Protocol type: Custom TCP

- Port range: 8898/8898
- Authorization object: 100.104.0.0/16

- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only after you associate an EMR compute engine instance with the workspace on the Workspace Management page. For more information, see Associate an EMR cluster with a workspace.
- If you integrate Hive with Ranger in EMR, you must modify whitelist configurations and restart Hive before you develop EMR nodes in DataWorks. Otherwise, the error message **Cannot modify spark.yarn.queue at runtime** or **Cannot modify SKYNET_BIZDATE at runtime** is returned if you run EMR nodes.
  i. You can modify the whitelist configurations by using custom parameters in EMR. You can append key-value pairs to the value of a custom parameter. In this example, the custom parameter for Hive components is used. The following code provides an example:

  ```
  hive.security.authorization.sqlstd.confwhitelist.append=tez.*|spark.*|mapred.*|mapreduce.*|ALISA.*|SKYNET.*
  ```

  > **Note** In the code, `ALISA.*` and `SKYNET.*` are configurations in DataWorks.

  ii. After the whitelist configurations are modified, restart the Hive service to make the configurations take effect.

Create an EMR Spark Shell node and use the node to develop data

1. Log on to the DataWorks console.
2. Create an **EMR Spark Shell** node.
   i. On the DataStudio page, move the pointer over the icon and choose **EMR > EMR Spark Shell**.

   You can also find the workflow in which you want to create the EMR Spark Shell node, right-click the workflow name, and then choose **Create > EMR > EMR Spark Shell**.

   ii. In the **Create Node** dialog box, set the **Node Name**, **Node Type**, and **Location** parameters.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

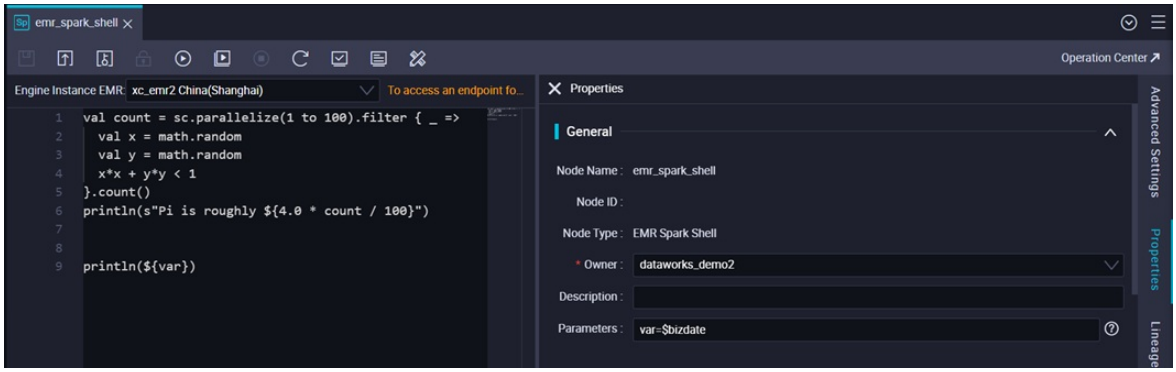
   iii. Click **Commit**. Then, the configuration tab of the **EMR Spark Shell** node appears.
3. Use the **EMR Spark Shell** node to develop data.

   The following code provides an example:

   ```
   val count = sc.parallelize(1 to 100).filter { _ =>
     val x = math.random
     val y = math.random
     x*x + y*y < 1
   }.count()
   println(s"Pi is roughly ${4.0 * count / 100}")
   println(${var})
   ```

   Scheduling parameters are supported. For more information, see Scheduling parameters

   If you want to change the values that are assigned to the parameters in the code, click the Run with Parameters icon in the top toolbar.



4. Click the **Advanced Settings** tab in the right-side navigation pane. In the Advanced Settings panel, change the values of the parameters.
   - "USE_GATEWAY":true: If you set this parameter to true, the EMR Spark Shell node is automatically committed to the master node of an EMR gateway cluster.
   - "SPARK_CONF": "--conf spark.driver.memory=2g --conf xxx=xxx": the parameters that are required to run Spark jobs. You can configure multiple parameters in the --conf xxx=xxx format.
   - "queue": the scheduling queue to which jobs are committed. Default value: default.
   - "vcores": the number of CPU cores. Default value:1.
   - "memory": the memory that is allocated to the launcher. Unit: MB. Default value: 2048.
   - "priority": the priority. Default value: 1.
   - "FLOW_SKIP_SQL_ANALYZE": specifies how SQL statements are executed. A value of false indicates that only one SQL statement is executed at a time. A value of true indicates that multiple SQL statements are executed at a time.
5. Configure scheduling properties for the EMR Spark Shell node.

   If you want the system to periodically run the EMR Spark Shell node, you can click the **Properties** tab in the right-side navigation pane to configure scheduling properties for the node based on your business requirements.
6. Commit and deploy the EMR Spark Shell node.
   i. Click the icon in the top toolbar to save the node.
   ii. Click the icon in the top toolbar to commit the node.
   iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
   iv. Click **OK**.
7. View the EMR Spark Shell node.
   i. On the configuration tab of the EMR Spark Shell node, click **Operation Center** in the upper-right corner to go to Operation Center.
   ii. View the scheduled EMR Spark Shell node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.8. Create an EMR Impala node

This topic describes how to create an EMR Impala node. EMR Impala nodes allow you to perform interactive analysis and queries by executing SQL statements on petabytes of data.

Prerequisites

- An EMR cluster is created. An inbound rule that contains the following content is added to the security group to which the EMR cluster belongs:
  - Action: Allow

- Protocol type: Custom TCP
- Port range: 8898/8898
- Authorization object: 100.104.0.0/16

- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only after you associate an EMR compute engine instance with the workspace on the Workspace Management page. For more information, see Associate an EMR cluster with a workspace.
- If you integrate Hive with Ranger in EMR, you must modify whitelist configurations and restart Hive before you develop EMR nodes in DataWorks. Otherwise, the error message **Cannot modify spark.yarn.queue at runtime** or **Cannot modify SKYNET_BIZDATE at runtime** is returned if you run EMR nodes.
  i. You can modify the whitelist configurations by using custom parameters in EMR. You can append key-value pairs to the value of a custom parameter. In this example, the custom parameter for Hive components is used. The following code provides an example:

```
hive.security.authorization.sqlstd.confwhitelist.append=tez.*|spark.*|mapred.*|mapreduce.*|ALISA.*|SKYNET.*
```

  > **Note** In the code, `ALISA.*` and `SKYNET.*` are configurations in DataWorks.

  ii. After the whitelist configurations are modified, restart the Hive service to make the configurations take effect.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, move the pointer over the icon and choose **EMR > EMR Impala**.

   You can also find the required workflow, right-click the workflow name, and then choose **Create > EMR > EMR Impala**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**. Then, the configuration tab of the **EMR Impala** node appears.
5. On the node configuration tab, enter the code for the node.

   Sample code:

```
-- SQL statement example
-- The size of SQL statements cannot exceed 130 KB.
show tables;
-- Scheduling parameters are supported.
CREATE TABLE IF NOT EXISTS userinfo (
ip STRING COMMENT'IP address',
uid STRING COMMENT'User ID'
)PARTITIONED BY(
dt STRING
);
ALTER TABLE userinfo ADD IF NOT EXISTS PARTITION(dt=${bizdate});
-- The system automatically adds limit 10000 to the SELECT statement.
select * from userinfo ;
```

   For more information about the scheduling parameters, see Scheduling parameters.

If you want to change the values that are assigned to the parameters in the code, click the Run with Parameters icon in the top toolbar.

> **Note** If multiple EMR compute engine instances are associated with the current workspace, you must select one EMR compute engine instance. If only one EMR compute engine instance is associated with the current workspace, you do not need to make a choice.

6. Click the **Advanced Settings** tab in the right-side navigation pane. In the Advanced Settings panel, change the values of the parameters.
   - "USE_GATEWAY":true: If you set this parameter to true, the EMR Impala node is automatically committed to the master node of an EMR gateway cluster.
   - "SPARK_CONF": "--conf spark.driver.memory=2g --conf xxx=xxx": the parameters that are required to run Spark jobs. You can configure multiple parameters in the --conf xxx=xxx format.
   - "queue": the scheduling queue to which jobs are committed. Default value: default.
   - "vcores": the number of CPU cores. Default value:1.
   - "memory": the memory that is allocated to the launcher. Unit: MB. Default value: 2048.
   - "priority": the priority. Default value: 1.
   - "FLOW_SKIP_SQL_ANALYZE": specifies how SQL statements are executed. A value of false indicates that only one SQL statement is executed at a time. A value of true indicates that multiple SQL statements are executed at a time.
7. Configure scheduling properties for the EMR Impala node.

   If you want the system to periodically run the EMR Impala node, you can click the **Properties** tab in the right-side navigation pane to configure scheduling properties for the node based on your business requirements.
8. Commit and deploy the EMR Impala node.
   i. Click the icon in the top toolbar to save the node.
   ii. Click the icon in the top toolbar to commit the node.
   iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
   iv. Click **OK**.
9. View the EMR Impala node.
   i. On the configuration tab of the EMR Impala node, click **Operation Center** in the upper-right corner to go to Operation Center.
   ii. View the scheduled EMR Impala node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.9. Create and use an EMR Presto node

This topic describes how to create an EMR Presto node in DataWorks. EMR Presto nodes allow you to perform interactive analysis and queries on large amounts of structured and unstructured data.

Prerequisites

- An EMR cluster is created. An inbound rule that contains the following content is added to the security group to which the EMR cluster belongs:
  - Action: Allow
  - Protocol type: Custom TCP
  - Port range: 8898/8898
  - Authorization object: 100.104.0.0/16
- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only

after you associate an EMR compute engine instance with the workspace on the Workspace Management page. For more information, see Associate an EMR cluster with a workspace.

- If you integrate Hive with Ranger in EMR, you must modify whitelist configurations and restart Hive before you develop EMR nodes in DataWorks. Otherwise, the error message **Cannot modify spark.yarn.queue at runtime** or **Cannot modify SKYNET_BIZDATE at runtime** is returned if you run EMR nodes.
  i. You can modify the whitelist configurations by using custom parameters in EMR. You can append key-value pairs to the value of a custom parameter. In this example, the custom parameter for Hive components is used. The following code provides an example:

  ```
  hive.security.authorization.sqlstd.confwhitelist.append=tez.*|spark.*|mapred.*|mapreduce.*|ALISA.*|SKYNET.*
  ```

  > **Note** In the code, `ALISA.*` and `SKYNET.*` are configurations in DataWorks.

  ii. After the whitelist configurations are modified, restart the Hive service to make the configurations take effect.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, move the pointer over the icon and choose **EMR > EMR Presto**.

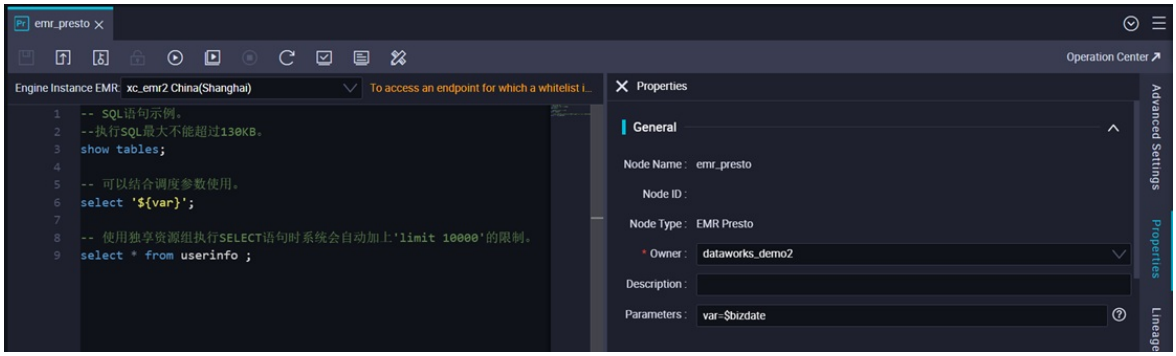
   You can also find the workflow in which you want to create the EMR Presto node, right-click the workflow name, and then choose **Create > EMR > EMR Presto**.
3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**. Then, the configuration tab of the **EMR Presto** node appears.
5. On the node configuration tab, write code for the node.

   ```
   -- SQL statement example
   -- The size of SQL statements cannot exceed 130 KB.
   show tables;
   -- Scheduling parameters are supported.
   select '${var}';
   -- The system automatically adds limit 10000 to the SELECT statement.
   select * from userinfo ;
   ```

   For more information about the scheduling parameters, see Scheduling parameters.

   If you want to change the values that are assigned to the parameters in the code, click the Run with Parameters icon in the top toolbar.



> **Note** If multiple EMR compute engine instances are associated with the current workspace, you must select one EMR compute engine instance. If only one EMR compute engine instance is associated with the current workspace, you do not need to make a choice.

6. Click the **Advanced Settings** tab in the right-side navigation pane. In the Advanced Settings panel, change the values of the parameters.
   - "USE_GATEWAY":true: If you set this parameter to true, the EMR Presto node is automatically committed to the master node of an EMR gateway cluster.
   - "SPARK_CONF": "--conf spark.driver.memory=2g --conf xxx=xxx": the parameters that are required to run Spark jobs. You can configure multiple parameters in the --conf xxx=xxx format.
   - "queue": the scheduling queue to which jobs are committed. Default value: default.
   - "vcores": the number of CPU cores. Default value:1.
   - "memory": the memory that is allocated to the launcher. Unit: MB. Default value: 2048.
   - "priority": the priority. Default value: 1.
   - "FLOW_SKIP_SQL_ANALYZE": specifies how SQL statements are executed. A value of false indicates that only one SQL statement is executed at a time. A value of true indicates that multiple SQL statements are executed at a time.
7. Configure scheduling properties for the EMR Presto node.

   If you want the system to periodically run the EMR Presto node, you can click the **Properties** tab in the right-side navigation pane to configure scheduling properties for the node based on your business requirements.
8. Commit and deploy the EMR Presto node.
   i. Click the icon in the top toolbar to save the node.
   ii. Click the icon in the top toolbar to commit the node.
   iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.
   iv. Click **OK**.
9. View the EMR Presto node.
   i. On the configuration tab of the EMR Spark Shell node, click **Operation Center** in the upper-right corner to go to Operation Center.
   ii. View the scheduled EMR Presto node. For more information, see Manage auto triggered nodes.

2.1.5.5.3.10. Create and use an EMR JAR resource

DataWorks allows you to create EMR JAR resources in the DataWorks console. You can upload a Java Archive (JAR) file that contains user-defined functions (UDFs) or open source MapReduce code as an EMR JAR resource. Then, you can reference the resource in compute nodes such as an EMR MR node. This topic describes how to create an EMR JAR resource by uploading a file, commit the resource, and reference the resource in compute nodes such as an EMR MR node.

Prerequisites

- An EMR cluster is created. An inbound rule that contains the following content is added to the security group to which the EMR cluster belongs:
  - Action: Allow
  - Protocol type: Custom TCP
  - Port range: 8898/8898
  - Authorization object: 100.104.0.0/16

- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only after you associate an EMR compute engine instance with the workspace on the Workspace Management page.
- If you integrate Hive with Ranger in EMR, you must modify whitelist configurations and restart Hive before you develop EMR nodes in DataWorks. Otherwise, the error message **Cannot modify spark.yarn.queue at runtime** or **Cannot modify SKYNET_BIZDATE at runtime** is returned if you run EMR nodes.
  i. You can modify the whitelist configurations by using custom parameters in EMR. You can append key-value pairs to the value of a custom parameter. In this example, the custom parameter for Hive components is used. The following code provides an example:

  ```
  hive.security.authorization.sqlstd.confwhitelist.append=tez.*|spark.*|mapred.*|mapreduce.*|ALISA.*|SKYNET.*
  ```

  > **Note** In the code, `ALISA.*` and `SKYNET.*` are configurations in DataWorks.

  ii. After the whitelist configurations are modified, restart the Hive service to make the configurations take effect.

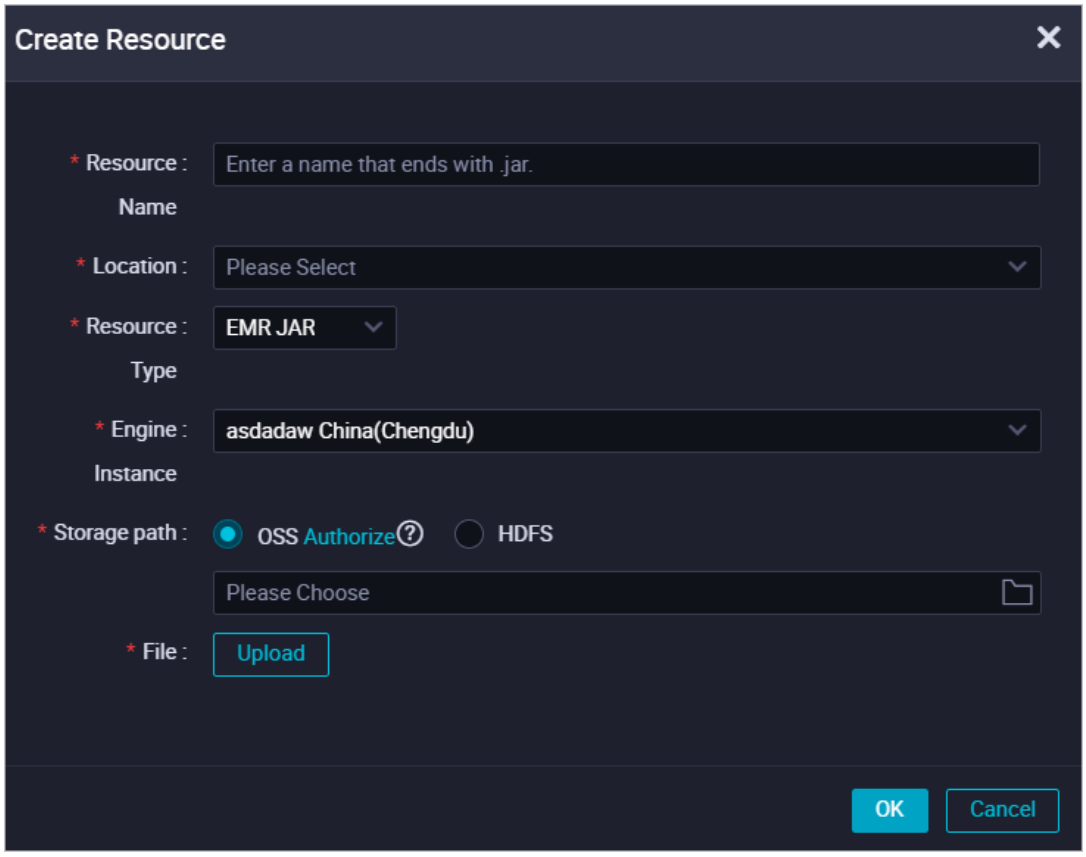
Limits

If Kerberos authentication is enabled for an EMR cluster., you cannot create tables, resources, and functions in a visualized manner for this cluster.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, move the pointer over the icon and choose **EMR > Resource > EMR JAR**.

   You can also find the required workflow, right-click the workflow name, and then choose **Create > EMR > Resource > EMR JAR**.
3. In the **Create Resource** dialog box, set the following parameters.

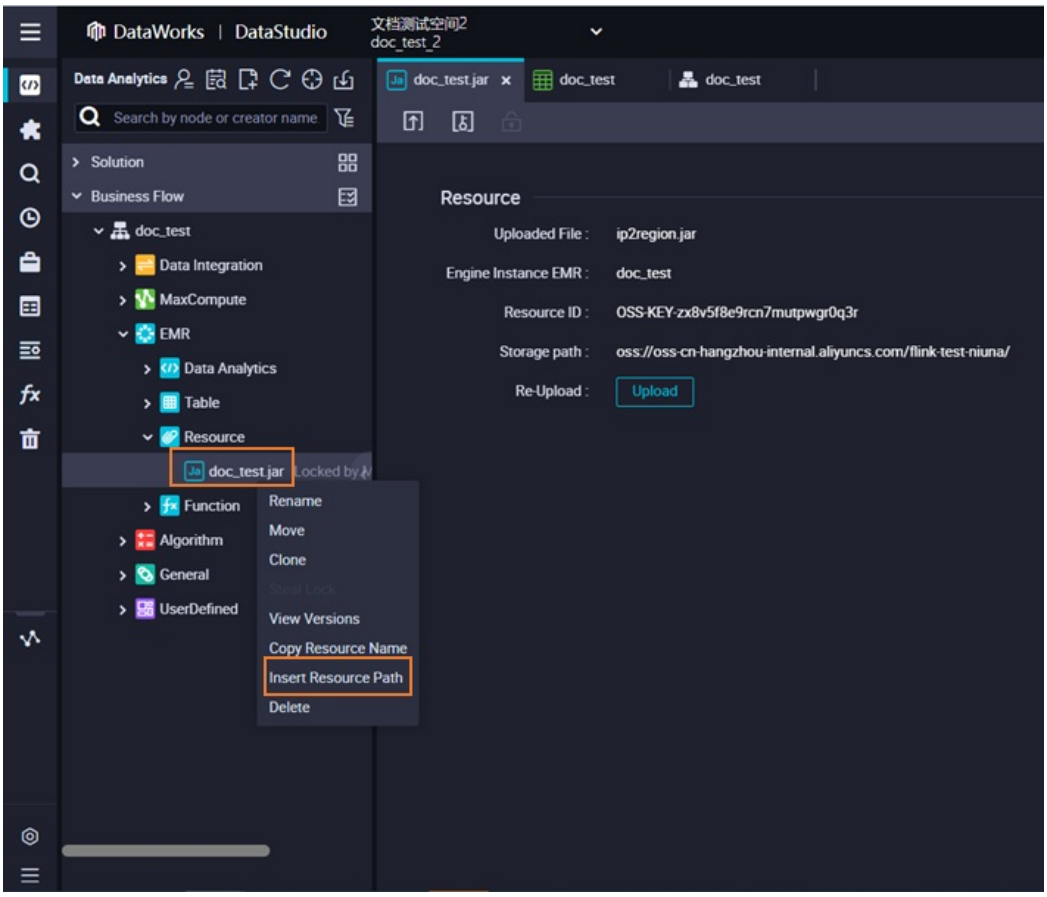


Parameter	Description
Resource Name	The name of the resource that you want to create. The resource name must have the suffix .jar.
Location	The folder for storing the resource. The default value is the path of the current folder. You can modify the path based on your business requirements.
File Type	The type of the resource. Set the parameter to EMR JAR.
Engine Instance	The EMR compute engine instance to which the resource belongs. Select an instance from the drop-down list.
Storage path	The storage path of the resource. Valid values: **OSS** and **HDFS**. ◦ If you select **OSS**, you must click Authorize next to OSS to authorize DataWorks and EMR to access Object Storage Service (OSS). Then, select a folder. ◦ If you select **HDFS**, enter a storage path.
File	The file that you want to upload. You can click **Upload**, select a file from your on-premises machine, and then click **Open**.

4. Click **Create**.
5. Click the and icons in the top toolbar to save and commit the resource to the development environment.

What's next

After you create an EMR JAR resource, you can reference the resource in the code of compute nodes such as an EMR MR node. The following figure shows how to reference the resource. For more information, see Create an EMR MR node.



2.1.5.5.3.11. Create an EMR table

This topic describes how to create an EMR table.

Prerequisites

- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only after you associate an EMR compute engine instance with the workspace on the Workspace Management page.
- The metadata of an EMR data source is collected in Data Map so that you can select an EMR database when you create a table.

Limits

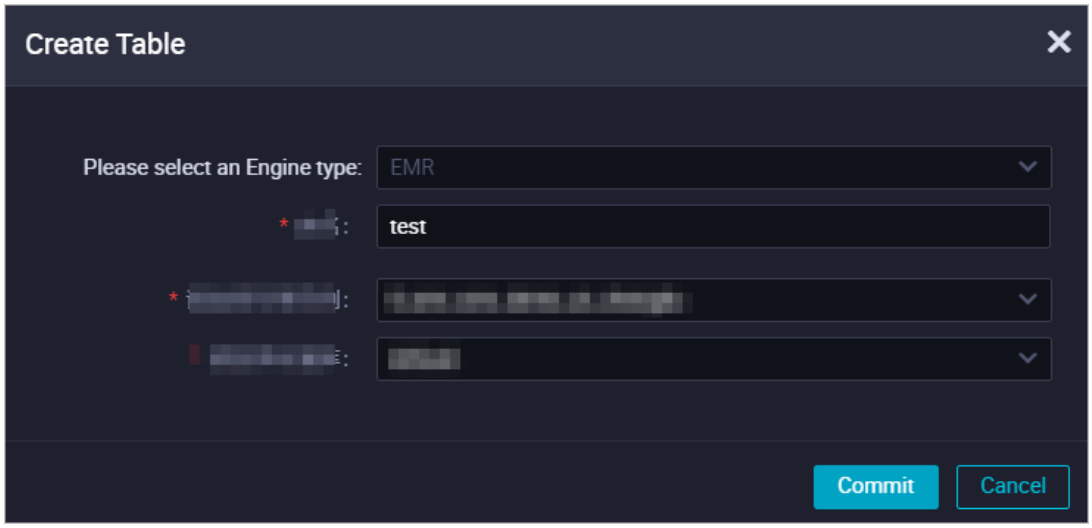
If Kerberos authentication is enabled for an EMR cluster., you cannot create tables, resources, and functions in a visualized manner for this cluster.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **EMR > table**.

   You can also find the workflow in which you want to create an EMR table, right-click **EMR**, and then choose **Create > Table**.

3. In the **Create Table** dialog box, set the parameters as required.

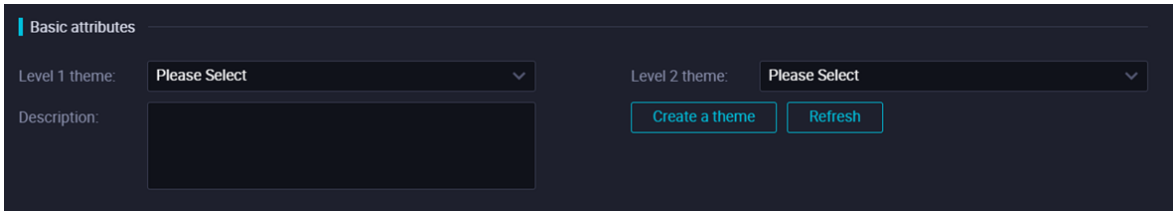


Parameter	Description
Engine type	The default value is EMR, which cannot be changed.
Table Name	The name of the EMR table.
Engine Instance	Select a required compute engine instance from the drop-down list.
Database	Select the database in which the compute engine instance resides from the drop-down list. **Note** You must collect metadata before you can select a database.

4. Click **Create**. The table configuration tab appears.

   The upper part of the tab shows the configurations that you specified in the **Create Table** dialog box. You can change the database where the EMR compute engine instance resides. To create a database, click **Create a database**. In the **Create a database** dialog box, set the parameters as required and click **OK**.

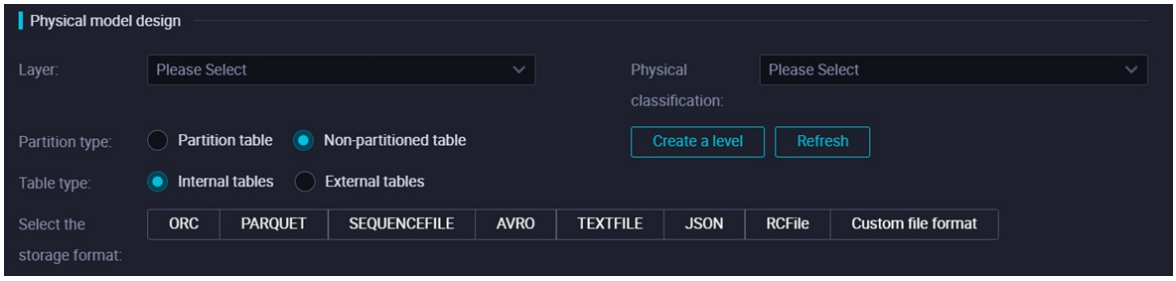
5. In the **Basic attributes** section, set the parameters as required.



Parameter	Description
Level 1 theme	The name of the level-1 folder where the table resides. **Note** The level-1 and level-2 folders show the table locations in DataWorks for you to manage tables with ease.

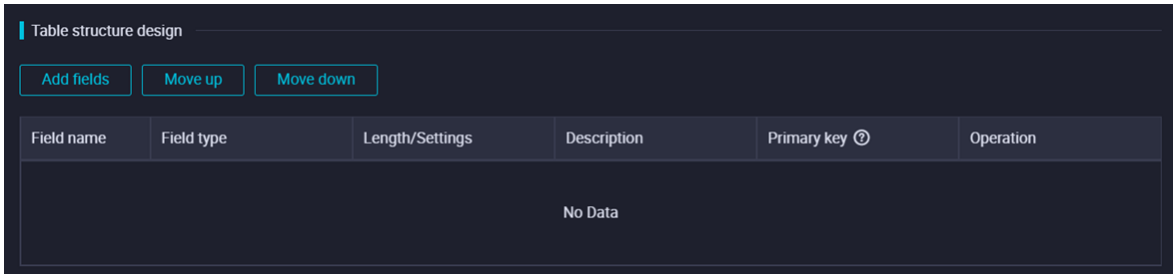
Parameter	Description
Level 2 theme	The name of the level-2 folder where the table resides.
Create a theme	Click **Create a theme** to go to the **Folder Management** tab. On this tab, you can create level-1 and level-2 folders.
Refresh	After you create a folder, click **Refresh**.
Description	The description of the table.

6. In the **Physical model design** section, set the parameters as required.



Parameter	Description
Layer	The levels and categories of the table. Select the appropriate level and category from the drop-down lists. To add levels and categories, click **Create a level** to go to the **Level Management** tab. After you create levels and categories, click **Refresh**.
Physical classification	
Partition type	Valid values: **Partition table** and **Non-partitioned table**.
Table type	Valid values: **Internal tables** and **External tables**.

7. In the **Table structure design** section, set the parameters as required.



Parameter	Description
Add fields	To add a field, click **Add fields**, configure the field information, and then click **Save** in the Operation column.
Move up	Adjusts the field sequence of a table that has not been created. If you want to adjust the sequence of fields in an existing table, you must delete the table and create another table with the same name. These operations are forbidden in the production environment.
Move down	
Field name	The name of the field, which can contain letters, digits, and underscores (_).

Parameter	Description
Data type	The EMR table supports the following data types: TINYINT, SMALLINT, INT, BIGINT, FLOAT, DOUBLE, DECIMAL, VARCHAR, CHAR, STRING, BINARY, DATETIME, DATE, TIMESTAMP, BOOLEAN, ARRAY, MAP, and STRUCT.
Length/Settings	You must set this parameter if the data type that you specify for the field has a length limit.
Description	The description of the field.
Primary key	Specifies whether the field serves as the primary key. The primary key ensures that each record is unique for your business. DataWorks does not impose a limit on the field that can be specified as the primary key.
Edit	After you save the field, you can click **Edit** to edit the field and then click **Save**.
Delete	Deletes a created field. **Note** If you want to delete a field from an existing table and then commit the table, you must delete the table and create another table with the same name. These operations are forbidden in the production environment.
Add partitions	If you set the **Partition type** parameter to **Partition table** in the **Physical model design** section, you must configure a partition for the table. You can add a partition to the current table. If you want to add a partition to an existing table and then commit the table, you must delete the table and create another table with the same name. These operations are forbidden in the production environment.

8. Click the icon in the top toolbar to commit the EMR table to the production environment.

   If you are using a workspace in standard mode, commit the table to the development environment and the production environment in sequence.

   Notice You cannot create an EMR table in DDL mode.

2.1.5.5.3.12. Create an EMR function

This topic describes how to create an EMR function.

Prerequisites

- An EMR cluster is created. An inbound rule that contains the following content is added to the security group to which the EMR cluster belongs:
  - Action: Allow
  - Protocol type: Custom TCP
  - Port range: 8898/8898
  - Authorization object: 100.104.0.0/16
- An EMR compute engine instance is associated with the current workspace. The EMR folder is displayed only after you associate an EMR compute engine instance with the workspace on the Workspace Management page.

- The required resources are uploaded.

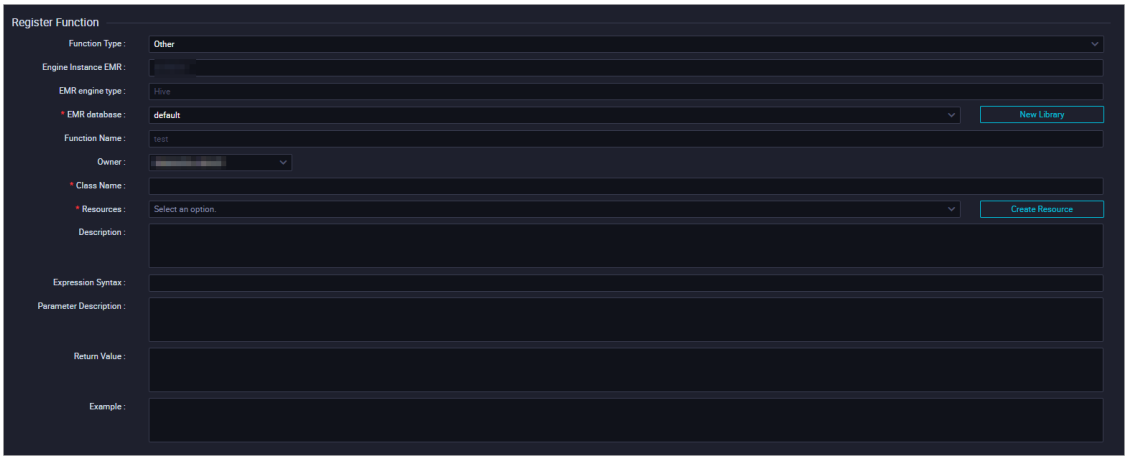
Limits

If Kerberos authentication is enabled for an EMR cluster., you cannot create tables, resources, and functions in a visualized manner for this cluster.

Procedure

1. Log on to the DataWorks console.
2. Create a workflow. For more information, see Overview.
3. Write code in a local Java environment and compress the code to a JAR package. Then, create a JAR resource and commit the resource. For more information, see Create and use an EMR JAR resource.
4. Create a function.
   i. Click the workflow in the Scheduled Workflow pane, right-click **EMR**, and then choose **Create > Function**.
   ii. In the **Create Function** dialog box, set the **Function Name**, **Engine Instance**, and **Location** parameters.
   iii. Click **Create**.

iv. In the **Function information** section of the configuration tab that appears, set the parameters.



Parameter	Description
Function Type	The type of the function. Valid values: **Mathematical Operation Functions**, **Aggregate Functions**, **String Processing Functions**, **Date Functions**, **Window Functions**, and **Other Functions**.
Engine Instance	The EMR compute engine instance. By default, the system automatically selects the EMR compute engine instance. You cannot change the value.
Engine Type	The type of the compute engine instance. By default, the system automatically selects EMR. You cannot change the value.
EMR database	The database where the EMR cluster resides. Select a database from the drop-down list. To create a database, click **New Library**. In the **New Library** dialog box, set the parameters and click **OK**.
Function Name	The name of the function. You can use this name to reference the function in SQL statements. The function name must be globally unique and cannot be changed after the function is created.
Owner	The value of this parameter is automatically displayed.
Class Name	Required. The name of the class that implements the function.
Resource	Required. The resource to be used in the function. Select a resource from the ones that are created in the current workspace from the drop-down list. To create a resource, click **Create Resource**. In the **Create Resource** dialog box, set the parameters and click **Create**.
Description	The description of the function.
Expression Syntax	The syntax of the function. Example: `test`.
Parameter Description	The description of the input and output parameters that are supported.
Return Value	Optional. The return value. Example: 1.
Example	Optional. The example of the function.

5. Click the icon in the top toolbar.
6. Commit the function.

i. Click the icon in the top toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

iii. Click **OK**.

2.1.5.5.4. Hologres

2.1.5.5.4.1. Create a Hologres SQL node

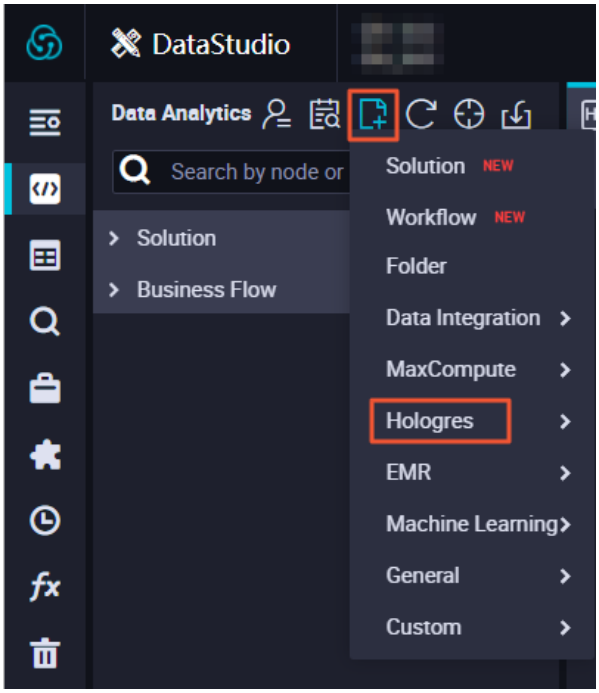
This topic describes how to create a Hologres SQL node. Hologres seamlessly integrates with MaxCompute at the underlying layer. This integration allows you to use standard PostgreSQL statements to query and analyze large volumes of data stored in MaxCompute. In this case, you do not need to transfer data. This allows you to quickly obtain query results.

Prerequisites

A **Hologres** compute engine instance is added on the **Project Management** page. This ensures that the **Hologres** folder is displayed on the page on which you want to create a Hologres SQL node.

Procedure

1. Log on to the DataWorks console.
2. Move the pointer over the icon and choose **Hologres > Hologres SQL**.



3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

> **Note** The name of the node must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the tab that appears, edit and run the code in the code editor.

   After the Hologres SQL node is created, edit the code in compliance with the required SQL syntax.
6. On the configuration tab of the node, click the **Properties** tab in the right-side navigation pane. On the

Properties tab, configure properties for the node. For more information, see Basic properties.

7. Save and commit the node.

   > **Notice** You must set the **Rerun** and **Parent Nodes** parameters before you commit the node.

   i. Click the icon in the top toolbar to save the node.

   ii. Click the icon in the top toolbar.

   iii. (Optional)In the **Commit Node** dialog box, enter your comments in the **Change description** field.

   iv. Click **OK**.

   If the workspace that you use is in standard mode, you must click **Deploy** in the top navigation bar after you commit the node. For more information, see Deploy nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.5. AnalyticDB for PostgreSQL

2.1.5.5.5.1. Create an AnalyticDB for PostgreSQL node

You can create AnalyticDB for PostgreSQL nodes in the DataWorks console to build an online extract, transform, load (ETL) process.

Prerequisites

The AnalyticDB for PostgreSQL compute engine is associated with the workspace in which you want to create an AnalyticDB for PostgreSQL node. The AnalyticDB for PostgreSQL folder is displayed in a workspace only after you associate an AnalyticDB for PostgreSQL compute engine instance with the workspace on the **Workspace Management** page. For more information, see Create an AnalyticDB for PostgreSQL node.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, move the pointer over the icon and choose **AnalyticDB > ADB for PostgreSQL**.

   Alternatively, you can find the required workflow, right-click the workflow name, and then choose **Create > AnalyticDB for PostgreSQL > ADB for PostgreSQL**.

3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The name of the node must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Configure the AnalyticDB for PostgreSQL node.

   i. Select a data source from the **Select a connection** drop-down list.

   > **Notice**
   > - When you associate the AnalyticDB for PostgreSQL compute engine with the workspace, DataWorks automatically creates an AnalyticDB for PostgreSQL data source.
   > - You can select a data source that is added only by using the connection string mode.

ii. Compile SQL statements.

After you select a data source, compile SQL statements based on the syntax that is supported by AnalyticDB for PostgreSQL.

iii. Click the icon in the top toolbar to save the SQL statements.

iv. Click the icon in the top toolbar to execute the SQL statements.

6. Click **Properties** in the right-side navigation pane. In the Properties panel, configure scheduling properties for the node. For more information, see Basic properties.
7. Save and commit the node.

> **Notice** You must specify the **Rerun** and **Parent Nodes** parameters in the Properties panel before you commit the node.

i. Click in the top toolbar to save the node.

ii. Click the icon in the top toolbar.

iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

iv. Click **OK**.

If the workspace that you use is in standard mode, you must click **Deploy** in the upper-right corner after you commit the AnalyticDB for PostgreSQL node. For more information, see Deploy nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.5.2. Create an AnalyticDB for PostgreSQL table

This topic describes how to create an AnalyticDB for PostgreSQL table.

Prerequisites

- An AnalyticDB for PostgreSQL instance is associated with the workspace in which you want to create an AnalyticDB for PostgreSQL table. The AnalyticDB for PostgreSQL folder is displayed on the DataStudio page of a workspace only after you associate an AnalyticDB for PostgreSQL instance with the workspace on the **Project Management** page. For more information, see Create an AnalyticDB for PostgreSQL table.
- The metadata of the associated AnalyticDB for PostgreSQL instance is collected on the **Data Map** page. For more information, see Collect metadata from an AnalyticDB for PostgreSQL data source.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, move the pointer over the icon and choose **AnalyticDB > table**.

   Alternatively, you can find your workflow in the Business Flow section, right-click **AnalyticDB for PostgreSQL**, and then choose **Create > ADB visual table creation**.
3. In the **Create Table** dialog box, set **Table Name**.

> **Notice**
>
> - The table name must be in the format of schema_name.table_name.
> - The values of schema_name and table_name must be 1 to 63 characters in length and can contain letters, digits, and underscores (_). The values must start with a letter or underscore (_).
> - If you associate multiple AnalyticDB for PostgreSQL instances with the current workspace, you must select one based on your business requirements.

4. Click **Commit**. The table configuration tab appears.

   The upper part of the table configuration tab displays the table name and AnalyticDB for PostgreSQL instance name.

5. In the **General** section, set the parameters.

Parameter	Description
Level 1 theme	The name of the level-1 folder where the table resides. **Note** Level-1 and level-2 folders show the table locations in DataWorks for you to manage tables more conveniently.
Level 2 theme	The name of the level-2 folder where the table resides.
Create a theme	Click **Create a theme** to go to the **Folder Management** tab. On this tab, you can create level-1 and level-2 folders for tables. After you create a folder, click the icon next to Create Folder to synchronize the folder.
Description	The description of the table.

6. In the **Physical model design** section, set the parameters.

Parameter	Description
Level selection	The layer where the table data is stored or processed. A data warehouse consists of the operational data store (ODS), common data model (CDM), and application data store (ADS) layers. You can customize a name for each layer.
Physical classification	The category of the table. Tables are categorized into basic services, advanced services, and other services. You can customize a name for each category. **Note** Categories are designed only for your management convenience and do not involve underlying implementation.
New Level	The levels and categories that you want to create. To add levels and categories, click **New Level** to go to the **Hierarchical management** tab. After levels and categories are created, click the icon.

7. In the **AnalyticDB for PostgreSQL table design** section, set the parameters.

   You can configure the schema of an AnalyticDB for PostgreSQL table on the following tabs: **Column information settings**, **Index settings**, **Sub-table design**, and **Partition settings (optional)**.

Tab	Parameter	Description
Column information settings	**New columns**	Allows you to click the button and set the relevant parameters to create a field.
	Name	The name of the field.
	Field type	The data type of the field.
	Field length	The length of the field. You can specify the length for fields only of some specific data types.
	Default value	The default value of the field.
	Allow to be empty	Specifies whether the field can be empty.
	Is it the primary key?	Specifies whether the field serves as the primary key.
	Foreign key	Specifies whether the field serves as a foreign key.
	Operation	◦ You can perform the following operations on a new field: save, cancel, delete, move up, and move down. ◦ You can perform the following operations on an existing field: modify, delete, move up, and move down.
Index settings	**New columns**	Allows you to click the button and set the relevant parameters to create an index.
	Index name	The name of the index. Make sure that you specify a unique name.
	Include columns	The field on which the index will be created. To select a field, click **Edit**. In the **Select at least one index** dialog box, click the **+** icon. All the created fields appear in the Column information drop-down list. Select the field from the **Column information** drop-down list and click **Save**.
	Index type	The type of the index. Valid values: **Normal**, **Primary Key**, and **Unique**.
	Index mode	The mode for indexing data in the fields. Valid values: **B-tree**, **Bitmap**, and **GiST**.
	Operation	◦ You can perform the following operations on a new index: save, cancel, delete, move up, and move down. ◦ You can perform the following operations on an existing index: modify, delete, move up, and move down.
Sub-table design	**Hash (Recommended)**, **Copy Schema**, and **Random (Not Recommended)**	The way in which the partition key is generated. Take **Hash (Recommended)** as an example. Click **New columns** and select the target field from the **Name** drop-down list. The information about the selected field appears. Click **Save**. For more information, see the **Column information settings** section of this table.

Tab	Parameter	Description
Partition settings (optional)	**Partition settings (optional)**	The partitions of the table. You can configure the partitions based on your business requirements.

8. Click **Submit to development environment** and **Submit to production environment** in sequence.

   If you are using a workspace in basic mode, you need only to click **Submit to production environment**.

9. In the **Submit changes** dialog box, confirm that the table creation statements are correct, select a resource group from the **Select a resource group** drop-down list, and then click **Confirm execution**.

What's next

After the AnalyticDB for PostgreSQL table is created, you can query the table data, modify the table, or delete the table. For more information, see Manage tables.

2.1.5.5.6. AnalyticDB for MySQL

2.1.5.5.6.1. Create and use an AnalyticDB for MySQL node

You can create an AnalyticDB for MySQL node and use SQL statements to develop data for an AnalyticDB for MySQL data source. This topic describes how to create and use an AnalyticDB for MySQL node.

Prerequisites

- An AnalyticDB for MySQL instance is purchased and associated with the current DataWorks workspace in the **Workspace Management** page of DataWorks. For more information, see Associate an AnalyticDB for MySQL instance with a workspace.
- A workflow is created. For more information, see Create a workflow.

Create an AnalyticDB for MySQL node and use the node to develop data

1. Log on to the DataWorks console.
2. On the **DataStudio** page, move the pointer over the icon and choose **AnalyticDB for MySQL > ADB for MySQL**.

   You can also find the required workflow, right-click the workflow name, and then choose **Create > AnalyticDB for MySQL > ADB for MySQL**.

3. In the **Create Node** dialog box, set the **Node Name** and **Location** parameters.

   > **Note** The name of the node must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Configure the AnalyticDB for MySQL node.
   i. Select a data source from the **Select Data Source** drop-down list.

   > **Notice**
   > - When you associate the AnalyticDB for MySQL compute engine instance with the workspace, DataWorks automatically adds an AnalyticDB for MySQL data source.
   > - You can select a data source that is added only by using the connection string mode.

ii. Write the SQL statements of the node.

After you select a data source, write the SQL statements of the node based on your business requirements.

iii. Click the icon in the top toolbar to save the SQL statements.

iv. Click the icon in the top toolbar to execute the SQL statements.

5. Click the **Properties** tab in the right-side navigation pane. In the Properties panel, configure scheduling properties for the node. For more information, see Basic properties.
6. Save and commit the node.

> **Notice** You must set the **Rerun** and **Parent Nodes** parameters in the Properties panel before you commit the node.

i. Click the icon in the top toolbar to save the node.

ii. Click the icon in the top toolbar.

iii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

iv. Click **OK**.

If the workspace that you use is in standard mode, you must click **Deploy** in the upper-right corner after you commit the AnalyticDB for MySQL node. For more information, see Deploy nodes.

7. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.7. Algorithm

2.1.5.5.7.1. Create a PAI node

PAI nodes are used to call tasks that are created on PAI and schedule production activities based on the node configuration.

Prerequisites

To create a PAI node in DataWorks, you must first create a PAI experiment in PAI.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **Machine Learning > PAI Experiment**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **Algorithm**, and then choose **Create > PAI Experiment**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

> **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Select the PAI experiment that you have created from the **Experiment** drop-down list and load it.

   If you want to modify the PAI experiment, click **Edit in PAI Console**.
6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information,

see Basic properties.

7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.8. General

2.1.5.5.8.1. Create a for-each node

This topic describes how to use a for-each node to repeat a loop twice and display the loop count.

Prerequisites

The MaxCompute module is available on the DataStudio page only after you bind a MaxCompute compute engine to the current workspace on the **Project Management** page.

Context

You can use a for-each node to repeat a loop for a maximum of 128 times. If the loop count exceeds this limit, an error occurs.

If the for-each node needs to perform logic judgment and result traversal, you can use the branch node. However, the branch node must be used with the merge node for result traversal.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > for-each**.

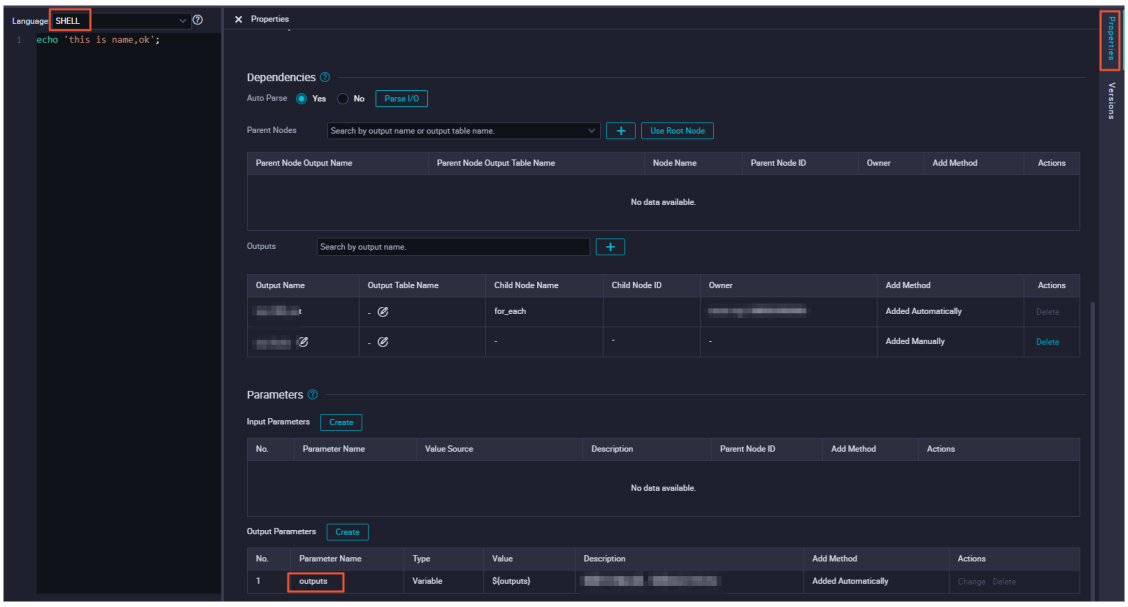
   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > for-each**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.
5. Create a workflow with an assignment node as the parent node and a for-each node as the child node. For more information, see Create a workflow.

i. Double-click the created assignment node. Set the language of the assignment node to SHELL, and enter the following code:

```
echo 'this is name,ok';
```

On the node configuration tab, click the **Properties** tab in the right-side navigation pane. By default, the **outputs** parameter appears in the **Output Parameters** section.



ii. Double-click the created for-each node. Enter the following code for the for-each node:

```
echo ${dag.loopTimes} ----Display the loop count.
```

> **Note**
>
> - The start and end nodes of the for-each node have fixed logic and cannot be edited.
> - After you modify the code of the Shell node, save the modification. No message will appear to remind you to save the modification when you commit the node. If you do not save the modification, the code cannot be updated to the latest version in time.

A for-each node supports the following environment variables:

- ${dag.foreach.current}: the current data row.
- ${dag.loopDataArray}: the input dataset.
- ${dag.offset}: the offset of the loop count to 1.
- ${dag.loopTimes}: the loop count, whose value equals to the value of ${dag.offset} plus 1.

```
// Compare the code of the Shell node with that of a common for loop.
data=[]  // It is equivalent to ${dag.loopDataArray}.
// i is equivalent to ${dag.offset}.
for(int i=0;i<data.length;i++) {
  print(data[i]);  // data[i] is equivalent to ${dag.foreach.current}.
}
```

The ${dag.loopDataArray} parameter is the default input parameter of the for-each node. Set this parameter to the value of the outputs parameter of the parent node. If you do not set this parameter, an error occurs when you commit the node.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side

navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.

7. Commit the node.

   > **Notice** You can commit the node only after you specify the **Rerun** and **Parent Nodes** parameters.

   i. Click the icon in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Change description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you must click **Publish** in the upper-right corner after you commit the node. For more information, see Publish nodes.

8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.5.8.2. Create a do-while node

You can define mutually dependent nodes, including a loop decision node named end, in a do-while node. DataWorks repeatedly runs the nodes and exits the loop only when the end node returns False.

Context

> **Note** A loop can be repeated for a maximum of 128 times. If the loop count exceeds this limit, an error occurs.

The do-while node supports the MaxCompute SQL, SHELL, and Python languages. If you use MaxCompute SQL, you can use a `CASE WHEN` statement to evaluate whether the specified condition for exiting the loop is met.

Simple example

This section describes how to use a do-while node to repeat a loop five times and display the loop count each time the loop runs.

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > do-while**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > do-while**.

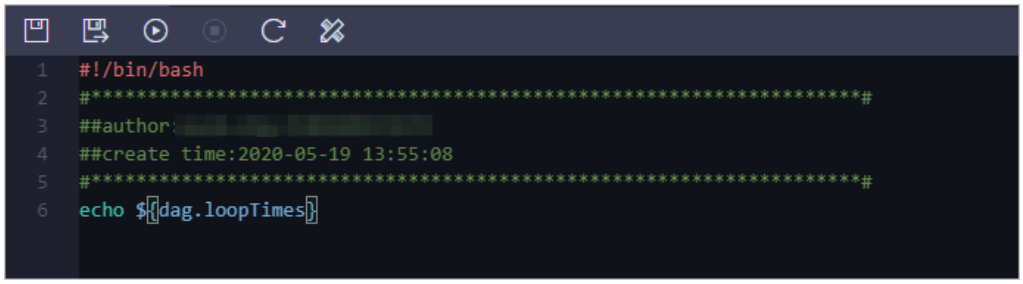
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. Define the loop body.

   By default, the do-while node consists of the start, SQL, and end nodes.

   - The start node marks the startup of a loop and does not have any business effect.
   - DataWorks provides the SQL node as a sample business processing node. You must replace the SQL node with your own business processing node, for example, a Shell node named Display loop count.



- The end node marks the end of a loop and determines whether to start the loop again. In this example, it defines the condition for exiting the loop for the do-while node.

  The end node is an assignment node. It generates only True or False, indicating whether to start the loop again or exit the loop.

  The ${dag.loopTimes} variable is used in both the Display loop count node and the end node. It is a reserved variable of DataWorks. This variable indicates the loop count and the value increments from 1. All internal nodes of the do-while node can reference this variable.

  In the code shown in the preceding figure, the value of the `dag.loopTimes` variable is compared with 5 to limit the loop count. The value of the dag.loopTimes variable is 1 when the loop runs for the first time and is incremented by 1 each time, for example, 2 for the second time. In the fifth loop, the value is 5. In this case, the result of ${dag.loopTimes}<5 is False, and the do-while node exits the loop.

6. Run the do-while node.

   You can configure the scheduling properties for the do-while node as needed and commit it to **Operation Center** for running.

   - do-while node: The do-while node appears as a whole node in Operation Center. To view the loop details about the do-while node, right-click the node in the DAG and select **View Internal Nodes**.
   - Internal loop body: This view is divided into three parts.
     - The left pane of the view lists the rerun history of the do-while node. A record is generated each time a do-while node instance is run.
     - The middle pane of the view shows a loop record list. A record is generated each time the loop of the do-while node is run. The running status of each loop also appears.
     - The right pane of the view shows the details about the do-while node each time the loop is run. You can click a record in the loop record list to view the running details.

7. View the running result.

   View the internal loop body. In the loop record list, click the record corresponding to the third loop. The loop count is 3 in the runtime logs.

   You can also view the runtime logs of the end node that are generated when the loop runs for the third time and for the fifth time, respectively.

   Based on the preceding simple example, the do-while node works in the following way:

   i. Run from the start node.
   ii. Run nodes in sequence based on the defined node dependencies.
   iii. Define the condition for exiting the loop in the end node.
   iv. Run the conditional statement of the end node after the loop ends for the first time.
   v. Record the loop count as 1 and start the loop again if the conditional statement returns True in the runtime logs of the end node.
   vi. Exit the loop if the conditional statement returns False in the runtime logs of the end node.

Complex example

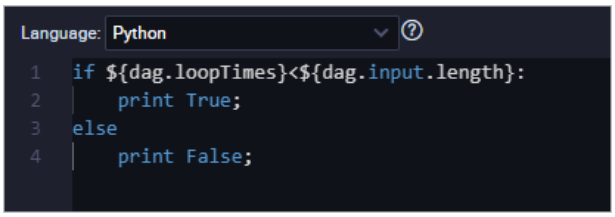
In addition to simple scenarios, do-while nodes can also be used in complex scenarios where each row of data is processed in sequence by using a loop. Before you process data in such scenarios, make sure that:

- You have deployed a parent node that can export queried data to the do-while node. You can use an assignment node to meet this condition.
- The do-while node can obtain the output of the parent node. You can configure the node context and dependencies to meet this condition.
- The internal nodes of the do-while node can reference each row of data. In this example, the existing node context is enhanced and the system variable ${dag.offset} is used to reference the context of the do-while node.

This section describes how to use the do-while node to display the data entries in a table in sequence until all data entries in the table are displayed. Each time the loop runs, a data entry is displayed.

1. On the **Data Analytics** tab, double-click the created do-while node.
2. Define the loop body.
   i. Create an assignment node named Initialize dataset and add it as the parent node of the do-while node. The parent node generates a test dataset.
   ii. On the Properties tab of the do-while node, define an input parameter in the **Parameters** section. Set Parameter Name to input and Value Source to the output of the parent node.
   iii. Write code for the business processing node named Print each data row.
      - `${dag.offset}`: a reserved variable of DataWorks. This variable indicates the offset of the loop count to 1. For example, the offset is 0 when the loop runs for the first time and 1 for the second time. The offset equals to the loop count minus 1.
      - `${dag.input}`: the context that you configure for the do-while node. In the preceding steps, the input parameter is defined for the do-while node and the value of the input parameter is the output of the parent node named Initialize dataset.

        The internal nodes of the do-while node can directly use ${dag.${ctxKey}} to reference the context. In this example, ${ctxKey} is set to input. Therefore, you can use ${dag.input} to reference the context.
      - `${dag.input[${dag.offset}]}`: the data obtained from the table generated by the Initialize dataset node. DataWorks can obtain a row of data from the table based on the specified offset. The value of the ${dag.offset} variable increments from 0. Therefore, the data entries such as ${dag.input[0]} and ${dag.input[1]} are returned until all data entries in the dataset are returned.
   iv. Define the condition for exiting the loop for the end node. The values of the ${dag.loopTimes} and ${dag.input.length} variables are compared, as shown in the following figure. If the value of the former is less than that of the latter, the end node returns True and the do-while node continues the loop. Otherwise, the end node returns False and the do-while node exits the loop.



> **Note** The system automatically sets the ${dag.input.length} variable to the number of rows in the array specified by the input parameter based on the context configured for the do-while node.

3. Run the do-while node and view the running result.

Summary

- Compared with the while, foreach, and do...while statements, a do-while node has the following characteristics:

- A do-while node contains a loop body that runs a loop before evaluating the conditional statement. This node functions the same as the do...while statement. A do-while node can also use the system variable ${dag.offset} and the node context to implement the feature of the foreach statement.
- A do-while node cannot achieve the feature of the while statement because a do-while node runs a loop before evaluating the conditional statement.

- A do-while node works in the following way:
  i. Run nodes in the loop body starting from the start node based on node dependencies.
  ii. Run the code defined for the end node.
    - Run the loop again if the end node returns True.
    - Exit the loop if the end node returns False.
- How to use the node context: The internal nodes of a do-while node can use ${dag.${ctxKey}} to reference the context defined for the do-while node.
- System parameters: DataWorks provides the following system variables for the internal nodes of the do-while node:
  - ${dag.loopTimes}: the loop count, starting from 1.
  - ${dag.offset}: the offset of the loop count to 1, starting from 0.

2.1.5.5.8.3. Create a merge node

This topic describes the definition of merge nodes and how to create a merge node and define the merging logic. It also provides an example to show the scheduling configuration and running details of a merge node.

A merge node is a logical control node in DataStudio. It can merge the running results of its parent nodes, regardless of their running statuses. It aims at facilitating the running of nodes that depend on the output of the child nodes of a branch node.

You cannot change the running status of a merge node. A merge node merges the running results of multiple child nodes of a branch node and sets the running status to Successful. To guarantee the proper running of a node that depends on the output of the child nodes of a branch node, you can configure the node to directly depend on the merge node.

For example, Branch node C has two logically exclusive branches C1 and C2. These two branches use different logic to write data to the same MaxCompute table. Assume that Node B depends on the output of this MaxCompute table. To make sure that Node B can run properly, you must use Merge node J to merge the running results of branches C1 and C2, and then configure Merge node J as the parent node of Node B. If Node B directly depends on branches C1 and C2, one of the branches will fail to run because only one branch meets the branch condition each time Branch node C runs. In this case, Node B cannot be triggered as scheduled.

Create a merge node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > MERGE Nodes**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > MERGE Nodes**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.

Define the merging logic

After the merge node is created, the node configuration tab appears. Specify the branches to be merged for the node. Enter the output name or output table name of the parent node, and click the **Add** icon. You can view the running status in the Result section. The available running statuses are **Successful** and **Branch Not Running**.

Click the **Properties** tab in the right-side navigation pane and configure the scheduling properties of the merge node.

Run the merge node

If a branch meets the specified condition, the branch is run. You can select the branch and view the running details on the **Runtime Logs** tab.

If a branch does not meet the specified condition, the branch is skipped. You can select the branch and view related information on the **Runtime Logs** tab.

2.1.5.5.8.4. Create a branch node

A branch node is a logical control node in DataStudio. It can define the branch logic and the direction of branches under different logical conditions.

Prerequisites

Generally, branch nodes need to be used with assignment nodes.

Create a branch node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Branch Node**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Branch Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. Define the branch logic
   i. In the **Definition** section, click **Add Branch**.

ii. In the **Branch Definition** dialog box, set the parameters.

Parameter	Description
Condition	The condition of the branch. ■ You can only use Python comparison operators to define logical conditions for the branch node. ■ If the result of the expression is *true* when the node is running, the corresponding branch condition is met. ■ If the expression fails to be parsed when the node is running, the whole branch node fails. ■ To define branch conditions, you can use global variables and parameters defined in the node context. For example, the ${input} variable can be used as an input parameter of the branch node.
Associated Node Output	The associated node output of the branch. ■ The node output is used to configure dependencies for the child nodes of the branch node. ■ If the branch condition is met, the child node corresponding to the node output is run. If the child node also depends on the output of other nodes, the status of these nodes is considered. ■ If the branch condition is not met, the child node corresponding to the node output is not run. The child node is set to the `Not Running` state.
Description	The description of the branch. For example, the branches ${input}==1 and ${input}>2 are defined.

iii. Click **OK**.

After you add a branch, you can click **Change** or **Delete** in the Actions column of the branch to modify or delete it.

- Click **Change** to modify the branch and related dependencies.
- Click **Delete** to delete the branch and related dependencies.

6. On the configuration tab of the branch node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section.

After the branch conditions are defined, the output names are automatically added to the **Outputs** section on the **Properties** tab. Then, you can associate child nodes with the branch node based on the output names.

> **Note**
> - Child nodes inherit dry-run properties of the parent node. Therefore, we recommend that you do not create a node depending on its last-cycle instance as the branch.
> - The dependencies established by drawing lines between nodes on the dashboard of a workflow are not recorded on the Properties tab. You must manually enter these dependencies.

7. Commit the node.

> **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

i. Click  in the toolbar.

ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

iii. Click **OK**.

In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.

8. Test the node.

Supported Python comparison operators

In the following table, assume that the value of the a variable is 10 and that of the b variable is 20.

Comparison operator	Description	Example
==	Equal: checks whether two objects are equal.	(a==b) returns false.
! =	Not equal: checks whether two objects are not equal.	(a! =b) returns true.
<>	Not equal: checks whether two objects are not equal.	(a<>b) returns true. This operator is similar to ! =.
>	Greater than: checks whether the variable on the left side of the operator is greater than that on the right side.	(a>b) returns false.
<	Less than: checks whether the variable on the left side of the operator is less than that on the right side. If the return result is 0 or 1, 0 indicates false and 1 indicates true. These two results are equivalent to the special variables true and false, respectively.	(a<b) returns true.
>=	Greater than or equal to: checks whether the variable on the left side of the operator is greater than or equal to that on the right side.	(a>=b) returns false.
<=	Less than or equal to: checks whether the variable on the left side of the operator is less than or equal to that on the right side.	(a<=b) returns true.

2.1.5.5.8.5. Create an assignment node

An assignment node uses one of the three value assignment languages MaxCompute SQL, SHELL, and Python to assign values by using the outputs parameter. This node is used to transmit data between a parent node and a child node based on context-based parameters.

Context

The outputs parameter has the following limits:

- The value of the outputs parameter is taken only from the output of the last line of the code.
  - If you use MaxCompute SQL, the output of the SELECT statement in the last line is used.
  - If you use SHELL, the output of the ECHO statement in the last line is used.
  - If you use Python, the output of the PRINT statement in the last line is used.
- The passed value of the outputs parameter is limited to 2 MB in size. If the output of the assignment statement exceeds this limit, the assignment node fails to run.

> **Note** If you use Python or SHELL, the value of the outputs parameter is a one-dimensional array where elements are separated with commas (,). If you use MaxCompute SQL, the value of the outputs parameter is passed to child nodes as a two-dimensional array.

Create an assignment node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Assignment Node**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Assignment Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Notice** A node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

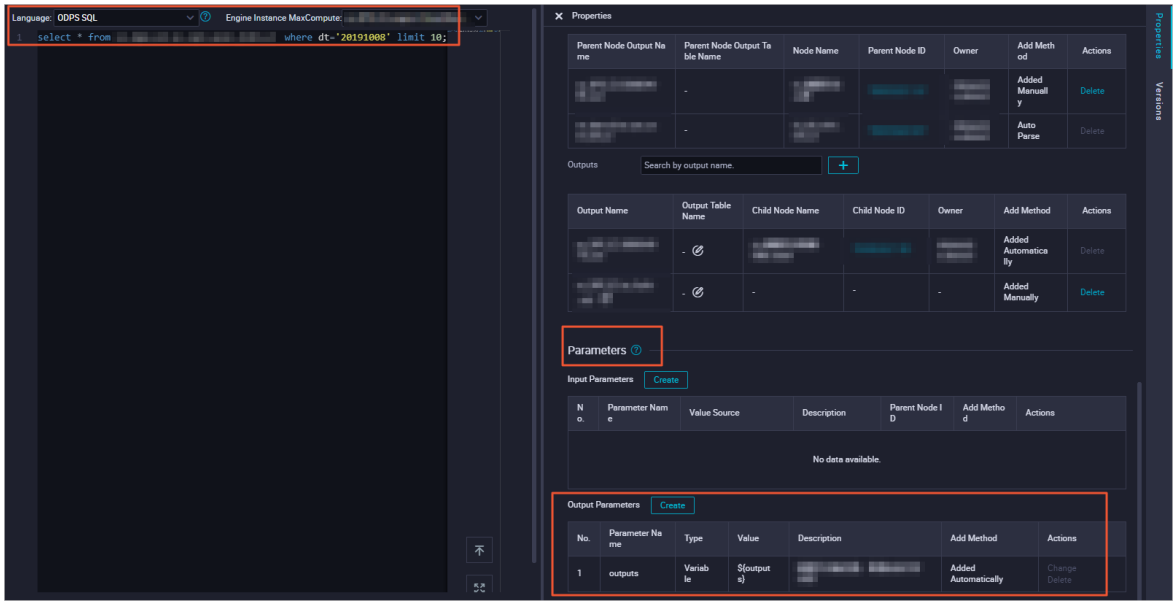
   This following sections describe how to use assignment nodes that use the Python, MaxCompute SQL, and SHELL languages respectively to pass data between a parent node and a child node named Assignment node value comparison_shell by using context-based parameters.

   After the assignment nodes that use the Python, MaxCompute SQL, and SHELL languages are created, you must set the dependencies so that the child node can reference the parameter values passed by these nodes.
4. Click **Commit**.

Configure the child node to reference the output values of the assignment node that uses MaxCompute SQL

1. Find the target workflow and double-click the assignment node fuzhi_sql that uses MaxCompute SQL.
2. On the configuration tab of the fuzhi_sql node that appears, click **Properties** in the right-side navigation pane.
3. Configure the fuzhi_sql node.

   The fuzhi_sql node assigns the results queried from a specified table to the outputs parameter.



4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_sql

node.

5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node.

   The Assignment node value comparison_shell node depends on the fuzhi_sql node and uses the value of the outputs parameter of the fuzhi_sql node as the value of its input parameter sql_inputs.

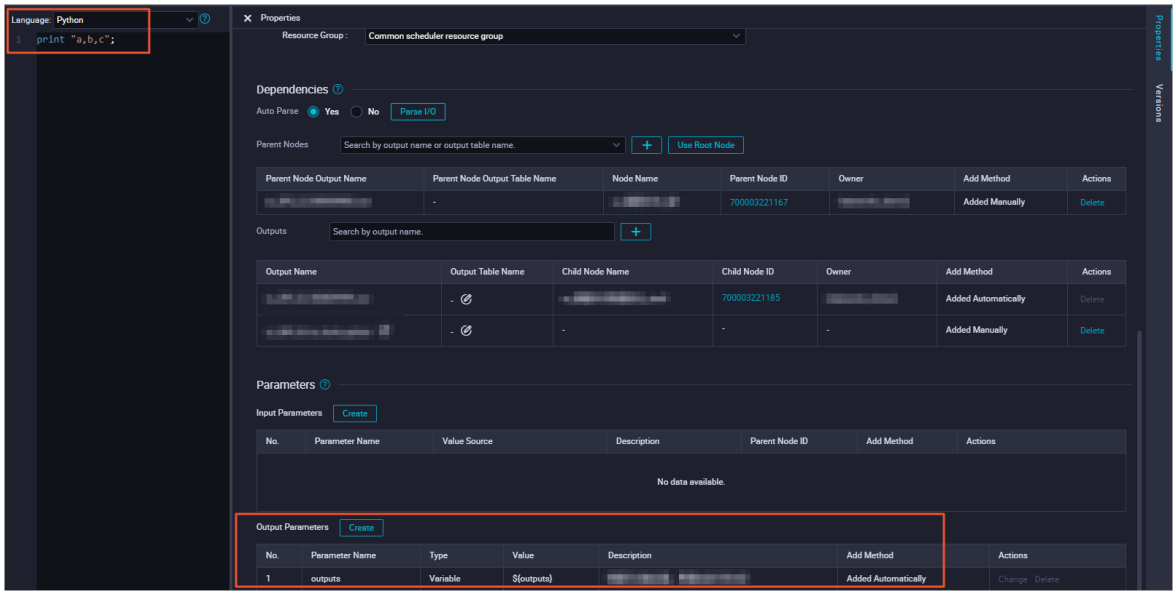
```
echo '${sql_inputs}';
echo 'Use the value in the first line in the output of the fuzhi_sql node as the input'${sql_inp
uts[0]};
echo 'Use the value in the second line in the output of the fuzhi_sql node as the input'${sql_in
puts[1]};
echo 'Use the value of the second field in the first line in the output of the fuzhi_sql node as
the input'${sql_inputs[0][1]};
echo 'Use the value of the third field in the second line in the output of the fuzhi_sql node as
the input'${sql_inputs[1][2]};
```

6. Click in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

Configure the child node to reference the output values of the assignment node that uses Python

1. Find the target workflow and double-click the assignment node fuzhi_python that uses Python.
2. On the configuration tab of the fuzhi_python node that appears, click **Properties** in the right-side navigation pane.
3. Configure the fuzhi_python node.

   The fuzhi_python node assigns the values a,b,c to the outputs parameter.



4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_python node.
5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node.

   The Assignment node value comparison_shell node depends on the fuzhi_python node and uses the value of the outputs parameter of the fuzhi_python node as the value of its input parameter python_inputs.

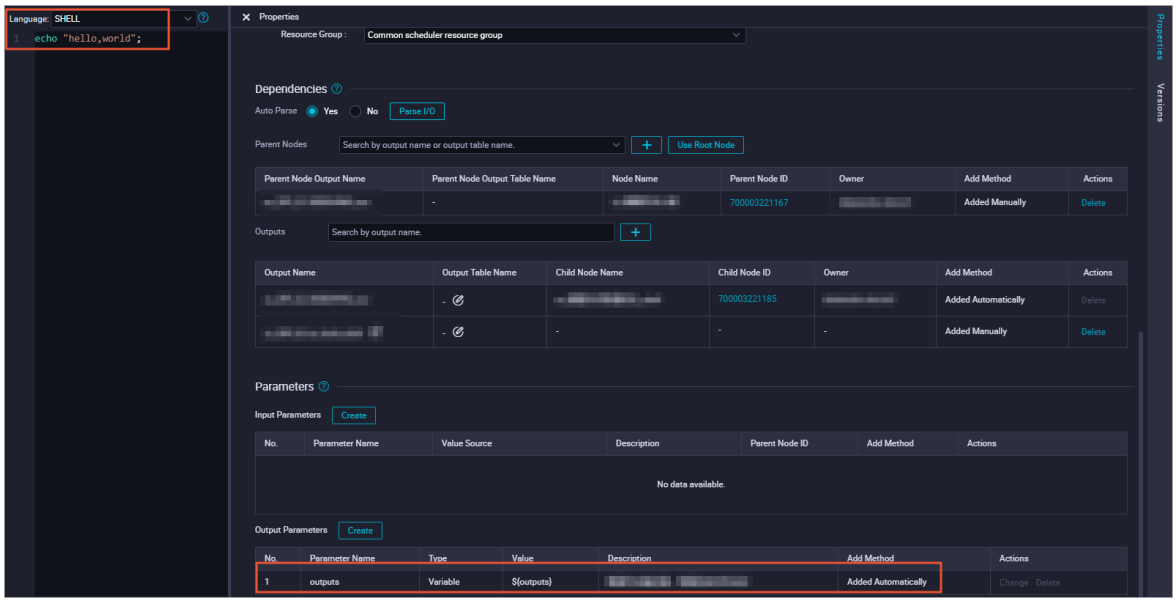
```
echo 'The output of the fuzhi_python node'${python_inputs};
echo 'Use the first value in the output of the fuzhi_python node as the input'${python_inputs[0]
};
echo 'Use the second value in the output of the fuzhi_python node as the input'${python_inputs[1
]};[1]}
```

6. Click in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

Configure the child node to reference the output values of the assignment node that uses SHELL

1. Find the target workflow and double-click the assignment node fuzhi_shell that uses SHELL.
2. On the configuration tab of the fuzhi_shell node that appears, click **Properties** in the right-side navigation pane.
3. Configure the fuzhi_shell node.

   The fuzhi_shell node assigns the values hello,world to the outputs parameter.



4. Double-click the Assignment node value comparison_shell node, which is the child node of the fuzhi_shell node.
5. On the configuration tab of the Assignment node value comparison_shell node that appears, click **Properties** in the right-side navigation pane and configure the node.

   The Assignment node value comparison_shell node depends on the fuzhi_shell node and uses the value of the outputs parameter of the fuzhi_shell node as the value of its input parameter shell_inputs.

```
echo 'The output of the fuzhi_shell node'${shell_inputs};
echo 'Use the first value in the output of the fuzhi_shell node as the input'${shell_inputs[0]};
echo 'Use the second value in the output of the fuzhi_shell node as the input'${shell_inputs[1]}
;
```

6. Click in the toolbar.
7. In the **Warning** message, click **Continue to Run**.
8. View the result.

2.1.5.5.8.6. Create a Shell node

Shell nodes support standard shell syntax but not interactive syntax.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Shell**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Shell**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. Edit the Shell node.
   i. Edit the code on the configuration tab of the Shell node.

   To call the system scheduling parameters for the Shell node, execute the following statement:

   ```
   echo "$1 $2 $3"
   ```

   > **Note** Separate multiple parameters with spaces.

   i. Click in the toolbar to save the SQL statement to the server.

   ii. Click in the toolbar to execute the SQL statement you have saved.

   If you need to change the resource group used to test the Shell node on the **DataStudio** page, click in the toolbar and select your desired exclusive resource group.
6. On the configuration tab of the Shell node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section.
7. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.
8. Test the node.

2.1.5.5.8.7. Create a zero-load node

A zero-load node is a control node, which only supports dry-run scheduling and does not generate any data. It usually serves as the root node of a workflow.

Context

You can configure an output table for a zero-load node so that the output table can be used as an input table of another node. However, the zero-load node does not process the table data.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, move the pointer over and choose **General > Zero-Load Node**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Zero-Load Node**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
4. Click **Commit**.
5. On the configuration tab of the zero-load node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, set parameters in the Schedule section. For more information, see Basic properties.
6. Commit the node.

   > **Notice** You must set **Rerun** and **Parent Nodes** before you can commit the node.

   i. Click in the toolbar.

   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.

   iii. Click **OK**.

   In a workspace in standard mode, you need to click **Deploy** in the upper-right corner after you commit the branch node.
7. Test the node.

2.1.5.5.8.8. Create a cross-tenant collaboration node

Cross-tenant collaboration nodes are used to associate nodes from different tenants. Cross-tenant collaboration nodes are classified into sender nodes and receiver nodes.

Prerequisites

A sender node and its receiver node use the same CRON expression. You can click the **Properties** tab in the right-side navigation pane of a node configuration tab and view the CRON expression in the **Schedule** section.

Create a cross-tenant collaboration node

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **General > Cross-Tenant Collaboration**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Cross-Tenant Collaboration**.
3. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

4. On the node configuration tab, set the parameters in the **Cross-Tenant Collaboration** section.

Parameter	Description
Type	The type of the cross-tenant collaboration node. Valid values: **Sender** and **Receiver**.
Location	The path of the cross-tenant collaboration node. The node path cannot be modified.
Collaborative Workspaces	The workspace name and Apsara Stack tenant account of the peer node. This example sets the node type to Sender. Therefore, you must enter the workspace name and Apsara Stack tenant account of the receiver node.

5. After the sender node is created, follow the same procedure to create the receiver node under the Apsara Stack tenant account and workspace to which the receiver node belongs.

   Set the node type to **Receiver**. The information about available sender nodes appears. You must also set **Timeout**. This parameter indicates the timeout period of the receiver node after it starts running.

   The sender node first sends a message to the message center. After the message is delivered, the status of the sender node is set to successful. The receiver node continuously pulls messages from the message center. If a message is received within the timeout period, the status of the receiver node is set to successful.

   If the receiver node does not receive any messages within the timeout period, the receiver node fails. The lifecycle of a message is 24 hours.

   Assume that an auto triggered instance was run on October 8, 2018. A message indicating the completion of the instance was then sent to the message center. If you create a retroactive instance for the receiver node with the data timestamp set to October 7, 2018, the status of the generated receiver node instance is set to successful.

6. After the configuration is completed, save and commit the node.

2.1.5.5.8.9. Create a data analysis report node

A data analysis report node is used to associate a report in the DataAnalysis module with the parent nodes on which the report depends and update the report as scheduled.

Prerequisites

A table is created on the **Report** page of the **DataAnalysis** module.

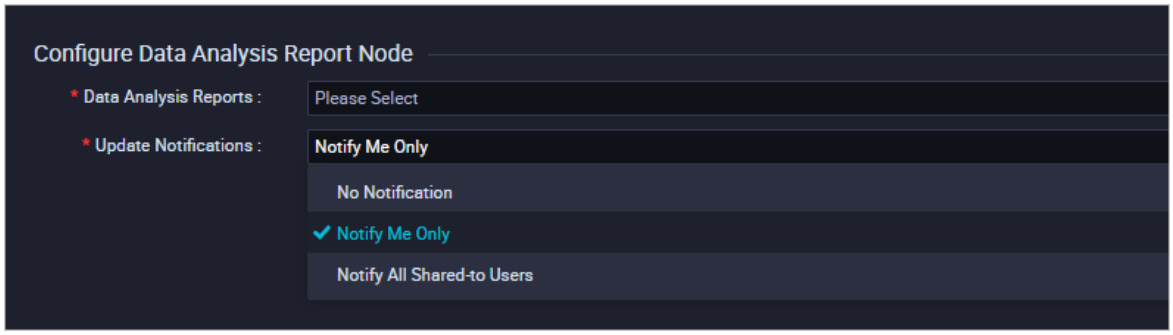
Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over  and choose **General > Data Analysis Reports**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **General**, and then choose **Create > Data Analysis Reports**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).

4. Click **Commit**.
5. On the node configuration tab, set the parameters in the **Configure Data Analysis Report Node** section.



Parameter	Description
Data Analysis Reports	The report for which you want to receive the notifications about the updates. Select a report created on the **Report** page of the **DataAnalysis** module.
Update Notifications	Specifies the users who can receive the notifications when the report is updated. Valid values: **No Notification**, **Notify Me Only**, and **Notify All Shared to Users**.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the data analysis report node. For more information, see Manage auto triggered nodes.

   After the node is run in the production environment, you can view updates of the report on the Report page of the **DataAnalysis** module.

2.1.5.5.9. Custom

2.1.5.5.9.1. Create a Hologres development node

This topic describes how to create and modify a Hologres development node and update the node version.

Procedure

1. Log on to the DataWorks console.
2. On the Data Analytics tab, move the pointer over and choose **Custom > Hologres Development**.

   Alternatively, you can click a workflow in the Business Flow section, right-click **UserDefined**, and then choose **Create > Hologres Development**.
3. In the **Create Node** dialog box, specify **Node Name** and **Location**.

   > **Note** The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.).
4. Click **Commit**.

5. On the node configuration tab that appears, select a Hologres development node.

If no Hologres node is available, click **Create** to create one. You can also click **Change** to modify an existing node.

6. On the configuration tab of the batch synchronization node, click the **Properties** tab in the right-side navigation pane. On the Properties tab, configure parameters in the Schedule section. For more information, see Basic properties.
7. Commit the node.
   i. Click in the toolbar.
   ii. In the **Commit Node** dialog box, enter your comments in the **Description** field.
   iii. Click **OK**.

   In a workspace in standard mode, you must click **Deploy** in the upper-right corner after you commit the node. For more information, see Publish nodes.
8. Test the node. For more information, see Manage auto triggered nodes.

2.1.5.6. Schedule

2.1.5.6.1. Basic properties

On the Properties tab of a node, you can set parameters of the node in the General, Schedule, Dependencies, and Parameters sections. The General section allows you to set the basic properties of the node.

On the **Data Analytics** tab of the DataStudio page, double-click a node. On the node configuration tab that appears, click the **Properties** tab in the right-side navigation pane and set the parameters in the **General** section.

Parameter	Description
Node Name	The name of the node that you set when creating the node. To modify the name, right-click the node in the left-side navigation pane and select **Rename**.
Node ID	The unique ID of the node. The node ID is generated when the node is committed at the first time. The node ID cannot be modified.
Node Type	The type of the node that you set when creating the node. The node type cannot be modified.
Owner	The owner of the node. By default, the owner of a newly created node is the current logon user. You can change the owner. **Note** Only a member in the workspace where the node resides can be selected as the owner.
Description	The description of the node, such as the business and usage.
Arguments	The parameter used to assign a value to a variable in the code during node scheduling. You can enter multiple parameters. Separate multiple parameters with spaces.

Parameter value assignment formats for various node types

- Format for ODPS SQL and ODPS MR nodes: `Variable name 1=Parameter 1 Variable name 2=Parameter 2`. Separate multiple parameters with spaces.
- Format for Shell nodes: `Parameter 1 Parameter 2`. Separate multiple parameters with spaces.

For more information about the built-in scheduling parameters, see Parameter configuration.

2.1.5.6.2. Scheduling parameters

In common data development scenarios, the code of different types of nodes may be subject to change from time to time. You must dynamically modify the values of some parameters, such as the date and time, based on the requirement changes and time changes.

In this case, you can use the scheduling parameter configuration feature of DataWorks. After relevant parameters are set, auto triggered nodes can automatically parse the code to obtain required data. Configurable parameters in DataWorks are classified into system parameters and custom parameters. We recommend that you use custom parameters.

```
{
    "data":[
    {
        "beginRunningTime":"1564019679966",
        "beginWaitResTime":"1564019679966",
        "beginWaitTimeTime":"1564019679506",
        "bizdate":"1559318400000",
        "createTime":"1564019679464",
        "dagId":332455685,
        "dagType":5,
        "finishTime":"1564019679966",
        "instanceId":2427622331,
        "modifyTime":"1564019679966",
        "nodeName":"vi","status":6
    }
    ],
    "errCode":"0",
    "errMsg":"",
    "requestId":"E17535-8C06-43F6-B1EA-6236FE9",
    "success":true
    }
```

Auto-completion is supported when you specify a data type for a parameter.

Parameter types

Parameter type	Configuration method	Applicable to	Example

Parameter type	Configuration method	Applicable to	Example
System parameters: including bdp.system.bizdate and bdp.system.cyctime	To use the system parameters in the scheduling system, reference ${bdp.system.bizdate} and ${bdp.system.cyctime} in the code, instead of setting them in the Arguments field. The system can automatically replace the values of the parameters that reference the system parameters in the code.	All nodes	N/A
Non-system parameters: custom parameters (recommended)	Reference ${key1} and ${key2} in the code and set them in the Arguments field, for example, `"key1=value1 key2=value2"`.	Non-Shell nodes	• **Constant parameters**: param1="abc"param2=1234. • **Variables**: param1=$[yyyymmdd], the value of which is calculated based on the value of bdp.system.cyctime.
	Reference $1, $2, and $3 in the code and set them in the Arguments field, for example, `"value1 value2 value3"`.	Shell nodes	• **Constant parameters**: "abc" 1234. • **Variables**: $[yyyymmdd], the value of which is calculated based on the value of bdp.system.cyctime.

As described in the preceding table, the values of custom variables are calculated based on the values of system parameters. You can use custom variables to flexibly define the data to be obtained and the data format. For custom parameters, the following types of brackets are used:

- Braces { } define the data timestamp. For example, the value of {yyyymmdd} is calculated based on the value of bdp.system.bizdate.
- Brackets [ ] define the running time. For example, the value of [yyyymmddhh] is calculated based on the value of bdp.system.cyctime.

Note Nodes can be scheduled only in the production environment. Therefore, the values of scheduling variables are replaced only after nodes are run in the production environment.

After you set the scheduling variables for a node, you can click the **Run Smoke Test in Development Environment** icon on the node configuration tab to test whether the values of scheduling variables can be replaced as expected during node scheduling.

You can click the **Properties** tab in the right-side navigation pane, and assign values to scheduling variables in the **Arguments** field in the **General** section. Note the following issues when you set parameters:

- Do not add spaces on either side of the equal sign (=) for a parameter. For example, enter `bizdate=$bizdate`.
- Separate multiple parameters (if any) with spaces. For example, enter `bizdate=$bizdate datetime=${yyyymmdd}`.

System parameters

DataWorks provides the following system parameters:

- ${bdp.system.cyctime}: the scheduled time to run an instance. Default format: yyyymmddhh24miss. This parameter can specify the hour and minutes of the scheduled time.
- ${bdp.system.bizdate}: the timestamp of data to be analyzed by an instance. Default format: yyyymmdd. The default data timestamp is one day before the scheduled time.

Use the following formula to calculate the running time based on the data timestamp: `Running time = Data timestamp + 1`.

To use the system parameters, you can reference them in the code, instead of setting them in the Arguments field. The system can automatically replace the values of the parameters that reference the system parameters in the code.

> **Note** The scheduling properties of an auto triggered node are configured to define the scheduling rules of the running time. Therefore, you can calculate the data timestamp based on the scheduled time to run an instance and obtain the values of system parameters for the instance.

Example of system parameters

For example, to set an ODPS SQL node to run once per hour from 00:00 to 23:59 every day, perform the following steps if you want to use system parameters in the code:

1. Reference system parameters in the code.

```
insert overwrite table tb1 partition(ds ='20150304') select
c1,c2,c3
from (
select * from tb2
where ds ='${bdp.system.cyctime}') t
full outer join(
select * from tb3
where ds = '${bdp.system.bizdate}') y
on t.c1 = y.c1;
```

2. After the preceding step, your node is partitioned by using the system parameters. Set the scheduling properties and dependencies. For more information, see Schedule and Dependencies. In this example, the node is scheduled by hour.
3. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in Manage auto triggered nodes. The scheduling system generates instances for the auto triggered node from the second day. You can right-click an instance in the directed acyclic graph (DAG) and select **View Runtime Log** to view the parsed values of the system parameters.

   For example, the scheduling system generated 24 running instances for the node on January 14, 2019. The data timestamp is January 13, 2019 for all instances. Therefore, the value of ${bdp.system.bizdate} is 20190113. The running time is the running date appended with the scheduled time. Therefore, the value of ${bdp.system.cyctime} is 20190114000000 plus the scheduled time of each instance.

   Open the runtime logs of each instance and search for the replaced values of the system parameters in the code:

   - The scheduled time for the first instance is January 14, 2019 00:00:00. Therefore, bdp.system.bizdate is replaced with 20190113 and bdp.system.cyctime is replaced with 20190114000000.
   - The scheduled time for the second instance is January 14, 2019 01:00:00. Therefore, bdp.system.bizdate is replaced with 20190113 and bdp.system.cyctime is replaced with 20190114010000.
   - Similarly, the scheduled time for the twenty-fourth instance is January 14, 2019 23:00:00. Therefore, bdp.system.bizdate is replaced with 20190113 and bdp.system.cyctime is replaced with 20190114230000.

Custom parameters for non-Shell nodes

To set scheduling variables for a non-Shell node, add ${Variable name} in the code to reference the function and assign a value to the scheduling variable.

> **Note** The name of a variable in the SQL code can contain only letters, digits, and underscores (_). If the variable name is date, the value of $bizdate is automatically assigned to this variable. For more information, see the "Built-in scheduling parameters" section in this topic. You do not need to assign a value in the Arguments field. Even if another value is assigned, it is not used in the code because the value of $bizdate is automatically assigned in the code.

Example of custom parameters for non-Shell nodes

For example, to set an ODPS SQL node to run once per hour from 00:00 to 23:59 every day, perform the following steps if you want to use the hour-related custom variables thishour and lasthour in the code:

1. Reference the parameters in the code.

```
insert overwrite table tb1 partition(ds ='20150304')  select
 c1,c2,c3
from (
 select * from tb2
 where ds ='${thishour}') t
full outer join(
 select * from tb3
 where ds = '${lasthour}') y
on t.c1 = y.c1;
```

2. Click the **Properties** tab in the right-side navigation pane of the node configuration tab. Assign values to the custom parameters referenced in the code in the **Arguments** field in the **General** section.

   Set the custom parameters in the following formats:

   - thishour=$[yyyy-mm-dd/hh24:mi:ss]
   - lasthour=$[yyyy-mm-dd/hh24:mi:ss-1/24]

   > **Note** The value of yyyy-mm-dd/hh24:mi:ss corresponds to that of cyctime. For more information, see the "Custom parameters" section in this topic.

   You can enter `thishour=$[yyyy-mm-dd/hh24:mi:ss] lasthour=$[yyyy-mm-dd/hh24:mi:ss-1/24]` in the **Arguments** field.

3. Set the node to run once per hour.
4. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in Manage auto triggered nodes. The scheduling system generates instances for the auto triggered node from the second day. You can right-click an instance in the DAG and select **View Runtime Log** to view the parsed values of the custom parameters. The value of cyctime is 20190114010000. Therefore, the value of thishour is 2019-01-14/01:00:00 and the value of lasthour, which indicates the last hour, is 2019-01-14/00:00:00.

Custom parameters for Shell nodes

The parameter configuration procedure of a Shell node is similar to that of a non-Shell node, except that the variable naming rules are different. Variable names for a Shell node cannot be customized, but must follow the $1,$2,$3... format. For example, add $1 in the code of a Shell node and enter the built-in scheduling parameter $xxx in the Arguments field. Then, the value of $xxx can replace that of $1 in the code.

> **Note** If the number of parameters in a Shell node reaches 10, use ${10} to declare the tenth variable.

Example of custom parameters for Shell nodes

For example, set a Shell node to run at 01:00 every day. To use the custom constant parameter myname and the custom variable ct in the code, perform the following steps:

1. Reference the parameters in the code.

```
echo "hello $1, two days ago is $2, the system param is ${bdp.system.cyctime}";
```

2. Click the **Properties** tab in the right-side navigation pane of the node configuration tab. Assign values to the custom parameters referenced in the code in the **Arguments** field in the **General** section. Separate multiple parameters with spaces, for example, enter Parameter 1 Parameter 2 Parameter 3. The custom parameters are parsed based on the parameter sequence. For example, $1 is replaced with the value of Parameter 1. In this example, enter abcd $[yyyy-mm-dd-2] in the Arguments field to set $1 and $2 to abcd and $[yyyy-mm-dd-2], respectively.
3. Set the node to run at 01:00 every day.
4. After you set the recurrence and dependencies, commit and deploy the node. Then, you can check the node in Operation Center. The scheduling system generates instances for the auto triggered node from the second day. Right-click an instance in the DAG and select **View Runtime Log**. The logs show that $1 in the code is replaced with abcd, $2 is replaced with 2019-01-12 (two days before the running date), and ${bdp.system.cyctime} is replaced with 20190114010000.

Custom parameters

Custom parameters are divided into constant parameters and variables based on the value type. DataWorks provides some built-in scheduling parameters as variables.

- Constant parameters

  For example, for an SQL node, add ${Variable name} in the code and set the following parameter for the node: Variable name=Fixed value.

  - Code: `select xxxxxx type='${type}'`
  - Value assigned to the scheduling variable: type='aaa'. When the node is run, the variable in the code is replaced with type='aaa'.

- Variables

  Variables are built-in scheduling parameters whose values depend on the system parameters ${bdp.system.bizdate} and ${bdp.system.cyctime}.

  For example, for an SQL node, add ${Variable name} in the code and set the following parameter for the node: Variable name=Scheduling parameter.

  - Code: `select xxxxxx dt=${datetime}`
  - Value assigned to the scheduling variable: datetime=$bizdate

    If the node is run on July 22, 2017, the variable in the code is replaced with dt=20170721.

Built-in scheduling parameters

- $bizdate
  - Parameter description: the data timestamp in the format of yyyymmdd. By default, the value of this parameter is one day before the scheduled time to run a node.
  - For example, the code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=$bizdate. If the node is run on July 22, 2017, $bizdate is replaced with pt=20170721.
- $cyctime

- Parameter description: the scheduled time to run a node. If no scheduled time is configured for a node scheduled by day, $cyctime is set to 00:00 of the day. The time is accurate to seconds. This parameter is usually used for nodes scheduled by hour or minute.

  > **Note**
  > - Pay attention to the difference between the time parameters configured by using $[] and ${}. $bizdate specifies the data timestamp, which is one day before the current day by default.
  > - $cyctime specifies the scheduled time to run a node. If no scheduled time is configured for a node scheduled by day, $cyctime is set to 00:00 of the day. The time is accurate to seconds. This parameter is usually used for nodes scheduled by hour or minute.
  >
  >   For example, if a node is scheduled to run at 00:30 on the current day, $cyctime is set to yyyy-mm-dd 00:30:00.
  > - If a time parameter is configured by using ${}, $bizdate is used as the benchmark for running nodes. The time parameter is replaced with the data timestamp selected for retroactive data generation.
  > - If a time parameter is configured by using $[], $cyctime is used as the benchmark for running nodes. The time is calculated in the same way as the time in Oracle. The time parameter is replaced with the data timestamp selected for retroactive data generation plus one day.
  >
  >   For example, if the data timestamp is set to 20140510 for retroactive data generation, $cyctime is replaced with 20140511.

- The following examples show the values of custom parameters when $cyctime is set to 20140515103000:
  - $[yyyy] = 2014, $[yy] = 14, $[mm] = 05, $[dd] = 15, $[yyyy-mm-dd] = 2014-05-15, $[hh24:mi:ss] = 10:30:00, $[yyyy-mm-dd hh24:mi:ss] = 2014-05-1510:30:00
  - $[hh24:mi:ss - 1/24] = 09:30:00
  - $[yyyy-mm-dd hh24:mi:ss -1/24/60] = 2014-05-1510:29:00
  - $[yyyy-mm-dd hh24:mi:ss -1/24] = 2014-05-15 09:30:00
  - $[add_months(yyyymmdd,-1)] = 20140415
  - $[add_months(yyyymmdd,-12*1)] = 20130515
  - $[hh24] =10
  - $[mi] =30
- Method for testing the $cyctime parameter:

  After an instance starts to run, right-click the instance in the DAG and select **More**. Check whether the scheduled time is the time at which the instance is run.

- $jobid
  - Parameter description: the ID of the workflow to which a node belongs.
  - Example: jobid=$jobid.
- $nodeid
  - Parameter description: the ID of a node.
  - Example: nodeid=$nodeid.
- $taskid
  - Parameter description: the instance ID of a node.
  - Example: taskid=$taskid.
- $bizmonth

- Parameter description: the month of the data timestamp in the format of yyyymm. If the month of a data timestamp is the current month, the value of $bizmonth is the month of the data timestamp minus 1. Otherwise, the value of $bizmonth is the month of the data timestamp.
- For example, the code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=$bizmonth.

  Assume that the current day is July 22, 2017. If the node is run on July 22, 2017, $bizmonth is replaced with pt=201706.

- ${...} custom parameters
  - You can customize a time format based on the value of $bizdate, where yyyy indicates the four-digit year, yy indicates the two-digit year, mm indicates the month, and dd indicates the day. You can use any combination of these parameters, for example, ${yyyy}, ${yyyymm}, ${yyyymmdd}, and ${yyyy-mm-dd}.
  - $bizdate is accurate to the day. Therefore, ${...} can specify only the year, month, or day.
  - The following table describes how to specify other intervals based on $bizdate.

Interval	Expression
N years later	${yyyy+N}
N years before	${yyyy-N}
N months later	${yyyymm+N}
N months before	${yyyymm-N}
N weeks later	${yyyymmdd+7*N}
N weeks before	${yyyymmdd-7*N}
N days later	${yyyymmdd+N}
N days before	${yyyymmdd-N}

- $gmtdate
  - Parameter description: the current date in the format of yyyymmdd. By default, the value of this parameter is the current date. During retroactive data generation, the input value is the data timestamp plus one day.
  - For example, the code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=$gmtdate. Assume that the current day is July 22, 2017. If the node is run on July 22, 2017, $gmtdate is replaced with pt=20170722.

- ${yyyymmdd}
  - Parameter description: the data timestamp in the format of yyyymmdd. The value of this parameter is the same as that of $bizdate. This parameter supports delimiters, for example, yyyy-mm-dd.

    By default, the value of this parameter is one day before the scheduled time to run a node. You can customize a time format for this parameter, for example, yyyy-mm-dd for ${yyyy-mm-dd}.

- Examples:
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyy-mm-dd}. If the node is run on July 22, 2018, ${yyyy-mm-dd} is replaced with pt=2018-07-21.
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyymmdd-2}. If the node is run on July 22, 2018, ${yyyymmdd-2} is replaced with pt=20180719.
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyymm-2}. If the node is run on July 22, 2018, ${yyyymm-2} is replaced with pt=201805.
  - The code of an ODPS SQL node includes pt=${datetime}, and the parameter configured for the node is datetime=${yyyy-2}. If the node is run on July 22, 2018, ${yyyy-2} is replaced with pt=2016.
  - You can assign values to multiple parameters when configuring an ODPS SQL node. For example, set startdatetime=$bizdate enddatetime=${yyyymmdd+1} starttime=${yyyy-mm-dd} endtime=${yyyy-mm-dd+1}.

FAQ

- Q: The table partition format is pt=yyyy-mm-dd hh24:mi:ss, but spaces are not allowed in scheduling parameters. How can I configure the format of $[yyyy-mm-dd hh24:mi:ss]?

  A: Use the custom variables datetime=$[yyyy-mm-dd] and hour=$[hh24:mi:ss] to obtain the date and time. Then, join them together to form pt="${datetime} ${hour}" in the code. Separate the two variables with a space.

- Q: The table partition is pt="${datetime} ${hour}" in the code. To obtain the data for the last hour when the node is run, the custom variables datetime=$[yyyymmdd] and hour=$[hh24-1/24] can be used to obtain the date and time, respectively. However, for an instance running at 00:00, it analyzes data for 23:00 of the current day, instead of 23:00 of the previous day. What measures can I take in this case?

  A: Modify the formula of datetime to $[yyyymmdd-1/24] and keep the formula of hour unchanged at $[hh24-1/24]. Then, the node can be run properly.

  - For an instance that is scheduled to run at 2015-10-27 00:00:00, the values of $[yyyymmdd-1/24] and $[hh24-1/24] are 20151026 and 23, respectively. This is because the scheduled time minus 1 hour is a time value that belongs to yesterday.
  - For an instance that is scheduled to run at 2015-10-27 01:00:00, the values of $[yyyymmdd-1/24] and $[hh24-1/24] are 20151027 and 00, respectively. This is because the scheduled time minus 1 hour is a time value that belongs to the current day.

DataWorks offers the following node running modes:

- Manually run a node in DataStudio: You must assign temporary values to parameters in the code to ensure proper running of the node. The assigned values are not saved as node properties and do not take effect in other node running modes.
- Automatically run a node at specified intervals: No configuration is needed in the Arguments field. The scheduling system automatically replaces the values of parameters based on the scheduled time of the current instance.
- Test a node or generate retroactive data: You must specify the data timestamp. The scheduled time of each instance can be calculated based on the formula described earlier in this topic.

2.1.5.6.3. Scheduling properties

This topic describes how to configure the scheduling properties of a node, including the recurrence and dependencies.

You can click the **Properties** tab in the right-side navigation pane of the node configuration tab and set the parameters in the **Schedule** section.

Node status

- **Normal**: If you select this option, the node is run based on the recurrence. By default, this option is selected for a node.
- **Dry Run**: If you select this option, the node is run based on the recurrence. However, the scheduling system does not actually run the code but directly returns a success response.
- **Retry Upon Error**: If you select this check box, the node is rerun when it encounters an error. By default, a node can be automatically rerun for a maximum of three times at an interval of 2 minutes.
- **Skip Execution**: If you select this check box, the node is run based on the recurrence. However, the scheduling system does not actually run the code but directly returns a failure response. You can select this check box if you want to suspend a node and run it later.

Recurrence

After a node is committed and deployed, the scheduling system generates instances every day from the next day based on the scheduling properties of the node. Then, the scheduling system runs the instances based on the running results of ancestor instances and the scheduled time. If a node is committed and deployed after 23:30, the scheduling system generates instances for it from the third day.

> **Note**
>
> If you schedule a node to run every Monday, the node is run only on Mondays. On the other days, the scheduling system does not actually run the code but directly returns a success response. When you test a node scheduled by week or generate retroactive data for the node, you must set the data timestamp to one day earlier than the scheduled time to run the node.
>
> For an auto triggered node, its dependencies take priority over other scheduling properties. That is, when the scheduled time arrives, the scheduling system does not immediately run a node instance but first checks whether all the ancestor instances are run.
>
> - The node instance is in the Not Running state if any ancestor instances are not run when the scheduled time arrives.
> - The node instance is in the Pending (Schedule) state if the scheduled time does not arrive but all the ancestor instances are run.
> - The node instance is in the Pending (Resources) state if all the ancestor instances are run and the scheduled time arrives.

Cross-cycle dependencies

DataWorks supports the following three types of cross-cycle dependencies:

- Dependency on instances of child nodes
  - Node dependency: The current node depends on the last-cycle instances of its child nodes. For example, Node A has three child nodes B, C, and D. If you select this node dependency, Node A depends on the last-cycle instances of nodes B, C, and D.
  - Business scenario: The current node depends on instances of child nodes in the last cycle to cleanse the output tables of the current node and check whether the final result is generated properly.
- Dependency on instances of the current node
  - Node dependency: The current node depends on its last-cycle instances.
  - Business scenario: The current node depends on the data output result of its last-cycle instances.
- Dependency on instances of custom nodes: If you select this node dependency, enter the IDs of the nodes on which the current node depends. You can specify multiple nodes and separate their IDs with commas (,). For example, enter 12345,23456.
  - Node dependency: The current node depends on the last-cycle instances of custom nodes.

- Business scenario: In the business logic, the current node depends on the proper output of other business data that is not processed by the current node.

> **Note** The difference between cross-cycle dependencies and dependencies in the current cycle lies in that cross-cycle dependencies are displayed as dotted lines in Operation Center.
>
> Before deleting a node from Operation Center, you must delete all dependencies of the node so that other nodes can run properly.

Scheduled by day

Nodes scheduled by day are automatically run once per day. When you create an auto triggered node, the node is set to run at 00:00 every day by default. You can specify another time as needed. In the example shown in the following figure, the time is specified as 13:00.

- If you select Customize Runtime, the node is run at the specified time every day. The time format is YYYY-MM-DD HH:MM:SS.

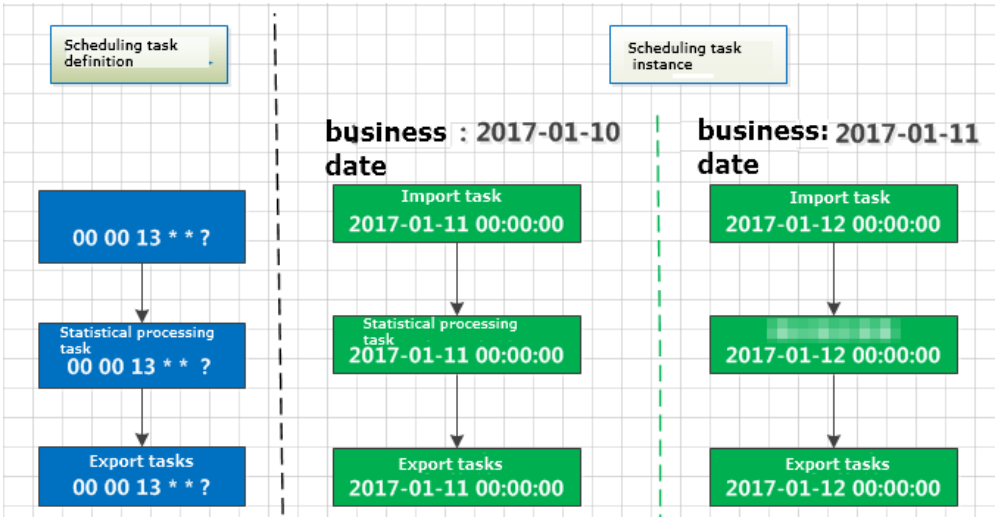
  > **Note** An auto triggered node can be run only when all the ancestor instances are run and the scheduled time arrives. Both prerequisites are indispensable and have no specific chronological order.

- If you clear Customize Runtime, the scheduled time of the node is randomly set in the range of 00:00 to 00:30.

Scenarios:

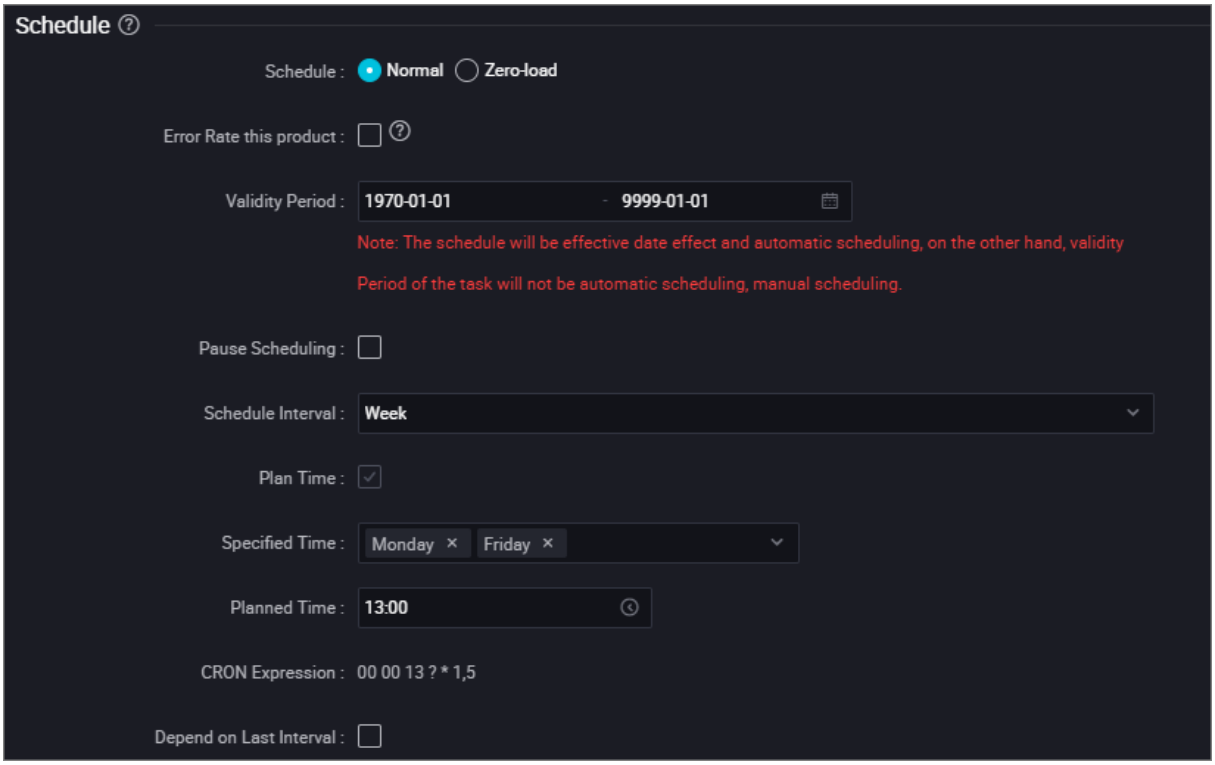
For example, you have created an import node, an analytics node, and an export node. They are all scheduled to run at 13:00 every day. The analytics node depends on the import node, and the export node depends on the analytics node. The following figure shows that the analytics node is configured to depend on the import node.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the nodes, as shown in the following figure.



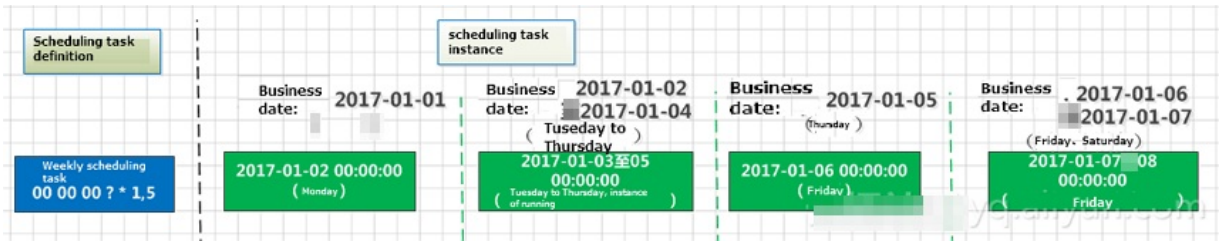
Scheduled by week

Nodes scheduled by week are automatically run at a specified time of specified days every week. On the other days, the scheduling system still generates instances to make sure the proper running of descendant instances. However, the system does not actually run the code or consume resources but directly returns a success response.



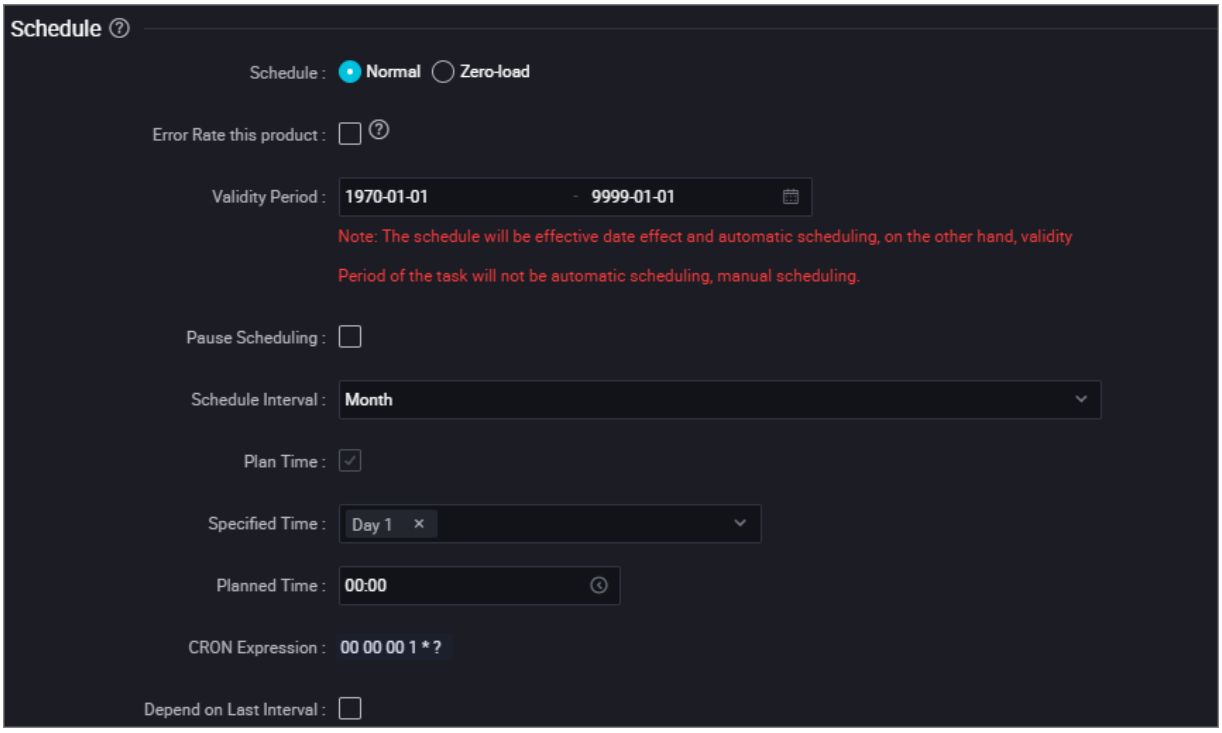
For example, you have created a node. As shown in the preceding figure, the scheduling system runs instances generated on Mondays and Fridays, but returns success responses without running the code for instances generated on Tuesdays, Wednesdays, Thursdays, Saturdays, and Sundays.

Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.



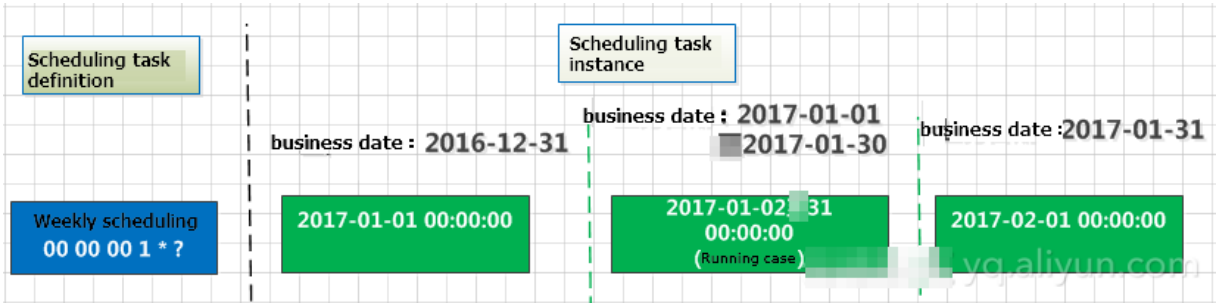
Scheduled by month

Nodes scheduled by month are automatically run at a specified time of specified days every month. On the other days, the scheduling system still generates instances to make sure the proper running of descendant instances. However, the system does not actually run the code or consume resources but directly returns a success response.



For example, you have created a node. As shown in the preceding figure, the scheduling system runs the instance generated on the first day of each month, but returns success responses without running the code for instances generated on the other days.

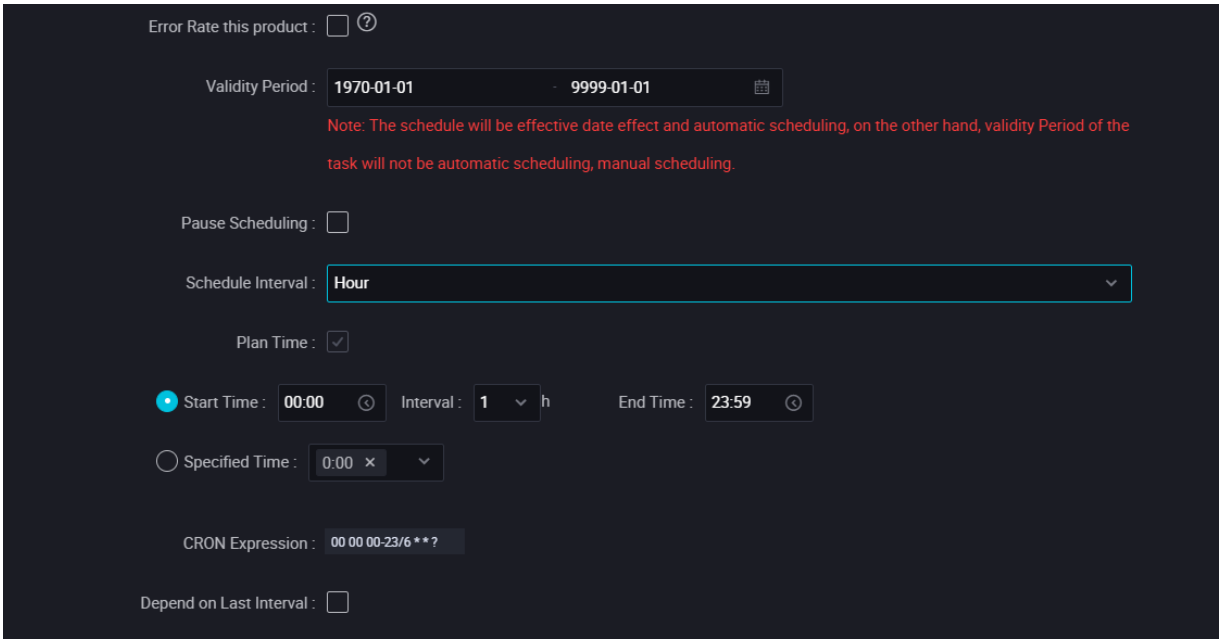
Based on the preceding node scheduling properties, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.



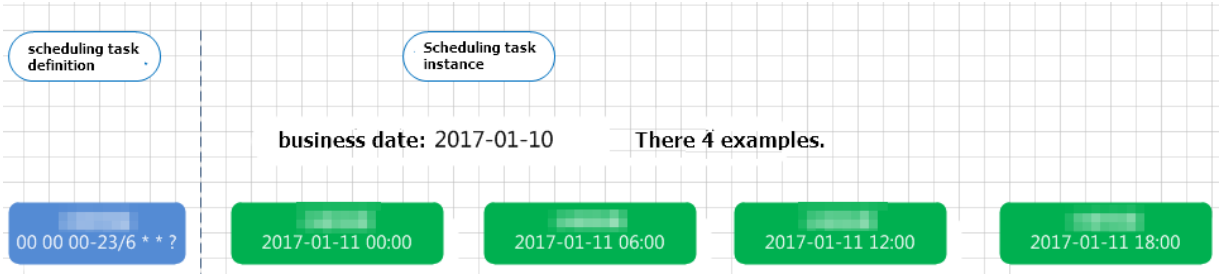
Scheduled by hour

Nodes scheduled by hour are automatically run once every N hours in a specific time period every day. For example, a node is run once per hour from 01:00 to 04:00 every day.

> **Note** The time period is a closed interval. For example, if a node is scheduled to run once per hour in the period from 00:00 to 03:00, the scheduling system generates four instances every day, which are run at 00:00, 01:00, 02:00, and 03:00, respectively.



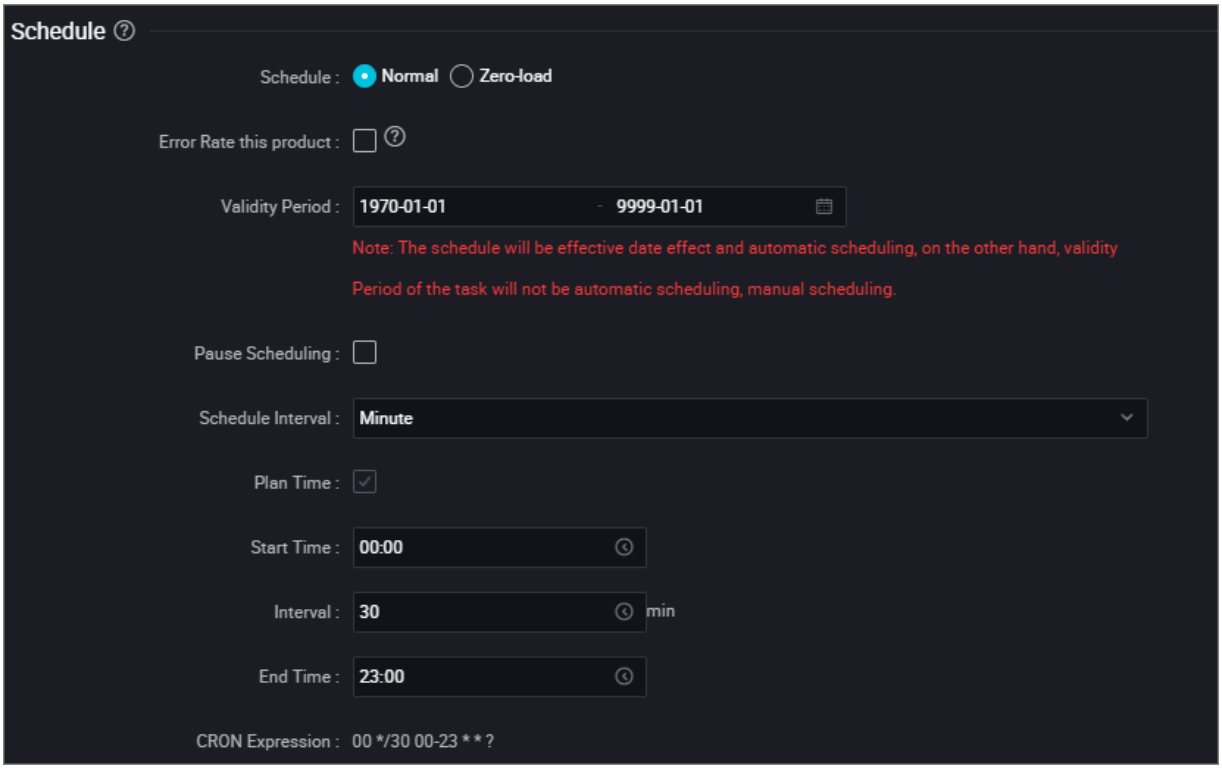
For example, you have created a node. As shown in the preceding figure, the node is automatically run every 6 hours in the period from 00:00 to 23:59 every day. In this case, the scheduling system automatically generates and runs instances for the node, as shown in the following figure.



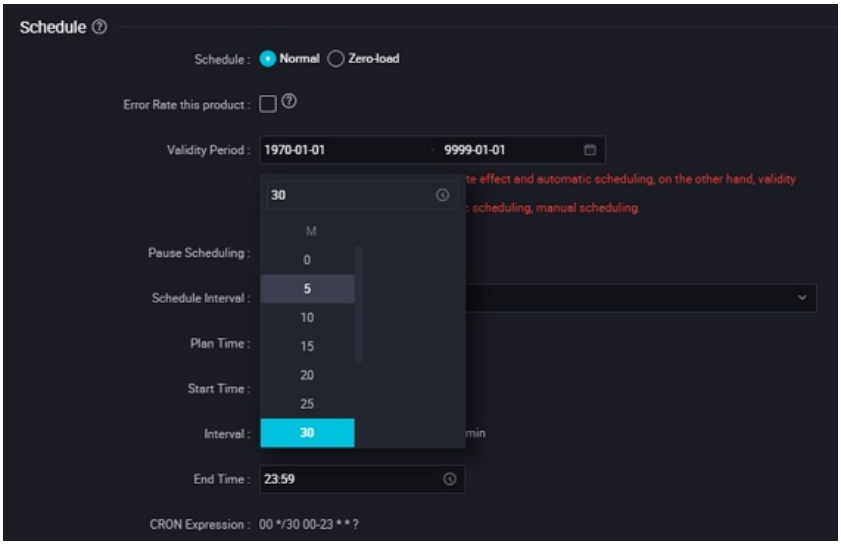
Scheduled by minute

Nodes scheduled by minute are automatically run once every N minutes in a specific time period every day.

For example, you have created a node. As shown in the following figure, the node is run every 30 minutes in the period from 00:00 to 23:00 every day.



Currently, a minimum interval of 5 minutes is supported. The time expression is automatically generated based on the time you select and cannot be modified.



FAQ

- Q: Node A is scheduled by hour and Node B is scheduled by day. How do I enable Node B to automatically run every day after all instances of Node A are run?

  A: A node scheduled by day can depend on a node scheduled by hour. To enable Node B to automatically run every day after all 24 instances of Node A are run, do not specify the time to run Node B every day. Then, configure Node A as an ancestor of Node B. For more information, see the Dependencies topic. A node can depend on any other node, regardless of the recurrence. The recurrence of each node is specified in its scheduling properties.

- Q: Node A is run once per hour on the hour every day and Node B is run once per day. How do I enable Node B to automatically run after Node A is run for the first time every day?

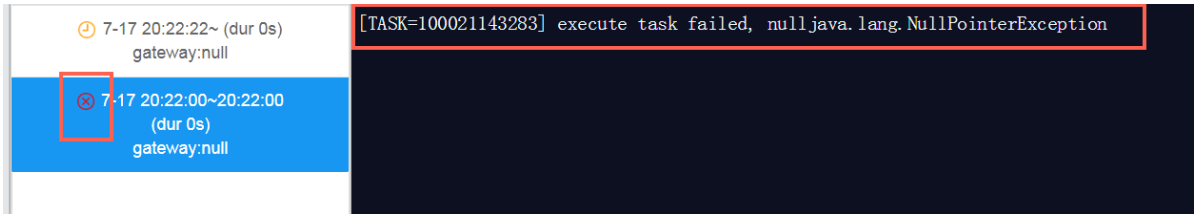
  A: When configuring the scheduling properties of Node A, select **Cross-Cycle Dependencies** and select **Instances of Current Node** from the Depend On drop-down list. When configuring the scheduling properties of Node B, configure Node B to depend on Node A and set the scheduled time of Node B to 00:00 every day. In this way, instances of Node B only depend on the instance of Node A generated at 00:00 every day, that is, the first instance of Node A.

- Q: Node A is run once every Monday and Node B depends on Node A. How do I enable Node B to run once every Monday?

  A: Set the scheduling properties of Node B to be the same as those of Node A. That is, select **Week** as the instance recurrence and select **Monday**.

- Q: How are the instances of a node affected when the node is deleted?

  A: When a node is deleted, its instances are retained because the scheduling system still generates one or more instances for the node based on the scheduling properties. However, when the scheduling system runs such instances after the node is deleted, an error message appears because the required code is unavailable, as shown in the following figure.

- Q: Can I enable a node to process monthly data on the last day of each month?

  A: No, DataWorks does not support setting a node to run on the last day of each month. If you enable a node to run on the thirty-first day of each month, the scheduling system runs a node instance in each month that has 31 days and returns a success response without running the code in any other month.

  We recommend that you configure a node to process the data of the past month on the first day of each month.

- Q: If a node scheduled by day depends on a node scheduled by hour, how do I enable the node scheduled by day to run at 00:00 every day?

  A: You can configure the node scheduled by day to depend on the data generated on the day before for the node scheduled by hour. If the node scheduled by day depends on the data generated on the current day for the node scheduled by hour, the instances of the node scheduled by day can be run only on the next day.

  In the Schedule section of the node scheduled by day, select **Cross-Cycle Dependencies**, select **Instances of Custom Nodes** from the Depend On drop-down list, and then enter the ID of the node scheduled by hour on which the node scheduled by day depends. Commit and deploy the node scheduled by day.

- Q: What can I do if I do not know when the output data of the ancestor node is generated?

  A: You can set the cross-cycle dependency for the current node to depend on the last-cycle instances of the ancestor node.

- Q: After a modified node is committed and deployed to the production environment, will the node instances that were originally faulty in the production environment be overwritten?

  A: No, the node instances that have been generated will not be overwritten. The updated code is used to run the node instances that are newly generated and have not been run. If the scheduling properties are modified, the modified configuration also applies to the newly generated node instances.

2.1.5.6.4. Dependencies

Scheduling dependencies are the foundation for building orderly workflows. You must configure correct dependencies between nodes to make sure that business data is produced effectively and in a timely manner. This helps standardize data development activities.

DataWorks allows you to automatically parse node dependencies from the code or manually customize node dependencies. You can configure correct relationships between ancestor and descendant nodes and monitor the running status of nodes to make sure the orderly production of business data.

The purpose of configuring node dependencies is to check the data output time of the table queried by SQL statements and check whether data is properly produced from an ancestor node based on the node status.

You can set the output of an ancestor node as the input of a descendant node to configure a dependency between the two nodes.

Regardless of the dependency configuration mode, the overall scheduling logic is that descendant nodes can be run only after ancestor nodes are run. Therefore, each node in a workflow must have at least one parent node. The dependencies between the parent nodes and child nodes are the core of scheduling dependencies. The following sections describe the principles and configuration methods of scheduling dependencies in detail.

Differences between automatic parsing and custom dependencies

DataWorks can automatically parse the input and output of a node based on the lineage parsed from the code.

If the lineage parsed from the code is inaccurate, you can add custom dependencies as needed. We recommend that you write the code correctly to parse the lineage from the code and reduce custom dependencies. The following example shows how to configure the input and output of a node.

Auto Parse: If you select Yes, node dependencies are automatically parsed from the code.

For example, the code of an ODPS SQL node is as follows:

```
insert overwrite table table_a as select * from project_b_name.table_b;
```

From the code, DataWorks determines that the current node depends on the node that generates table_b and the current node generates table_a. Therefore, the output name of the parent node is project_b_name.table_b and the output name of the current node is project_name.table_a.

- If you do not want to parse node dependencies from the code, select **No** for Auto Parse.
- If a table in an SQL statement is both an output table and a referenced table on which another node depends, the table is parsed only as an output table.
- If a table in an SQL statement is used as an output table or a referenced table multiple times, only one scheduling dependency is parsed.
- If the SQL code contains a temporary table, the table is not involved in a scheduling dependency. Temporary tables are prefixed with t_. For more information, see Project Configuration.

Parent nodes

In the Dependencies section of a node, you must specify an ancestor node as the parent node on which the current node depends. You must enter the output name of the ancestor node, rather than the ancestor node name. A node may have multiple output names. Enter an output name as needed. You can search for an output name of the ancestor node to be added, or click Parse I/O to parse the output name based on the lineage parsed from the code.

> **Note** You must enter an output name or output table name to search for the ancestor node.
>
> If you enter an output name to search for the ancestor node, DataWorks searches for the output name among the output names of nodes that have been committed to the scheduling system.

- Search by entering an output name

You can enter an output name to search for the ancestor node and configure the node as the parent node of the current node to create a dependency.

- Search by entering an output table name

  When using this method, make sure that the entered output table name of the ancestor node is the table name used in the INSERT or CREATE statement of the current node, such as Project name.Table name . Such output names can be automatically parsed.

  After you click the **Submit** icon, the output table name of the parent node configured for the current node can be found when you enter an output table name to search for the ancestor node for other nodes.

Outputs

You can click the **Properties** tab in the right-side navigation pane to view and configure the output of the current node.

DataWorks assigns a default output name that ends with .out to each node. You can also customize an output name or click Parse I/O to parse the output name based on the lineage parsed from the code.

> **Note** The output name of each node must be globally unique.

FAQ

- Q: After DataWorks automatically parses the input and output of a node, the node fails to be committed. An error message appears to indicate that the parsed output name workshop_yanshi.tb_2 of the parent node does not exist and you must commit the parent node before committing the current node. Why does this error occur?

  A: The possible causes are as follows:

  - The ancestor node is not committed. Commit the ancestor node and try again.
  - The ancestor node is committed, but workshop_yanshi.tb_2 is not an output name of the ancestor node.

  > **Note** Usually, the output names of the parent node and the current node are automatically parsed based on the table name that is used in the INSERT or CREATE statement or follows the FROM keyword. Make sure that you follow the principles of automatic parsing in the Differences between automatic parsing and custom dependencies section.

- Q: In the output of the current node, the descendant node name and ID are empty and cannot be specified. Why does this happen?

  A: If the current node does not have a descendant node, the descendant node name and ID are empty. After a descendant node is configured for the current node, the corresponding content can be automatically parsed.

- Q: What is the output name of a node used for?

  A: The output name of a node is used to establish dependencies between nodes. For example, if the output name of Node A is ABC and Node B uses ABC as its input, a dependency is established between nodes A and B.

- Q: Can a node have multiple output names?

  A: Yes, a node can have multiple output names. If a descendant node references an output name of the current node as the output name of the parent node, a dependency is established between the descendant node and the current node.

- Q: Can multiple nodes have the same output name?

  A: No, the output name of each node must be unique under your Apsara Stack tenant account. If multiple nodes export data to the same MaxCompute table, we recommend that you use Table name_Partition ID as the output name format of these nodes.

- Q: How can I avoid intermediate tables when I enable DataWorks to automatically parse node dependencies?

  A: Right-click an intermediate table name in the SQL code and select **Delete Input** or **Delete Output**. Then, click Parse I/O to parse the input and output of the node.

- Q: How do I configure dependencies for the upmost node in a workflow?

  A: You can set the node to depend on the root node of the current workspace.

- Q: Why do I find a non-existent output name of Node B when I enter an output name to search for the ancestor node for Node A?

  A: DataWorks searches for the output name among the output names of nodes that have been committed to the scheduling system. After Node B is committed, if you delete the output name of Node B and does not commit Node B to the scheduling system again, the deleted output name of Node B can still be found.

- Q: How do I enable nodes A, B, and C to run in sequence once per hour?

  A: Set the output of Node A as the input of Node B and the output of Node B as the input of Node C. Also, set nodes A, B, and C to run once per hour.

- Q: An error message is returned to indicate that the parent node ID fails to be automatically parsed based on an output table name. Why does this error occur?

  A: This error does not indicate that the table does not exist. Instead, it indicates that the table is not the output of a specific node. Therefore, the table name cannot be used to find the node that generates the table data. In this case, the dependency on the node cannot be created.

  According to the principles of automatic parsing described in this topic, a dependency is created after the output of an ancestor node is set as the input of a descendant node. If no ancestor node can be parsed based on the xc_demo_partition table referenced in SQL statements, no node uses the xc_demo_partition table as its output.

  You can resolve this problem in the following way:

  i. Find the node that generates the table data and view the node output.

     If you do not know which the target node is, you can enter keywords to search the code for the node in fuzzy match mode.

  ii. If the table data is uploaded from a local server or you do not need to depend on the node, you can right-click the table name in the code and select **Delete Input**.

  > **Note** We recommend that you write the code correctly to parse the lineage from the code and reduce custom dependencies.

2.1.5.7. Components

2.1.5.7.1. Create a script template

This topic describes the definition and composition of script templates and how to create a script template.

Definition

A script template defines an SQL code process that involves multiple input and output parameters. Each SQL code process references one or more source tables. You can filter source table data, join source tables, and aggregate them to generate a result table required for new business.

Value

In actual business, many SQL code processes are similar. The input and output tables in these processes may have the same or compatible schema but different names. In this case, developers can abstract an SQL code process as a script template to reuse the SQL code. The script template extracts input parameters from input tables and generates output parameters in output tables.

To create SQL script templates, you can select script templates from the script template list based on your business process and configure specific input and output tables in your business for the selected script templates, without repeatedly copying the code. This greatly improves the development efficiency and avoids repeated development. You can deploy and run the created SQL script templates in the same way as other SQL nodes.

Composition

Similar to a function, a script template consists of input parameters, output parameters, and an SQL code process.

Input parameters

The input parameters of a script template have the properties such as the parameter name, parameter type, parameter description, and parameter definition. The parameter type can be table or string.

- A table-type parameter specifies the table to be referenced in an SQL code process. When you use a script template, you can specify the input table required for the specific business.
- A string-type parameter specifies the variable control parameter in an SQL code process. For example, to export only the sales amount of the top N cities in each region in a result table of an SQL code process, you can use a string-type parameter to specify the value of N.

  To export the total sales amount of a province in a result table of an SQL code process, you can set a string-type parameter to specify the province and obtain the sales data of the specified province.
- The parameter description specifies the role of a parameter in an SQL code process.
- The parameter definition is a text definition of the table schema, which is required only for table-type parameters. When you specify the parameter definition for a table-type parameter, you must provide an input table that contains the same field names and compatible types defined by the table-type parameter so that the SQL code process can run properly. Otherwise, an error is returned when the SQL code process runs because the specified field name cannot be found in the input table. The input table must contain the field names and types defined by the table-type parameter. The input table can also contain other fields. The field names and types in the input table can be in any order. The parameter definition is for reference only.
- We recommend that you enter the parameter definition in the following format:

  ```
  Name of field 1 Type of field 1 Description of field 1
  Name of field 2 Type of field 2 Description of field 2
  Name of field n Type of field n Description of field n
  ```

  Examples:

  ```
  area_id string 'Region ID'
  city_id string 'City ID'
  order_amt double 'Order amount'
  ```

Output parameters

- The output parameters of a script template have the properties such as the parameter name, parameter type, parameter description, and parameter definition. The parameter type must be table. A string-type output parameter has no logical meaning.
- A table-type parameter specifies the table to be generated in an SQL code process. When you use a script template, you can specify the result table that the SQL code process generates for the specific business.
- The parameter description specifies the role of a parameter in an SQL code process.
- The parameter definition is a text definition of the table schema. When you specify the parameter definition

for a table-type parameter, you must provide an output table that contains the same number of fields and compatible types defined by the table-type parameter so that the SQL code process can run properly. Otherwise, an error is returned when the SQL code process runs because the number of fields does not match or the field type is incompatible. The field names of the output table do not need to be consistent with those defined by the table-type parameter. The parameter definition is for reference only.

- We recommend that you enter the parameter definition in the following format:

```
Name of field 1 Type of field 1 Description of field 1
Name of field 2 Type of field 2 Description of field 2
Name of field n Type of field n Description of field n
```

Examples:

```
area_id string 'Region ID'
city_id string 'City ID'
order_amt double 'Order amount'
rank bigint 'Ranking'
```

SQL code process

The parameters in an SQL code process are referenced in the following format: `@@{Parameter name}`.

By containing an abstract SQL code process, a script template controls and processes an input table based on input parameters to generate an output table with business value.

To develop an SQL code process, you must use input and output parameters in the code properly to make sure that they can be set as needed and correct SQL code can be generated and run during the process.

Create a script template

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Snippets** icon.
3. On the Snippets tab, move the pointer over and choose **Create > Snippet**.
4. In the **Create Snippet** dialog box, set **Snippet Name**, **Description**, and **Location**.
5. Click **Commit**.

Source table schema

The following table describes the schema of a source MySQL table that contains sales data.

Field	Data type	Description
order_id	varchar	The ID of the order.
report_date	datetime	The date of the order.
customer_name	varchar	The name of the customer.
order_level	varchar	The level of the order.
order_number	double	The number of orders.
order_amt	double	The amount of the order.
back_point	double	The discount.
shipping_type	varchar	The transportation method.

Field	Data type	Description
profit_amt	double	The amount of the profit.
price	double	The unit price.
shipping_cost	double	The transportation cost.
area	varchar	The region.
province	varchar	The province.
city	varchar	The city.
product_type	varchar	The type of the product.
product_sub_type	varchar	The subtype of the product.
product_name	varchar	The name of the product.
product_box	varchar	The packaging of the product.
shipping_date	datetime	The shipping date.

Business implication

Script template name: get_top_n

This script template uses the specified sales data table as the table-type input parameter, the number of the top cities as the string-type input parameter, and the total sales amount of the cities for ranking. By using this SQL code process, you can obtain the rankings of the specified top cities in each region with ease.

Script template parameters

Input parameter 1

- Parameter name: myinputtable
- Type: table

Input parameter 2

- Parameter name: topn
- Type: string

Output parameter 3

- Parameter name: myoutput
- Type: table

Parameter definition:

- area_id string
- city_id string
- order_amt double
- rank bigint

You can execute the following statement to create a table for storing the sales data of a specified number of top cities:

```
CREATE TABLE IF NOT EXISTS company_sales_top_n
(
area STRING COMMENT 'Region',
city STRING COMMENT 'City',
sales_amount DOUBLE COMMENT 'Sales amount',
rank BIGINT COMMENT 'Ranking'
)
COMMENT 'Company sales rankings'
PARTITIONED BY (pt STRING COMMENT '')
LIFECYCLE 365;
```

Example of defining an SQL code process

```
INSERT OVERWRITE TABLE @@{myoutput} PARTITION (pt='${bizdate}')
    SELECT r3.area_id,
    r3.city_id,
    r3.order_amt,
    r3.rank
from (
SELECT
    area_id,
    city_id,
    rank,
    order_amt_1505468133993_sum as order_amt ,
    order_number_150546813****_sum,
    profit_amt_15054681****_sum
FROM
    (SELECT
    area_id,
    city_id,
    ROW_NUMBER() OVER (PARTITION BY r1.area_id ORDER BY r1.order_amt_1505468133993_sum DESC)
AS rank,
    order_amt_15054681****_sum,
    order_number_15054681****sum,
    profit_amt_1505468****_sum
FROM
    (SELECT area AS area_id,
     city AS city_id,
     SUM(order_amt) AS order_amt_1505468****_sum,
     SUM(order_number) AS order_number_15054681****_sum,
     SUM(profit_amt) AS profit_amt_1505468****_sum
FROM
    @@{myinputtable}
WHERE
    SUBSTR(pt, 1, 8) IN ( '${bizdate}' )
GROUP BY
    area,
    city )
    r1 ) r2
WHERE
    r2.rank >= 1 AND r2.rank <= @@{topn}
ORDER BY
    area_id,
    rank limit 10000) r3;
```

Sharing scope

Script templates can be shared within a workspace or made public.

By default, a deployed script template is visible and available to users within the current workspace. The developer of a script template can click the **Publish Snippet** icon to make the general-purpose script template public to the current tenant account so that all users under the account can view and use the script template.

You can view the **Publish Snippet** icon in the toolbar of the configuration tab of a script template. If the icon is clickable, the script template is made public.

Use of script templates

For more information about how to use a developed script template, see Use components.

Reference records

In the script template list, double-click a script template. On the configuration tab that appears, click the **Snippet Nodes** tab in the right-side navigation pane to view the reference records of the script template.

2.1.5.7.2. Use a script template

To improve development efficiency, you can create data analytics nodes by using the script templates provided by workspace members and tenants.

Note the following points when you use script templates:

- The script templates provided by members of the current workspace are available on the **Workspace-Specific** tab.
- The script templates provided by tenants are available on the **Public** tab.

GUI elements

Icon or tab	Description
Save icon	Saves the settings of the current script template.
Steal Lock icon	Allows you to steal the lock of the current script template and then edit it if you are not the owner of the script template.
Submit icon	Commits the current script template to the development environment.
Publish Snippet icon	Makes the current general-purpose script template public to the current tenant account so that all users under the account can view and use the script template.
Parse I/O Parameters icon	Parses input and output parameters from the code. **Note** Typically, the parameters entered here are table names instead of scheduling parameters.
Run icon	Runs the current script template in the development environment.
Stop icon	Stops running the current script template.
Format icon	Formats the code based on keywords.
Parameters tab	Allows you to view the basic information and set input and output parameters for the current script template.

Icon or tab	Description
Versions tab	Allows you to view the deployed versions of the current script template.
Snippet Nodes tab	Lists the reference records of the current script template.

2.1.5.8. Custom plug-ins

2.1.5.8.1. Overview

DataStudio supports default node types such as ODPS SQL and Shell nodes. You can also create custom node types to meet your requirements.

To create a custom node type, you need to create a custom wrapper and use it to define a custom node type.

Entry

1. Log on to the DataWorks console.
2. Click **Node Market** in the upper-right corner to go to the node configuration page.

> **Note** Only the workspace owner and administrators can access this page.

View the list of wrappers

The Wrappers page displays all the wrappers you have created. You can click **Create** in the upper-right corner to create a custom wrapper.

The values displayed in the Latest Version, Version in Development, and Version in Production Environment columns for the created wrappers follow these rules:

- If a created wrapper has not been deployed, the values of both the Version in Development and Version in Production Environment columns are **Not Deployed**.
- If a wrapper has been deployed, the version and the deployment time appear in these columns.
- If a wrapper is under deployment, the values of both the Version in Development and Version in Production Environment columns are **Deploying**.

You can click **Settings**, **View Versions**, or **Delete** in the Actions column of each wrapper.

Action	Description
Settings	You can click **Settings** to configure the wrapper. The page that appears depends on the wrapper status. The **Deploy in Production Environment** page appears if the wrapper has been deployed in the production environment.
View Versions	You can click **View Versions** to view all historical versions of the wrapper. • **View**: You can click this button to view the settings of the selected version. • **Roll Back**: You can click this button to roll back to the selected version. After you click this button, the system creates a new version for the wrapper. In the new version, the wrapper uses the basic settings and the resource file of the selected version. The new version number equals the latest version number among all the versions plus 1. • **Download**: You can click **Download** to download the resource file of the selected version.

Action	Description
Delete	If an error occurs while a node type is using the wrapper, you need to delete the node type. **Note** Before deleting a wrapper, ensure that no node type is associated with the wrapper.

Create a custom wrapper

A wrapper is the core processing logic of a node type. For example, after you compile an SQL statement in the editor for an ODPS SQL node and submit the statement, the system calls the corresponding wrapper to parse and run the statement. You need to create a wrapper before creating a custom node type. Currently, only the Java programming language is supported.

The procedure of creating a wrapper includes four steps: specify settings for the wrapper, deploy the wrapper in the development environment, test the wrapper in the development environment, and deploy the wrapper in the production environment. For more information, see Create a custom wrapper.

View the list of custom node types

The Custom Node Types page displays all custom node types in the workspace. You can click **Create** in the upper-right corner to create a custom node type. For more information, see Create a custom node type.

Currently, you can only create custom node types in DataStudio.

The workspace owner or node type creator can **change** or **delete** existing node types.

- **Change**: You can click **Change** to edit the settings for the node type as needed.
- **Delete**: You can click this button to delete the node type that no node uses. If any node uses the node type, a message appears, indicating that you need to disable the node first before deleting the node type.

Use a custom node type

After creating a custom node type, go to the **Data Analytics** page.

Move the pointer over the **Create** icon and click **Data Analytics**. In the list that appears, select the created node type to create a node.

2.1.5.8.2. Create a custom wrapper

The procedure of creating a wrapper includes four steps: specify settings for a wrapper, deploy the wrapper in the development environment, test the wrapper in the development environment, and deploy the wrapper in the production environment.

Specify settings for a wrapper

1. Click **Wrappers** in the left-side navigation pane. On the page that appears, click **Create** in the upper-right corner.
2. Specify the parameters in the **Settings** step.

Parameter	Description
Name	The name of the wrapper. It must start with a letter and can only contain letters, digits, and underscores (_).

Parameter	Description
Owner	The owner of the wrapper. You can select an owner from the workspace members. You are not allowed to edit wrappers owned by other members even if you are an administrator. Only the workspace owner can edit the wrappers of other members.
Resource Type	The type of the resource package for configuring the wrapper. Valid values: **JAR** and **Archive**. The size of the resource package can be up to 50 MB.
Resource File	The local resource file or OSS object for configuring the wrapper. **Note** The size of a local file can be up to 50 MB, and the size of a file that is stored in an OSS bucket can be up to 200 MB.
Class Name	The full path of the class for implementing the user wrapper.
Parameter Example	The parameters designed based on the JAR package you upload.
Version	The version of the configured wrapper. Select Create Version if you are creating a new wrapper. Select Overwrite Version if you are editing and rolling back a version. **Note** The version number is automatically generated.
Description	The description of the wrapper version.

3. Click **Save** and then click **Next**.

> **Note** The settings are updated to the database after you click Save.
> - If you only modify basic settings of a wrapper without changing the resource file, the modification takes immediate effect after you click Save.
> - If you change the resource file, the change only applies after deployment.

Deploy the wrapper in the development environment

After you specify the parameters in the **Settings** step and click **Next**, the information in the Deploy in Development Environment step is updated accordingly. You can identify the changes by checking the file name and MD5 checksum.

Click **Deploy in Development Environment**. You can view the **deployment progress** in real time. After the wrapper is deployed, click **Next**.

Test the wrapper in the development environment

Specify the parameters for testing and click **Test** to send the parameters to the wrapper. This step is to validate the deployment and logic of the wrapper. You can also locally test the wrapper before uploading it for deployment.

After the test, review the output logs in the Test Results section on the right to determine whether the test is passed. If the test is passed, select **Test Passed** and click **Next**.

> **Note** The **Next** button is operable only after you select **Test Passed**.

Deploy the wrapper in the production environment

Click **Deploy in Production Environment**. In the **Confirm** dialog box that appears, click **OK**. The wrapper is deployed in the production environment. You can view the deployment progress in real time.

> **Note** The wrapper to be deployed in the production environment must be of the latest version, have been deployed in the development environment, and have passed the test. Otherwise, a message appears, indicating that the deployment in the production environment fails.

Click **Complete**. You can view and edit the created wrapper on the **Wrappers** page.

2.1.5.8.3. Create a custom node type

The Configure Custom Node Type page consists of three sections: Basic Information, Interaction, and Wrapper.

1. On the DataStudio page, click **Node Market** in the top navigation bar. On the page that appears, click **Custom Node Types** in the left-side navigation pane.
2. Click **Create** in the upper-right corner.
3. Specify the parameters in the **Basic Information** section.

Parameter	Description
Name	The name of the node type, which cannot be changed after being saved. Each node type has a unique name within the workspace. The name can be up to 20 characters in length, and can only contain letters, spaces, and underscores (_).
Icon	The icon of the node type.
Tabs	The template of the node type. Currently, only **Data Analytics** is available.
Folder	The folder where the node type belongs. You can select **Data Integration** or **Data Analytics**.

4. Specify the parameters in the **Interaction** section.

Parameter	Description
Shortcut Menu	◦ The options to appear in the shortcut menu. The following options are selected by default: Rename, Move, Clone, Steal Lock, View Versions, Locate in Operation Center, Delete, and Submit for Review. ◦ More options include Edit, Copy Resource Name, and Send to DataWorks Desktop (Shortcut).
Tool Bar	◦ The options to appear in the top navigation bar. The following options are selected by default: Save, Commit, Commit and Unlock, Steal Lock, Run, Show/Hide, Run with Arguments, Stop, Reload, Run Smoke Test in Development Environment, View Smoke Test Log in Development Environment, Run Smoke Test, View Smoke Test Log, Go to Operation Center of Development Environment, and Format. ◦ More options include Operation Center, Deploy, and Precompile.
Editor Type	The type of the editor. Currently, only **Editor Only** is available.
Right-Side Bar	◦ The options to appear in the right-side bar. The following options are selected by default: Code Structure and Properties. ◦ More options include Version, Lineage, and Parameters.

Parameter	Description
Auto Parse Option	Specifies whether to display the Auto Parse option for this type of node. If you turn on this switch, the Auto Parse option is displayed on the Properties tab. Otherwise, it is not displayed. In an automatic parsing process, the system parses the input and output of a node based on the lineage specified in the code.

5. Specify the parameters in the **Wrapper** section.

Parameter	Description
Wrapper	The wrapper used for running the type of node. Select a wrapper that has been deployed.
Editor Language	The language used for writing the code in the editor. Currently, only ODPS SQL is available.
Use MaxCompute as Engine	Specifies whether to use MaxCompute as the compute engine. If your wrapper uses MaxCompute as the compute engine, select Yes. Otherwise, select No. Default value: Yes.

6. Click **Save and Exit**. Then, go to the **Data Analytics** page to use the custom node type that is created.

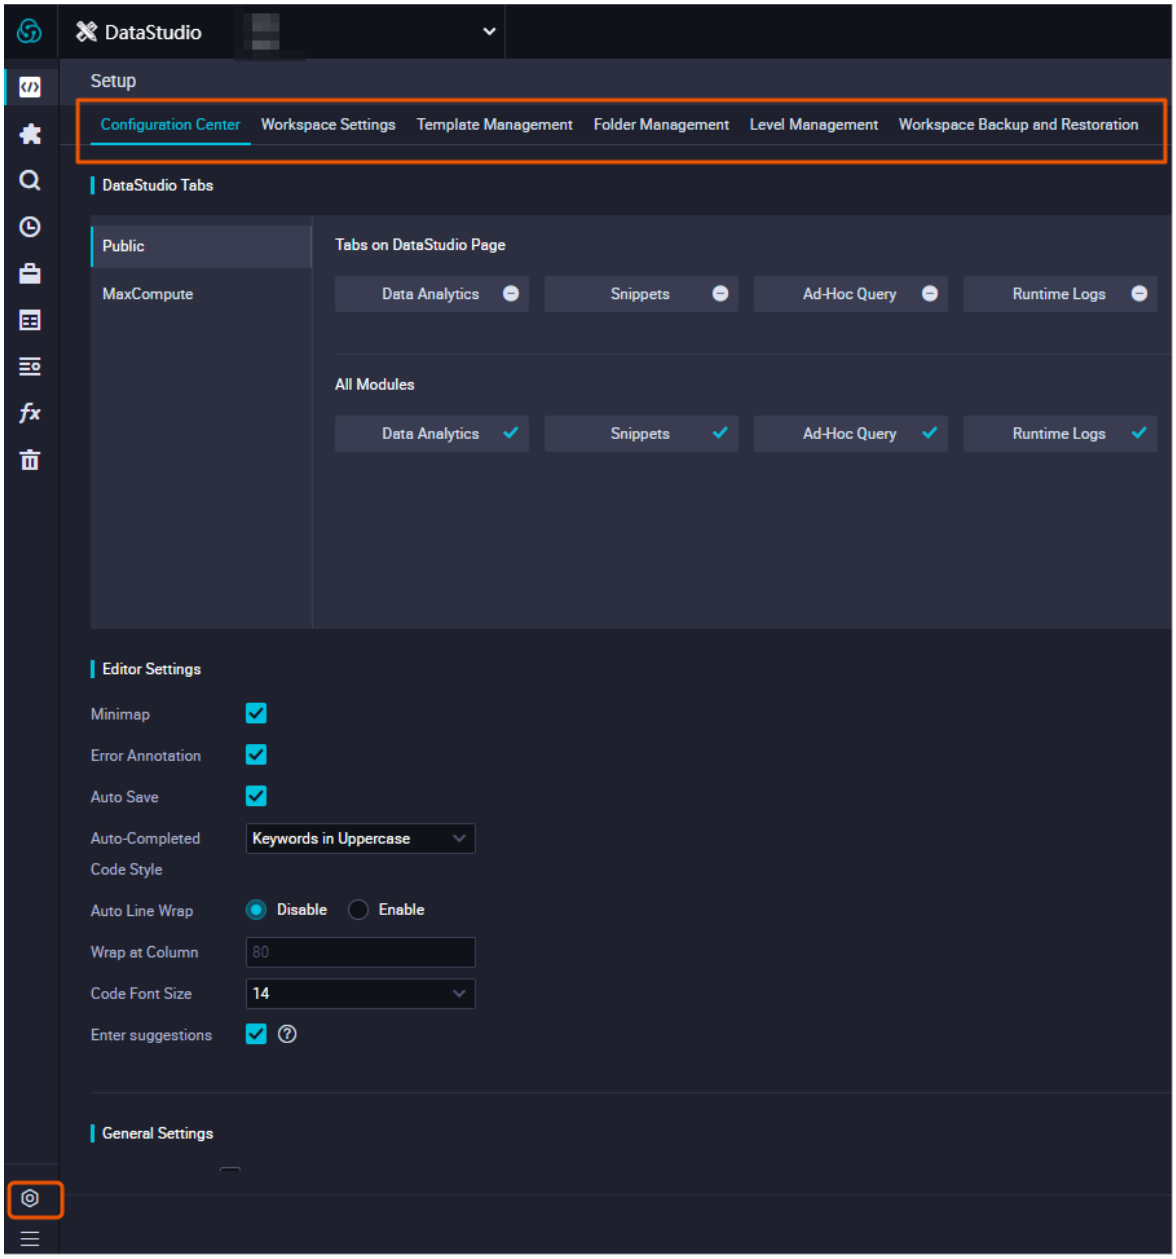
2.1.5.9. Setup

2.1.5.9.1. Setup

On the Setup page, you can add and delete modules. You can also configure code templates, folders, and table levels on this page.

Procedure

1. Log on to the DataWorks console.
2. Click  in the lower-left corner of the **DataStudio** page to go to the **Setup** page.



You can perform operations on the following tabs:

- Configuration Center
- Project Configuration
- Template management
- Folder management
- Level management

2.1.5.9.2. Configuration center

You can combine your DataStudio modules and specify editor settings on the Configuration Center tab.

Go to Configuration Center

1. Log on to the DataWorks console.
2. Click in the lower-left corner of the **DataStudio** page. The **Configuration Center** tab appears.

The Configuration Center tab includes three sections: **DataStudio Tabs**, **Editor Settings**, and **General Settings**. After the configurations are completed, you can click **Apply to All Workspaces** in the lower-right corner of the page to apply the settings to all existing workspaces.

DataStudio tabs

On the **DataStudio Tabs** tab, you can add and delete public and MaxCompute functional modules, and drag modules to change their orders.

- Under **Tabs on DataStudio Page**, click next to a module to delete it. Deleted modules will not appear in the left-side navigation pane of the **DataStudio** page.
- Under **All Modules**, click the desired module to add it. Added modules will appear in the left-side navigation pane of the **DataStudio** page.

> **Note** The module settings take effect immediately for the current workspace. To make the module settings effective for all workspaces, click **Apply to All Workspaces** in the lower-right corner of the page.

Editor settings

You can configure the code editor in the Editor Settings section. The editor settings take effect immediately for the current workspace without requiring you to refresh the page.

- **Minimap**

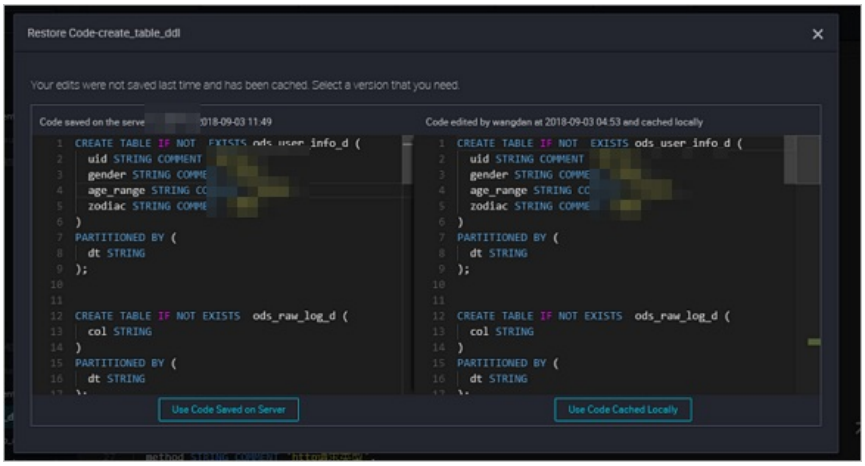
  The masked code in the current interface is displayed in the minimap in the upper-right corner of the page. When the code is long, you can move the pointer to specify the code block to be displayed in the minimap.

- **Error Annotation**

If you select this check box, DataWorks marks potential syntax errors with a red squiggly line. When you see a syntax error, you can move the pointer over the underlined code to view the error message.

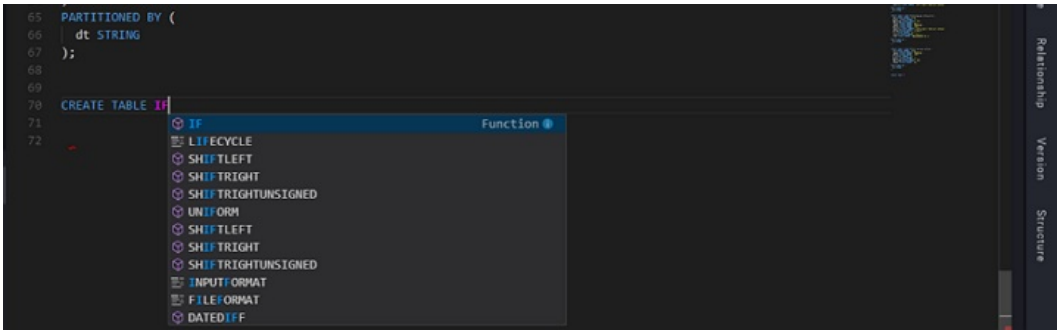
- **Auto Save**

  If you select this check box, DataWorks automatically saves the code being edited at a specific interval. In this way, if the code editor of a node is closed unexpectedly, you can click **Use Version Saved on Server** or **Use Version Saved in Local Cache** to re-open the node.



- **Auto-Completed Code Style**

  You can set the code style to uppercase or lowercase as required.



- **Auto Line Wrap**

  You can set Auto Line Wrap to **Disable** or **Enable**.

- **Wrap at Column**
  - If Auto Line Wrap is set to **Disable**, the value of Wrap at Column is 80 by default, which cannot be modified.
  - If Auto Line Wrap is set to **Enable**, you can set a value for Wrap at Column as required.

- **Code Font Size**

  Valid values: 12 to 18. You can change the font size based on your habits and code size.

- **Enter suggestions**

  If you select this check box, the system automatically displays suggestions on how to set a field when you press Enter. If you clear this check box, a new line is started after you press Enter. In addition to the Enter key, you can also use the Tab key to enter prompted suggestions.

- **Auto Completion**

  You can specify whether to enable the following code hints when you enter the code:

  - **Continuous Smart Tips**: specifies whether to automatically add a space after each auto-completed term such as a keyword, table name, or field name.
  - **Keyword**: specifies whether to enable keyword hints.
  - **Syntax Template**: specifies whether to enable syntax template hints.
  - **Project**: specifies whether to enable project name hints.
  - **Table Name**: specifies whether to enable table name hints. When this feature is enabled, the system gives higher priority to tables used recently.
  - **Field**: specifies whether to enable field name hints.

General settings

- **Display Node Engine Information on DAG**

  You can specify whether to display node engine information on the DAG.

- **Theme**

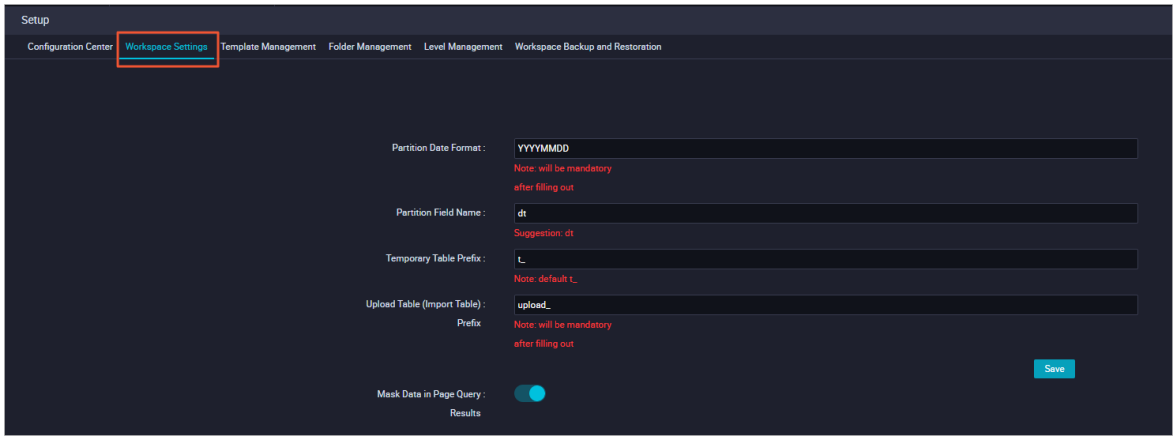
  You can set the DataStudio theme to black or white.

2.1.5.9.3. Configure a workspace

The Workspace Settings tab displays five parameters: Partition Date Format, Partition Field Name, Temporary Table Prefix, Upload Table (Import Table) Prefix, and Mask Data in Page Query Results.

Go to the Workspace Settings tab

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the lower-left corner.
3. On the **Setup** page, click the **Workspace Settings** tab.



Parameter	Description
Partition Date Format	The default date format of partition field values. You can modify the format based on your business requirements.

Parameter	Description
Partition Field Name	The default name of the partition field.
Temporary Table Prefix	The prefix of temporary table names. By default, tables with the prefix t_ in their names are identified as temporary tables.
Upload Table (Import Table) Prefix	The prefix of the names of tables uploaded on the **DataStudio** page.
Mask Data in Page Query Results	Specifies whether to mask the data in query results. If the switch is turned on, the result returned for an ad hoc query node in the current workspace is masked.

Enable data masking for DataWorks workspaces

Data masking needs to be enabled for DataWorks workspaces one by one. After data masking is enabled, the results returned for ad hoc query nodes in the current workspace are masked. The data stored at underlying layers is not affected because only dynamic data masking is performed. For example, data masking is enabled for Workspace A but is disabled for Workspace B. If you initiate a request in Workspace B to query tables in Workspace A, the query result is displayed in plaintext.

On the **Workspace Settings** tab, turn on **Mask Data in Page Query Results**. Then, click **Save** in the lower-right corner of the tab. The results returned for ad hoc query nodes in the current workspace will be masked.

> **Note** By default, the Mask Data in Page Query Results switch is turned off, and you are not allowed to download data.

After data masking is enabled for a DataWorks workspace, data of the types listed in the following table is masked by default.

Type	Data masking rule	Raw data	Data after masking
ID card number	Only the first and last digits in a 15- or 18-digit ID card number are displayed in plaintext. All the other digits are displayed as asterisks (*).	512345678943215678	5**********8
Mobile phone number	Only the first three and last two digits in a mobile number in mainland China are displayed in plaintext. All the other digits are displayed as asterisks (*).	18112345678	181******78
Email address	If the string before the at sign (@) in an email address contains three or more characters, only the leftmost three characters are displayed in plaintext, followed by three asterisks (*). If the string before the at sign (@) contains only one or two characters, the entire string is displayed in plaintext, followed by three asterisks (*).	• eftry.abc@gmail.com • af@abc.com	• eft***@gmail.com • af***@abc.com
Bank card number	Only the last four digits in a credit or deposit card number are displayed in plaintext. All the other digits are displayed as asterisks (*).	• 1234576834509782 • 643257829145430986	• **********9782 • **********0986

Type	Data masking rule	Raw data	Data after masking
IP address or MAC address	Only the first segment in an IP address or a MAC address is displayed in plaintext. All the other characters are displayed as asterisks (*).	• 192.000.0.0 • ab:cd:11:a3:a0:50	• 192.***.*.* • ab:**:**:**:**:**
License plate number	Only the one-character provincial abbreviation and the last three characters in a license plate number in mainland China are displayed in plaintext. All the other characters are displayed as asterisks (*).	• (One-character provincial abbreviation)AP555B • (One-character provincial abbreviation)ADP555T	• (One-character provincial abbreviation)A**55B • (One-character provincial abbreviation)A***55T

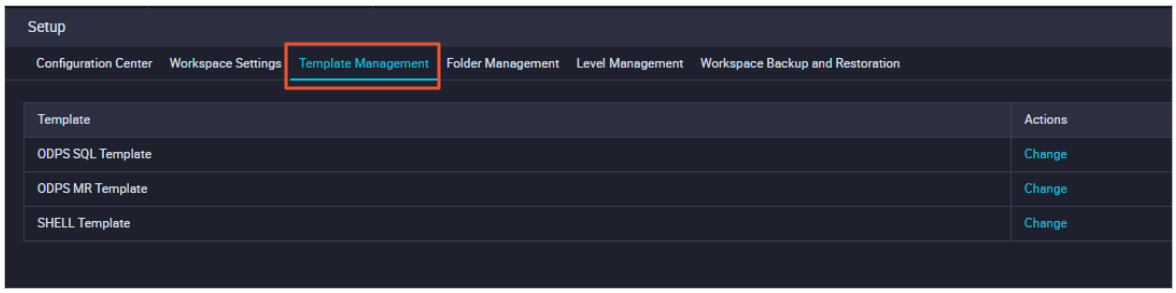
Note If you want to mask more types of data or have special requirements on the formats in which data is masked, complete your data masking settings in Data Protection. The data masking feature for DataWorks workspaces must work with Data Protection. For more information, see Overview of Data Protection.

2.1.5.9.4. Template management

The Template Management page displays code templates. Workspace administrators can change the display formats of the templates as required.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Template Management** tab.



Note Templates are only available for ODPS SQL, ODPS MR, and Shell nodes.

4. Find the target template and click **Change** in the Actions column.
5. In the **Node Template** dialog box, enter the template as required.
6. Click **Save**.

2.1.5.9.5. Folder management

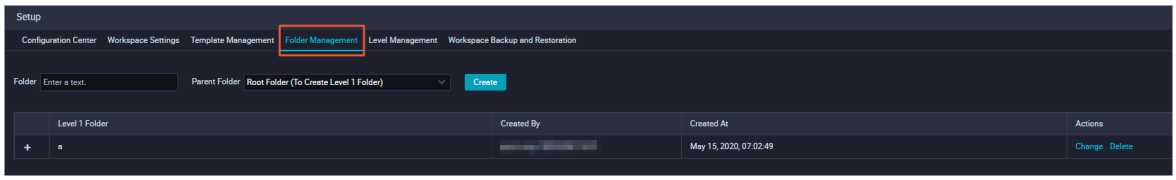
Each workspace can hold a great number of tables. For easy management, you can organize tables in two levels of folders.

Context

Folders are used to store tables. A workspace administrator can add multiple folders and classify tables by purpose and name.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Folder Management** tab.



On the page that appears, you can add, modify, and delete folders.

- Add a folder

  Enter a custom folder name in the **Folder** field, select a parent folder from the **Parent Folder** drop-down list, and then click **Create**.

- Modify a folder

  Find the target folder and click **Change** in the Actions column. In the **Change Folder** dialog box, enter a new folder name and click **OK**.

- Delete a folder

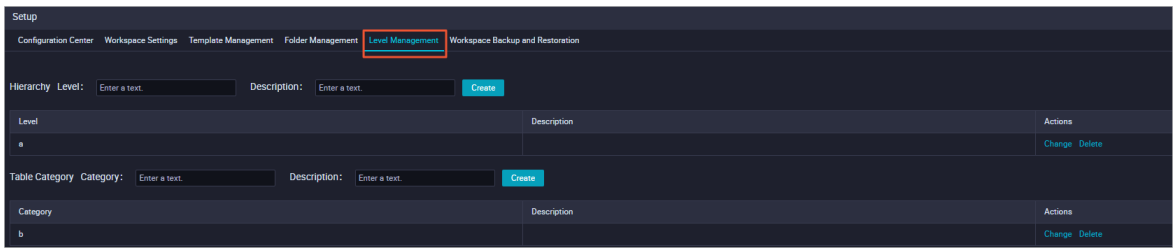
  Find the target folder and click **Delete** in the Actions column. In the **Delete Folder** message, click **OK**.

2.1.5.9.6. Level management

On the Level Management tab, you can design physical levels of tables.

Procedure

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Level Management** tab.



You can classify tables based on their importance. Level management allows you to precisely locate incorrectly organized tables and ensures normal running of published jobs.

If a workspace does not contain default table levels, the workspace owner or workspace administrator must add them as required.

On the **Level Management** tab, you can add, modify, and delete table levels.

- To add a table level, perform the following steps:
  a. In the **Hierarchy** section, set **Level** and **Description**.
  b. Click **Create**.
- To modify a table level, perform the following steps:
  a. Find the target table level and click **Change** in the Actions column.
  b. In the **Change Level** dialog box, modify **Level** and **Description** as needed.
  c. Click **OK**.
- To delete a table level, perform the following steps:
  a. Find the target table level and click **Delete** in the Actions column.
  b. In the **Delete Level** message, click **OK**.

On the **Level Management** tab, you can also add, modify, and delete table categories.

- To add a table category, perform the following steps:
  a. In the **Table Category** section, set **Category** and **Description**.
  b. Click **Create**.
- To modify a table category, perform the following steps:
  a. Find the target table category and click **Change** in the Actions column.
  b. In the **Change Category** dialog box, modify **Category** and **Description** as needed.
  c. Click **OK**.
- To delete a table category, perform the following steps:
  a. Find the target table category and click **Delete** in the Actions column.
  b. In the **Delete Category** message, click **OK**.

2.1.5.9.7. Workspace backup and restore

On the Workspace Backup and Restoration tab, you can migrate code between workspaces. This topic describes how to back up and restore a workspace.

Prerequisites

Workspaces are created. For more information, see Create a workspace.

Go to the Workspace Backup and Restoration tab

1. Log on to the DataWorks console.
2. On the **Data Analytics** tab, click in the lower-left corner.
3. On the **Setup** page, click the **Workspace Backup and Restoration** tab.

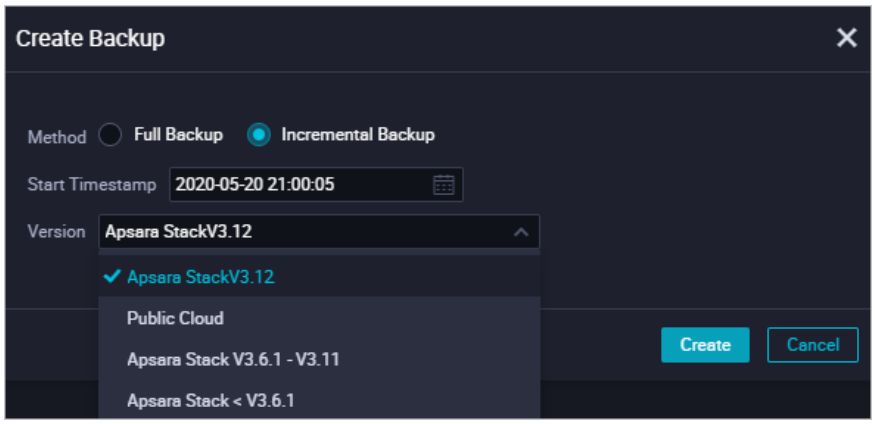
   On the page that appears, you can back up and restore workspaces.
   - On the Backup tab, you can compress the node code, node dependencies, resources, and functions in a workspace into one package.
   - On the Restore tab, you can restore a workspace to its original scheduling settings. After the workspace is restored, all nodes in the workspace are saved but not committed.

Back up a workspace

A workspace backup is a compressed package containing the node code, node dependencies, resources, and functions in the workspace.

- Only workspace administrators can export backups and restore data from backups.
- Workflows and node groups of earlier versions cannot be backed up. We recommend that you use the latest version for data analytics.
- A node backed up to a path in the workspace will override the original node with the same name in the path. We recommend that you create another workspace to restore data.
- Data in tables is not backed up when you back up a workspace. You can synchronize the table data in the following ways:
  - Click the **Workspace Manage** icon in the upper-right corner. On the page that appears, click **Data Source** and configure a MaxCompute connection. Then, create a sync node to back up the data.
  - In workspace A, run the data definition language (DDL) statement `create table select * from workspace B. Table name` to migrate data.

1. On the **Workspace Backup and Restoration** tab, click **Backup**.
2. Click **Create Backup** in the upper-right corner.
3. In the **Create Backup** dialog box, set the parameters as required.



Parameter	Description
Method	The method used to back up the workspace. Valid values: ○ **Full Backup**: Back up all the node code, node dependencies, resources, and functions in the workspace. ○ **Incremental Backup**: Back up all the new or modified nodes from the timestamp specified by the **Start Timestamp** parameter to the current time. **Note** If you use the incremental backup method, make sure that the dependencies between incremental sync nodes are correct. Otherwise, the workspace may fail to be restored. We recommend that you set this parameter to **Full Backup**.
Start Timestamp	The start time point at which data in the workspace is backed up. This parameter is available only when you set **Method** to **Incremental Backup**.
Version	The version of the workspace to be backed up. Valid values: **Apsara StackV3.12**, **Public Cloud**, **Apsara Stack V3.6.1 - V3.11**, and **Apsara Stack < V3.6.1**.

4. Click **Create**.

   After the data is backed up, click **Download** to download the backup data to a local device.

Restore a workspace

1. On the **Workspace Backup and Restoration** tab, click **Restore**.
2. Click **Restore** in the upper-right corner.
3. In the **Restore** dialog box, click **Select File**.

   > **Note** You can upload the compressed package that you previously backed up to the workspace.

4. Click **Restore**.
5. Click **Set Compute Engine Mapping**. In the dialog box that appears, set the mapping between the compute engines of the current workspace and the destination workspace.
6. Click **OK**.

   If the workspace that you backed up contains multiple compute engines, the system scans all compute engine instances during restoration. The system only restores nodes of the existing compute engines in the workspace to be restored. In this case, you must configure the mappings between the compute engines before restoring the destination workspace.

   > **Note**
   > - If the workspace to be restored does not contain a compute engine type such as E-MapReduce, or no instance is available for the compute engine type, nodes of this engine type are not restored.
   > - Compute engine mappings must be configured for custom node types.

2.1.5.10. Deploy

2.1.5.10.1. Deploy nodes

In a rigorous data development process, developers develop and debug code and configure dependencies and scheduling properties for nodes in the development environment. Then, developers commit and deploy the nodes to run them in the production environment.

DataWorks workspaces in standard mode can process data seamlessly from the development environment to the production environment within a single workspace. We recommend that you use workspaces in standard mode to develop and produce data.

Deploy nodes in a workspace in standard mode

Each DataWorks workspace in standard mode is linked with two MaxCompute projects, one as the development environment and the other as the production environment. You can directly commit and deploy nodes from the development environment to the production environment.

Follow these steps:

1. On the **DataStudio** page, configure and debug the code of nodes. Then, double-click the target workflow in the left-side navigation pane. On the dashboard of the workflow that appears, click the **Submit** icon to check whether the dependencies between nodes are correct and commit the nodes.
2. After the nodes are committed, click the **Deploy** icon.
3. On the **Create Deploy Task** page that appears, select the target nodes and click **Add to List**. The nodes are added to the to-be-deployed node list.

   You can search for nodes by condition, such as the committer, node type, change type, time when a node is committed, node name, and node ID. If you click Deploy Selected, the selected nodes are deployed to the production environment.

4. Click **View List**. In the Nodes to Deploy dialog box that appears, click **Deploy All**. All nodes in the list are

deployed to the production environment.

> **Note** Workspaces in standard mode protect tables in the production environment from being manipulated, and therefore provide the stable, secure, and reliable production environment. We recommend that you use workspaces in standard mode to deploy and run nodes.

Clone nodes between workspaces in basic mode

You cannot deploy nodes in workspaces in basic mode. If you want to isolate the development environment from the production environment for workspaces in basic mode, create two workspaces, one for development and the other for production. You can clone nodes from the development workspace to the production workspace.

As shown in the following figure, two workspaces in basic mode are created, one for development and the other for production. You can use the cross-workspace cloning feature to clone nodes from Workspace A to Workspace B, and then commit the cloned nodes to the scheduler for scheduling.

> **Note**
> - Permission requirement: Only workspace administrators and Resource Access Management (RAM) users who have the O&M permissions can clone nodes.
> - Workspace type: You can only clone nodes in workspaces in basic mode, but cannot clone those in workspaces in standard mode.
> - Prerequisites: The source workspace in basic mode and the destination workspace in basic mode are created.

1. Commit nodes.

   After you create and configure nodes in the source workspace, commit the nodes on the dashboard of the target workflow.

2. Click **Cross-Workspace Cloning**.
3. On the Create Clone Task page that appears, select the target nodes and the destination workspace, and then click **Add to List**.
4. Clone the nodes. Click **View List**. In the To-Be-Cloned Nodes dialog box that appears, check the nodes to be cloned and click **Clone All**.

   In the Create Clone Task dialog box that appears, click **Clone**.

5. View the cloned nodes.

   You can view the successfully cloned nodes on the View Clone Tasks page of the source workspace.

   Switch to the destination workspace. You can find that the nodes are cloned from the source workspace.

2.1.5.10.2. Overview of cross-workspace cloning

For workspaces under the same Apsara Stack tenant account, you can use the cross-workspace cloning feature to clone and deploy workflows across these workspaces. You can also use this feature to clone nodes, such as computing or sync nodes, across workspaces. This topic describes how to process the dependencies between nodes during cross-workspace cloning.

If you clone nodes across workspaces by using the **cross-workspace cloning** feature, DataWorks automatically changes the output names of the cloned nodes in the destination workspace to distinguish nodes in different workspaces under the same Apsara Stack tenant account. This allows you to successfully clone node dependencies.

> **Note** **Cross-workspace cloning** cannot be used to clone nodes across workspaces in different regions.

You can set the owner of cloned nodes in the destination workspace to **Default** or **Clone Task Creator**.

- If you clone nodes owned by the workspace administrator:

  After the nodes are cloned to the destination workspace, their owner is set to the original owner preferentially. If the original owner is not added to the destination workspace, you will become the owner.

- If you clone nodes owned by yourself:

  After the nodes are cloned to the destination workspace, their owner is set to you preferentially. If you are not added to the destination workspace, you are asked whether to change the owner. If you agree to change the owner, you will be added to the destination workspace and become the owner of the cloned nodes. If you do not agree to change the owner, the clone task is canceled.

Clone a workflow

Assume that the output of the task_A node in the project_1 workspace is project_1.task_A_out. If you clone a workflow that contains the task_A node to the destination workspace project_2, the node output name changes to project_2.task_A_out in the destination workspace.

Clone node dependencies

Assume that the task_ B node in the project_1 workspace depends on the task_A node in the project_3 workspace. If you clone the task_B node in the project_1 workspace to the destination workspace project_2, the dependency between the task_A and task_B nodes is also cloned. The task_B node in the project_2 workspace also depends on the task_A node in the project_3 workspace.

2.1.5.10.3. Clone nodes across workspaces

This topic describes how to clone nodes across workspaces with an example of cloning a workflow from one workspace to another.

Prerequisites

Two workspaces named Weisong_dataworks_test and Weisong_dataworks_test2 respectively are created. For more information about how to create a workspace, see Create a workspace.

Context

You can clone nodes across workspaces in the following scenarios:

- Clone nodes from a workspace in the basic mode to another workspace in the basic mode.
- Clone nodes from a workspace in the basic mode to another workspace in the standard mode.

After you clone a node, the folder and workflow to which the node belongs are cloned to the destination workspace. Any change to the node, folder, or workflow can also be cloned to the destination workspace.

Procedure

1. Log on to the DataWorks console. On the DataStudio page that appears, switch to the Weisong_dataworks_test workspace in the top navigation bar.
2. Select the target workflow.

   In the Data Analytics section, double-click the target workflow. On the workflow configuration page that appears, click **Cross-Workspace Cloning** in the upper-right corner. The Create Clone Task page appears.
3. Select the destination workspace, node type, and change type.

   On the **Create Clone Task** page, set **Target Workspace** to Weisong_dataworks_test2. Select the node type and change type of the node for the clone task as required, and select one or more target nodes that appear in the list. Then, click **Clone Selected**.
4. In the **Create Clone Task** dialog box that appears, check the destination workspace, target node, and change type, and then click **Clone**.

5. After the system message that indicates the target node is cloned successfully and is being committed to the destination workspace appears, switch to the Weisong_dataworks_test2 workspace. In the **Data Analytics** section, view the workflow that has been successfully cloned to the current workspace.

2.1.5.11. Create an ad hoc query node

The Ad-Hoc Query tab allows you to test your code in the development environment. You can check for errors and check whether your code works as expected.

Context

You do not need to commit and deploy ad hoc query nodes or configure scheduling policies for ad hoc query nodes. You can configure scheduling policies only for nodes created under **Business Flow** on the **Data Analytics** tab.

Create a folder

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Ad-Hoc Query** icon.

   Click  in the lower-left corner to show or hide the left-side navigation pane.
3. On the Ad-Hoc Query tab, move the pointer over  and select **Folder**.
4. In the **Create Folder** dialog box, set **Folder Name** and **Location**.

   > Note
   > - The folder name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
   > - DataWorks supports multi-level folders. You can save a newly created folder under another folder that already exists.
5. Click **Commit**.

Create an ad hoc query node

You can create **ODPS SQL** and **Shell** nodes on the **Ad-Hoc Query** tab. This topic describes how to create an ODPS SQL node.

1. On the **Ad-Hoc Query** tab, right-click the target folder and choose **Create Node > ODPS SQL**.
2. In the **Create Node** dialog box, set **Node Name** and **Location**.

   > Note The node name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.
3. Click **Commit**.
4. On the node configuration tab that appears, enter an SQL statement.
5. Click  in the toolbar.

2.1.5.12. View runtime logs

The Runtime Logs tab displays the records of all nodes that have been run in the last three days. You can click a node to view its runtime logs.

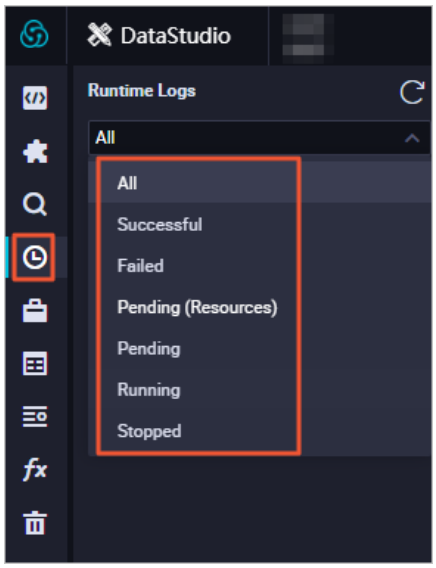
Context

The runtime logs are retained for only three days.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Runtime Logs** icon.

   Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. Select a node state from the drop-down list to view the runtime logs of nodes in the specified state.



4. Click a record to view the runtime log on the right.

   If you need to save the SQL statements in the runtime log, click in the toolbar. In the **Create Node** dialog box, set the parameters and click **Commit** to save the SQL statements that have been run as an ad hoc query node.

2.1.5.13. View tenant tables

On the Tenant Tables tab, you can view tables of all workspaces of the current tenant account.

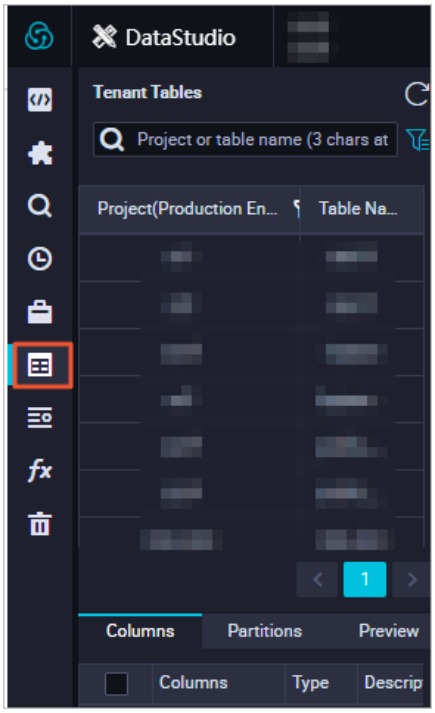
Prerequisites

The **Tenant Tables** tab appears only after you bind a MaxCompute compute engine on the **Project Management** page. For more information, see Configure a workspace.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Tenant Tables** icon.

   Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. View MaxCompute tenant tables.



Parameter or tab	Description
Project Name	The name of the workspace in the corresponding environment. Click next to the search box and select the target environment to switch to the environment. **Note** ◦ For a workspace in standard mode, the **Tenant Tables** tab displays tables in both the development environment and the production environment. For a workspace in basic mode, the **Tenant Tables** tab displays only the tables in the production environment. ◦ The current environment is marked in blue.
Table Name	The name of the table in the corresponding workspace.
Columns tab	Displays the name, data type, and description of fields in the table.
Partitions tab	Displays the partition information of the current table. A maximum of 60,000 partitions are supported. If you have specified the TTL for partitions, the number of partitions depends on the TTL. **Notice** The partition information is displayed only for MaxCompute tenant tables.
Preview tab	Displays the data of the current table. **Notice** You can preview only the data of MaxCompute tenant tables.

2.1.5.14. Manage tables

This topic describes how to view, modify, and delete MaxCompute tables, and the basic knowledge about data hierarchy.

Prerequisites

The **Workspace Tables** tab appears only after you bind a MaxCompute compute engine on the **Project Management** page. For more information, see Configure a workspace.

Manage tables

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Workspace Tables** icon.

   Click in the lower-left corner to show or hide the left-side navigation pane.

3. View and manage tables.

   The following section describes how to view, modify, and delete a MaxCompute table. For more information about how to create a table, see Create a MaxCompute table.

Operation	Description
View a table	Click next to the search box and select the target environment to switch to the environment. **Note** ◦ For a workspace in standard mode, the **Workspace Tables** tab displays tables in both the development environment and the production environment. For a workspace in basic mode, the **Workspace Tables** tab displays only the tables in the production environment. ◦ The current environment is marked in blue. Double-click a table to view its details on the table configuration tab.
Import data to a table	On the **Workspace Tables** tab, click to import data to a table. For more information, see Create tables and import data.

Divide a data warehouse into layers

In the **Physical Model** section of the configuration tab of a table, you can define table layers for a data warehouse. This allows you to have better planning and control over your data.

Typically, a data warehouse consists of the following layers:

- ODS: The ODS layer stores raw data of the source system based on the original data structure. The ODS layer serves as the data staging area of the data warehouse. It imports basic data to MaxCompute and records historical changes of basic data.
- CDM: The CDM layer consists of the dimension data (DIM), data warehouse detail (DWD), and data warehouse service (DWS) layers. The CDM layer processes and integrates the data of the ODS layer to define conformed dimensions, create reusable detailed fact tables for data analysis and statistics collection, and aggregate common metrics.

- The DIM layer defines conformed dimensions for an enterprise based on the concepts of dimensional modeling. It reduces the risk of inconsistent statistical criteria and algorithms.

  Tables at the DIM layer are also called logical dimension tables. Generally, each dimension corresponds to a logical dimension table.

- The DWS layer is driven by analyzed subjects during data modeling. Based on the metric requirements of upper-layer applications and products, the DWS layer creates fact tables to aggregate common metrics and builds a physical data model by using wide tables. The DWS layer creates statistical metrics in compliance with uniform naming conventions and statistical criteria, provides common metrics for the upper layer, and generates aggregate wide tables and detailed fact tables.

  Tables at the DWS layer are also called logical aggregate tables, which are used to store derived metrics.

- The DWD layer is driven by business processes during data modeling. It creates detailed fact tables at the finest granularity based on each specific business process. In combination with the data usage habits of an enterprise, you can duplicate some key attribute fields of dimensions in detailed fact tables to create wide tables.

  Tables at the DWD layer are also called logical fact tables.

- ADS: The ADS layer stores personalized statistical metrics of data products. It processes the data of the CDM and ODS layers.

2.1.5.15. View built-in functions

The Built-In Functions tab displays functions built in MaxCompute. You can view the types, description, and examples of functions on this tab.

Procedure

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Built-In Functions** icon.

   Click ☰ in the lower-left corner to show or hide the left-side navigation pane.

3. View the types, description, and examples of the built-in functions.

   Functions are categorized into aggregate functions, analytic functions, date functions, mathematical functions, string functions, and other functions. The preceding functions are built in MaxCompute. You can click a function to view its description.

2.1.5.16. Manage deleted nodes

DataWorks provides a recycle bin to store all deleted nodes in the current workspace. You can restore or permanently delete the nodes.

Go to the Recycle Bin tab

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Recycle Bin** icon.

   Click ☰ in the lower-left corner to show or hide the left-side navigation pane.

3. View all the deleted nodes in the current workspace.

   On this tab, you can delete or restore a deleted node.

> **Notice**
>
> - The recycle bin displays only 100 nodes. If more than 100 nodes are deleted, the nodes deleted earlier are deleted permanently from the recycle bin.
> - Deleted node groups are not displayed in the recycle bin.

Restore a node in the recycle bin

1. On the **Recycle Bin** tab, right-click a deleted node.
2. Select **Restore**.
3. In the **Restore Node** message, click **OK**.

> **Note** After you restore a node, a new node ID is generated for scheduling and all the information about the node is restored.

Permanently delete a node from the recycle bin

1. On the **Recycle Bin** tab, right-click a deleted node.
2. Select **Delete**.
3. In the **Delete** message, click **OK**.

> **Note** Nodes permanently deleted from the recycle bin cannot be restored. The recycle bin displays only deleted nodes.

2.1.5.17. Create a manually triggered workflow

In a manually triggered workflow, all nodes must be manually triggered, and cannot be automatically scheduled by DataWorks. Therefore, you do not need to specify parent nodes or outputs for nodes in manually triggered workflows.

Create a manually triggered workflow

1. Log on to the DataWorks console.
2. On the left-side navigation submenu, click the **Manually Triggered Workflows** icon.

   Click ☰ in the lower-left corner to show or hide the left-side navigation pane.
3. Right-click **Manually Triggered Workflows** and select **Create Workflow**.
4. In the **Create Workflow** dialog box, set **Workflow Name** and **Description**.

> **Notice** The workflow name must be 1 to 128 characters in length and can contain letters, digits, underscores (_), and periods (.). It is not case-sensitive.

5. Click **Create**.

Composition of a manually triggered workflow

> **Note** We recommend that you create a maximum of 100 nodes in a manually triggered workflow.

A manually triggered workflow consists of the nodes of the following modules. After you create a manually triggered workflow, open this workflow and create nodes of various types for each module. For more information, see Node types.

- **Data Integration**

  Double-click **Data Integration** under the created workflow to view all the data integration nodes.

  Right-click **Data Integration** and choose **Create > Batch Synchronization** to create a batch sync node. For more information, see Create a batch sync node.

- **MaxCompute**

  The MaxCompute compute engine consists of data analytics nodes, such as ODPS SQL, SQL Snippet, ODPS Spark, PyODPS, ODPS Script, and ODPS MR nodes. You can also view and create tables, resources, and functions.

  - **Data Analytics**

    Show **MaxCompute** under the created workflow and right-click **Data Analytics** to create a data analytics node. For more information, see Create an ODPS SQL node, Create an SQL Snippet node, Create an ODPS Spark node, Create a PyODPS node, Create an ODPS Script node, and Create an ODPS MR node.

  - **Table**

    Show **MaxCompute** under the created workflow and right-click **Table** to create a table. You can also view all the tables created for the current MaxCompute compute engine. For more information, see Create a MaxCompute table.

  - **Resource**

    Show **MaxCompute** under the created workflow and right-click **Resource** to create a resource. You can also view all the resources created for the current MaxCompute compute engine. For more information, see Create, reference, and download resources.

  - **Function**

    Show **MaxCompute** under the created workflow and right-click **Function** to create a function. You can also view all the functions created for the current MaxCompute compute engine. For more information, see Register a UDF.

- **Algorithm**

  Click the created workflow and right-click **Algorithm** to create an algorithm. You can also view all the PAI nodes created in the current manually triggered workflow. For more information, see Create a PAI node.

- **General**

  Click the created workflow and right-click **General** to create relevant nodes. For more information, see Create a Shell node and Create a zero-load node.

- **UserDefined**

  Click the created workflow and right-click **UserDefined** to create relevant nodes. For more information, see Create a Hologres development node.

GUI elements

The following table describes the icons and tabs on the Manually Triggered Workflows page.

No.	Icon or tab	Description
1	**Submit icon**	Commits all nodes in the current manually triggered workflow.
2	**Run icon**	Runs all nodes in the current manually triggered workflow. Nodes in this workflow do not have dependencies, and therefore they can run at a time.
3	**Stop icon**	Stops all running nodes in the current manually triggered workflow.
4	**Deploy icon**	Navigates to the Deploy page. On this page, you can deploy some or all nodes that are committed but not deployed to the production environment. **Note** This icon is available only when the workspace is in standard mode.
5	**Go to Operation Center icon**	Navigates to the Operation Center page.
6	**Box. icon**	Box-selects a node group consisting of required nodes.
7	**Refresh icon**	Refreshes the page of the current manually triggered workflow.
8	**Auto Layout icon**	Sorts the nodes in the current manually triggered workflow.
9	**Zoom In icon**	Zooms in the current page.
10	**Zoom Out icon**	Zooms out the current page.
11	**Search icon**	Searches for a node in the current manually triggered workflow.
12	**Toggle Full Screen View icon**	Displays nodes in the current manually triggered workflow in the full screen.
13	**Show Engine Information/Hide Engine Information icon**	Shows or hides engine information.

No.	Icon or tab	Description
14	**Workflow Parameters tab**	Allows you to set parameters. Parameters set on this tab have a higher priority than those specified on the corresponding node configuration tab. If two values are set separately, the value set on the Workflow Parameters tab takes effect.
15	**Change History tab**	Allows you to view the operation records of all nodes in the current manually triggered workflow.
16	**Versions tab**	Allows you to view the deployment records of all nodes in the current manually triggered workflow.

2.1.5.18. Editor keyboard shortcuts

This section describes keyboard shortcuts available for the code editor.

Google Chrome in Windows OS

`Ctrl + S` : Save changes to a node.

`Ctrl + Z` : Undo an action.

`Ctrl + Y` : Redo an action.

`Ctrl + D` : Select occurrences.

`Ctrl + X` : Cut a line.

`Ctrl + Shift + K` : Delete a line.

`Ctrl + C` : Copy a line.

`Ctrl + I` : Select a line.

`Alt + Shift + Drag` : Select a block.

`Alt + Click` : Insert an additional cursor.

`Ctrl + Shift + L` : Select all occurrences.

`Ctrl + F` : Search for text in a node.

`Ctrl + H` : Replace text in a node.

`Ctrl + G` : Locate a line.

`Alt + Enter` : Select all matched strings.

`Alt + Up or down arrow` : Move a line up or down.

`Alt + Shift + Up or down arrow` : Duplicate a line.

`Ctrl + Shift + K` : Delete a line.

`Ctrl + Enter or Ctrl + Shift + Enter` : Insert a line break downwards or upwards.

`Ctrl + Shift + Back slash (\)` : Jump to the parenthesis, bracket, or brace that matches the adjacent one.

`Ctrl + Left bracket (]) or right bracket ([)` : Increase or decrease the indent of a line.

`Home or End` : Move the cursor to the beginning or end of a line.

`Ctrl + Home or End` : Move the cursor to the top or bottom of a node.

`Ctrl + Left or Right arrow` : Move the cursor one word to left or right.

`Ctrl + Shift + Left bracket (]) or right bracket ([)` : Hide or show a block.

`Ctrl + K + Left bracket (]) or right bracket ([)` : Hide or show sub-blocks in a block.

`Ctrl + K + 0 or J` : Hide or show all blocks.

`Ctrl + Slash (/)` : Comment out or uncomment the selected lines or blocks.

Google Chrome in Mac OS

`Command-S` : Save changes to a node.

`Command-Z` : Undo an action.

`Command-Y` : Redo an action.

`Command-D` : Select occurrences.

`Command-X` : Cut a line.

`Shift-Command-K` : Delete a line.

`Command-C` : Copy a line.

`Command-I` : Select a line.

`Command-F` : Search for text in a node.

`Option-Command-F` : Replace text in a node.

`Option-Up or down arrow` : Move a line up or down.

`Option-Shift-Up or down arrow` : Duplicate a line.

`Shift-Command-K` : Delete a line.

`Command-Enter or Shift-Command-Enter` : Insert a line break downwards or upwards.

`Shift-Command-Back slash (\)` : Jump to the parenthesis, bracket, or brace that matches the adjacent one.

`Command-Left bracket (]) or right bracket ([)` : Increase or decrease the indent of a line.

`Command-Left or right arrow` : Move the cursor to the beginning or end of a line.

`Command-Up or down arrow` : Move the cursor to the top or bottom of a node.

`Option-Left or right arrow` : Move the cursor one word to left or right.

`Option-Command-Left bracket (]) or right bracket ([)` : Hide or show a block.

`Command-K-Left bracket (]) or right bracket ([)` : Hide or show sub-blocks in a block.

`Command-K-0 or J` : Hide or show all blocks.

`Command-Slash (/)` : Comment out or uncomment the selected lines or blocks.

Insert multiple cursors and select multiple occurrences or lines

`Option-Click` : Insert an additional cursor.

`Option-Command-Up or down arrow` : Insert an additional cursor to the previous or next line.

`Command-U` : Undo a cursor-related operation.

`Option-Shift-I` : Insert a cursor at the end of each selected line.

`Command-G or Shift-Command-G` : Select the next or previous matched string.

`Command-F2` : Select the nearest character of each cursor.

`Shift-Command-L` : Select the nearest word of each cursor.

`Option-Enter` : Select all the matched strings.

`Option-Shift-Drag` : Multi-select lines

`Option-Shift-Command-Up or down arrow` : Extend a selection one line up or down.

`Option-Shift-Command-Left or right arrow` : Extend a selection one character to the left or right.

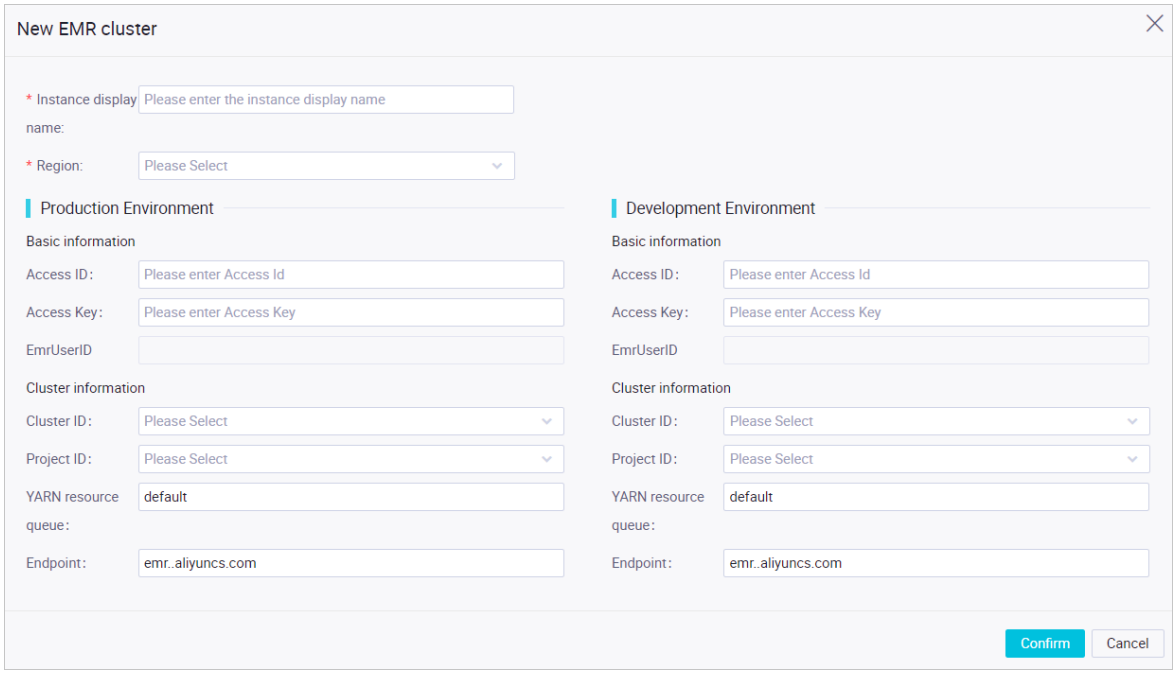
2.1.5.19. Use E-MapReduce in DataWorks

This topic describes how to use E-MapReduce (EMR) in DataWorks.

Bind an EMR project to a DataWorks workspace

Note Before you bind an EMR project to a DataWorks workspace, you must obtain the information about the EMR project.

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-right corner. The **Project Management** page appears.
3. In the **Computing Engine information** section of the **Project Management** page, click the **E-MapReduce** tab. On this tab, you can view the information about all available EMR compute engine instances in the current workspace.
4. Click **Add instances**.
5. In the **New EMR cluster** dialog box, configure the parameters.



Parameter	Description
Instance display name	The display name of the compute engine instance.
Region	The region where the current workspace resides.
Access ID	The AccessKey ID of the account that is authorized to access the EMR cluster.

Parameter	Description
Access Key	The AccessKey secret of the account that is authorized to access the EMR cluster.
Cluster ID	The ID of the EMR cluster.
EmrUserID	The ID of the user who created the EMR cluster.
Project ID	The ID of the project that is associated with the EMR cluster.
YARN resource queue	The name of the resource queue in the EMR cluster. Unless otherwise specified, set the parameter to *default*.
Endpoint	The endpoint of the EMR cluster. You can obtain the endpoint from the EMR console.

6. Click **Confirm**. After the EMR project is bound to your workspace, you can create EMR nodes on the **DataStudio** page.

> **Note** If the binding fails, check whether the failure is caused by one of the following reasons:
> - The EMR user ID is bound to another tenant account.
> - The specified cluster name already exists.

Create an EMR node

EMR nodes are categorized into four types: EMR Hive, EMR Spark SQL, EMR Spark, and EMR MR. For more information, see Create an EMR node.

Reference resource files

EMR resource files are categorized into two resource types: EMR JAR and EMR File.

Reference EMR resource files by using the following methods:

- For EMR Hive and EMR MR nodes, add `--@resource_reference{"Resource name"}` to the first line of the code.
- For EMR Spark nodes, add `##@resource_reference{"Resource name"}` to the first line of the code.

Manage data

DataWorks allows you to query EMR metadata and synchronize it for data development.

2.1.5.20. Migrate nodes in DataStudio

This topic describes how to migrate nodes in DataStudio that are created in a workflow of an earlier version to a workflow of a later version.

Migrate nodes in DataStudio

1. Log on to the DataWorks console. The DataStudio page appears.
2. Click **Business Flow** in the DataStudio pane to show all the created workflows. In the preceding figure, the workflow indicated by 1 is a workflow of an earlier version, and the workflow indicated by 2 is a workflow of a later version.
3. Click the desired workflow to open it and click Data Integration. Then, right-click a node that you want to migrate in the Data Integration folder, and select **Move**.
4. In the **Move Node** dialog box, set **Location** to the path of the destination workflow of a later version.

5. Click **OK**.

2.1.6. HoloStudio

2.1.6.1. Overview

Holo Studio provides Hologres users with standardized, easy-to-use development management services and end-to-end real-time data warehouse construction services by using a visualized user interface and a wizard. In addition to standard management available in PostgreSQL, Holo Studio provides more interactive analytics features.

Description

- **Hologres management**

  Holo Studio allows you to create a PostgreSQL table on a visual user interface or by using SQL statements.

- **Data development**

  Holo Studio allows you to create multiple external tables at a time and synchronize data based on the underlying capabilities of DataWorks. Holo Studio also provides the end-to-end, stable, and efficient extract, transform, load (ETL) service.

- **SQL Console**

  The SQL Console of Holo Studio allows you to use an SQL editor to perform data development and queries.

- **Visualized control**

  Holo Studio seamlessly interconnects with the Hologres console and allows you to easily and rapidly manage Hologres instances and instance objects, such as users and databases.

2.1.6.2. Bind a Hologres database to Holo Studio

Before you use Holo Studio on Apsara Stack, you must bind a Hologres instance to Holo Studio. If you are not authorized to access the instance, use your Alibaba Cloud account to apply for the access permissions on the Hologres instance. This topic describes how to bind a Hologres instance on which you have obtained the access permissions to Holo Studio as a superuser.

> **Note**
>
> - The user who has obtained the access permissions on the Hologres instance is the superuser of the instance. Other users can access the Hologres instance only after the users are granted the related permissions by the superuser.
> - It is optional for common users to apply for the access permissions on a Hologres instance. A common user can use Hologres if the user can use a database in the instance. To obtain more permissions, a common user must submit a request to the superuser.

1. **Log on to Holo Studio**

   Log on to the Apsara Uni-manager Management Console. In the top navigation bar, choose **Products > DataWorks** to go to the DataStudio page. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Holo Studio** to go to Holo Studio.

2. **Bind a database to Holo Studio**

On the Holo Studio page, click the icon in the left-side navigation pane to go to the PG management tab.

Move the pointer over the icon and select **Database**. In the Create Database dialog box, configure the parameters. After you configure all the parameters, click **Test connectivity**. If the system displays a message indicating that the connectivity test is passed, the database is connected. Then, click **Completed**.

Parameter	Description	Remarks
Connect To	The type of the data source. Default value: Interactive Analytics.	The value cannot be changed.
Server	The endpoint of the Hologres instance.	The value of this parameter is automatically generated after the Hologres instance is created.
Port	The port number of the Hologres instance.	The value of this parameter is automatically generated after the Hologres instance is created.
Database Name	The name of the Hologres database.	By default, a database named **postgres** is generated after the access permissions on the Hologres instance are requested. You can directly bind the database to the workspace. For actual business scenarios, you need to bind a new database.
User name	The AccessKey ID of your Apsara Stack tenant account.	You can click User Info in the upper-right corner to view the AccessKey ID.
Password	The AccessKey secret of your Apsara Stack tenant account.	You can click User Info in the upper-right corner to view the AccessKey secret.
JDBC Extension	The extension parameters used to establish a Java Database Connectivity (JDBC) connection to Hologres.	Example: `?preferQueryMode=simple&tcpKeepAlive=true`.
Test connectivity	You can click this button to test whether the database is connected.	None.

Note If the Hologres instance is deleted, the instance and all databases within the instance are unavailable. You must create another instance and bind it to Holo Studio again.

3. **Create another database to develop data**

After the Hologres instance is bound to the workspace, click the icon on the **PG management** tab, and the new database appears. Then, you can use the new database to develop data.

By default, a database named postgres is created after a Hologres instance is created. However, the resources that are allocated to this database are insufficient. Therefore, to meet your business requirements, we recommend that you create a database and use the database to develop data. For more information about how to create a database, see Database management.

2.1.6.3. SQL Console

The SQL Console in Holo Studio is an editor for executing SQL statements. In the SQL Console, you can execute SQL statements to analyze data in Hologres and quickly obtain the query results. This topic describes the basic features and usage of the SQL Console in Holo Studio.

Folder

The Folder module stores new ad hoc queries, which allows you to easily manage ad hoc queries.

Go to the DataStudio page. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Holo Studio**.

In the left-side navigation pane of the **Holo Studio** page, click the icon. The **SQL Console** tab appears. Move the pointer over the icon and select **Folder**. In the Create Folder dialog box, specify Folder Name to create a folder. The name can contain letters and underscores. You can create an ad hoc query in the folder and execute standard SQL statements to perform operations on tables. You can also right-click a table in the folder and select the relevant options to move, rename, or delete the table.

SQL Console

The SQL Console module can generate an SQL editor in which you can execute standard SQL statements.

1. In the left-side navigation pane of the **Holo Studio** page, click the icon. Then, the **SQL Console** tab appears.
2. Move the pointer over the icon and select **SQL Console**. In the Create Node dialog box, configure basic information for the node.

   You can also click **Create SQL Console** on the right side of the **SQL Console** tab to configure the node.

Parameter	Description
Node Name	The name of the ad hoc query node. The name can contain letters, digits, underscores (_), and periods (.).
Location	The folder in which the ad hoc query node is stored.
Database	The database to which the ad hoc query applies.

3. Write SQL statements used in the ad hoc query and click the icon in the top toolbar to run the ad hoc query node. Then, you can view the query result. The following example shows how to create a table, import data to the table, and query the data in the table:

```
CREATE TABLE supplier (
 s_suppkey bigint NOT NULL,
 s_name text NOT NULL,
 s_address text NOT NULL,
 s_nationkey bigint NOT NULL,
 s_phone text NOT NULL,
 s_acctbal bigint NOT NULL,
 s_comment text NOT NULL,
PRIMARY KEY (s_suppkey)
);
INSERT INTO supplier VALUES
(1,    'Supplier#000000001', 'gf0JBoQDd7tgrzrddZ',    17,    '27-918-335-1736',    575594,    'e
ach slyly above the careful'),
(6,    'Supplier#000000006',    'tQxuVm7s7CnK',    14,    '24-696-997-4969',    136579,    'fina
l accounts. regular dolphins use against the furiously ironic decoys. '),
(10, 'Supplier#000000010',    'Saygah3gYWMp72i PY', 24, '34-852-489-8585', 389191, 'ing waters.
regular requests ar'),
(18, 'Supplier#00000001',    'PGGVE5PWAMwKDZw', 16, '26-729-551-1115', 704082, 'accounts snooze
slyly furiously bold'),
(39, 'Supplier#000000039', 'SYpEPWr1yAFHaC91qjFcijjeU5eH',    8, '18-851-856-5633    611565', 88
990, 'le slyly requests. special packages shall are blithely. slyly unusual packages sleep'),

(48, 'Supplier#000000048',    'FNPMQDuyuKvTnLXXaLf3Wl6OtONA6mQlWJ',    14,    '24-722-551-9498',
563062, 'xpress instructions affix. fluffily even requests boos');
SELECT * FROM supplier;
```

Note The SQL Console does not support transaction-related statements, such as `BEGIN, COMMIT, and CALL_SET_TABLE`. If you want to execute such SQL statements, go to the DataStudio page.

Parameter	Description
SQL editor	You can write SQL statements in the SQL editor.
Save	You can click this icon to save all statements in the SQL editor.
Run	You can click this icon to run all statements in the SQL editor. The result appears at the lower part of the tab. You can also select an SQL statement to be run. In this case, the system only runs this statement.
Reload	You can click this icon to refresh the content in the SQL editor. The system retains only the saved content after the refresh.
Stop	You can click this icon to stop running SQL statements.
Operational Log	You can check the running results and error messages.
Result	You can check the table content after the SQL statements are run.

Holo Studio also allows you to directly manage the queried data. For example, you can hide columns, copy data, and search for data.

> **Note** For statements without results returned, such as the `CREATE TABLE` statement, only operational logs are generated after the statements are executed.

2.1.6.4. PostgreSQL management

2.1.6.4.1. Manage databases

The PG management module of Holo Studio allows you to manage databases and tables with one click in a visualized manner. In addition, Holo Studio supports interactive queries with a response time within seconds. This topic describes how to manage databases on the PG management tab.

Bind a Hologres database to a workspace

Before you bind a Hologres database to a workspace, you must create a Hologres database. You can create a database in the Hologres console in a visualized manner. You can also create a database in the SQL Console by using SQL statements. To create a Hologres database, perform the following steps:

1. Create a database.

   Log on to the Hologres console. Then, click **Instances** in the left-side navigation pane. On the Instances page, click **DataWorks**. On the DataStudio page, click the icon in the upper-left corner, move the pointer over **All Products**, and then choose **All Products** > **Data Development** > **Holo Studio**. On the **Holo Studio** page, click the icon in the left-side navigation pane. Then, the SQL Console tab appears.

   Enter the following SQL statement in the SQL Console to create a database:

   ```
   create database dbname;
   create database testdb; // Create a database named testdb.
   ```

2. Bind the database.

   After the database is created, click the PG management icon in the left-side navigation pane of the Holo Studio page to bind the database. On the PG management tab, move the pointer over the first icon on the right side of PG management and select **Database** to bind the database.

3. Configure the database.

   In the **Create Database** dialog box, configure the parameters and click **Test connectivity**. If the system displays a message indicating that the connectivity test is passed, the specified database is connected. Then, click **Completed**.

Parameter	Description	Remarks
Connect To	The type of the data source. Default value: Interactive Analytics.	The value cannot be changed.
Server	The endpoint of the Hologres instance.	You can view the endpoint on the Basic Information page of the Hologres instance in the Hologres console.
Port	The port number of the Hologres instance.	You can view the port number on the Basic Information page of the Hologres instance in the Hologres console.

Parameter	Description	Remarks
Database Name	The name of the created database.	The value of this parameter must be the same as the name of the database created by using the SQL statement, such as **testdb**.
User name	The AccessKey ID of your Apsara Stack tenant account.	You can click User Info in the upper-right corner to view the AccessKey ID.
Password	The AccessKey secret of your Apsara Stack tenant account.	You can click User Info in the upper-right corner to view the AccessKey secret.
JDBC Extension	The extension parameters used to establish a Java Database Connectivity (JDBC) connection to Hologres.	Example: `?preferQueryMode=simple&tcpKeepAlive=true`.
Test connectivity	You can click this button to check whether the database is connected.	If the system displays a message indicating that the connectivity test is passed, the specified database is connected.

Delete a database

The PG management module of Holo Studio allows you to delete a database. On the left-side navigation pane, click the **PG management** icon. On the PG management tab, find the database that you want to delete, right-click the database name, and then select **Delete Database**.

In the Delete Database message, click **Ok**.

> **Note** Only a superuser of a database or the database owner configured by a superuser can delete the database.

2.1.6.4.2. Manage tables

Similar to PostgreSQL, Hologres manages data by using tables. The PG management module of Holo Studio allows you to manage tables in a visualized manner. You can quickly create, check, or delete a table. This topic describes how to use the PG management module of Holo Studio to manage tables.

Create a table

1. **Create a table.**

   On the Holo Studio page, click the  in the left-side navigation pane to go to the PG management tab. On the PG management tab, move the pointer over the  icon and select **Table** to create a table.

   You can also click **Create Table** on the right side of the **PG management** tab to create a table.

2. **Configure the table.**

   On the tab that appears, configure the parameters for the table and click **Commit**. The following figure shows an example of how to create a common column-oriented table that has a primary key.

Item	Parameter	Description
General	Interactive Analytics Database	The database to which the table belongs.
	Table Name	The name of the table.
	Description	The description of the table.
Field	Field Name	The name of the field in the table.
	Data Type	The data type of the field.
	Primary Key Field	Specifies whether to use the field as the primary key for the table.
	Optional	Specifies whether the field can be empty.
	Array	Specifies whether the field is an array.
	Description	The description of the field.
	Actions	The operations that you can perform on the field. For example, you can delete the field from the table, or move up the position of the field in the table.
Properties	Storage Mode	The storage mode of the table. Valid values: Row Store and Column Store. Default value: Column Store.
	Lifecycle (Seconds)	The lifecycle of data in the table. Default value: Permanent.
	Clustering Index	The index used for sorting.
	Dictionary Code Columns	The column whose values are used to build a dictionary mapping.
	Bitmap Column	The column on which bit code is built.
Partitioned Table	PARTITION BY LIST	The partition field.

View a table

1. **Generate DDL statements.**

   In the left-side navigation pane, click **PG management**. On the PG management tab, double-click the table that you want to view and click **Generate DDL Statement**. Then, you can view the SQL statement used to create the table.

2. **Preview data.**

   In the left-side navigation pane, click **PG management**. Double-click the table you want to view and click **Data Preview** to view the table data. If the table contains no data, you can only view the fields of the table.

Delete a table

In the left-side navigation pane, click **PG management**. Right-click the table that you want to delete and select **Delete Table** to delete the table.

In the Delete message, click **OK**.

2.1.6.4.3. Manage foreign tables

In Hologres, a foreign table does not store data but maps the table from the external data source. The PG management module of HoloStudio allows you to create, query, or delete foreign tables. You can only analyze foreign tables sourced from MaxCompute. This helps you obtain the query results.

This topic describes how to use the PG management module of HoloStudio to manage foreign tables.

Create a foreign table

On the left-side navigation submenu, click **PG management**. On the PG management tab, move the pointer over the Create icon and select **External Table**. On the tab that appears, set parameters for creating a foreign table and click **Commit**. An existing MaxCompute table is used in the following example. After you search for a MaxCompute table by entering its name, HoloStudio automatically generates a foreign table based on the fields of the MaxCompute table after you click Commit.

> **Note**
>
> 1. Before you create a foreign table in Hologres, make sure that its source table exists in a MaxCompute project.
> 2. The fields of a foreign table in Hologres have a one-to-one mapping with those of the source table in MaxCompute. You can query specific fields or all fields.

Section or icon	Parameter	Description
General	Interactive Analytics Database	The database where the foreign table to be created resides.
	Table Name	The name of the foreign table.
External Service	Types	The service type of the external table. You can only set this parameter to MaxCompute.
Table	Table	The source table in MaxCompute to be mapped.
Commit	Commit	You can click this button to commit the foreign table that you create.

Check a foreign table

1. **Preview data.**

   On the left-side navigation submenu, click **PG management**. On the PG management tab, double-click the foreign table you want to check, and click **Data Preview** to check the content of the foreign table.

2. **View the DDL statement used to create the table.**

   On the left-side navigation submenu, click **PG management**. On the PG management tab, double-click the foreign table you want to check, and click **Generate DDL Statement** to check the SQL statement used to create the foreign table.

Delete a foreign table

On the left-side navigation submenu, click **PG management**. On the PG management tab, right-click the foreign table you want to delete and select **Delete Table**. In the Delete message, click **Ok** to delete the foreign table.

2.1.6.5. Data analytics

2.1.6.5.1. Overview

The Data Analytics module of HoloStudio is seamlessly integrated with DataWorks for node scheduling and provides all-in-one, stable, and efficient extract, transform, load (ETL) services. It can also synchronize MaxCompute table schemas and data and allows you to upload local files for data analytics.

The Data Analytics module consists of the following submodules:

1. Folder: stores data analytics nodes, helping you manage data analytics nodes of each database.
2. Interactive Analytics Development: is integrated with DataWorks to schedule ETL nodes.
3. One-click MaxCompute table structure synchronization: allows you to create multiple foreign tables sourced from MaxCompute at a time.
4. One-click MaxCompute data synchronization: provides a visualized user interface for you to synchronize MaxCompute data to Hologres.
5. One-click local file Upload: allows you to upload local files to Hologres.

Folder

Folders store data analytics nodes, helping you manage data analytics nodes of each database.

On the left-side navigation submenu, click **Data Analytics**. On the Data Analytics tab, move the pointer over the Create icon and select **Folder**. In the Create Folder dialog box, enter a folder name and click **Commit**.

2.1.6.5.2. Use the Interactive Analytics Development submodule

The Interactive Analytics Development submodule is seamlessly integrated with DataWorks. You can use HoloStudio to import data from MaxCompute to Hologres. You can also use DataWorks to schedule nodes to periodically import data to Hologres. This topic describes how to use HoloStudio to map the source data stored in a MaxCompute table to Hologres for periodic scheduling.

1. **Prepare a MaxCompute table.**

   Create a table in MaxCompute and import data to the table. You can also select a table with data from Data Map. In this example, an existing table in Data Map is used. The following Data Definition Language (DDL) statement is used to create the table:

```
CREATE TABLE IF NOT EXISTS bank_data_odps
(
 age             BIGINT COMMENT 'age',
 job             STRING COMMENT 'job type',
 marital         STRING COMMENT 'marital status',
 education       STRING COMMENT 'education level',
 card         STRING COMMENT 'credit card available or not',
 housing         STRING COMMENT 'mortgage',
 loan            STRING COMMENT 'loan',
 contact         STRING COMMENT 'contact',
 month           STRING COMMENT 'month',
 day_of_week     STRING COMMENT 'day in a week',
 duration        STRING COMMENT 'duration',
 campaign        BIGINT COMMENT 'number of contacts during the campaign',
 pdays           DOUBLE COMMENT 'interval from the last contact',
 previous        DOUBLE COMMENT 'number of contacts with the customer',
 poutcome        STRING COMMENT 'result of the previous marketing campaign',
 emp_var_rate    DOUBLE COMMENT 'employment change rate',
 cons_price_idx  DOUBLE COMMENT 'consumer price index',
 cons_conf_idx   DOUBLE COMMENT 'consumer confidence index',
 euribor3m       DOUBLE COMMENT 'euro deposit rate',
 nr_employed     DOUBLE COMMENT 'number of employees',
 y               BIGINT COMMENT 'fixed time deposit available or not'
);
```

2. **Create a foreign table.**

   Go to the HoloStudio page. On the left-side navigation submenu, click **PG management** or **SQL Console**. On the tab that appears, create a foreign table for mapping data in the MaxCompute source table. In this example, use the following SQL statements to create a foreign table:

```
BEGIN;
CREATE FOREIGN TABLE if not EXISTS bank_data_foreign_holo (
 age int8,
 job text,
 marital text,
 education text,
 card text,
 housing text,
 loan text,
 contact text,
 month text,
 day_of_week text,
 duration text,
 campaign int8,
 pdays float8,
 previous float8,
 poutcome text,
 emp_var_rate float8,
 cons_price_idx float8,
 cons_conf_idx float8,
 euribor3m float8,
 nr_employed float8,
 y int8
)
SERVER odps_server
OPTIONS (project_name 'projectname', table_name 'bank_data_odps');
GRANT SELECT ON bank_data_foreign_holo TO PUBLIC;
COMMIT;
```

> **Note** The OPTIONS parameter contains two fields: project_name, which is the name of the MaxCompute project, and table_name, which is the name of the MaxCompute table.

3. **Create a data storage table.**

   Create a table in HoloStudio to receive and store data. The fields in this table must be of the same data types as those in the foreign table. In this example, use the following SQL statements to create the storage table:

```
BEGIN;
CREATE TABLE if not EXISTS bank_data_holo (
 age int8,
 job text,
 marital text,
 education text,
 card text,
 housing text,
 loan text,
 contact text,
 month text,
 day_of_week text,
 duration text,
 campaign int8,
 pdays float8,
 previous float8,
 poutcome text,
 emp_var_rate float8,
 cons_price_idx float8,
 cons_conf_idx float8,
 euribor3m float8,
 nr_employed float8,
 y int8,
 ds text NOT NULL
)
PARTITION  BY LIST(ds);
CALL SET_TABLE_PROPERTY('bank_data_holo', 'orientation', 'column');
CALL SET_TABLE_PROPERTY('bank_data_holo', 'time_to_live_in_seconds', '700000');
COMMIT;
```

4. **Create a partitioned table.**

   On the HoloStudio page, click **Data Analytics** on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **Interactive Analytics Development** to create a Hologres development node. Then, go to the SQL editor of the node and enter SQL statements to create a partitioned table for obtaining the required data. After you enter the SQL statements, click the **Run** icon. In the Field dialog box, set a value for the ${bizdate} parameter. After the SQL statements are executed, click the **Save** icon and then **Go to DataStudio for Scheduling** to schedule the node. You can enter the following sample SQL statements:

```
create table if not exists bank_data_holo_1_${bizdate} partition of bank_data_holo
  for values in ('${bizdate}');
insert into bank_data_holo_1_${bizdate}
select
    age as age,
    job as job,
    marital as marital,
    education as education,
    card as card,
     housing as housing,
    loan as loan,
    contact as contact,
    month as month,
    day_of_week as day_of_week,
     duration as duration,
    campaign as campaign,
     pdays as pdays,
    previous as previous,
    poutcome as poutcome,
     emp_var_rate as emp_var_rate,
    cons_price_idx as cons_price_idx,
    cons_conf_idx as cons_conf_idx,
    euribor3m as euribor3m,
    nr_employed as nr_employed,
    y as y,
    '${bizdate}' as ds
from bank_data_foreign_holo;
```

5. **Schedule the partitioned table.**

   Go to the DataStudio page and create a Hologres development node. In the SQL editor of the node, enter SQL statements to synchronize the partitioned table information to the node and click **Update Code**. Before you create the node, make sure that a workflow is created.

6. **Set parameters for scheduling the data analytics node.**

   On the editing tab of the Hologres development node, click the **Properties** tab in the right-side navigation pane to set parameters for scheduling the node.

   i. **Set parameters in the General section.**

      In the **Arguments** field, specify a value for the ${bizdate} variable.

   ii. **Set parameters in the Schedule section.**

      Select Normal for **Execution Mode** and set other parameters as required.

   iii. **Set parameters in the Dependencies section.**

      Select **Yes** for **Auto Parse** and click **Use Root Node**. After DataStudio automatically parses and displays the root node as a parent node, change the value of Auto Parse to **No**. You can also select a table that is scheduled as a parent node.

7. **Save and deploy the node for scheduling.**

   After you set the scheduling parameters for the node, click the **Save** icon and then the **Submit** icon. After that, click **Deploy** in the upper-right corner.

8. **Deploy the node in Operation Center.**

   On the **Create Package** page, find the target node and click Publish in the Actions column. After the node is deployed, click **Operation Center** in the top navigation bar to generate retroactive data for the node.

   In **Operation Center**, right-click the published node and choose **Run > Current Node Retroactively**. Configure the node based on your business requirements.

9. **Check the content of the table in HoloStudio.**

   After the retroactive data generation node is run, go back to HoloStudio. On the left-side navigation submenu, click **PG management**. On the PG management tab, click a database and choose Mode > public > **Table**. Double-click the partitioned table that is scheduled and click **Data Preview** to check whether the data is imported to the table.

2.1.6.5.3. Create multiple foreign tables at a time

Seamlessly integrated with MaxCompute at the underlying layer, Hologres allows you to create foreign tables to query MaxCompute data in an accelerated manner. You can create multiple foreign tables at a time by using the IMPORT FOREIGN TABLE statement. To free you from SQL operations, HoloStudio provides the following submodule for you to create foreign tables in a visualized manner: One-click MaxCompute table structure synchronization.

1. **Create a schema sync node.**

   On the HoloStudio page, click **Data Analytics** on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **One-click MaxCompute table structure synchronization**. In the Create Node dialog box, set relevant parameters and click Commit. The schema sync node is created.

2. **Set parameters for synchronizing the table schema.**

   After the schema sync node is created, you must set parameters for synchronizing the table schema based on your needs.

Parameter	Description	Remarks
Target Library	The name of the Hologres database where the foreign tables are to be created.	N/A
Target Schema	The name of the schema in the specified Hologres database.	The default value is public. If you have created a schema, you can select the created schema.
Remote Service type	The type of the external service. You can create only foreign tables sourced from MaxCompute.	The default value is odps.
Remote server	The external server. The default value is odps_server.	After you purchase a Hologres instance, the system automatically creates a server named odps_server. You can directly use it.
Remote library	The name of the MaxCompute project where the tables mapping the foreign tables to be created reside.	N/A

Parameter	Description	Remarks
Table name rules	The regular expression for specifying the tables whose schema is to be synchronized. By default, the schema of all tables in the specified MaxCompute project will be synchronized.	◦ If a foreign table to be created is named the same as an existing foreign table in Hologres, the foreign table is not created. ◦ If a MaxCompute table whose schema is to be synchronized contains data types that Hologres does not support, an error is thrown. In this case, exclude this MaxCompute table in the regular expression. ◦ For more information, see IMPORT FOREIGN SCHEMA.
Regular preview	The execution result of the regular expression.	N/A

3. **Run the schema sync node.**

   Click the **Save** icon and then click the **Run** icon to run the schema sync node. After the schema sync node is run, click PG management on the left-side navigation submenu. The created foreign tables appear. You can query the table data.

2.1.6.5.4. Import MaxCompute data

To improve the efficiency of querying MaxCompute data, Hologres allows you to import MaxCompute data to Hologres for queries. HoloStudio provides the following submodule for you to directly import MaxCompute data in a visualized manner: One-click MaxCompute data synchronization.

1. **Create a data sync node.**

   On the HoloStudio page, click Data Analytics on the left-side navigation submenu. On the Data Analytics tab, move the pointer over the Create icon and select **One-click MaxCompute data synchronization**. In the Create Node dialog box, enter the node information and click Commit. The data sync node is created.

2. **Set parameters for synchronizing data.**

   After the data sync node is created, you must set parameters for synchronizing data.

Section	Parameter	Description	Remarks
MaxCompute Source table selection	External table source	The source of the foreign table. Valid values: External table already exists and New external table.	◦ If you select External table already exists, the existing foreign table mapping the MaxCompute table will be used. ◦ If you select New external table, you must create a foreign table mapping the MaxCompute table.

Section	Parameter	Description	Remarks
	External table table name	The name of the existing foreign table.	The foreign table must map the MaxCompute table whose data will be synchronized.
Target table settings	Target Library	The name of the Hologres database to which the MaxCompute data will be synchronized.	N/A
	Target schema	The name of the schema in the specified Hologres database.	The default value is public. If you have created a schema, you can select the created schema.
	Destination Table Name	The name of the target table to which the MaxCompute data will be synchronized.	The table name can be customized.
	Target table description	The description of the target table.	N/A
Synchronization settings	Synchronization field	The fields to be synchronized from the specified MaxCompute table.	You can select specific or all fields in the MaxCompute table.
	Partition configuration	The partition fields to be synchronized.	Hologres supports a maximum of one level of partitions.
	Index configuration	The index to be built for the target table.	N/A
SQL Script	SQL Script	The SQL statements that are executed when the data sync node is run.	N/A

3. **Run the data sync node.**

   Click the **Save** icon and then click the **Run** icon to run the data sync node. After the node is run, you can query the imported data in SQL Console or PG management.

2.1.6.5.5. Upload local files

This topic describes how to upload local files in HoloStudio in a visualized manner.

Hologres allows you to use the COPY statement to import data from the standard input of a client to a specified table. For more information, see COPY. HoloStudio allows you to import data in a local file to a specified table by uploading the local file in a visualized manner. To upload a local file in HoloStudio, perform the following steps:

1. **Create a table.**

   In SQL Console or PG management, create a table to which data in the local file will be imported. In this example, use the following SQL statements to create a table:

```
BEGIN;
CREATE TABLE if not EXISTS holo_bank (
 age int8,
 job text,
 marital text,
 education text,
 card text,
 housing text,
 loan text,
 contact text,
 month text,
 day_of_week text,
 duration text,
 campaign int8,
 pdays float8,
 previous float8,
 poutcome text,
 emp_var_rate float8,
 cons_price_idx float8,
 cons_conf_idx float8,
 euribor3m float8,
 nr_employed float8,
 y int8
);
COMMIT;
```

2. **Create a node for uploading the local file.**

   Go to the HoloStudio page. On the left-side navigation submenu, click Data Analytics. On the Data Analytics tab, move the pointer over the Create icon and select **Upload files locally with one click**.

3. **Enter the node information.**

   In the **One-click local file Upload** dialog box, set the parameters based on your business needs and click Next Step.

Parameter	Description	Remarks
Target Library	The name of the Hologres database where the target table resides.	N/A
Target Schema	The name of the schema where the target table resides.	The default value is public. If you have created a schema, you can select the created schema.
Select the data table to import	The name of the target table to which data in the local file will be imported.	N/A

4. **Select the local file to upload and set other required parameters.**

   After you click Next Step, select the local file to upload, set other required parameters, and then click Commit.

Parameter	Description	Remarks
Select File	The local file to upload.	You can select a local file only in the .txt, .csv, or .log format.

Select separator	The delimiter of fields in the file. Select Comma (,) or Space ( ).	N/A
Original character set	The character set of the file.	○ GBK ○ UTF-8 ○ CP936 ○ ISO-8859
First behavior title	Specifies whether to use the first line as the header line.	N/A

5. **View the imported data.**

   After you click **Commit**, data in the selected local file is imported to the specified table. You can go to SQL Console or PG management to view the imported data.

2.1.6.6. Hologres console

2.1.6.6.1. Overview

Hologres is a real-time interactive analytics service that is fully compatible with PostgreSQL and seamlessly integrated with the big data ecosystem. Hologres delivers high-concurrency and low-latency performance in analyzing trillions of data records. Hologres allows you to use mainstream Business Intelligence (BI) tools to gain an analytical insight into data from multiple dimensions and explore business data in an efficient and cost-effective manner.

For the convenience of business, Apsara Stack provides the Hologres console independent of the DataWorks console for you to manage Hologres instances, users, and databases.

Log on to the Apsara Uni-manager Management Console. In the top navigation bar, choose **Products > Hologres**. On the page that appears, specify Organization and Region, and click Access as Administrator to go to the Hologres console.

2.1.6.6.2. View the instance list

The Instances page lists all the Hologres instances that belong to your Apsara Stack tenant account. On this page, you can perform operations such as viewing instance statuses, changing instance configurations, and creating instances. You can also click Manage in the Actions column that corresponds to an instance to go to the instance details page. On this page, you can manage objects in the instance, including databases and users.

Instance list

Log on to the Apsara Uni-manager Management Console. In the top navigation bar, choose **Products > Hologres**. On the page that appears, specify Organization and Region, and click Interactive Analytics to go to the Hologres console. In the left-side navigation pane of the Hologres console, click **Instances**.

1. **Create Instance button**

   On the Instances page, click **Create Instance**. In the Create Instance dialog box, enter an instance name and select instance specifications to create a Hologres instance.

2. **Search box**

   If you have purchased multiple Hologres instances, you can enter a keyword of an instance name in the search box to find the desired instance.

3. **Status column**

The Status column displays the running status of each Hologres instance. An instance can be in one of the following states:

- Running: The instance is running as expected.
- Creating: The instance is being created. You must wait for 3 minutes to 5 minutes.
- Stop: The instance is suspended, and you cannot connect to it.

Actions column

The Actions column allows you to perform the following operations on Hologres instances:

1. **Manage**

   Find the desired instance and click **Manage** in the Actions column. On the page that appears, you can view and manage objects in the instance, including databases and users.

2. **Configure**

   If your instance cannot meet your business requirements or has a large number of surplus resources, you can click **Configure** in the Actions column. In the **Configure** dialog box, change the specifications of the instance based on your business requirements to upgrade or downgrade the instance.

3. **Stop**

   Find the desired instance and click **Stop** in the Actions column to suspend the instance. After the state of the instance changes to **Stop**, the instance is suspended, and you cannot connect to it.

2.1.6.6.3. Manage instances

This topic describes how to view and change instance configurations, select a network type, and select a connection method on the Basic information page in the Hologres console.

View and change instance configurations

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. The Basic information page displays basic information about a Hologres instance, including the instance name, instance ID, region, instance version, billing method, instance specification, and creation time.

If you need to change the instance specifications, click **Change configuration**. In the Change configuration dialog box, upgrade or downgrade the instance specifications based on your business needs.

Select a network type

The following table lists the supported network type.

Network type	Domain name	Scenario
Internal network	`<instancename>-cn-<region>-internal.hologres.aliyuncs.com:80`	Select this network type when you want to connect to the Hologres instance by using the classic network, without charges on the Internet traffic.

Select a connection method

Hologres is compatible with PostgreSQL. You can connect to a Hologres instance from the PostgreSQL client or over JDBC interfaces by using ETL or BI tools.

The Connection Methods section offers methods for you to use common development tools to connect to a Hologres instance. You can select a development tool and connection method based on your business needs and preference.

1. **Connect from the PostgreSQL client**

   To connect to a Hologres instance from the PostgreSQL client, use the following connection string:

   ```
   PGUSER=<AccessId> PGPASSWORD=<AccessKey> psql -p <Port> -h <Endpoint> -d <Database>
   ```

2. **Connect over JDBC**

   To connect to a Hologres instance over JDBC, use the following connection string:

   ```
   postgres://<AccessId>:<AccessKey>@<Endpoint>:<Port>/<database>? preferQueryMode=simple&tcpKeepAlive=true
   ```

2.1.6.6.4. Manage users

This topic describes how to manage users on the User Management page in the Hologres console.

Overview

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. On the page that appears, click **User Management**. On the User Management page, you can manage users on a Hologres instance without executing cumbersome SQL statements. For example, you can add and delete users and grant permissions to users on this page.

After you create a Hologres instance with your Apsara Stack tenant account, this account becomes a superuser of the instance. A superuser has all permissions on the Hologres instance. By default, the User Management page displays only the information of the Apsara Stack tenant account that creates the Hologres instance. The information of a Resource Access Management (RAM) user appears on this page only after you use the Apsara Stack tenant account to add it to the instance.

Column	Description	Remarks
Members	Displays the usernames of the Apsara Stack tenant account and RAM users on the Hologres instance.	Generally, a username appears in the xxx format.
Cloud account	Displays the account IDs of users on the Hologres instance.	N/A
Type	Displays the roles assigned to users on the Hologres instance.	The user can be a superuser or normal user.

Add a user

On the User Management page, you can create RAM users on a Hologres instance without executing the SQL CREATE statement.

Click **Add new user**. In the Add new user dialog box, select existing RAM users under your Apsara Stack tenant account to add them to the Hologres instance. If no RAM user exists under your Apsara Stack tenant account, create a RAM user first.

When you add a RAM user, you can assign the superuser or normal user role to the user.

- Superuser: A superuser has all permissions on the Hologres instance without the need for additional authorization.
- Normal user: A normal user cannot view or manage any objects on the Hologres instance, including databases, schemas, and tables. A normal user must be authorized before it can view and manage objects in the instance.

We recommended that you go to the DB management page to grant permissions to RAM users as required. Alternatively, you can use SQL statements to grant permissions to RAM users.

Delete a user

Find the target user on the User Management page and click **Delete** in the Operation column to delete the user from the Hologres instance. A deleted user has no access to the Hologres instance.

2.1.6.6.5. Manage databases

This topic describes how to manage databases on the DB management page in the Hologres console.

Overview

In the Hologres console, click **Instance List** in the left-side navigation pane. In the instance list, find the target instance and click **Management** in the **Operation** column. On the page that appears, click **DB management**. On the DB management page, you can manage all databases on the current Hologres instance. You can create databases, select a permission management mode for the databases, and view database information.

> **Note** A default database named postgres is automatically created after you create a Hologres instance. This database is provided for management purposes only and does not appear on the DB management page. This database is allocated with limited resources. Create databases on this page based on your business needs.

Create a database

Hologres allows you to create a database with one click on the graphical user interface (GUI), eliminating the need for SQL operations.

Click **New Database**. In the New Database dialog box, enter a name for the database and set the Simple permissions model parameter to Open or Close. To simplify authorization, we recommend that you set the Simple permissions model parameter to Open.

Hologres provides two permission models for you to authorize users in a convenient way.

- Standard PostgreSQL authorization: Compatible with PostgreSQL, Hologres provides a permission model that is exactly the same as the standard PostgreSQL authorization model. You can authorize RAM users by using the standard PostgreSQL GRANT statement.
- SPM: Backed by the understanding of customers' business and its practical experience, Alibaba Cloud introduced a simple permission model (SPM) to Hologres to simplify the management of user permissions. The SPM is a coarse-grained model that authorizes users by user group.

After a database is created, you can use a development tool to connect to the database to analyze data.

Authorize a user

After the SPM is enabled for a new database, you can authorize RAM users with one click in the Hologres console. Perform the following steps:

1. **Open the Permission management right-side pane.**

   Find the target RAM user and click **User authorization** in the Operation column. You can grant permissions to a RAM user by adding the user to the desired user group.

2. **Add a RAM user to a user group.**

   In the Permission management right-side pane, click **Add authorization**. In the Add authorization dialog box, select the account to which you want to grant permissions, select the desired user group below Permissions policy, and then click **OK**.

Revoke permissions

If the SPM is enabled for your database, you can revoke the permissions of a RAM user with one click in the Hologres console.

On the instance details page, click **DB management**. On the DB management page, find the target database and click **User authorization** in the Operation column. In the Permission management right-side pane, find the target RAM user and click **Delete authorization** in the Operation column.

Delete a database

On the DB management page, find the database no longer required and click Delete in the Operation column to delete the database. After a database is deleted, data in the database is also deleted and cannot be recovered.

2.1.7. DataAnalysis

2.1.7.1. Overview

DataAnalysis provides the features of building and sharing workbooks, dimension tables, and visual reports. These features help developers and business personnel analyze data.

Benefits

Compared with offline data analysis, DataAnalysis has the following benefits:

- High efficiency: DataAnalysis analyzes data in a database by using online data analysis tools, such as pivot tables. For example, in a user profile table, you can create a pivot table for a partition that belongs to September. When data for October is obtained, you can update the source data and reuse the configuration of the pivot table for September to obtain a pivot table for October. This avoids repeated operations.
- High capacity: DataAnalysis efficiently analyzes large amounts of data with the help of compute engines.
- Data sharing: DataAnalysis can analyze data obtained from the databases of different business systems. DataAnalysis allows you to export data to MaxCompute tables. It also allows you to share data with specified members and grant them access permissions. This way, data can be shared between different systems and different users.
- High security: DataAnalysis allows you to analyze data online without the need to download data. It also allows you to manage the permissions that allow users to analyze and share data.

Description

- **Workbook**

  Workbooks are the core feature of DataAnalysis. A workbook is a workspace in which you can obtain, explore, and analyze data. A workbook is in the form of an online table and offers common table features. After you import data from data sources or import local data to workbooks, you can perform data pivoting and profiling.

- **Dimension table**

  The dimension table feature allows you to create MaxCompute tables without the need to write SQL code. It also allows you to collaboratively edit MaxCompute tables with other users online. The dimension table feature also allows you to import data to MaxCompute tables in a visualized manner. For more information, see Create and manage dimension tables.

- **Report**

  You can create and design visual reports by dragging and configuring controls without the need to execute SQL statements.

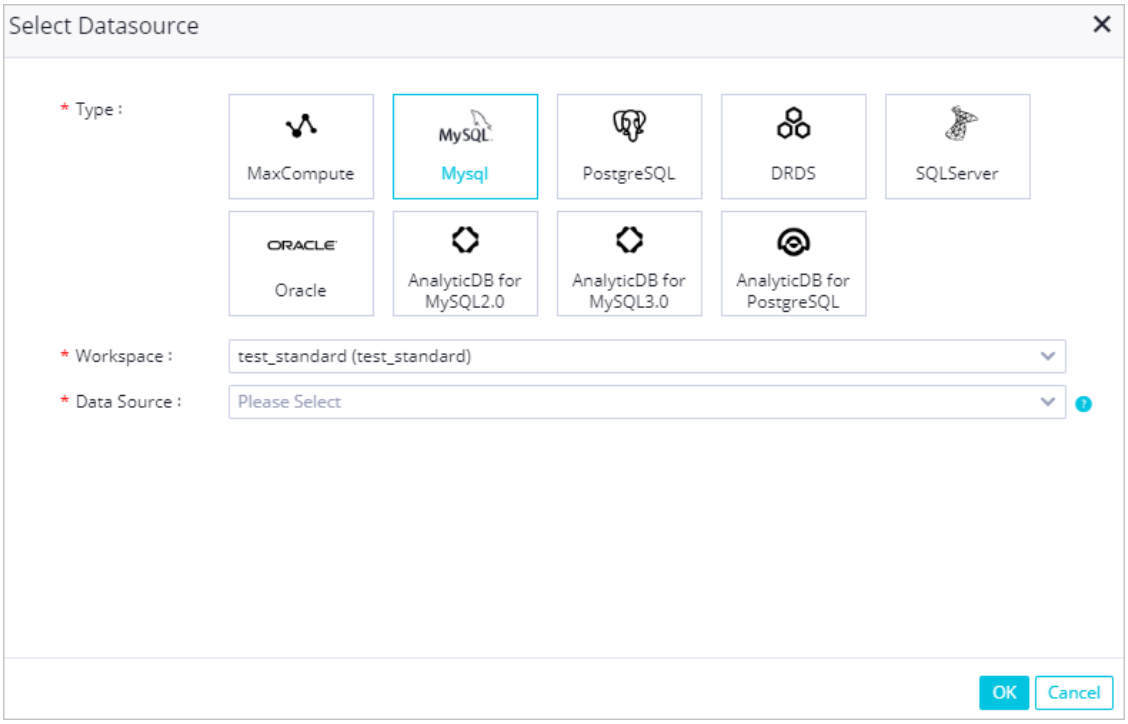
2.1.7.2. SQL queries

DataWorks allows you to import data from a data source and perform queries and analysis of data by using the SQL query feature. This topic describes how to use the SQL query feature.

Create an SQL query task

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. On the **DataAnalysis** page, click **SQL Query** in the top navigation bar to go to the **SQL Query** page.
3. Specify the data source to be queried.
   i. On the left side of the **SQL Query** page, click the + icon in the **Data source** section.

   The first time you go to the **SQL Query** page, you must click **Add Now** first.
   ii. In the **Select Datasource** dialog box, set the parameters as required.

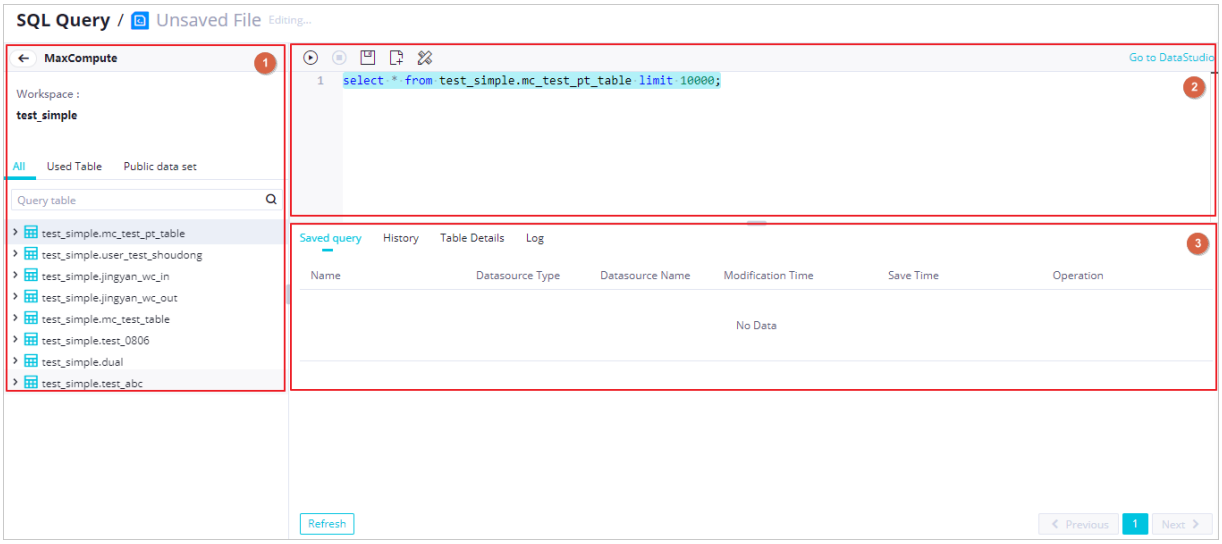


Parameter	Description
Type	Specify the type of the data source to be queried.
Workspace	The workspace in which the specified data source resides.
Data Source	Select the data source to be queried from the drop-down list. **Note** If you set the **Type** parameter to MaxCompute, this parameter is not displayed.

   iii. Click **OK** to create an SQL query task. On the SQL Query page, you can use SQL statements to query and analyze data for the created SQL query task.

Perform and manage SQL queries

On the SQL Query page, you can use SQL statements to query and analyze data from the specified data source. You can also view saved queries, execution history, and logs of the SQL queries.



Area No.	Description
1	This section displays the tables that are contained in the specified data source for which you perform the SQL queries in the current workspace. You can also search for a table by entering keywords in the search box.
2	This section allows you to run SQL statements to query data. After you enter the SQL statement to be executed, click the icon in the toolbar to run the statement. You can also click **Go to DataStudio** to copy the SQL statement and go to the DataStudio page. On the DataStudio page, you can develop data and schedule ETL tasks.
3	In this section, you can view the details of the saved queries, execution history, and logs of SQL queries. You can also preview, load, rename, and delete historical SQL queries on the Saved query tab.

2.1.7.3. Workbook

2.1.7.3.1. Create and manage workbooks

Before data analysis, you must create a workbook to store the data to be analyzed. This topic describes how to create, view, and manage workbooks.

Create a workbook

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. In the top navigation bar of the DataAnalysis page, click **Spreadsheet**.

3. On the **Spreadsheet** page, click the + icon in the **New Spreadsheet** section to go to the workbook editing page. On this page, you can import data for analysis.

View and manage workbooks

1. On the workbook editing page, click **Spreadsheet** in the upper-left corner or **Spreadsheet** in the top navigation bar to go back to the Spreadsheet page.
2. In the **All Spreadsheets** section of the **Spreadsheet** page, select **I created** or **Share it with me** from the drop-down list in the upper-right corner to view the workbooks in the corresponding category.
3. Click the file name of a workbook to go to the workbook editing page.

   In the All Spreadsheets section, you can also perform the following operations on a workbook:

   - To rename a workbook, find the workbook and click the icon in the Operation column. In the **Rename** dialog box, enter a new name in the **File Name** field and click **OK**.
   - To change the owner of a workbook, find the workbook and click the icon in the Operation column. In the **Change Owner** dialog box, select an owner from the drop-down list and click **OK**.
   - To clone a workbook, find the workbook and click the icon in the Operation column. The generated workbook appears in the workbook list. The name of the generated workbook contains the _copy suffix.
   - To delete a workbook, find the workbook and click the icon in the Operation column. In the **Delete** message, click **OK**.

2.1.7.3.2. Edit a workbook

This topic describes how to edit a workbook. For example, you can import data to, export data from, and share a workbook, create a pivot table in a workbook, and use the Data Profiling feature.

Go to the workbook editing page

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. On the DataAnalysis page, click **Spreadsheet** in the top navigation bar to go to the **Spreadsheet** page.
3. On the Spreadsheet page, find the workbook that you want to edit in the **All Spreadsheets** section and click the name of the workbook that you want to edit in the **File Name** column to go to the workbook editing page.

Apply a template to a workbook or save a workbook as a template

You can perform the following steps to apply an existing template to the current workbook:

1. In the upper-right corner of the workbook editing page, choose **Template > Import Template**.
2. In the **Import Template** dialog box, click the template you want to use.

   > **Note** The data of the template will overwrite that of the current workbook.

3. Click **OK**.

You can also perform the following steps to save the current workbook as a template:

1. In the upper-right corner of the workbook editing page, choose **Template > Save as Template**.

2. In the **Template settings** dialog box, set the **Type**, **Name**, and **Description** parameters.

   > **Notice** The template name cannot exceed 256 characters in length, and the template description cannot exceed 1,024 characters in length.

3. Click **OK**.

Import the data on your on-premises machine

On the workbook editing page, move the pointer over **Import** in the upper-right corner and select **Local File** or **File Data** to import the data on your on-premises machine.

- If you select **Local File**, you can import only Excel files from your on-premises machine. Data in all the sheets of a selected Excel file is imported.

  Choose **Import > Local File**. Select the Excel file that you want to import and click **Open** to import data in all the sheets of the Excel file to the workbook.

- If you select **File Data**, you can import data from workbooks or import CSV files or Excel files from your on-premises machine. If you import data from a workbook or an Excel file, you can specify the sheet from which you want to import data.

  Choose **Import > File Data**. In the **Import** dialog box, select one of the following types of source files based on your business requirements:

  - **Spreadsheet**

    In the **Import** dialog box, click **Spreadsheet**, set the parameters, and then click **OK**.

Parameter	Description
Spreadsheet	The workbook from which you want to import data. Select a workbook from the **Spreadsheet** drop-down list.
Sheet	The sheet from which you want to import data. Select a sheet from the **Sheet** drop-down list.
Data Preview	Displays the data in the selected workbook.
Import Start Row	The row from which the data starts to be imported. Default value: 1.
Placement Location	The location where the data you want to import is placed. Valid values: **Current Worksheet** and **New Worksheet**.
Placement Method	The way in which the data you want to import is placed. Valid values: **Append**, **Overwrite**, and **Active Cell**.

- **Local CSV File**

  In the **Import** dialog box, click **Local CSV File**, set the parameters, and then click **OK**.

Parameter	Description
File	The CSV file from which you want to import data. Click **Select File(.csv)**, select the required CSV file from your on-premises machine, and then click **Open**.
Original Character Set	The character set that is used by the selected CSV file. Valid values: **UTF-8** and **GBK**. If garbled characters appear, you can change the character set.
Separator	The row delimiter and column delimiter. ■ The following row delimiters are supported: \r\n, \n, and \r. ■ The following column delimiters are supported: commas (,), semicolons (;), and \t. If the cell data cannot be correctly separated, you can change the delimiters.
Data Preview	Displays the data in the selected CSV file.
Import Start Row	The row from which the data starts to be imported. Default value: 1.
Placement Location	The location where the data you want to import is placed. Valid values: **Current Worksheet** and **New Worksheet**.
Placement Method	The way in which the data you want to import is placed. Valid values: **Append**, **Overwrite**, and **Active Cell**.

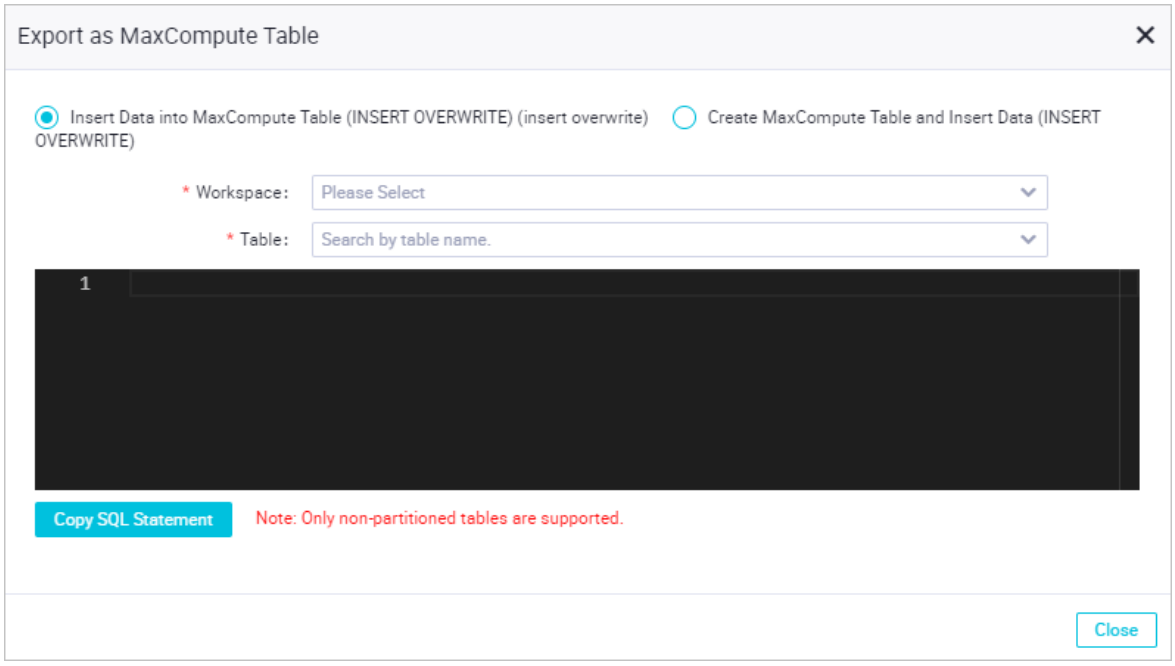
- **Local Excel file**

  In the **Import** dialog box, click **Local Excel File**, set the parameters, and then click **OK**.

Parameter	Description
File	The Excel file from which you want to import data. Click **Select File(.xlsx)**, select the required Excel file from your on-premises machine, and then click **Open**.
Sheet	The sheet from which you want to import data. Select a sheet from the **Sheet** drop-down list.
Data Preview	Displays the data in the selected Excel file.
Import Start Row	The row from which the data starts to be imported. Default value: 1.
Placement Location	The location where the data you want to import is placed. Valid values: **Current Worksheet** and **New Worksheet**.
Placement Method	The way in which the data you want to import is placed. Valid values: **Append**, **Overwrite**, and **Active Cell**.

Export data from a workbook to a MaxCompute table

1. In the upper-right corner of the workbook editing page, choose **Export** > **Generate MaxCompute Build Table Statement**.
2. In the **Export as MaxCompute Table** dialog box, set the parameters.



Insert mode	Parameter	Description
Insert Data into MaxCompute Table (INSERT OVERWRITE) (insert overwrite)	**Workspace**	The workspace corresponding to the MaxCompute project to which the MaxCompute table belongs.
	Table	The MaxCompute table to which you want to insert data.
Create MaxCompute Table and Insert Data (INSERT OVERWRITE)	**Workspace**	The workspace corresponding to the MaxCompute project to which the MaxCompute table belongs.
	Table Name	The name of the MaxCompute table that you want to create and to which you want to insert data. Make sure that the table name is unique. You can click **Check Duplicate Names** to check whether the table name already exists.

3. After the parameters are set, click **Copy SQL Statement**.

> **Notice** Only non-partitioned tables are supported.

Create a pivot table

1. On the workbook editing page, select the data for which you want to create a pivot table and click **Pivot** in the upper-right corner.
2. In the **Create Pivot Table** dialog box, specify the data that you want to analyze.

   You can set the Choose Data parameter to **Select Range** or **Use External Data Source**.

   - **Select Range**

The value of the **Range** parameter changes when you select the cells for which you want to create a pivot table.

- **Use External Data Source**

  You can select a data source of the **MaxCompute**, **MySQL**, **Data Services**, or **PostgreSQL** type. If you use an external data source, prepare the required data source or API in advance and select the data source or API based on the business requirements. For more information about how to configure a data source, see Data sources.

3. Click **OK**. The pivot table editing panel appears.

   In this example, **Select Range** is selected.

   - **Data Source**: the range of the selected data in the workbook.
   - **Pivot Table Fields**: the names of the fields in the selected data.
   - **Row**: Drag a field to the **Row** section. Each value of the field added to the **Row** section occupies a row in the pivot table.
   - **Column**: Drag a field to the **Column** section. Each value of the field added to the **Column** section occupies a column in the pivot table.
   - **Indicator**: To modify the settings of a metric, move the pointer over the metric, click the ⋮ icon, and then select **Edit**.

   In the **Property settings** dialog box, set the **Summary method** parameter and click **OK**. By default, the display name of the metric is in the format of **Aggregation method:Source field name** and cannot be modified.

   - **Filters**: To filter data, click **Set Filter**. In the **Set Filter** dialog box, click **Add Condition**, specify the filter conditions, and then click **OK**.
   - **Sort**: To sort data based on a field specified in the **Row** section, click **Set Sort**. In the **Set Sort** dialog box, specify the sorting rule and click **OK**.

Share and download a workbook

> **Note** To share and download a workbook, you must choose More > Management in the top navigation bar, and turn on **Allow Sharing** and **Allow Download** in the Spreadsheet section of the **Configuration Management** tab. Then, you can share and download a workbook.

In the upper-right corner of the workbook editing page, click **Share**. In the dialog box that appears, configure the sharing mode.

You must configure the following information before you can share a workbook:

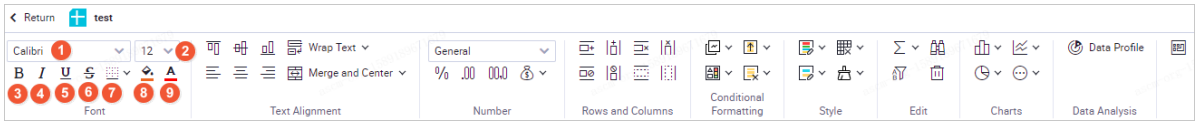
- **Link**: After you specify Users with Edit Access and Users with Read Access, click **Copy Link** to copy the URL and send the copied URL to specified users.
- **Users with Edit Access**: In the **Users with Edit Access** section, click **Add**. In the dialog box that appears, select members with whom you want to share the workbook and click **OK**.
- **Visible to All**: To share the workbook with all members, turn on **Visible to All**.
- **Users with Read Access**: To share the workbook with some members, turn off **Visible to All** and click **Add** in the **Users with Read Access** section. In the Share File with These Users dialog box, select members with whom you want to share the workbook and click **OK**.

> **Note** If you are prompted that the number of members with whom you want to share the workbook reaches the upper limit, you can upgrade the DataWorks edition to increase the upper limit.

In the upper-right corner of the workbook editing page, click **Download** to download the workbook to your on-premises machine.

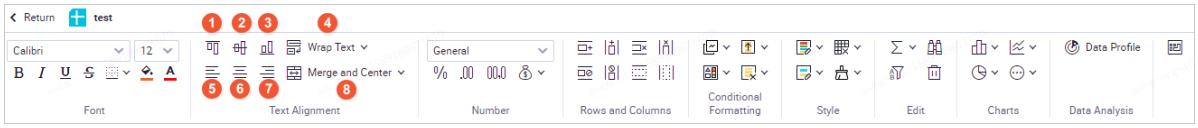
Menu bar

- **Font**



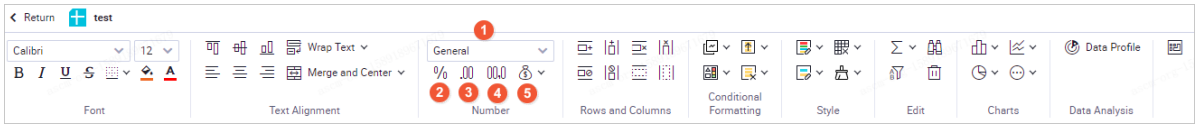
No.	GUI element	Description
①	**Font**	Select a font based on your business requirements.
②	**Font size**	Select a font size based on your business requirements.
③	**Bold**	Set text in bold.
④	**Italic**	Set text in italic.
⑤	**Underline**	Underline text.
⑥	**Strikethrough**	Add a strikethrough to text.
⑦	**Borders**	Add borders to text.
⑧	**Background color**	Specify the background color of text.
⑨	**Text color**	Specify the text color.

- **Text Alignment**



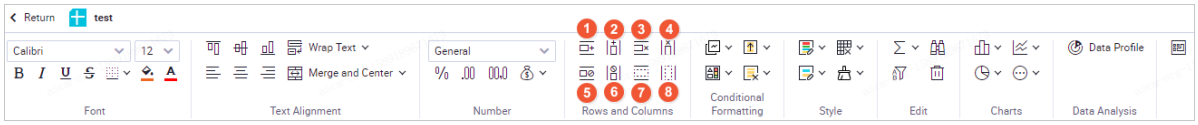
No.	GUI element	Description
①	**Top Align**	Align text to the top.
②	**Middle Align**	Vertically align text to the center.
③	**Bottom Align**	Align text to the bottom.
④	**Wrap Text**	Display long text in multiple lines to make it easy to view all the text.
⑤	**Align Left**	Align text to the left.
⑥	**Center**	Align text to the center.
⑦	**Align Right**	Align text to the right.
⑧	**Merge and Center**	Merge multiple cells to one cell and center the text in the cell.

- Number



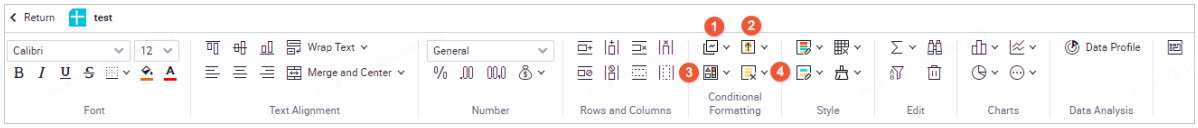
No.	GUI element	Description
①	**Number format**	Specify the number format for selected cells. You can select General, Number, Currency, Short Date, Long Date, Time, Percentage, Fraction, Scientific, or Text from the drop-down list.
②	**Percentage**	Apply the percentage format to numbers.
③	**Two Decimal Places**	Round numbers to two decimal places.
④	**1000 Separator**	Display numbers with thousands of separators, such as **1,005**.
⑤	**Currency**	Add a currency sign to numbers. Valid values: ¥ Chinese (PRC), $ English (United States), £ English (United Kingdom), € Euro, and Fr Franc.

- Rows and Columns



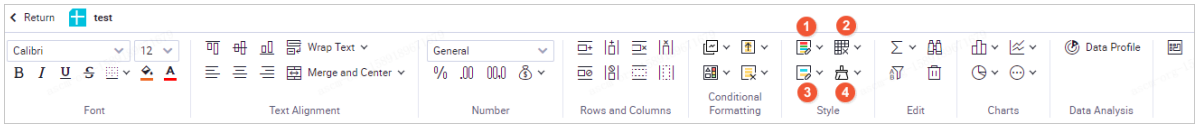
No.	GUI element	Description
①	**Insert Row**	Insert one or more rows to the workbook.
②	**Insert Column**	Insert one or more columns to the workbook.
③	**Delete Row**	Delete one or more selected rows from the workbook.
④	**Delete Column**	Delete one or more selected columns from the workbook.
⑤	**Lock Row**	Lock one or more selected rows in the workbook.
⑥	**Lock Column**	Lock one or more selected columns in the workbook.
⑦	**Hide Row**	Hide one or more selected rows in the workbook.
⑧	**Hide Column**	Hide one or more selected columns in the workbook.

- **Conditional Formatting**



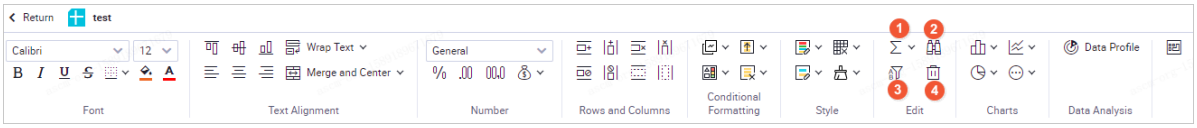
No.	GUI element	Description
①	**Highlight cell rules**	Specify the rules for highlighting cells. Highlighting rules are divided into two categories: **Highlight Cells Rules** and **Top/Bottom Rules**.
②	**Data Bar/Color Scale**	Format selected cells by using gradient or solid data bars and color scales.
③	**Icon Set**	Format selected cells by using icon sets. The icon sets include directional icons, shapes, indicators, and rating icons.
④	**Clear Rule**	Clear the formatting. You can select **Clear Rules from Selected Cells** or **Clear Rules from Entire Sheet** from the drop-down list.

- **Style**



No.	GUI element	Description
①	**Apply table style**	Apply a table style.
②	**Delete**	Remove the applied table style.
③	**Cell Style**	Set the cell style.
④	**Clear**	Clear the content or style for selected cells. You can select **Clear All**, **Clear Content**, or **Clear Style** from the drop-down list.

- **Edit**



No.	GUI element	Description
①	**AutoSum**	Select an aggregation method. You can select **Sum**, **Average**, **Count Numbers**, **Max**, or **Min** from the drop-down list.
②	**Search**	Click **Search** or press **Ctrl+F** to open the search box.
③	**Sort and Filter**	Filter data and sort data in ascending or descending order.
④	**Clear**	Clear the selected content.

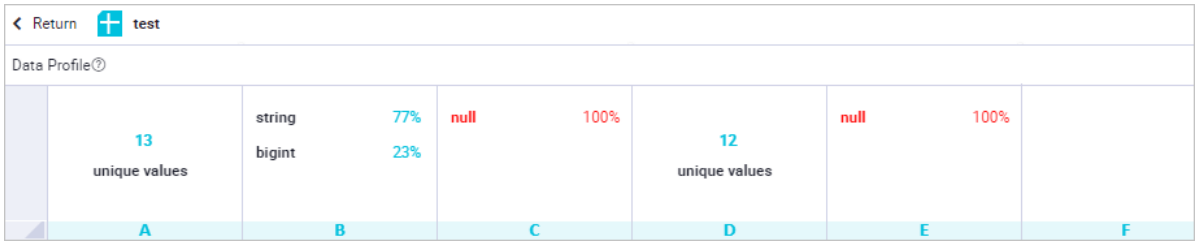
- **Charts**

  - **Column Chart**: After you click the **Column Chart** icon, you can select **Column Chart**, **Stacked Column Chart**, and **100% Stacked Column Chart**.
  - **Line Chart**: After you click the **Line Chart** icon, you can select **Line Chart**, **Stacked Line Chart**, **100% Stacked Line Chart**, **Line Chart with Markers**, **Stacked Line Chart with Markers**, and **100% Stacked Line Chart with Markers**.
  - **Pie Chart**: After you click the **Pie Chart** icon, you can select includes **Pie Chart** and **Doughnut Chart**.
  - **More**: After you click the **More** icon, you can view more chart types, including area charts, bar charts, scatter charts, and stock charts.

- **Data Profile**

  The data profiling feature allows you to analyze the quality, structure, distribution, and statistics of the data. It also allows you to preview, detect, process, analyze, and visualize data. The data profiling feature analyzes data by column and allows you to view the data types and value distribution of each column.

Select the data that you want to analyze and click **Data Profile** in the menu bar. Then, you can view the data types and value distribution of each column above the workbook in the form of charts and rich text.



The simple mode of the data profiling feature has the following capabilities:

- For a column whose values are of the STRING or DATE data type: displays the values that rank top 2 and their percentages, and the percentage of other values in the form of rich text. If the number of unique values exceeds 50% of the total number of values, the number of unique values is displayed.
- For a column whose values are of the INTEGER or FLOAT type: displays the value distribution in the form of a histogram.
- For a column whose values are of the BOOLEAN type: displays the proportions of different values in the form of a pie chart.
- For a column whose values are of two or more data types: displays the proportions of different data types in the form of a pie chart. The system reminds you that the current column contains dirty data. After the dirty data is cleared, the simple mode displays value distribution in one of the preceding forms based on the data type.
- For a column whose values are null values: displays the percentage of the null values in red.

Click **Detailed Mode** in the upper-right corner. In the **Data Profile** dialog box, you can view the profiling result of each column. The profiling result information includes the column name, value distribution information, data type, and data source.

The detailed mode of the data profiling has the following capabilities:

- For a column whose values are of the STRING or DATE type: displays basic information and the values that rank top 5 based on frequency. The basic information includes the number of fields, unique values, valid values, and the percentage of null values.
- For a column whose values are of the INTEGER or FLOAT type: displays basic information, the values that rank top 5 based on frequency, statistics, and a histogram. The basic information includes the number of fields, unique values, zeros, and the percentage of null values.
- For a column whose values are of the BOOLEAN type: displays basic information, the values that rank top 5 based on frequency, and a pie chart. The basic information includes the number of fields, unique values, zeros, and the percentage of null values.

> **Note** The system considers the true and false strings and the 0 and 1 integers as values of the BOOLEAN type.

- **List of Shortcut Keys**

  Click the icon to view the shortcut keys for different features.

2.1.7.4. Dimension tables

2.1.7.4.1. Create and manage dimension tables

The dimension table feature allows you to create MaxCompute tables, import data on your on-premises machine to MaxCompute tables, and edit MaxCompute tables in a visualized manner.

Prerequisites

1. A MaxCompute compute engine instance is associated with a DataWorks workspace. For information about how to associate a MaxCompute compute engine instance, see Configure a workspace.
2. A MaxCompute table is created. For more information, see Create a MaxCompute table.

Limits

- To create a dimension table in DataAnalysis, you must be an administrator, an owner, or a developer of a DataWorks workspace.
- For a MaxCompute table that is created by using the dimension table feature, all fields in the MaxCompute table are of the STRING type. If you want to use fields of other data types, execute data definition language (DDL) statements to create a MaxCompute table on the **DataStudio** page.

Create a dimension table

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. In the top navigation bar of the DataAnalysis page, choose **More > Dimension Table** to go to the **Dimension Table** page.
3. On the **Dimension Table** page, click the icon in the **New Dimension Table** section.
4. In the **New Dimension Table** dialog box, set the parameters as required.

Parameter	Description
Target Workspace	The workspace corresponding to the MaxCompute project to which the MaxCompute table belongs.
Table Name	The name of the dimension table. A MaxCompute table will be used in the production environment. **Note** The table name can contain only letters, digits, and underscores (_), and must start with a letter.
Table Description	The description of the table, such as the purpose or features.
Field	The fields in the table. Only fields of the STRING type can be added.
Lifecycle	The lifecycle of the table. The table occupies storage resources in MaxCompute. To ensure that the resources can be recycled, select an appropriate lifecycle for the table from the drop-down list. If the specified lifecycle is exceeded, the table is deleted.

5. Select **I have known this risk and confirmed that as owner of this table, I am responsible for the subsequent changes to this table.** and click **OK** to go to the dimension table editing page to view and modify information about the table. For information about how to edit a dimension table, see Edit a dimension table.

   The MaxCompute table created in DataAnalysis is maintained in the production environment. The creator of the table is responsible for the creation and maintenance of the table.

View and manage dimension tables

1. On the dimension table editing page, click **Dimension Table** in the upper-left corner or **Dimension Table** in the top navigation bar to go back to the Dimension Table page.
2. In the **All Dimension Tables** section, select **I created** or **Share it with me** from the drop-down list in the upper-right corner to view the tables in the corresponding category.

   You can also share dimension tables with specific members. For information about how to share a dimension table, see Share a dimension table.
3. Click the file name of a required table or click **Edit** in the Operation column of the table to go to the dimension table editing page.

   In the All Dimension Tables section, you can perform the following operations on a dimension table:

   - To change the owner of a dimension table, find the table and click the icon in the Operation column. In the **Change Owner** dialog box, select an owner from the drop-down list and click **OK**.
   - To delete a dimension table, find the dimension table and click the icon in the Operation column. In the **Delete** message, click **OK**.

What's next

After you create a dimension table, go to the dimension table editing page and import data to this table. For information about how to edit a dimension table, see Import data to a dimension table.

2.1.7.4.2. Import data to a dimension table

After you create a dimension table, you can write data to the table for data analysis. You can also import data from a workbook, local CSV file, or local Excel file to the table for data analysis. This topic describes how to import data to a dimension table.

Prerequisites

A dimension table is created. For more information about how to create a dimension table, see Create a dimension table.

Procedure

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. In the top navigation bar of the DataAnalysis page, choose **More > Dimension Table** to go to the **Dimension Table** page.
3. In the **All Dimension Tables** section, click the name of the dimension table in the **File Name** column to go to the dimension table editing page.

   If no dimension table exists and you create one, the table editing page appears after the table is created. For more information about how to edit a dimension table, see Edit a dimension table.
4. On the dimension table editing page, click **Import** in the upper-right corner.
5. In the **Import** dialog box, select the type of the file that contains the data to be imported and set parameters.

   > **Note** Only data of the STRING type can be imported to a dimension table. Data that is not of the STRING type will be automatically converted to the STRING type when it is imported.

   - **Spreadsheet**

Parameter	Description
Spreadsheet	The workbook from which you want to import data. Select a workbook from the **Spreadsheet** drop-down list.
Sheet	The sheet from which you want to import data. Select a sheet from the **Sheet** drop-down list.
Data Preview	Displays the data in the selected sheet. When you preview the data in the selected sheet, you can determine whether to use the values in the first row as the column names by selecting or clearing **First Row as Field Names**.
Field Mapping	The mappings between the columns in the selected sheet and the fields in the dimension table.
Import Data Mode	The mode used to import data. Valid values: **Append** and **Overlay**.

- Local CSV File

Parameter	Description
File	The CSV file from which you want to import data. Click **Select File(.csv)**, select the required CSV file from your on-premises machine, and then click **Open**.
Original Character Set	The character set that is used by the selected CSV file. Valid values: **UTF-8** and **GBK**. If garbled characters appear, you can change the character set.
Separator	The row delimiter and column delimiter. ■ Valid values of row delimiters: \r\n, \n, and \r. ■ Valid values of column delimiters: commas (,), semicolons (;), and \t. If the cell data cannot be correctly separated, you can change the delimiters.
Data Preview	Displays the data in the selected sheet. When you preview the data in the selected sheet, you can determine whether to use the values in the first row as the column names by selecting or clearing **First Row as Field Names**.
Field Mapping	The mappings between the columns in the selected sheet and the fields in the dimension table.
Import Data Mode	The mode used to import data. Valid values: **Append** and **Overlay**.

- Local Excel file

Parameter	Description
File	The Excel file from which you want to import data. Click **Select File(.xlsx)**, select the desired Excel file from your on-premises machine, and then click **Open**.
Sheet	The sheet from which the data is to be imported. Select a sheet from the **Sheet** drop-down list.
Data Preview	Displays the data in the selected sheet. When you preview the data in the selected sheet, you can determine whether to use the values in the first row as the column names by selecting or clearing **First Row as Field Names**.

Parameter	Description
Field Mapping	The mappings between the columns in the selected sheet and the fields in the dimension table.
Import Data Mode	The mode used to import data. Valid values: **Append** and **Overlay**.

6. Click **OK**.
7. Click **Save** in the upper-right corner of the page.

   After you save the dimension table, you can click **Diff** in the upper-right corner of the page to check whether the changes meet expectations to prevent accidental operations.

2.1.7.4.3. Edit a dimension table

This topic describes how to edit a dimension table in a visualized manner to modify the information of a MaxCompute table that you created. You do not need to write SQL code.

Prerequisites

A dimension table is created. For more information about how to create a dimension table, see Create a dimension table.

Procedure

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. In the top navigation bar of the DataAnalysis page, choose **More > Dimension Table** to go to the **Dimension Table** page.
3. In the **All Dimension Tables** section of the **Dimension Table** page, click the name of the table that you want to edit in the **File Name** column to go to the dimension table editing page.
4. On the dimension table editing page, view and modify the information about the dimension table.

   In the left-side pane of the dimension table editing page, you can view the table information, such as the workspace, table name, table description, lifecycle, and field description. To view the details of the dimension table, click the link below **Table Details** to go to the **Data Map** page. For more information, see View the details of a table.

   To modify the settings of the dimension table, perform the following steps: Click **Modify field settings**. In the **Modify the field settings dimension table** dialog box, change the values of the **Table Description** and **Lifecycle** parameters and click OK. You can also add fields to the table in this dialog box.

   The right side of the dimension table editing page displays all the data in the MaxCompute table as a workbook. The values in the first row are field names. You can double-click a cell to modify the content of a field in the corresponding row.
5. Click **Save** in the upper-right corner of the page to save the changes.

   After you save the dimension table, you can view all the data in the table. You can also click **Diff** in the upper-right corner to view the differences from the previous version in the **Diff From the Previous Version** dialog box.

2.1.7.4.4. Share a dimension table

If you want to collaboratively edit a dimension table with multiple members, you can share the dimension table and grant the members the permissions to edit the table. This topic describes how to share a dimension table and grant edit or read permissions to specified members.

Prerequisites

Allow Sharing is turned on on the **Management** page.

Procedure

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. In the top navigation bar of the DataAnalysis page, choose **More > Dimension Table** to go to the **Dimension Table** page.
3. In the **All Dimension Tables** section of the **Dimension Table** page, click the name of the table that you want to edit in the **File Name** column to go to the dimension table editing page.

   If no dimension table exists and you created one, the dimension table editing page appears after the table is created. For information about how to edit a dimension table, see Edit a dimension table.
4. In the upper-right corner of the dimension table editing page, click **Share**. In the dialog box that appears, configure the sharing mode as required.

   You must configure the following information before you can share a dimension table with other members:

   - **Link**: After you specify Users with Edit Access and Users with Read Access, click **Copy Link** and send the copied URL to specified members.
   - **Users with Edit Access**: To specify members with permissions to edit the dimension table, click **Add** in the **Users with Edit Access** section. In the dialog box that appears, enter and select the names of the members to be granted the edit permissions, and click **OK**.

     > **Note** You can grant the edit permissions to a maximum of 10 members.

   - **Users with Read Access**: To specify members with permissions to read the dimension table, click **Add** in the **Users with Read Access** section. In the dialog box that appears, enter and select the names of the members to be granted the read permissions, and click **OK**.

     > **Note** You can grant the read permissions to a maximum of 30 members.

   After the sharing mode is configured, you can send the URL to specified members. The members can use the URL to access the dimension table. You can go back to the **Dimension Table** page to view the dimension tables that are shared with you.

2.1.7.5. Report

2.1.7.5.1. Create and manage reports

DataAnalysis allows you to explore data in a visualized manner and create reports. You can create reports by dragging and configuring controls without the need to write SQL code.

Create a report

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.

ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.

2. In the top navigation bar of the DataAnalysis page, choose **More > Reports** to go to the **Reports** page.
3. On the **Reports** page, click the + icon in the **New Report** section to go to the report editing page. You can edit the report on this page. For more information, see Edit a report.

   If you have templates within your account, you can click a template to create a report based on the template.

View and manage reports

1. On the report editing page, click **Reports** in the upper-left corner to go back to the Reports page.
2. In the **All Reports** section of the **Reports** page, you can view all reports.
3. Click the name of a report in the **File Name** column to go to the report editing page.

   On the Reports page, you can also perform the following operations on a report:

   - To rename a report, find the report and click the icon in the Operation column. In the **Rename** dialog box, enter a new name in the **File Name** field and click **OK**.
   - To delete a report, find the report and click the icon in the Operation column. In the **Delete** message, click **OK**.

What's next

After you create a report, go to the report editing page and edit the report in a visualized manner. For information about how to edit a report, see Edit a report.

2.1.7.5.2. Edit a report

This topic describes how to edit, preview, save, share, and publish a report, and save a report as a template.

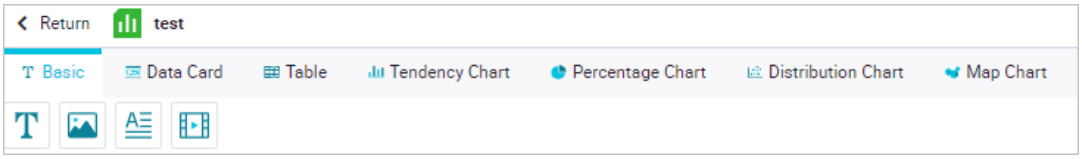
Procedure

1. Go to the DataAnalysis page.
   i. Log on to the DataWorks console.
   ii. In the left-side navigation pane, click the icon and choose **All Products > Data Development > DataAnalysis**. The **DataAnalysis** page appears.
2. In the top navigation bar of the DataAnalysis page, choose **More > Reports** to go to the **Reports** page.
3. Go to the editing page of a report.

   Use one of the following methods to go to the editing page of a report:

   - After you create a report, the editing page of the report appears. For more information, see Create and manage reports.
   - In the **All Reports** section of the Reports page, click the name of the report that you want to edit in the **File Name** column.
4. Drag controls from the menu bar to the canvas. In this topic, the **Bar Chart** control on the **Tendency Chart** tab is dragged to the canvas of the current report.

   You can drag a control from the menu bar to the canvas to use the control as a component in the report.



5. Click the **Bar Chart** component. Then, add a data source on the **Data Config** tab in the right-side configuration section.

   If a data source is added, click the name of the data source on the **Data Config** tab.

   If you want to add a data source, click **Add** on the **Data Config** tab. In the **Add** dialog box, configure the parameters and click **OK**.

   You can set the Choose Data parameter to Select a spreadsheet or Use External Data Source.

   - **Select a spreadsheet**: You can select an editable worksheet in a workbook of the current user as the data source.

Parameter	Description
Choose Data	The range of the data that you want to analyze. Select **Select a spreadsheet**.
Spreadsheet	The workbook from which the data is analyzed. Select a workbook from the **Spreadsheet** drop-down list.
SHEET	The worksheet of which the data is analyzed. Select a worksheet from the **SHEET** drop-down list.

   - **Use External Data Source**: You can add an external data source. The following types of external data sources are supported: **Mysql**, **PostgreSQL**, and **Data Services**.

Parameter	Description
Choose Data	The range of the data that you want to analyze. Select **Use External Data Source**.
Type	The type of the data source. Valid values: **Mysql**, **PostgreSQL**, and **Data Services**.
Workspace	The workspace in which the data source resides.
Data Source	The name of the data source. To add a data source, perform the following steps: Go to the DataStudio page. Click the **Workspace Manage** icon in the upper-right corner. On the page that appears, click **Data Source** in the left-side navigation pane. On the Data Source page, add a data source. **Note** This parameter is available only if the Type parameter is set to **Mysql**.
Table	The table of which the data is analyzed. **Note** This parameter is available only if the Type parameter is set to **Mysql**.

Parameter	Description
API Group	The API group to which the API belongs. **Note** This parameter is available only if the Type parameter is set to **Data Services**.
API	The API that you want to use as the data source. **Note** This parameter is available only if the Type parameter is set to **Data Services**.

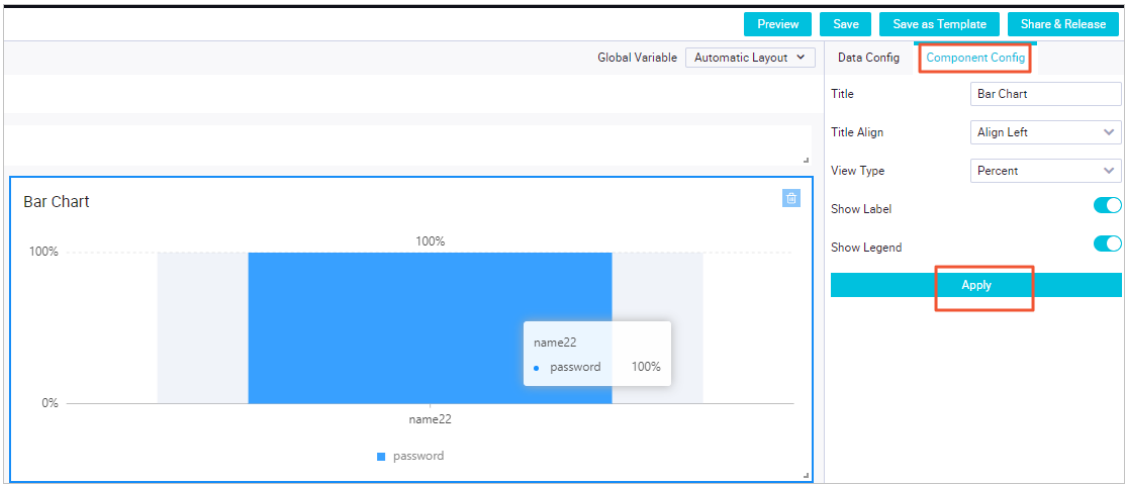
6. Select fields as statistical items.

   The fields that are required vary based on the chart type. For example, you must set the **X-Axis**, **Y-Axis**, **Split**, and **Filter** parameters in the Data Config section for a column chart by dragging fields from the **Pivot Table Fields** section. You can also set the **Limit Count** parameter.

   Multiple charts can use the same data source. They can use the data source in different ways without affecting each other. A chart can use only one data source. If you click a chart and drag fields from the Pivot Table Fields section to the Data Config section, the chart is associated with the data source.

7. Configure the column chart.
   i. On the canvas, click the **Bar Chart** component.
   ii. Click the **Component Config** tab in the right-side configuration section.

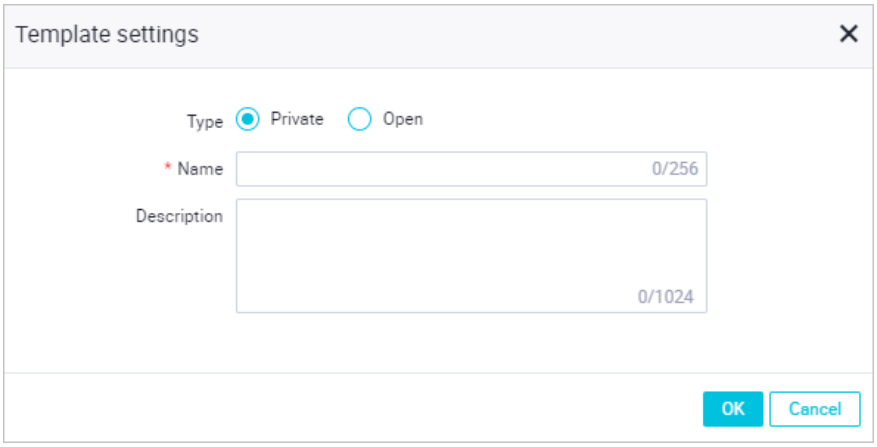
iii. On the **Component Config** tab, set the parameters.



Parameter	Description
Title	The title of the component.
Title Align	The alignment of the chart title. Valid values: **Align Left**, **Align Center**, and **Align Right**.
View Type	The display mode of vertical columns. Valid values: **Stack**, **Parallel**, and **Percent**.
Show Label	Specifies whether to display labels for the component.
Show Legend	Specifies whether to display legends for the component.

8. Click **Apply**.
9. Go back to the **Reports** page or preview, save, share, or publish the report based on your business requirements.
   - **Reports**: Click **Reports** in the upper-left corner to go back to the **Reports** page. On the Reports page, you can view other reports and go to the editing page of each of these reports.
   - **Preview**: Click **Preview** in the upper-right corner to preview the report.
   - **Save**: Click **Save** in the upper-right corner to save the report so that you can open and edit the saved report next time.
   - **Save as Template**: Save the report as a template. This way, you can use this template to create another report. Perform the following steps to save a report as a template:
     a. On the editing page of a report, click **Save as Template** in the upper-right corner.
     b. On the **Preview** page, click **Next Step (Template setup)**.

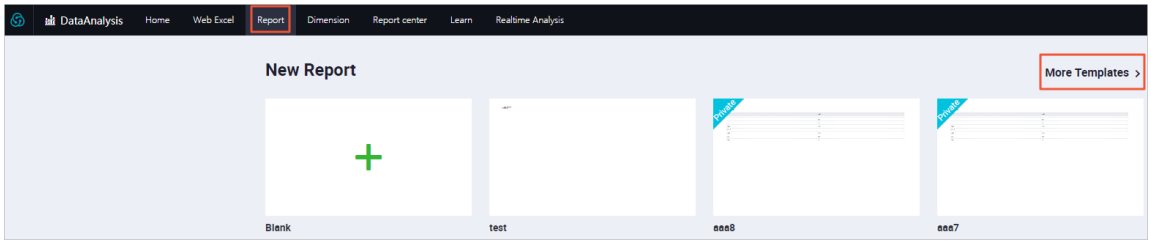
c. In the **Template settings** dialog box, set the parameters.



Parameter	Description
Type	Specifies whether to show the template to other users. Valid values: **Private** and **Open**.
Name	The name of the template. The name can be a maximum of 256 characters in length.
Description	The description of the template. The description can be a maximum of 1,024 characters in length.

d. Click **OK**.

After you save the report as a template, you can click the template in the New Report section of the **Reports** page to create a report.



- **Share & Release**: Click **Share & Release** in the upper-right corner to share and publish the report. You can share the report with specific or all users. If you want to share the report with specific users, click **Add** to specify the users.

2.1.8. Administration

2.1.8.1. Overview

Operation Center consists of the following modules: Overview, RealTime Task Maintenance, Cycle Task Maintenance, Alarm, and Engine Maintenance.

Module	Description
Overview	This module displays the running statuses of nodes in charts.

Module	Description
RealTime Task Maintenance	This module displays all the real-time data synchronization nodes that are committed to and run by the scheduling system. For more information, see Manage real-time synchronization nodes.
Cycle Task Maintenance	This module displays all the **auto triggered nodes** that are committed to and run by the scheduling system, the **instances** that are generated for the nodes, **retroactive instances**, and **test instances**. For more information, see Manage auto triggered nodes.
Trigger Task Maintenance	This module displays all the **manually triggered nodes** that are committed to the scheduling system and the **instances** generated for the nodes. For more information, see Manage manually triggered nodes.
Alarm	This module displays the running statuses of nodes that are monitored. You will receive alerts if monitored nodes are abnormal. For more information, see Overview.
Engine Maintenance	This module allows you to view the jobs, quota groups, and projects of MaxCompute. For more information, see MaxCompute engine O&M.

Scenarios

- You can view and manage your nodes and instances in Operation Center. You can also test nodes and generate retroactive data for the nodes.
- If you are using a workspace in standard mode, you can switch between the production and development environments by changing the URL of the Operation Center page. If the URL contains env=dev, Operation Center in the development environment is used. If the URL contains env=prod, Operation Center in the production environment is used. You can change the value of the env parameter to go to Operation Center of your desired environment.
- When you perform O&M for your nodes, you can view the instances of all the nodes and perform related operations on the instances. For example, you can stop and rerun instances.

> **Note** Instances are generated after nodes are run by the scheduling system. An instance is a snapshot of a node at a specific point in time. The instance contains information such as the time when the node is run, the running status of the node, and operational logs.

2.1.8.2. View the statistics on the Overview page

The Overview page displays the overall O&M information, including the metrics that require your special attention, overall running information about nodes, and trends on scheduling resource changes. It also displays information about Data Integration, including the distribution of batch synchronization nodes and real-time synchronization nodes in different states and the data synchronization progress of batch synchronization nodes and real-time synchronization nodes. This helps improve O&M efficiency.

Go to the Overview page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**. The **Workbench Overview** tab on the **Overview** page appears.

View the statistics on the Workbench Overview tab

The Workbench Overview tab displays the statistics only on auto triggered nodes and auto triggered node instances. You can view the following information on the **Workbench Overview** tab:

- The **Focus on** section displays the following information:
  - The numbers of auto triggered node instances that require your special attention, including **failed instances**, **slow running instances**, and **instances waiting for resources**. Statistics are collected on auto triggered node instances whose data timestamp is the day before the current date. A node instance is considered a **slow running instance** if it meets the following conditions:
    - The node instance is running.
    - The running time of the node instance exceeds 30 minutes.
    - The running time of the node instance is at least 15 minutes longer than the average running time of the node instance during the last 10 days.
  - The numbers of **isolated nodes**, **paused nodes**, and **expired nodes**.
    - An isolated node is a node that does not have an ancestor node. In this case, the node cannot be run. For example, if you change the output name for the ancestor node of a node, the dependency becomes invalid.
    - After a node is paused, the node no longer generates node instances and cannot be scheduled.
    - If a node is not run at the specified time, the node becomes expired.

  The statistics in the Focus on section are updated when you load the page. You can click a type of node or node instance to go to the details page and view the specific nodes or node instances. We recommend that you manage these nodes and node instances at the earliest opportunity to avoid impacts on your business.
- The **Running Status Distribution** section displays the distribution of auto triggered node instances in different states. The data timestamp of these node instances is the day before the current date. The statistics in this section are updated when you load the page. You can click a sector in the pie chart to view the auto triggered node instances in a specific state.
- The **Node Completion** section displays the completion status of auto triggered node instances between 00:00 and 23:00 of the current date. You can view the number of auto triggered node instances that are successfully run or not run today and yesterday. You can also view the historical average number of auto triggered node instances that are successfully run or not run. In addition, you can select a node type to view the status of specific auto triggered node instances.

  The line chart displays the number of auto triggered node instances that are run today, the number of auto triggered node instances that are run yesterday, and the historical average number of auto triggered node instances that are run. If the deviations among the three numbers are large, an exception occurred during a specified time period. You must perform a further check and analysis.

  > **Note** The statistical aggregation method used by Operation Center has been changed. Only auto triggered node instances in the production environment are counted. Therefore, the line that represents the number of auto triggered node instances that are run today shows obvious fluctuations.
- The **Scheduling Resource Allocation** section displays the resource usage of a specific resource group and the number of auto triggered node instances that were running at different points in time within the last 24 hours. You can select a resource group from the **Resource Group** drop-down list in the upper-right corner of this section.

  Number of Instances represents the number of node instances in the current workspace, and **Resource Usage** represents the resource usage of the resource group in the current region.

  > **Note** The resources that are used by Data Integration nodes of the resource group are not recorded.
- The **Runtime Ranking** section ranks nodes based on their running time, time spent in waiting for resources, and slow running time. The statistics in this section are updated every day. Nodes that are run successfully on the day before the current date are ranked in this section.
- The **Error Ranking in Recent Month** section ranks nodes on which errors occurred within the last month and

displays the top 10 nodes. The statistics in this section are updated every day. You can view the settings of **Node ID**, **Node Name**, and **Errors** for each node.

- The **Number of Auto Triggered Nodes** section displays the trends on the numbers of auto triggered nodes and auto triggered node instances in a specified time range in the production environment. The statistics in this section are updated every day. You can view the trends on the numbers of auto triggered nodes and auto triggered node instances in a time range as wide as one year.
- The **Node Types** section displays the distribution of nodes in a pie chart. The statistics in this section are updated when you load the page. The pie chart displays a maximum of eight node types. If you have created more than eight types of nodes, specific node types are merged for display.

View the statistics on batch synchronization nodes on the Data integration tab

Click **Data Integration** on the **Overview** page. The Data integration tab appears. By default, the Data integration tab displays the statistics on **batch synchronization nodes** within a specified time range. You can specify **Time range** in the upper-right corner.

You can view the statistics on batch synchronization nodes in the following sections:

- The **RUNNING state distribution** section displays the distribution of batch synchronization node instances in different states. The data timestamp of these node instances is in the specified time range. The statistics in this section are updated when you load the page. You can click a sector in the pie chart to view the node instances in a specific state.
- The **Data Synchronization progress** section displays information about the data that is involved in batch synchronization within the specified time range. The information includes the **total amount of data**, **total public traffic**, and **total number of records**.
- The **Synchronize data volume statistics** section displays the curves of the data that is read from or written to different data sources within the specified time range.
- The **Latest list Top10** section displays the latest 10 node instances that **failed** to be run and the latest 10 node instances that are run **successfully**. The statistics provide you with an overview of the latest node instance status.
- The **Synchronization task execution details** section allows you to specify filter conditions to search for node instances. The filter conditions include **Submission time**, **Status**, and **Task name**. You can click the ID of a node instance to view the running details of the node instance.

View the statistics on real-time synchronization nodes on the Data integration tab

Click **Data Integration** on the **Overview** page. On the **Data integration** tab, click **Real-time synchronization**. You can view the statistics on real-time synchronization nodes in the following sections:

- The **RUNNING state distribution** section displays the distribution of real-time synchronization node instances in different states. The statistics in this section are updated when you load the page. You can click a sector in the pie chart to view the node instances in a specific state.
- The **Overview** section displays the total data transmission speed and total recording speed of all real-time synchronization node instances in the current workspace.
- The **Task delay Top10** section displays the top 10 node instances with the highest latency. This helps you find node instances with high latency.
- The **Task alarm information** section displays information about the latest alerts. This helps you efficiently view exceptions.
- The **Failover information** section displays information about failovers within a specified time period. This provides you with an overview of failovers.

2.1.8.3. Manage real-time synchronization nodes

This topic describes how to manage real-time synchronization nodes on the Operation Center page.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click the icon in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **RealTime Task Maintenance > Real Time DI**.
4. On the **Real Time DI** page, find your desired real-time synchronization node, click the node name, and then view the operations and maintenance (O&M) details about the node.

   On this page, you can **start**, **stop**, **undeploy**, or **configure alerting** for the real-time synchronization node.

   - To start a node that is not running, perform the following steps:
     a. Find the node and click **Start** in the Operation column.
     b. In the **Start** dialog box, configure the parameters.

Parameter	Description
Whether to reset the site	Specifies whether to set the time point for the next startup. If you select Reset site, the **Start time point** and **Time zone** parameters are required.
Start time point	The date and time for starting the real-time synchronization node.
Time zone	The time zone where the source resides. Select a time zone from the **Time zone** drop-down list.
Failover	■ The condition for automatically terminating the real-time synchronization node. You can specify the maximum number of dirty data records allowed. If you set the value to 0, no dirty data records are allowed. If the value is empty, the running of the node continues no matter whether dirty data records exist. ■ You can also specify the maximum number of failover times. If you do not specify Failover, the node is automatically terminated if the node fails 100 times within 5 minutes. This avoids resource occupation caused by frequent startup.

     c. Click **OK**.
   - To stop a running node, perform the following steps:
     a. Find the node and click **Stop** in the Operation column.
     b. In the message that appears, click **Stop**.
   - To undeploy a node that is not running, perform the following steps:
     a. Find the node and click **Offline** in the Operation column.
     b. In the message that appears, click **Offline**.
   - Find the node and click **Alarm settings** in the Operation column. On the page that appears, you can view alert event information and alert rules on the **Alert event** and **Alarm rules** tabs.
   - To configure alert settings for a node, perform the following steps:
     a. Select your desired node and click **New Alarm** in the lower part of the page.

b. In the **New rule** dialog box, configure the parameters.

Parameter	Description
Name	Required. The name of the rule that you want to create.
Description	The description of the rule.
Indicators	The metrics in the rule that you want to create. Valid values: **Task Status**, **Business latency**, **Failover**, **Dirty Data**, and **DDL error**.
Threshold	The threshold for reporting an alert. The default value is 5 minutes for both **WARNING** and **CRITICAL** alerts.
Alarm interval	The interval at which an alert is reported. The default value is 5 minutes.
WARNING	The methods used to send alert notifications. Set the value to **Mail**.
CRITICAL	
Receiver	The alert recipient. Select a recipient from the **Receiver** drop-down list.

c. Click **OK**.

- To modify alert settings for a node, perform the following steps:
  a. Select your desired node and click **Operation alarm** in the lower part of the page.
  b. In the **Operation alarm** dialog box, specify the **Operation type** and **Alarm indicators** parameters.

     DataWorks automatically modifies all the rules for the selected alert types at a time.
  c. Click **OK**.

2.1.8.4. Auto triggered node O&M

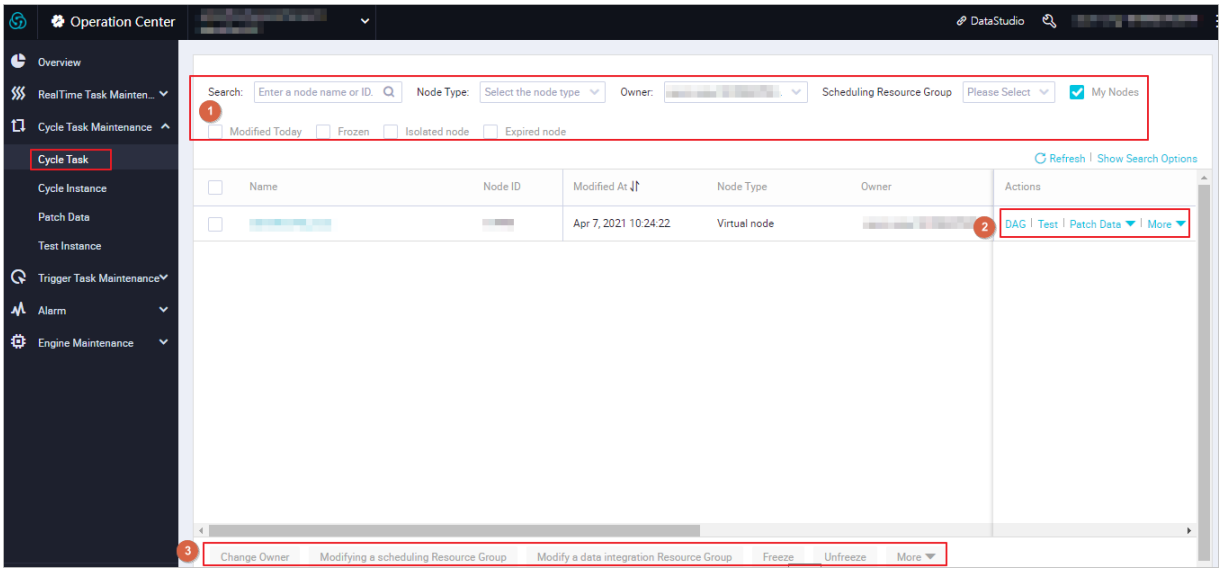
2.1.8.4.1. Manage auto triggered nodes

Auto triggered nodes are automatically run as scheduled after they are committed to the scheduling system. You can view the details of an auto triggered node from the directed acyclic graph (DAG) of the node or the auto triggered node list.

> **Note**
> - By default, the auto triggered node list displays nodes in all the workflows created by using the current account.
> - After you commit a node, the scheduling system automatically generates and runs an instance of the node at 23:30 the next day. If you commit a node after 23:30, the scheduling system generates and runs an instance of the node on the third day.
> - Do not perform operations on the **projectname_root** node, which is the root node of the workspace. All instances of auto triggered nodes depend on this node. If this node is frozen, the instances of auto triggered nodes cannot be run.

Manage auto triggered nodes in the node list

The **Cycle Task** page displays the auto triggered nodes that are committed to the scheduling system in a list.



Operation	Description
Filter	Allows you to specify filter conditions to search for the desired auto triggered nodes in the section marked with 1 in the preceding figure. You can search for the desired nodes by node name or node ID. You can also specify the filter conditions such as **Node Type**, **Owner**, **Scheduling Resource Group**, **My Nodes**, **Modified Today**, **Frozen Nodes**, **Isolated Nodes**, and **Expired Nodes** to perform the operation. **Note** When you search for the desired auto triggered nodes by node name, the search result is affected by other filter conditions that you specified. Only nodes that meet all filter conditions are displayed.
DAG	Allows you to view information such as the properties, operation logs, and code of the node. You can click **DAG** in the Actions column of the node to open the DAG in the section marked with 2 in the preceding figure.
Test	Allows you to test the node. You can click **Test** in the Actions column of the node in the section marked with 2 in the preceding figure. For more information, see Manage test instances.
Patch Data	Allows you to backfill data for the node. You can click **Patch Data** in the Actions column of the node in the section marked with 2 in the preceding figure. For more information, see Manage retroactive instances.

Operation	Description
More	Allows you to perform more operations on the node, such as freezing and unfreezing the node, and view the instances of the node. You can click **More** in the Actions column and perform the desired operation on the node in the section marked with 2 in the preceding figure. • Select **Freeze** to freeze the node. After the node is frozen, the system generates instances for the node but does not run the instances of the node and its dependent descendant instances. • Select **Unfreeze** to unfreeze the node. After the node is unfrozen, the system normally runs the instances of the node and its descendant instances. • Select **View Instances** to view the instances of the node. • Select **Configure Alert Rule** to configure alert rules for the node. • Select **Change Owner** to change the owner of the node. • Select **Add to Baseline** to add the node to a baseline. • Select **Change Resource Group** to change the resource group used to run the node if the workspace has multiple resource groups. • Select **Configure Data Quality Rules** to configure the rules that are used to monitor the data quality of the node. • Select **View Lineage** to view the lineage of the node. • Select **View Node Details** to go to the **Node Information** page. On this page, you can view the node information on the **Ancestor Nodes** and **Descendent Nodes** tabs.
Change Owner, **Modify Scheduling Resource Group**, **Modify Data Integration Resource Group**, **Freeze**, **Unfreeze**, **Configure Alert Rule**, **Add to Baseline**, and **Undeploy**	Allows you to select multiple nodes and perform operations on the nodes at a time. In the section marked with 3 in the preceding figure, you can click **Change Owner**, **Modify Scheduling Resource Group**, **Modify Data Integration Resource Group**, **Freeze**, or **Unfreeze**, or select **Configure Alert Rule**, **Add to Baseline**, or **Undeploy** after you click **More** to perform the related operation on the selected nodes.

Manage auto triggered nodes in a DAG

Find the desired node in the node list and click its name or **DAG** in the Actions column to view the DAG of the node. In the DAG, you can right-click the node to perform related operations.

Operation	Description
Show Ancestor Nodes or **Show Descendant Nodes**	Allows you to view the ancestor or descendant instances of the node at one or more levels. If a workflow contains three or more nodes, the system hides some nodes. Select the largest number to view the most node dependencies.
View Node Details	Allows you to go to the **Node Information** page to view the node information, including the input table, output table, ancestor nodes, and descendant nodes.
View Code	Allows you to view the code of the node.

Operation	Description
Edit Node	Allows you to go to the DataStudio page and modify the node.
View Instances	Allows you to view the instances of the node.
View Lineage	Allows you to view the lineage of the node.
Test	Allows you to perform smoke testing for the node. You must specify the **Test Name** and **Data Timestamp** parameters in the **Test** dialog box and click **OK**. Then, the Test Instance page appears.
Run	Allows you to backfill data for the node. The following modes for backfilling data are supported: **Current Node Retroactively**, **Current and Descendant Nodes Retroactively**, and **Mass Nodes Retroactively**.
Freeze	Allows you to freeze the node and pause the scheduling of the node.
Unfreeze	Allows you to resume the scheduling of the frozen node.
Configure Data Quality Rules	Allows you to configure the rules that are used to monitor the data quality of the node.

2.1.8.4.2. Manage auto triggered node instances

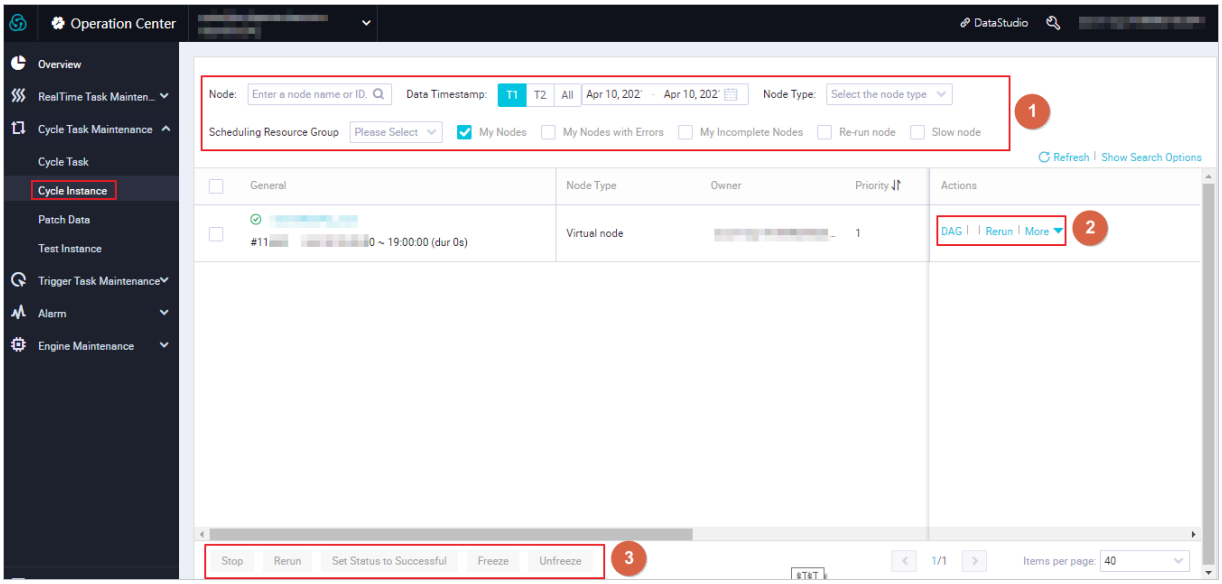
An auto triggered node instance is a snapshot that is taken for an auto triggered node at the time the node is scheduled to run.

An instance is generated each time an auto triggered node is run as scheduled. You can manage auto triggered node instances that have been scheduled. For example, you can view the status of instances, and stop, rerun, and unfreeze instances.

> **Note** Instances are generated as scheduled for auto triggered nodes. Each generated instance runs the latest code. If you modify and recommit the node code after instances are generated for the node, the latest code is run on the instances that have not been run.

Manage auto triggered node instances on the Cycle Instance page

You can manage auto triggered node instances in the instance list. For example, you can check operational logs, rerun instances, and stop running instances.



Operation	Description
Filter	You can specify filter conditions to search for your desired instance in the section marked with 1 in the preceding figure. You can search for instances by node name or node ID. You can also specify the following conditions to search for your desired instance: **Data Timestamp**, **Node Type**, **Scheduling Resource Group**, **My Nodes**, **My Nodes with Errors**, **My Incomplete Nodes**, **Rerun Nodes**, and **Slow Nodes**. **Note** By default, the date indicated by the value of the Data Timestamp parameter is one day before the current date.
Stop	Allows you to stop the instance. You can stop an instance only in the **Waiting time** or **Running** state. After you perform this operation, the instance enters the **Run failed** state.
Rerun	Allows you to rerun the instance. After the instance is rerun, its descendant instances that have not been run are run as scheduled. If an instance fails to be run or an instance is not run as scheduled, perform this operation. **Note** This operation applies only to the instances in the **Not Running**, **Succeeded**, or **Run failed** state.
Rerun Descendent Nodes	Allows you to rerun the instance and its descendant instances. You must specify the instances that you want to rerun. After they are run, the descendant instances that are not run are run as scheduled. Perform this operation to recover data. **Note** Only instances in the **Not Running**, **Succeeded**, or **Run failed** state can be selected. The value No appears in the **Meet Rerun Condition** column for instances in other states, and you cannot select these instances.

Operation	Description
Set Status to Successful	Allows you to set the state of the instance to **Succeeded** and run its descendant instances that are not run. If an instance fails to be run, perform this operation. **Note** This operation applies only to instances in the **Run failed** state.
Freeze	Allows you to freeze the instance in the running state.
Unfreeze	Allows you to unfreeze the instance that is frozen. • If the instance is not run, it is automatically run after the running of its ancestor instances is complete. • If all the ancestor instances are run, the state of the instance is directly set to Run failed. You must manually rerun the instance.
View Lineage	Allows you to view the lineage of the instance.
View Node Details	Allows you to view the details about the instance and its ancestor and descendant instances on the **Instance Information** page.
View Runtime Log	Allows you to view the operational logs of the instance.
Stop, Rerun, Set Status to Successful, Freeze, and Unfreeze	Allows you to perform operations on multiple instances at a time. You can click the following buttons in the section marked with 3 in the preceding figure to perform operations on multiple instances at a time: **Stop**, **Rerun**, **Set Status to Successful**, **Freeze**, and **Unfreeze**.

Manage an auto triggered node instance in a DAG

Click the name of an instance or **DAG** in the Actions column that corresponds to an instance to view the directed acyclic graph (DAG) of the instance. In the DAG, you can right-click the instance to perform related operations.

Operation	Description
Show Ancestor Nodes or **Show Descendant Nodes**	Allows you to view the ancestor or descendant instances of the instance at one or more levels. If a workflow contains three or more instances, the DAG displays only the current instance and hides its ancestor and descendant instances.
View Runtime Log	Allows you to view the operational logs of the instance in the Running, Succeeded, or Run failed state.
View Code	Allows you to view the code of the instance.
Edit Node	Allows you to go to the DataStudio page and modify the node to which the instance belongs.
View Lineage	Allows you to view the lineage of the instance.
More	Allows you to view more information about the instance on the **General**, **Context**, **Runtime Log**, **Operation Log**, and **Code** tabs.
Stop	Allows you to stop the instance. Only instances in the Waiting time or Running state can be stopped. After you perform this operation, the instance enters the Run failed state.

Operation	Description
Rerun	Allows you to rerun the instance. After the instance is rerun, its descendant instances that have not been run are run as scheduled. If an instance fails to be run or an instance is not run as scheduled, perform this operation. **Note** This operation applies only to instances in the **Not Running**, **Succeeded**, or **Run failed** state.
Rerun Descendent Nodes	Allows you to rerun the instance and its descendant instances. You must specify the instances that you want to rerun. After they are run, the descendant instances that are not run are run as scheduled. Perform this operation to recover data. **Note** Only instances in the **Not Running**, **Succeeded**, or **Run failed** state can be selected. The value No appears in the **Meet Rerun Condition** column for instances in other states, and you cannot select these instances.
Set Status to Successful	Allows you to set the state of the instance to Succeeded and run its descendant instances that have not been run. If an instance fails to be run, perform this operation. **Note** This operation applies only to instances in the **Run failed** state.
Resume	Allows you to continue to run the instance after it fails.
Emergency Operations	Allows you to perform emergency operations in emergencies only. The emergency operations include **Delete Dependencies**, **Change Priority**, and **Force Rerun**. The emergency operations take effect only once on the current instance. Select **Delete Dependencies** to delete the dependencies of the current instance. If the ancestor instances fail and the current instance does not depend on the data of the ancestor instances, you can perform this operation to start the current instance.
Freeze	Allows you to freeze the instance in the Running state.
Unfreeze	Allows you to unfreeze the instance that is frozen. • If the instance is not run, it is automatically run after the running of its ancestor instances is complete. • If all the ancestor instances of the instance are successfully run, the state of the instance is directly set to Run failed. You must manually rerun the instance.

Instance states

No.	State	Icon
1	Succeeded	
2	Not Running	
3	Run failed	

No.	State	Icon
4	Running	
5	Waiting time	
6	Freeze	

2.1.8.4.3. Manage data backfill node instances

Data backfill node instances are generated when DataWorks backfills data for auto triggered nodes. You can perform O&M for and manage data backfill node instances. For example, you can view the statuses of data backfill node instances and stop, rerun, or unfreeze data backfill node instances.

Limits

- When DataWorks backfills data for a node for a specific time range, if one instance of the node fails on a day within the time range, the data backfill node instance for that day is also set to Failed. DataWorks will not run the instances of this node for the next day. To sum up, DataWorks runs the instances of a node on a day only when all its instances on the previous day are successfully run.
- For a self-dependent auto triggered node, if the first instance for which data needs to be backfilled has a last-cycle instance that is not run on the previous day, the data backfill node instance cannot be run. If the first instance for which data needs to be backfilled does not have a last-cycle instance on the previous day, the data backfill node instance is directly run.
- DataWorks generates alerts only for auto triggered node instances that fail.
- If an auto triggered node instance is running for a node, the data backfill node and test instances of the node can be run only after the running of the auto triggered node instance is complete.
- If both an auto triggered node instance and a data backfill node instance are running for a node, you must stop the data backfill node instance to ensure that the auto triggered node instance can be run as expected.

Backfill data

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. On the Operation Center page, choose **Cycle Task Maintenance > Cycle Task** in the left-side navigation pane.
4. On the Cycle Task page, click the rightward arrow in the middle to show the node list. Find the required node, click **Patch Data** in the Actions column, and then select a mode to backfill data.

   You can also click DAG in the Actions column of the required node. In the panel that appears, right-click the node name in the directed acyclic graph (DAG), move the pointer over **Run**, and then select a mode to backfill data.

Backfill data for the current node

1. Find the required node and choose **Patch Data > Current Node Retroactively** in the Actions column.
2. In the **Patch Data** dialog box, configure the parameters.

Parameter	Description
Retroactive Instance Name	DataWorks automatically generates a data backfill node instance name for your node. You can modify the name.
Data Timestamp	The data timestamp of the data backfill node instance.
Node	The name of the node for which you want to backfill data. You cannot change the name.
Parallelism	Specifies whether to generate multiple data backfill node instances at a time. ○ If you do not select Parallelism, only one data backfill node instance is generated. The data backfill node instance is run multiple times in sequence based on the data timestamp. ○ If you select Parallelism, you can choose to use no more than 10 data backfill node instances to backfill data for the node at the same time. The data backfill node instances are run in parallel based on the data timestamp. ■ If the number of days in the data timestamp is less than the number of parallel instances, the data backfill node instances are run in parallel. For example, the data timestamp is from January 11 to January 13, and you set Number of Concurrent Nodes to 4. In this case, three data backfill node instances are generated for each day within the data timestamp and are run in parallel. ■ If the number of days in the data timestamp is greater than the number of parallel instances, some instances may be run multiple times in sequence whereas others are run in parallel. For example, the data timestamp is from January 11 to January 13, and you set Number of Concurrent Nodes to 2. In this case, two data backfill node instances are generated. They are run in parallel for once, and one of them must be run for the second time.

3. Click **OK**.

Backfill data for the current node and its descendant nodes

1. Find the required node and choose **Patch Data > Current and Descendent Nodes Retroactively** in the Actions column.
2. In the **Patch Data** dialog box, configure the parameters.

Parameter	Description
Retroactive Instance Name	DataWorks automatically generates a data backfill node instance name for your node. You can modify the name.
Data Timestamp	The data timestamp of the data backfill node instance.
Parallelism	Specifies whether to generate multiple data backfill node instances at a time. ○ If you do not select Parallelism, only one data backfill node instance is generated. ○ If you select Parallelism, you can choose to use no more than 10 data backfill node instances to backfill data at the same time for the node.
Nodes	You can specify the **Node Name** and **Node Type** parameters to search for nodes for which you want to backfill data.

3. Click **OK**.

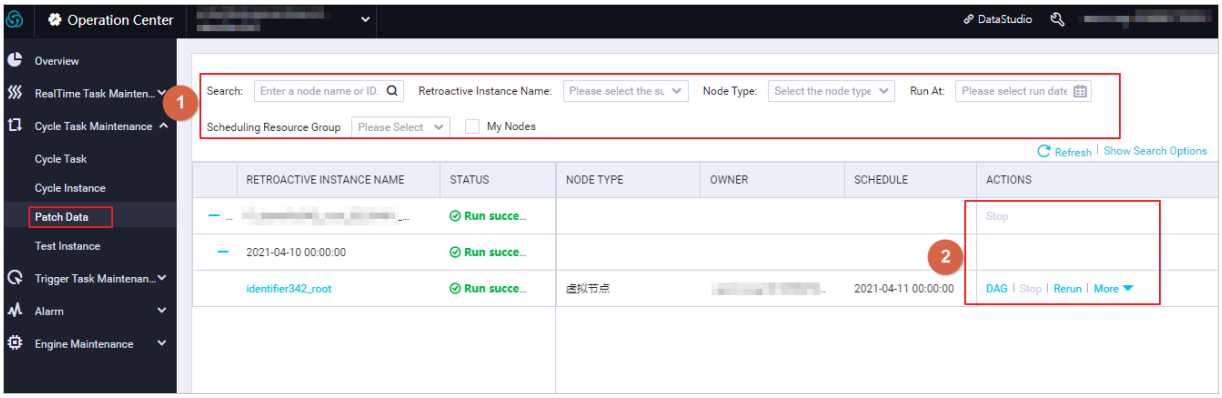
Backfill data for a large number of nodes

1. Find the required node and choose **Patch Data > Mass Nodes Retroactively** in the Actions column.
2. In the **Patch Data** dialog box, configure the parameters.

Parameter	Description
Retroactive Instance Name	DataWorks automatically generates a data backfill node instance name for your node. You can modify the name.
Data Timestamp	The data timestamp of the data backfill node instance. **Note** We recommend that you do not set this parameter to a long time range. Otherwise, the data backfill node instance may be delayed due to insufficient resources.
Nodes	◦ If you select **Current Node**, data backfill node instances are generated for the current node and its descendant nodes. ◦ If you do not select **Current Node**, a dry-run instance is generated for the current node, and data backfill node instances are generated for the descendant nodes of the node.
Workspaces	You can select workspaces from the **Available Workspaces** list and add them to the **Selected Workspaces** list. Fuzzy match is supported when you search for workspaces in the Available Workspaces list.
Node Whitelist	You can add the nodes that are not contained in the selected workspaces and for which you want to backfill data. **Note** You can search for nodes only by node ID.
Node Blacklist	You can add the nodes that are contained in the selected workspaces and for which you do not want to backfill data. **Note** You can search for nodes only by node ID.

3. Click **OK**.

Manage data backfill node instances in the instance list



Operation	Description
Filter	Allows you to search for the desired instances by specifying the filter conditions in the section marked with 1 in the preceding figure. You can search for the desired instances by node name or node ID. You can also specify the filter conditions such as **Retroactive Instance Name**, **Node Type**, **Run At**, **Scheduling Resource Group**, and **My Nodes** to perform the operation. **Note** The default data timestamp is the previous day of the current day.
DAG	Allows you to open the DAG of the current instance to view the running results of the instances.
Stop	Allows you to stop the instance. You can stop an instance only in the **Pending** or **Running** state. After you perform this operation, the instance enters the **Failed** state.
Rerun	Allows you to rerun the instance.
Rerun Descendent Nodes	Allows you to rerun the descendant instances of the current instance.
Set Status to Successful	Allows you to set the status of the instance to **Successful** and run its descendant instances that are not run. Perform this operation if an instance fails to be run.
Freeze	Allows you to freeze the instance and pause the scheduling of the instance.
Unfreeze	Allows you to resume the scheduling of the frozen instance.
View Lineage	Allows you to view the lineage of the instance.

Manage data backfill node instances in a DAG

Click the name of an instance or **DAG** in the Actions column of an instance to view the DAG of the instance. In the DAG, you can right-click the instance to perform the related operations.

Note After you click the **Refresh** icon in the upper-right corner, only the DAG of the instance is refreshed.

Operation	Description
Show Ancestor Nodes or **Show Descendant Nodes**	Allows you to view the ancestor or descendant instances of the instance at one or more levels. If a workflow contains three or more instances, the system shows only the current instance in the DAG. You can select the number of levels to view all instances at one or more levels.
View Runtime Log	Allows you to view the operational logs of the current instance that is in the states such as Running, Successful, or Failed.
View Code	Allows you to view the code of the instance.
Edit Node	Allows you to go to the **DataStudio** page to modify the node to which the instance belongs.
View Lineage	Allows you to view the lineage of the instance.
Stop	Allows you to stop the instance. You can stop an instance only in the **Pending** or **Running** state. After you perform this operation, the instance enters the **Failed** state.
Rerun	Allows you to rerun the instance if it is in the Failed or an abnormal state.
Rerun Descendent Nodes	Allows you to rerun all the descendant instances of the current instance. If the instance has multiple descendant instances, all these instances are rerun.
Set Status to Successful	Allows you to set the status of the current instance to Successful and run its pending descendant instances. Perform this operation if an instance fails to be run. **Note** Only the status of a **failed** instance can be set to successful. This operation does not apply to workflows.
Emergency Operations	Allows you to perform emergency operations in emergencies only. Emergency operations take effect only once on the current instance. Select **Delete Dependencies** to delete the dependencies of the current instance. You can perform this operation to start the current instance if the ancestor instances of the current instance fail and the current instance does not depend on the data of the ancestor instances.
Freeze	Allows you to freeze the current instance and pause the scheduling of the instance.
Unfreeze	Allows you to resume the scheduling of the frozen instance.

2.1.8.4.4. Manage test instances

Test instances are generated when you test auto triggered nodes. You can manage test instances.

Go to the Test Instance page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **Cycle Task Maintenance > Test Instance**. Then, you can view test instances and the directed acyclic graphs (DAGs) of the test instances.

Manage test instances in the instance list

You can manage test instances in the instance list. For example, you can rerun, freeze, or unfreeze instances, set the status of instances to successful, view the lineage of instances, and check operational logs.

Operation	Description
Filter	Allows you to specify filter conditions to search for the desired test instances. You can search for the desired test instances by node name or node ID. You can also specify the filter conditions such as **Node Type**, **Data Timestamp**, **Scheduling Resource Group**, **My Nodes**, **Tested by Me Today**, and **Frozen Nodes** to perform the operation.
Stop	Allows you to stop the test instance. You can stop a test instance only in the **Pending** or **Running** state. After you perform this operation, the test instance enters the **Failed** state.
Rerun	Allows you to rerun the test instance. After the test instance is rerun, the descendant test instances of the test instance that are not run will be run as scheduled. Perform this operation if a test instance fails to be run or a test instance is not run as scheduled. **Note** This operation applies only to test instances in the **Pending**, **Successful**, or **Failed** state.
Set Status to Successful	Allows you to set the status of the current test instance to Successful and run its pending descendant instances. Perform this operation if a test instance fails.
Freeze	Allows you to freeze the test instance and pause the scheduling of the test instance.
Unfreeze	Allows you to resume the scheduling of the frozen test instance.
Stop, Rerun, Set Status to Successful, Freeze, Unfreeze	Allows you to perform batch operations on multiple test instances at a time. You can select multiple test instances and click **Stop**, **Rerun**, **Set Status to Successful**, **Freeze**, or **Unfreeze** to perform the related operation on the instances.

Operation	Description
More	Allows you to perform other operations on the test instance. You can click **More** in the Actions column of the test instance and select an operation. The operations include **Set Status to Successful**, **Freeze**, **Unfreeze**, **View Lineage**, and **View Runtime Log**.

Manage test instances in a DAG

Click the name of a test instance or **DAG** in the Actions column of a test instance to view the DAG of the test instance. In the DAG, you can right-click the test instance to perform the related operations.

Operation	Description
View Runtime Log	Allows you to view the operational logs of the current test instance that is in the states such as Running, Successful, or Failed.
View Code	Allows you to view the code of the test instance.
Edit Node	Allows you to go to the **DataStudio** page to modify the node to which the test instance belongs.
View Lineage	Allows you to view the lineage of the test instance.
Stop	Allows you to stop the test instance. You can stop a test instance only in the **Pending** or **Running** state. After you perform this operation, the test instance enters the **Failed** state.
Rerun	Allows you to rerun the test instance. After the test instance is rerun, the descendant test instances of the test instance that are not run will be run as scheduled. Perform this operation if a test instance fails to be run or a test instance is not run as scheduled. **Note** This operation applies only to test instances in the **Pending**, **Successful**, or **Failed** state.
Set Status to Successful	Allows you to set the status of the test instance to **Successful** and run its descendant test instances that are not run. Perform this operation if a test instance fails. **Note** This operation applies only to failed test instances.
Freeze	Allows you to freeze the test instance and pause the scheduling of the test instance.
Unfreeze	Allows you to resume the scheduling of the test instance that is paused. • If the test instance is not run, the system automatically runs this test instance after the ancestor test instances of the instance are successfully run. • If all the ancestor test instances of the test instance are successfully run, the status of the test instance is directly set to Failed. You must manually rerun the test instance.

6	Freeze	

2.1.8.5. Manually triggered node O&M

2.1.8.5.1. Manage manually triggered nodes

Manually triggered nodes are the nodes that are created in a manually triggered workflow.

> **Note** After a manually triggered node is committed to the scheduling system, the node is run only after it is manually triggered.

Manage manually triggered nodes

On the Trigger Task page, all the manually triggered nodes that are committed are displayed.

Operation	Description
Filter	Allows you to specify conditions to search for the manually triggered nodes that you want to query. You can search for manually triggered nodes by node name or node ID. You can also specify the following conditions to search for your desired nodes: **Type**, **Node Type**, **Owner**, **Engine Type**, **Engine Instance**, **My Nodes**, and **Modified Today**. > **Note** When you search for nodes by node name, the search result is affected by other filter conditions that you specified. Only the nodes that meet all filter conditions are displayed.
DAG	Allows you to view the directed acyclic graph (DAG) of the node. You can view the node information, such as the code and lineage, in the DAG.
Run	Allows you to run the node to generate manually triggered node instances.
View Instances	Allows you to go to the **Trigger Instance** page to view the manually triggered node instances generated for the node.
More	Allows you to change the owner of the node. You can choose **More > Change Owner** to perform the operation.

Operation	Description
Change Owner, Modify Scheduling Resource Group, and Undeploy	Allows you to change the owners or the resource groups for scheduling of multiple nodes or undeploy multiple nodes at a time.

Manage manually triggered nodes in a DAG

Click the name of a manually triggered node or **DAG** in the Actions column to view the DAG of the node. In the DAG, you can right-click the node to perform the related operations.

Operation	Description
View Code	Allows you to view the code of the node.
Edit Node	Allows you to go to the **DataStudio** page to modify the node.
View Instances	Allows you to view the instances of the node.
View Lineage	Allows you to view the lineage of the node.
Run	Allows you to run the node to generate manually triggered node instances.
Modify Scheduling Resource Group	Allows you to change the resource group for the node.

2.1.8.5.2. Manage manually triggered node instances

DataWorks generates manually triggered node instances from manually triggered nodes. Manually triggered nodes do not have node dependencies, and you can manually trigger these nodes as needed.

> **Notice** DataWorks generates alerts only for auto triggered node instances that fail to run.

Go to the Trigger Instance page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **Trigger Task Maintenance > Trigger Instance**. Then, you can view the list and directed acyclic graphs (DAGs) of manually triggered workflows or manually triggered node instances.

Manage a manually triggered node instance in a manually triggered workflow

Operation	Description

Operation	Description
Filter	Allows you to specify filter conditions to search for the workflow to which the instance you want to manage belongs. You can specify a workflow name and one or more of the following parameters to perform the operation: **Type**, **Owner**, **Data Timestamp**, and **Run At**.
DAG	Allows you to view the instance in the **DAG** of the workflow. You can view the running result of the instance.
Stop	Allows you to stop the instance if it is in the Running state.
Rerun	Allows you to rerun the instance.
Stop	Allows you to stop multiple instances at a time. You can select multiple manually triggered workflows and click **Stop** in the lower part of the page to stop the instances in the selected workflows at a time.

Manage a manually triggered node instance in the DAG of a manually triggered workflow

Click the name of a manually triggered workflow or **DAG** in the Actions column of a manually triggered workflow to view the manually triggered node instance in the workflow. In the DAG, you can right-click the instance and select the desired operation.

> **Note** A manually triggered node in a manually triggered workflow does not have node dependencies. Therefore, only the instance that is generated from this node appears in the DAG of the workflow.

Operation	Description
View Runtime Log	Allows you to view the operational logs of the instance in a state such as Running, Successful, or Failed.
View Code	Allows you to view the code of the instance.
Edit Node	Allows you to go to the **DataStudio** page to modify the instance.
View Lineage	Allows you to view the lineage of the instance.
Stop	Allows you to stop the instance.
Rerun	Allows you to rerun the instance if it is in an abnormal state such as Failed.

2.1.8.6. MaxCompute engine O&M

DataWorks Operation Center provides the MaxCompute engine O&M feature. You can use this feature to view the jobs, quota groups, and projects of MaxCompute.

Prerequisites

A MaxCompute compute engine instance is added on the **Project Management** page.

Go to the MaxCompute page

1. Log on to the DataWorks console.

2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **Engine Maintenance > MaxCompute**. The **Job Queue** tab appears.

   You can view the jobs, quota groups, and projects of MaxCompute.

View jobs

Click the **Job Queue** tab. Then, you can view the total number of jobs and numbers of jobs in the **Running**, **Waiting for Resources**, and **Initializing** states.

You can also configure the **Quota Group** and **Project** parameters to search for jobs. You can view the information indicated by the following parameters for each job: **Instance**, **Execution Time**, **CPU Usage (Minimum/Maximum)**, **Memory Usage (Minimum/Maximum)**, **Priority**, **Node**, **Submitted By**, **Project**, **Type**, **Quota Group**, **Cluster**, **Status**, and **Start Time**.

View quota groups

On the **MaxCompute** page, click the **Quotas** tab.

On the **Quotas** tab, you can view the information indicated by the following parameters for each quota group: **Project**, **Quota Group**, **Default**, **Cluster**, **Minimum CPU (cores)**, **Maximum CPU (cores)**, **Minimum Memory (bytes)**, **Maximum Memory (bytes)**, and **Projects**.

You can click the name of a quota group to view the resource usage information about the quota group.

View projects

On the **MaxCompute** page, click the **Projects** tab.

On the **Projects** tab, you can view the information indicated by the following parameters for each project: **Project**, **Owner**, **Cluster**, **Quota Group**, **Storage Used**, **Storage Quota**, **Storage Usage**, and **Files**.

2.1.8.7. Monitor

2.1.8.7.1. Overview

The Monitor module is a node monitoring and analysis system of DataWorks. Based on monitoring rules and node running status, the Monitor module determines whether, when, and how to trigger an alert, and whom an alert is sent to. It automatically selects the most appropriate alerting time, notification methods, and recipients.

The Monitor module provides you with the following benefits:

- Improves your efficiency on configuring monitoring rules.
- Prevents invalid alerts from bothering you.
- Automatically covers all important nodes for you.

General monitoring systems cannot meet the requirement of DataWorks. The reasons are as follows:

- DataWorks has numerous nodes, so it is difficult for you to find out the nodes to be monitored. Some DataWorks businesses have a large number of nodes, and dependencies between the nodes are complex. Even if you know the most important node, it is difficult to find all ancestor nodes of the node and monitor them all. In this case, if you simply monitor all nodes, a large number of invalid alerts may be generated. In consequence, you may miss those useful alerts.
- The alerting method varies with nodes. For example, some monitoring tasks require the relevant nodes to run for more than one hour before triggering alerts, while other monitoring tasks require the relevant nodes to run for more than two hours. It is extremely complex to set a monitoring node for each node, and it is difficult to predict the alert threshold value for each node.
- The alerting time varies with nodes. For example, an alert for an unimportant node can be sent after you start

working in the morning. An alert for an important node needs to be sent immediately when an error occurs. General monitoring systems cannot tell the importance of each node.

- Different alerts require different operations to turn off.

The Monitor module provides comprehensive monitoring and alerting logic. You only need to provide the node name of your business. Then, the Monitor module automatically monitors the entire process of your node and creates standard alert triggers for the node. In addition, you can customize alerting triggers by completing basic settings.

Currently, the Monitor module has been used for monitoring all important businesses of Alibaba Group. Its full-path monitoring function guarantees the overall data output of all important businesses of Alibaba Group. In addition, it supports analyzing ancestor and descendant node paths to promptly detect risks and provide O&M advice for business departments. These functions of the Monitor module have guaranteed the long-term high stability of businesses in Alibaba Group.

2.1.8.7.2. Feature description

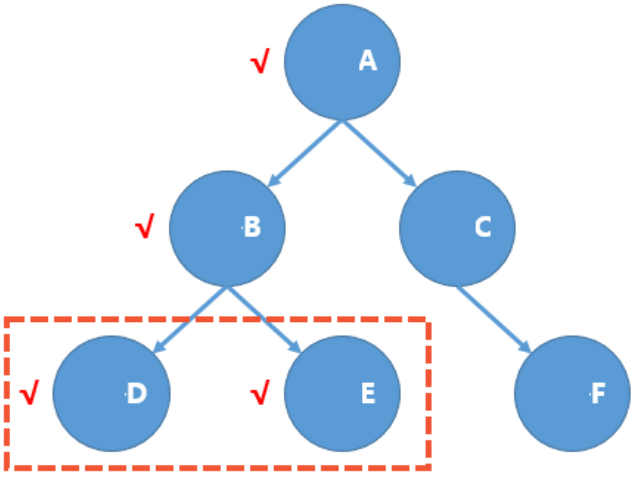
2.1.8.7.2.1. Baseline alert and event alert

This topic describes the functional logic of baseline alerts and event alerts from the aspects of monitoring scope, node capturing, alert object judgment, alerting time judgment, notification methods, and alert escalation.

Monitoring scope

A baseline is a management unit of a group of nodes, that is, a node group. You can specify nodes to monitor in a baseline.

After a baseline is monitored, all nodes of the baseline and its ancestor nodes are monitored. The Monitor module does not monitor all nodes by default. A node is monitored only when it has descendant nodes that are added to a monitoring baseline. If no descendant nodes are added to a monitoring baseline, the Monitor module does not report any alert even if the node fails.



As shown in the preceding figure, assume that DataWorks has only six nodes, and nodes D and E belong to a monitoring baseline. Nodes D and E and all their ancestor nodes are monitored by the Monitor module. That is, any error or slowdown on node A, B, D, or E will be detected by the Monitor module. However, nodes C and F are not monitored by the Monitor module.

Node capturing

After the nodes to be monitored are specified, if a monitored node incurs an exception, the Monitor module generates an event. All alert decisions are based on the analysis of this event. Two types of node exceptions are available. You can choose **Events > Event Type** to view them.

- **Error**: indicates that a node fails to run.

- **Slow**: indicates that the running time of a node is significantly longer than the average running time of the node in the past periods.

> **Note** If a node times out and then encounters an error, two events are generated.

Alerting time judgment

Buffer, an important concept in the Monitor module, refers to the maximum time period that a node can be delayed. The latest start time of a node is obtained by subtracting the average uptime from the baseline time.

The baseline time of baseline A is 05:00, you must set the latest start time of node E to 04:10. This time is calculated by subtracting the average uptime of node F (20 minutes) and node E (30 minutes) from the baseline time 05:00. This time is also the latest completion time of node B in baseline A.

To ensure that the baseline time of baseline B is 06:00, you must set the latest completion time of node B to 04:00. This time, which is earlier than 04:10, is calculated by subtracting the average uptime of node D (2 hours) from the baseline time 06:00. To meet the baseline time of both baseline A and baseline B, you must set the latest completion time of node B to 04:00.

The latest completion time of node A is 02:00, which is calculated by subtracting the average uptime of node B (2 hours) from 04:00. The latest start time of node A is 01:50, which is calculated by subtracting the average uptime of node A (10 minutes) from 02:00. If node A fails to run before 01:50, it is probable that baseline A is broken.

If node A fails to run at 01:00, its buffer is 50 minutes, which is the difference between 01:00 and 01:50. As demonstrated in this example, buffer reflects the degree of caution for a node exception.

Baseline alert

Baseline alerting is an additional feature developed for baselines that are enabled. Each baseline must provide an alert buffer and committed time. Baseline alerting is the action of notifying the preset alert recipient three times at the interval of 30 minutes when the baseline completion time estimated by the Monitor module exceeds the alert buffer.

Notification method

Currently, baseline alerts are sent to the baseline owner by default. On the **Alert Triggers** page, you can find **Global Baseline Alert Trigger**, click **View Details**, and change the alert trigger method and the alerting action.

Gantt chart function

The Gantt chart function reflects the key path of a node. The function is provided by the **Baseline Instances** module of Monitor.

> **Note** The key path is the slowest upstream link that causes the node to be completed at this time point.

2.1.8.7.2.2. Custom alert trigger

Alert trigger customization is a lightweight monitoring function of the Monitor module.

You can customize all monitoring alert triggers by setting the following parameters:

- Objects: You can specify nodes, baselines, and workspaces as objects.
- Trigger Condition: Valid values include Completed, Uncompleted, Error, Uncompleted Cycle, and Overtime.
- Notification Method: Valid values include SMS and Email.
- Maximum Alerts: This parameter indicates the maximum number of alert reporting times. If the number of alerting times exceeds the preset threshold, no alerts are generated.

- Minimum Alert Interval: This parameter indicates the minimum time interval at which DataWorks reports alerts.
- Quiet Hours: This parameter indicates the specified period during which no alerts are reported.
- Recipient: This parameter indicates the person who receives alerts. You can set this parameter to the node owner or another recipient.

A monitoring rule uses the following five alert trigger conditions: Completed, Uncompleted, Error, Uncompleted Cycle, and Overtime.

- **Completed**

  A completion alert can be set for nodes, baselines, and workspaces. Once all nodes of the preset objects are completed, the completion alert is reported. If you set a completion alert for a baseline, the alert is reported when all nodes of the baseline are completed.

- **Uncompleted**

  You can set alerts for nodes, baselines, or workspaces that are not completed at a certain time point. For example, if you require that a baseline be completed at 10:00, an alert containing a list of uncompleted nodes is reported once a node in the baseline is not completed at the specified time.

- **Error**

  An error alert can be set for nodes, baselines, and workspaces. Once a node has an error, an alert containing detailed node error information is sent to the recipient.

- **Uncompleted Cycle**

  For the monitoring rules of hourly scheduled nodes, you can separately specify the uncompleted time points in different periods.

- **Overtime**

  An overtime alert can be set for nodes, baselines, and workspaces. Once a monitored node of the preset object is not completed within the specified time, an alert is reported.

2.1.8.7.3. Instructions

2.1.8.7.3.1. Manage baselines

You can manage baselines on the Baseline Instance page.

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Operation Center**. The **Operation Center** page appears.
3. In the left-side navigation pane, choose **Alarm > Baseline Management**. On the **Baseline Management** page, click Create Baseline to create a baseline. For more information, see Create a baseline.

   > **Note** If you have created a baseline, skip this step.

4. In the left-side navigation pane, choose **Alarm > Baseline Instance**. The **Baseline Instance** page appears. You can search for baselines by condition, such as Data Timestamp, Owner, Event ID, Workspace, and Baseline Name. You can also click **View Details**, **Handle**, and **View Gantt Chart** in the Actions column that corresponds to a baseline to perform the related operations on the baseline.

   > **Note** After a baseline is created, you must enable the baseline so that instances can be generated for the baseline.

   A baseline can be in one of the following states:

   - **Normal**: indicates that the running of all the nodes associated with the baseline is complete before the alerting time.

- **Alerting**: indicates that the running of one or more nodes associated with the baseline is not complete after the alerting time but the committed time does not arrive.
- **Overtime**: indicates that the running of one or more nodes associated with the baseline is not complete after the committed time.
- **Others**: All nodes associated with the baseline are paused, or no nodes are associated with the baseline.

You can click **View Details**, **Handle**, or **View Gantt Chart** in the Actions column that corresponds to a baseline to perform the related operation on the baseline.

- **View Details**: Click **View Details** to view the details about the baseline on the **Baseline Instance Details** page.

  On the Baseline Instance Details page, you can view the information in the **General**, **Critical Path**, **Baseline Instance**, **History**, and **Events** sections.

  > **Note**
  > - In the preceding figure, the data timestamp is `one day before the system time`.
  > - When you create a baseline, you can select **By the Day Interval** or **By the Hour Interval** for the baseline. The Cycle parameter appears as the advanced setting of the **Committed Time** parameter only after you select **By the Hour Interval**.

- **Handle**: Click Handle to handle the alert that is generated for the baseline. During this period, alerting is paused.
- **View Gantt Chart**: Click **View Gantt Chart** to view the critical paths of the nodes associated with the baseline.

2.1.8.7.3.2. Manage baselines

You can create and define baselines on the Baseline Management page of Operation Center.

Create a baseline

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Operation Center** to go to the **Operation Center** page.
3. In the left-side navigation pane of the Operation Center page, choose **Alarm > Baseline Management**.
4. On the **Baseline Management** page, click **Create Baseline** in the upper-right corner.

   > **Note** Only workspace administrators can create baselines.

5. In the **Create Baseline** dialog box, configure the parameters and click **OK**.

Parameter	Description
Baseline Name	The name of the baseline.
Workspace	The workspace of the nodes that you want to associate with the baseline.
Owner	The owner of the baseline. You can search for an owner by owner name or ID.

Parameter	Description
Recurrence	Specifies whether the baseline detects nodes by day or hour. Valid values: ○ **By the Day Interval**: Select this option for nodes that are run on a daily basis. ○ **By the Hour Interval**: Select this option for nodes that are run on an hourly basis.
Node	○ **Node**: the node that you want to associate with the baseline. Enter the name or ID of a node and click the icon on the right to add the node. You can add one or more nodes. ○ **Workflow**: the workflow that you want to associate with the baseline. Enter the name or ID of a workflow and click the icon on the right to add the workflow. We recommend that you add only the last node instead of all nodes of a workflow.
Priority	The priority of the baseline. A baseline that has a higher priority is scheduled first.
Estimated Completion Time	The estimated completion time of the node. The time is estimated based on the average running duration of the node during previous scheduling. If no historical data is available, the message **The completion time cannot be estimated due to a lack of historical data** appears.
Committed Time	The committed completion time of the node. An alert is triggered if the node is still running until the time obtained by subtracting the alert margin threshold from the committed completion time.
Margin Threshold	The interval before an alert is triggered. For example, if you set Committed Time to 3:30 and Margin Threshold to 10 minutes, an alert is triggered if the node is still running at 3:20. If the average running duration of the node is 30 minutes and the node is not started at 2:50, an alert is triggered. **Note** The average running duration of a node can be calculated based on the data of the last 15 days.

6. To enable the baseline that you created, you can click **Enable** in the Actions column of the baseline.

   You can click **View Details**, **Change**, **Enable**, **Disable**, or **Delete** in the Actions column of the baseline to perform the related operations on the baseline.

   - **View Details**: Click **View Details** to view the basic information of the baseline.
   - **Change**: Click **Change** to modify the baseline.
   - **Enable** or **Disable**: Click Enable or Disable to enable or disable the baseline. You must enable a baseline before instances can be generated for the baseline.
   - **Delete**: Click **Delete** to delete the baseline.

Associate a node with a baseline

By default, all nodes in the production environment are associated with the **default workspace baseline**. After you create a baseline, the nodes that you specify are disassociated from the default workspace baseline and are associated with the baseline that you create.

> **Note** Each node must be associated with a baseline. If you want to disassociate a node from the default workspace baseline, you must create a baseline and associate the node with the new baseline. You can delete a baseline that you created. If you delete such a baseline, the nodes that are associated with the baseline are disassociated from it and are associated with the default workspace baseline again.

To change the baseline with which a node is associated, perform one of the following operations:

- On the **Baseline Management** page, click **Create Baseline** in the upper-right corner to create a baseline and associate the node with the baseline.
- In the left-side navigation pane, choose Cycle Task Maintenance > Cycle Task. On the **Cycle Task** page, find the node and choose **More > Add to Baseline** in the Actions column of the node to associate the node with another baseline.

2.1.8.7.3.3. Manage events

You can manage all the events that are related to slowdown or errors on the Event Management page.

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **Alarm > Event Management**. The **Event Management** page appears.

   You can search for events by condition, such as the event owner, time at which an event is detected, event status, event type, and name or ID of a node or node instance.

   In the search results, each event is displayed in a row and associated with a node that encounters errors. You can view the baseline with the minimum margin among the baselines affected by an event in the Worst Baseline column.

   - If you click **View Details** in the Actions column that corresponds to an event, you can view the time at which the event occurred, alerting time, the time at which the event was processed, historical operational logs of the node, and detailed log information.

     You can assign an alert recipient. After you click **View Alerts**, the alert details page that corresponds to the event appears. You can view all the descendant baselines that are affected by the node associated with the event in the Affected Baselines section. You can observe the descendant baselines and the impact on these baselines and analyze node logs to identify the cause of the event.
   - If you click **Handle**, the event was handled. DataWorks records this operation and does not report the event during the handling process.
   - If you click **Ignore**, the event is ignored. DataWorks records this operation and no longer reports the event.

2.1.8.7.3.4. Create a custom alert rule

This topic describes how to create a custom alert rule on the Rule Management page.

Create a custom alert rule

1. Log on to the DataWorks console.
2. On the DataStudio page, click the ☰ icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **Alarm > Rule Management**.
4. On the **Rule Management** page, click **Create Custom Rule**.
5. In the **Create Custom Rule** dialog box, configure the parameters.

Parameter	Description
Rule Name	The name of the custom alert rule.
Object Type	The type of object that you want to monitor. You can set this parameter to **Node**.
Object	The object to which the custom alert rule applies. You can enter an object name or ID and click Add next to the Object parameter to add the object.
Trigger Condition	The condition for triggering an alert. Valid values: **Completed**, **Uncompleted**, **Error**, **Uncompleted in Cycle**, and **Overtime**.
Maximum Alerts	The maximum number of times an alert is reported. If the number of times an alert is reported exceeds the specified threshold, the alert is no longer reported.
Minimum Alert Interval	The minimum interval at which an alert is reported.
Quiet Hours	The specified period during which no alerts are reported.
Notification Method	The method used to send alert notifications. Valid values: **Email**, **SMS**, DingTalk Chatbot, and WebHook.
Recipient	The object who receives alert notifications. Valid values: Node Owner and Others.
DingTalk Chatbot	You can use a DingTalk chatbot to receive alert notifications.

6. Click **OK**. A custom alert rule is created.

   On the **Rule Management** page, find the newly created custom alert rule and click **View Details** in the Actions column. Then, you can view the details of the custom alert rule.

Add a DingTalk chatbot and obtain a webhook URL

1. Go to the DingTalk group to which you want to send alert notifications and click the **Group Settings** icon in the upper-right corner.
2. Click **Group Assistant**.
3. In the **Group Assistant** panel, click **Add Robot**.
4. In the **ChatBot** dialog box, click the + icon.
5. In the **Please choose which robot to add** section, click **Custom**.
6. In the **Robot details** message, click **Add**.
7. In the **Add Robot** dialog box, configure the parameters that are described in the following table.

Parameter	Description
Chatbot name	The name of the custom chatbot.
Add to Group	The DingTalk group to which the chatbot is added. This group cannot be changed.

Parameter	Description
Custom Keywords	After you configure custom keywords, messages are sent only when these messages contain the specified keywords. We recommend that you specify the keyword DataWorks. **Note** You can configure a maximum of 10 keywords. A message can be sent only if it contains at least one of the specified keywords.

8. Read the terms of service, select **I have read and accepted <<DingTalk Custom Robot Service Terms of Service>>**, and then click **Finished**.
9. After you complete the security settings, copy the webhook URL of the chatbot and click **Finished**.

Notice

- Save the copied webhook URL and paste it in the **Webhook Address** field when you create an alert rule.
- Keep the webhook URL confidential. If the webhook URL is leaked, your business is at risk.

2.1.8.7.3.5. View alerts

You can view all alerts on the Alert Management page.

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Task Operation > Operation Center**.
3. In the left-side navigation pane of the Operation Center page, choose **Alarm > Alert Management**. The **Alert Management** page appears.

   You can search for alerts by condition, such as **Rule ID/Name**, **Recipient**, **Alert Time**, **Notification Method**, and **Rule Type**.

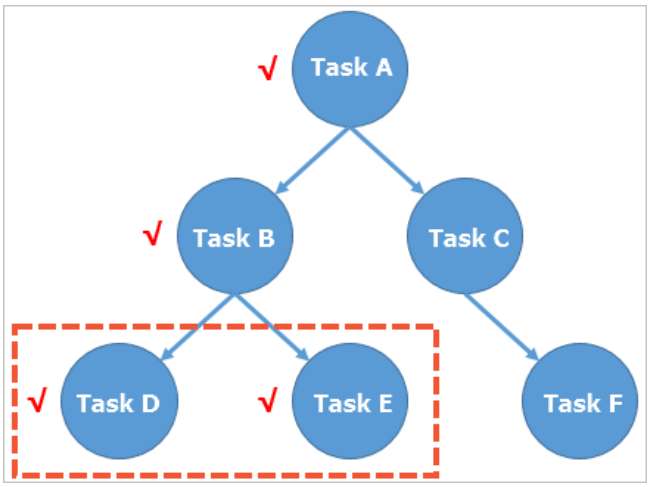
   You can also view alert details, such as the notification method and status. To view details about an alert, click **View Details** in the Actions column that corresponds to the alert.

2.1.8.7.4. FAQ

This topic describes the FAQ about the Monitor service.

What can I do if I do not need to receive alerts for a node?

After you create and enable a monitoring baseline, the Monitor service monitors all nodes in the baseline and their ancestor nodes. If a node in the baseline or an ancestor node of the baseline affects data generation of the monitored nodes in the baseline, the Monitor service reports an alert to the node owner.



As shown in the preceding figure, assume that DataWorks has only six nodes, and Nodes D and E belong to a monitoring baseline. The Monitor service monitors Nodes D and E and all their ancestor nodes. Namely, the Monitor service will detect any error or slowdown on Node A, B, D, or E. Nodes C and F are not monitored by the Monitor service.

Nodes A and B are ancestor nodes of Nodes D and E and may affect data generation of the monitored nodes in the baseline. When an error or slowdown occurs on Node A or B, the Monitor service reports an alert to the node owner.

If you do not need to receive alerts for a node, use the following methods:

- If the owners of Nodes D and E do not need to receive alerts, contact the baseline owner to remove Nodes D and E from the baseline.
- If the owner of Node A or B does not need to receive alerts, contact the owners of Nodes D and E to delete the dependency of Nodes D and E on Node A or B.

Why is no alert reported for a baseline in the Overtime state?

Baseline monitoring is controlled by the baseline switch and enabled for nodes. If all nodes are running properly, no alert will be triggered even in the Overtime state. This is because all the nodes are running properly and the Monitor service cannot determine which node has an error. Overtime is a baseline state, indicating that a node is still not completed after the committed time.

If the baseline still enters the Overtime state when all nodes are running properly, consider the following reasons:

- The baseline time is not properly set.
- The node dependency is not properly configured.

Can I disable the Monitor service from reporting an alert for a node that slows down?

The Monitor service reports a node slowdown alert only when a node meets both of the following conditions:

- The node is an ancestor node of an important baseline.
- Compared with its historical performance, the node does slow down.

You can view the descendant baseline affected by the node on the **Event Management** page. Then, you can confirm the impact with the party whose monitoring baseline contains descendant nodes of your node.

- If the node slowdown has a minor impact, you can ignore the alert.
- If the node slowdown has a major impact, maintain your node properly.

Why do I fail to receive an alert for an error node?

The Monitor service reports an alert only for specified nodes when an error occurs. An alert is reported for an error node only when the node meets one of the following conditions:

- The node is an ancestor node of a baseline that has been enabled.
- An alert trigger has been customized.

What can I do if I receive an alert at night?

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click ☰ in the upper-left corner and choose **All Products > Operation Center**.
3. In the left-side navigation pane, choose **Alarm > Event Management**.
4. On the **Event Management** page, disable the event alert. Disable the event alert in one of the following ways:
   - Handle the event that triggers an alert.
     a. Find the target event and click **Handle** in the Actions column.
     b. In the **Handle Event** dialog box, set the **Handling Time** parameter.
     c. Click **OK**.

     > **Note** DataWorks records the event handling operation and pauses alerting for the event when the event is being handled.
   - Ignore the event that triggers an alert.
     a. Find the target event and click **Ignore** in the Actions column.
     b. In the **Ignore Event** message, click **OK**.

     > **Note** DataWorks records the event ignoring operation and permanently stops alerting for the event.

2.1.9. Security Center (earlier version)

2.1.9.1. Overview

Security Center provides flexible permission management features. It allows you to request permissions and handle permission requests on the graphical user interface (GUI), and view and manage permissions. Security Center not only improves data security but also facilitates data permission management.

Log on to the DataWorks console. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Security Center**. The **Security Center** page appears.

Security Center consists of the following modules: **My Permissions**, **Authorizations**, and **Approval Center**.

Currently, Security Center provides the following features:

- Self-service permission request: Users can select the required tables to quickly initiate a permission request online. This online request mode is more efficient than the original mode in which users need to contact administrators offline.
- Permission management: Administrators can view the users who have permissions on database tables and revoke permissions as required. Users can also revoke unnecessary permissions themselves.
- Permission request approval: Before granting permissions to users, administrators approve permission requests initiated by users. This implements a visual and process-based permission management system, and supports reviewing the approval process.

In Security Center, you can view permissions on all the tables in an organization, request and revoke table permissions, and approve or reject permission requests.

Each operation in Security Center applies to all the workspaces of a tenant in standard mode and basic mode.

2.1.9.2. Permissions

On the My Permissions page, you can view your table or field permissions in a workspace, and request or revoke table or field permissions.

View table or field permissions

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > Security Center**. The **My Permissions** page appears.
3. On the Table tab of the **My Permissions** page, you can select a workspace in standard mode and an environment to view all the tables of the workspace in the specified environment. You can also enter a table name in the search box for fuzzy match.

   You can view the names, display names, and owners of tables in your workspace, view your permissions on the tables, and request or revoke table or field permissions.

Request table or field permissions

1. Select the tables or fields on which you want to request permissions.
   - Request permissions on a table or specific fields in the table

     Select the required fields on which you have no permissions in a table and choose **More > Request Permission** in the Actions column.

     Alternatively, choose **More > Request Permission** in the Actions column for a table without selecting any fields to request permissions on all the fields in the table.

     > **Note** You can request permissions on fields only in a workspace with LabelSecurity enabled. If LabelSecurity is disabled for a workspace, you can request permissions only on tables in this workspace.

   - Request permissions on multiple tables or specific fields in the tables

     Select all the required tables or fields and click **Request Permission**.

     > **Note** You can also click **Request Permission** without selecting any tables or fields to go to the **Table Permission Request** page.

2. On the **Table Permission Request** page, configure the parameters as required.

Parameter	Description
Workspace	The name of the workspace, which is automatically entered based on the information you specified on the My Permissions page. You can change the workspace as required.
Environment	The environment of the workspace.
MaxCompute Project	The name of the MaxCompute project.

Parameter	Description
Grant To	The account for which you request permissions. You can request permissions for the current account or a production account of another workspace that you joined.
Reason for Request	The reason why you request permissions.
Objects Requested	The tables on which you request permissions. The tables that you select on the previous page are displayed. You can add tables or delete existing tables as required.

3. After the configuration is complete, click **Submit**. If you do not want to request permissions, click **Cancel**.

2.1.9.3. Authorizations

On the Authorizations page, a workspace administrator can view the accounts that have permissions on tables and fields in each workspace, and revoke unnecessary table and field permissions.

You can move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **Authorizations**. On the **Table** tab that appears, you can view and search for tables in workspaces of the current organization.

On the Table tab, you can select a workspace and specify the environment (for a workspace in standard mode) to view all the tables of the workspace in the specified environment. You can also enter a table name in the search box to search for required tables in fuzzy match mode.

View accounts that have permissions on a table

On the **Table** tab of the **Authorizations** page, click the plus sign (+) in front of a table to view all the accounts that have permissions on the table.

Revoke table permissions

Click **Revoke Permission** in the Actions column for an account to revoke the permissions of the account on the current table.

View field permissions

Click **View Field Permissions** in the Actions column for an account to view the permissions of the account on the fields in the current table.

Revoke field permissions

If LabelSecurity is enabled for the workspace, select fields on the Field Permissions page and click **Revoke Field Permissions** to revoke the permissions on the fields.

2.1.9.4. Approval Center

On the Approval Center page, you can view your requests and their status, view and handle the requests pending your approval, and view the requests that you have handled.

My Requests

1. Move the pointer over the DataWorks icon in the upper-left corner, and click **Security Center**. In the left-side navigation pane, click **Approval Center**. On the Approval Center page, click the **My Requests** tab.

On this tab, you can view the information about each of your requests, including **Object Type**, **Workspace**, **Status**, **MaxCompute Project**, **Request Time**, and **Table**.

> **Note** If a request contains permission requests for tables that belong to different owners, Security Center automatically splits the request into multiple requests by table owner.

2. Click **View** in the Actions column to view the details about a request.

Pending My Approval

1. On the **Approval Center** page, click the **Pending My Approval** tab.

   On this tab, you can view the requests pending your approval. If a request is pending your approval, a red dot appears next to Approval Center and Pending My Approval to remind you.

   You can view the information about each of requests pending your approval, including **Object Type**, **Grant To**, **Request Time**, **Workspace**, **MaxCompute Project**, and **Table**.

2. Click **Handle** in the Actions column to view the details about a request and handle it on the Request Details page. The request details include the progress and objects requested.
3. Enter your comments and click Approve or Reject as required.

Handled by Me

1. On the **Approval Center** page, click the **Handled by Me** tab.

   On this tab, you can view the information about each request that you have handled, including **Object Type**, **Grant To**, **Result**, **Workspace**, **MaxCompute Project**, **Table**, and **Request Time**.

2. Click **View** in the Actions column to view the details about a request. The request details include the progress and objects requested.

2.1.9.5. FAQ

This topic describes the frequently asked questions (FAQs) about the Security Center service of DataWorks.

- Q: What permissions can I request in Security Center?

  A: In Security Center, you can request permissions on tables in DataWorks workspaces in the development environment and production environment.

- Q: What is the relationship between Data Management and Security Center?

  A: Security Center is a product that upgrades and replaces the permission and security features in Data Management. You can choose **Security Center > My Permissions** to view the permissions requested or granted by using the `odpscmd grant` command in **Data Management**.

  If you want to request other permissions and handle permission requests on the GUI, go to **Security Center** and perform operations as required. The **Data Management** service does not support permission request and approval any more.

- Q: Why cannot I select fields when I request permissions?

  A: If LabelSecurity is enabled for a workspace, you can request permissions on fields in this workspace. If LabelSecurity is disabled for a workspace, you can request permissions only on tables in this workspace.

- Q: Who will handle my request?

  A: Your request is handled by a workspace administrator or a table owner. After either of them approves or rejects your request, the request is closed.

- Q: Why do I find two requests on the **My Requests** page after I submit only one request?

  A: The tables in your request belong to two owners. In this case, Security Center automatically splits your request into two by table owner.

- Q: I request permissions on a field for one month only. Why does the validity period of the permissions become permanent after my request is approved?

  A: The security level of this field is zero or not higher than the security level of your account.

- Q: Why do I obtain permissions on some tables and fields on which I have not requested any permissions?

  A: The possible causes are as follows:

  - An administrator has granted the permissions to you by running commands in the DataWorks console.
  - After your request is approved in Security Center, Security Center also grants you the permissions on fields whose security level is zero or not higher than the security level of your account, even though you have not requested the permissions.

- Q: Why does a request disappear from the **Pending My Approval** tab before I handle it?

  A: Another workspace administrator or the table owner has approved or rejected the request. The request is closed and no longer needs to be handled.

- Q: What can I do if the message "An error occurred in the MaxCompute project" appears when I specify the workspace and environment?

  A: Send the error message and error code to a workspace administrator for troubleshooting.

- Q: Why do I fail to revoke permissions on a field?

  A: You can revoke permissions only on the fields whose security level is higher than the security level of your account.

- Q: Why do I fail to request permissions by using my tenant account?

  A: By default, a tenant account has all permissions. Therefore, you do not need to request permissions for your tenant account. The tenant account hides unnecessary operations such as permission request. This does not affect the use of the tenant account.

- Q: In **Security Center**, can I view the permission request and approval records of **Data Management**?

  A: Security Center and Data Management have not synchronized permission request and approval records yet. You need to go to **Data Management** to view the permission request and approval records of Data Management.

- Q: Can I revoke permissions based on the request records in Security Center?

  A: Currently, Security Center is not the only service that provides authorization. To facilitate permission revocation, the Authorizations page in Security Center provides an access control list (ACL) of all users, regardless of the authorization channel. You can revoke any granted permissions without using the request records.

- Q: A permission request submitted in **Data Management** has not been approved yet. Do I need to submit it again in Security Center?

  A: Security Center and Data Management have not synchronized permission request and approval records yet. You need to submit the permission request again in Security Center.

- Q: How do I specify the LabelSecurity parameter for fields?

  A: You need to go to **Data Map** to set the LabelSecurity parameter for fields.

2.1.10. Security Center (new version)

2.1.10.1. Overview

DataWorks Security Center helps you build a security system that can secure data and personal privacy. Security Center can meet various security requirements, such as auditing, in high-risk scenarios. You can use Security Center without the need to perform additional configurations.

Security Center provides security capabilities for big data systems in the cloud throughout the entire data security lifecycle. It also provides best practices for various security diagnostic scenarios based on security specifications. Security Center provides the following features:

- Data permission management

  Security Center supports fine-grained permission requesting, request processing, and permission auditing. This allows you to manage permissions based on the principle of least privilege. In addition, Security Center allows you to view the request processing progress and follow up request processing in real time. For more information, see Data access control.

- Security diagnosis

  Security Center provides features such as platform security diagnosis and data usage diagnosis. It also provides best practices for various security diagnosis scenarios based on security specifications. These features ensure that your business is run more effectively in a secure environment. For more information, see Platform security diagnosis.

2.1.10.2. Platform security diagnosis

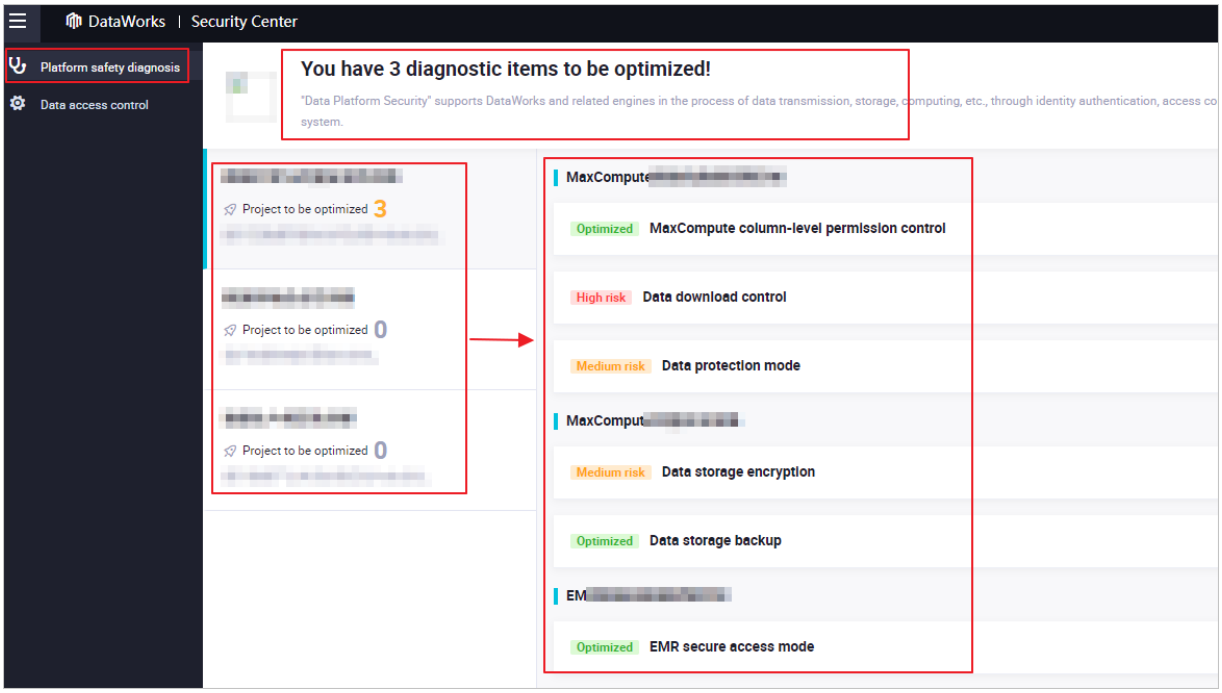
The platform security diagnosis feature of DataWorks provides security capabilities for features, such as identity authentication, access control, and development mode, during data transmission, storage, and computing on the nodes in the current DataWorks workspace and the associated compute engine. In addition, best practices are provided for security diagnosis. The platform security diagnosis feature helps you identify the security risks of your platform at the earliest opportunity and build a basic security system before you perform related transactions.

Go to the Platform safety diagnosis page

1. Log on to the DataWorks console.
2. In the upper-left corner of the page that appears, click the icon and choose **All Products > Data governance > Security Center**. The **Data access control** page appears.
3. In the left-side navigation pane, click **Platform safety diagnosis** to go to the **Platform safety diagnosis** page.

View diagnosis results

The **Platform safety diagnosis** page displays the security risks that are detected during business interactions between the current workspace and the associated compute engine instance based on the best practices for security risks. You can identify risk categories and levels based on the diagnosis results, view risk details, and process the items that can be optimized to ensure secure and reliable business interactions.



The following types of diagnostic items are provided:

- **Data calculation and storage**

  Diagnoses security issues for features such as data permission management, data storage encryption, and data storage backup, and identifies potential security risks at the earliest opportunity to improve security during data storage and access.

- **Data transmission security diagnosis**

  Diagnoses security issues for features such as the access control of data sources and the isolation of data sources in the production and development environments. In addition, this diagnostic item identifies security risks during data transmission so that you can manage these risks at the earliest opportunity. This diagnostic item ensures a secure and reliable environment for data transmission.

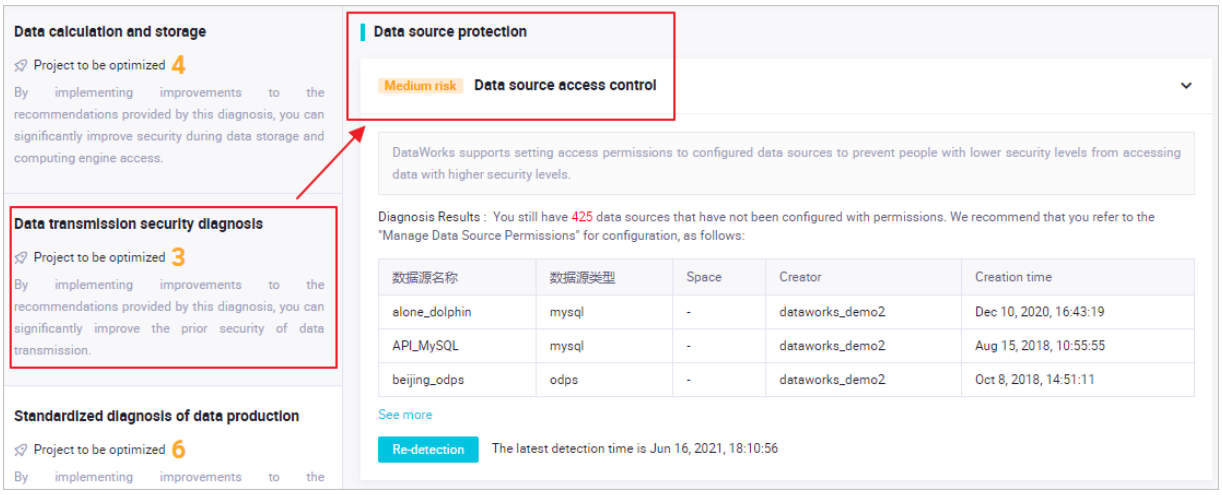
- **Standardized diagnosis of data production**

  Diagnoses security issues for production processes, such as the rationality of the roles, number of administrators, and deployment personnel within the current workspace, and allows you to identify and process security risks at the earliest opportunity. This diagnostic item improves the reliability and security of the data output system.

- **Platform security configuration diagnosis**

  Diagnoses security issues for features, such as auditing of operations on DataWorks, to improve the overall data security.

Potential security risks are classified as **medium** and **high** risks. You can click a security risk to view its details and manage the security risk at the earliest opportunity. The following figure shows the details about a **medium-level risk** of **data source access control**.



- Security risk

  Permissions are not configured on the data sources. This way, users of low security levels can access data of high security levels. This leads to insecure access to the data sources.

- Suggestion

  You can configure permissions for the data sources based on the provided suggestion to improve access security for the data sources.

2.1.10.3. Data access control

The data access control feature provides a visual interface that allows you to request permissions, process requests, view request processing progress, follow up request processing, and audit and manage permissions.

Limits

You can use the **data access control** feature to request only permissions on MaxCompute tables.

Usage note

The **Data access control** page displays the access control platform of the new version. If you want to use the access control platform of the earlier version, click **Return to old version** in the top navigation bar of the page. For more information about the access control platform of the earlier version, see Overview.

Go to the Data access control page

1. Log on to the DataWorks console.
2. In the upper-left corner of the page that appears, click the ☰ icon and choose **All Products > Data governance > Security Center**. The **Data access control** page appears.

Request permissions

1. Go to the **Permission application** tab.
2. Select the tables on which you want to request permissions.

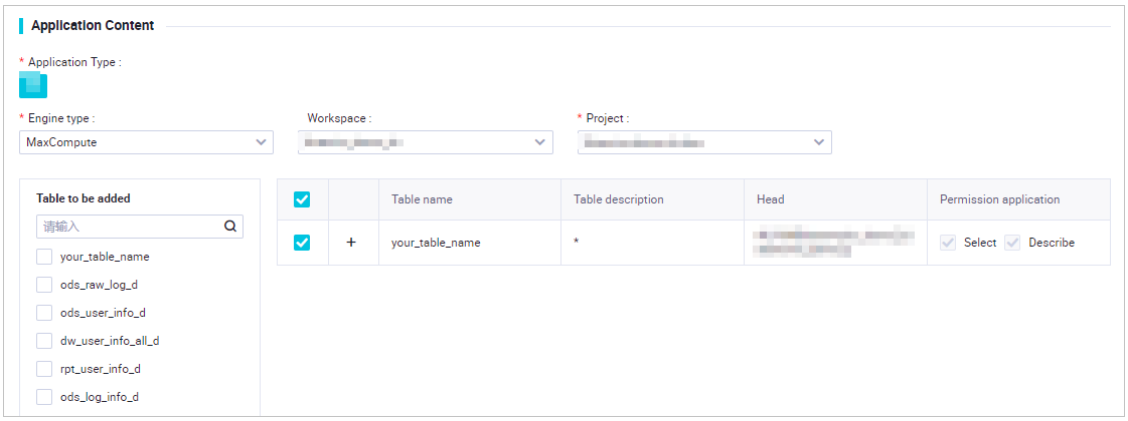
i. In the **Application Content** section, set the **Workspace** and the **Project** parameters.

You can use the **data access control** feature to request only permissions on MaxCompute tables.

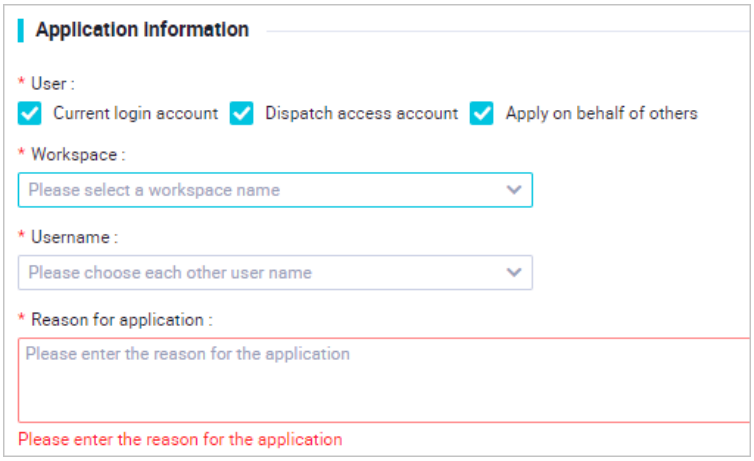
The default value of the **Application Type** parameter is **Table** and that of the **Engine type** parameter is **MaxCompute**.

ii. Select the tables on which you want to request permissions in the **Table to be added** section.

After you select tables, the information of the tables is displayed on the right. You can click the + icon on the left side of a table name to view all the fields in the table. You can request the permissions on some or all fields. By default, the permissions on all fields are requested.



3. In the **Application information** section, set the parameters.



Parameter	Description
User	◦ **Current login account**: Request the permissions on the tables for the account that is used to log on to the current workspace. ◦ **Dispatch access account**: Request the permissions on the tables for the account that has a scheduling access identity. If you select this option, you must set the **Workspace** parameter. ◦ **Apply on Behalf of others**: Request the permissions on the tables for an account that is not used to log on to the current workspace. If you select this option, you must set the **Username** parameter.

Parameter	Description
Workspace	The account that has a scheduling access identity.
Username	The username of the account that is not used to log on to the current workspace.
Reason for application	The reason why you want to request the permissions.

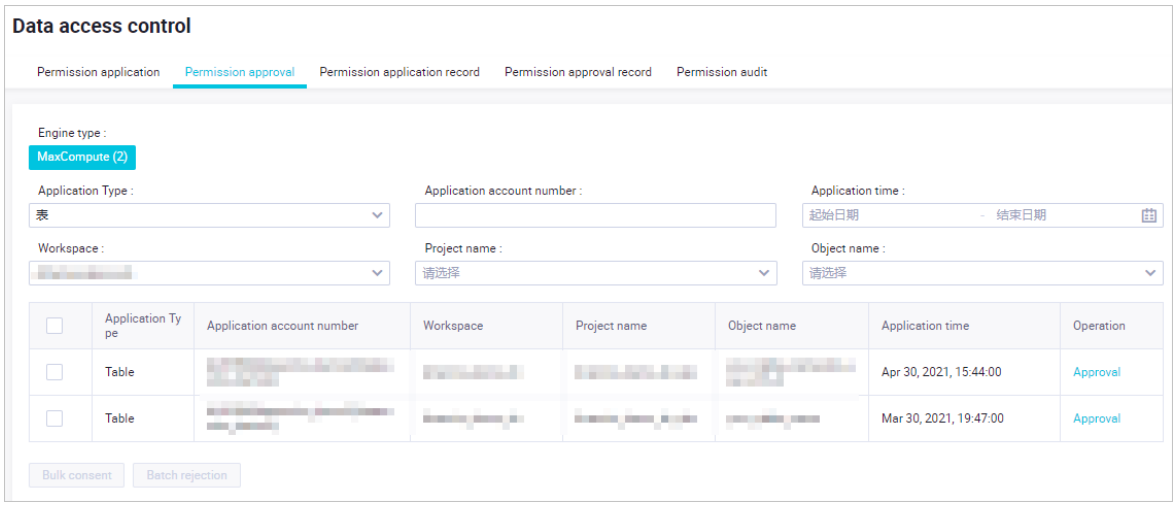
4. Click **Apply for permission** to submit the request.

   You can view the processing details and record of the current request on the **Permission application record** tab.

Process requests

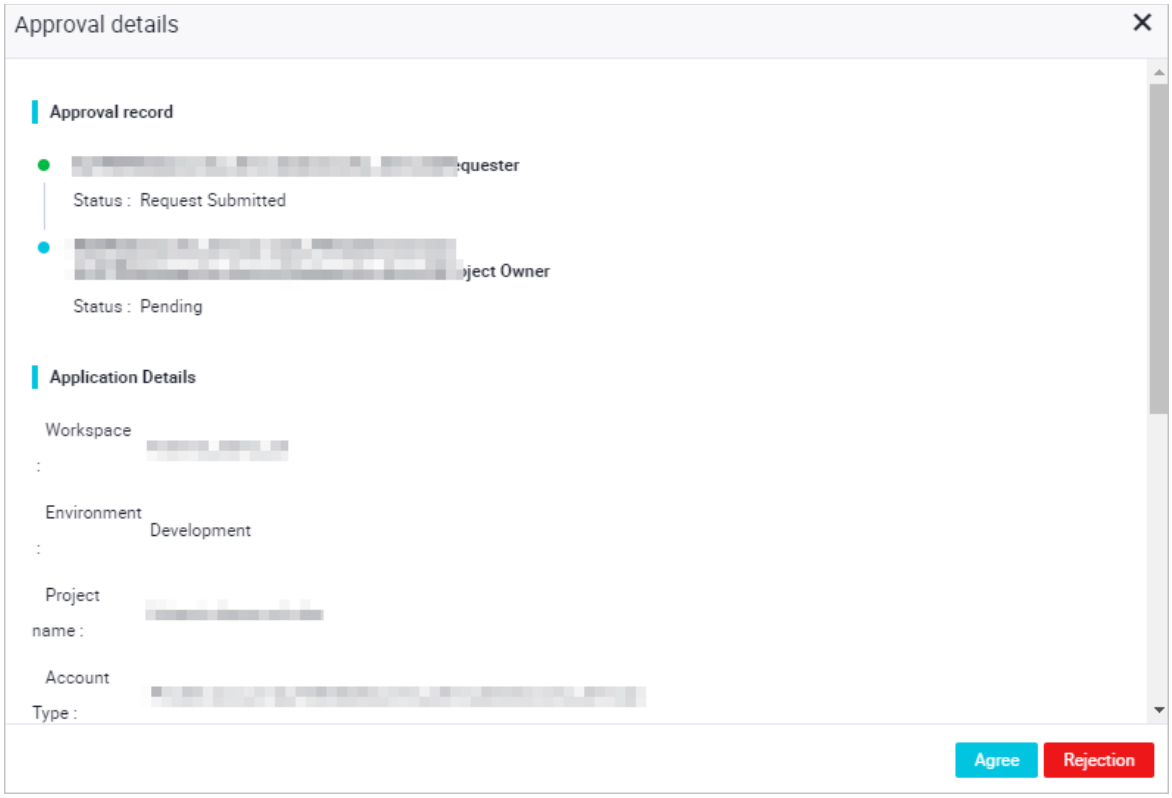
1. View the information about the pending requests.

   Go to the **Permission approval** tab. You can use the following parameters to find the pending requests within the current Apsara Stack tenant account: **Application account number**, **Application time**, **Workspace**, **Project name**, and **Object name**.



2. View the details about a request.

   Find the request and click **Approval** in the **Operation** column. Then, you can view the details and processing record of the request in the **Approval details** dialog box.



3. Process requests.

   To process a single request, enter your comments and click **Agree** or **Rejection** based on your business requirements.

   To process multiple requests at a time, you can select all the requests that you want to process on the **Permission approval** tab, click **Bulk consent** or **Batch rejection**, and then enter your comments.

View historical permission requests and their processing records

- Go to the **Permission application record** tab. Then, you can use the following parameters to find the historical permission requests within the current Apsara Stack tenant account: **Approval status**, **Application time**, **Workspace**, **Project name**, and **Table name**.

  You can click **View details** in the **Operation** column that corresponds to a request to view the details about the request. In addition, you can continue to process the requests whose approval states are **In approval**.

- Go to the **Permission approval record** tab. Then, you can use the following parameters to find the request processing records within the current Apsara Stack tenant account: **Application account number**, **Approval Results**, **Workspace**, **Project name**, **Object name**, and **Application time**.

  You can click **View details** in the **Operation** column that corresponds to a request to view the details about the request.

Audit permissions

Go to the **Permission audit** tab. Then, you can use the following parameters to find the permission requests that are processed for the workspace, project, or object in Security Center: **Workspace**, **Project name**, and **Object name**.

2.1.11. Data Quality

2.1.11.1. Overview

DataWorks provides a Data Quality service for you to control the data quality of disparate connections. In Data Quality, you can check data quality, configure alert notifications, and manage connections.

Relying on DataWorks, Data Quality provides a comprehensive data quality solution that has various features. For example, you can detect data, compare data, monitor data quality, and use intelligent alerting.

Data Quality monitors data in datasets. Currently, it allows you to monitor MaxCompute tables and DataHub topics. When offline MaxCompute data changes, Data Quality checks data and blocks nodes if it detects exceptions. This prevents nodes from being affected. In addition, Data Quality allows you to manage the check result history so that you can analyze and evaluate the data quality.

For streaming data, Data Quality uses DataHub to monitor data streams and sends alert notifications to subscribers if it detects stream discontinuity. You can also set the alert severity such as warning and error alerts, and the alert frequency to minimize repeated alerts.

The following figure shows the monitoring flowchart in Data Quality.

> **Note** Data Quality monitors the quality of data from MaxCompute and DataHub datasets. To use Data Quality features, you need to create tables and write data to the tables.
>
> You can create MaxCompute tables and write data to the tables in the MaxCompute console or in the DataWorks console.

Log on to the DataWorks console. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality** to go to the **Data Quality** page.

2.1.11.2. Features

2.1.11.2.1. Dashboard

As the homepage of Data Quality, the Dashboard page displays an overview of alerts and blocks for subscribed nodes. You can set filter conditions to view the required alerts and blocks.

Card	Description
My MaxCompute Partition Subscriptions	Displays the number of MaxCompute partitions with alerts or blocks and the number of normal MaxCompute partitions on the current day. You can click this card to go to the Search by Node page for the MaxCompute connection and view alert details.
My DataHub Topic Subscriptions	Displays the number of DataHub topics with alerts and the number of normal DataHub topics on the current day. You can click this card to go to the Search by Node page for the DataHub connection and view alert details.
Current task alarm condition	Displays alerts for MaxCompute and DataHub connections of the current workspace on the current day.
Current task blocking situation	Displays blocks for the MaxCompute connection of the current workspace on the current day.
Task Alarm Situation Trend	Displays the trend chart of alerts for MaxCompute and DataHub connections. You can view the alert trend in the past 7 or 30 days, or a custom time period within the past three months.
Task Blocking Situation Trend Graph	Displays the trend chart of blocks for MaxCompute and DataHub connections. You can view the block trend in the past 7 or 30 days, or a custom time period within the past three months.

2.1.11.2.2. My Subscriptions

The My Subscriptions page displays all nodes subscribed by your account.

Go to the My Subscriptions page

Currently, Data Quality allows you to monitor MaxCompute tables and DataHub topics. You can select a connection on the **My Subscriptions** page and search for subscribed nodes of the connection.

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
3. In the left-side navigation pane, click **My Subscriptions**. The **My Subscriptions** page appears.

Subscribed MaxCompute connections

On the **My Subscriptions** page, select **MaxCompute** from the connection drop-down list in the upper-left corner. All the subscribed MaxCompute connections appear.

- You can click a partition expression on the right to go to the **Rules** page.
- You can click **View Check Results** in the Actions column for a partition expression to go to the Search by Node page.
- Data Quality supports the following four notification methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.
- You can click **Cancel Subscription** to unsubscribe from the connection.

Subscribed DataHub connections

On the **My Subscriptions** page, select **DataHub** from the connection drop-down list in the upper-left corner. All the subscribed DataHub connections appear.

- After you click **Alerts** for a topic, the **Alerts** page appears, allowing you to view detailed information about the rule alert.
- You can click **Notification Method** for a topic to change the notification method of the rule alert.
- You can click **Cancel Subscription** in the Actions column for a topic to unsubscribe from the topic.

2.1.11.2.3. Configure monitoring rules

Data Quality can monitor data in the MaxCompute, DataHub, and E-MapReduce data stores. This topic describes how to configure a rule for monitoring a table or topic.

Go to the Monitoring Rules page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
3. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane. On the Monitoring Rules page, you can select ODPS, Datahub, or EMR from the Engine/Data Source drop-down list.
   - If you select ODPS or EMR, all tables in the current MaxCompute or E-MapReduce data store appear. You can also switch to another data store or enter a keyword in the search box to search for topics or tables.
   - If you select Datahub, all topics and dimension tables in the current DataHub data store appear. You can also switch to another data store or enter a keyword in the search box to search for topics or tables.
4. Find the target table or topic and click **View Monitoring Rules** in the Actions column. The rule configuration page for the table or topic appears.

   Data Quality allows you to configure template rules and custom rules for a table or topic.

> **Note** Before you configure a template rule for a table, you must configure a partition filter expression.

Create a template rule

1. Click **View Monitoring Rules** in the Actions column of a table or topic.
2. On the rule configuration page that appears, click the partition filter expression for which you want to configure a template rule. Then, click **Create rules**. In the Create rules right-side pane, the **Template Rules** tab appears.

   On the **Template Rules** tab, click **Add Monitoring Rule** or **Quick Create** to create a template rule.

   - **Click Add Monitoring Rule.**

     Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Rule Type	The type of the rule. Valid values: Rule Type and Soft. ■ If you select Rule Type, error alerts are reported and descendant nodes are blocked, whereas warning alerts are reported but descendant nodes are not blocked. ■ If you select Soft, error alerts are reported but descendant nodes are not blocked, whereas warning alerts are not reported and descendant nodes are not blocked.
Field	The fields to be monitored. You can select **All Fields in Table** or select a field of a numeric type or non-numeric type.
Template	The template to apply to the rule. Data Quality supports 37 rule templates. **Note** You can set field-specific rules of the average value, accumulated value, minimum value, and maximum value only for numeric fields.
Comparison Method	The comparison method of the rule. Valid values: **Absolute Value**, **Raise**, and **Drop**.

Parameter	Description
Thresholds	■ You can calculate the fluctuation by using the following formula: Fluctuation = (Sample - Baseline)/Baseline ■ You can calculate the fluctuation variance only for numeric fields such as BIGINT and DOUBLE fields by using the following formula: Fluctuation variance = (Sample - Baseline)/Standard deviation **Note** The sample and baseline are defined in the following way: ■ Sample: the sample value for the current day. For example, if you need to check the fluctuation of table rows on an SQL node in a day, the sample is the number of table rows on the current day. ■ Baseline: the comparison value from the previous N days. Examples: ■ If you need to check the fluctuation of table rows on an SQL node in a day, the baseline is the number of table rows on the previous day. ■ If you need to check the fluctuation of the average number of table rows on an SQL node in seven days, the baseline is the average number of table rows in the last seven days. You can set **Warning Threshold** and **Error Threshold** to monitor data at different severities: ■ If the fluctuation does not exceed the warning threshold, Data Quality determines that data is normal. ■ If the fluctuation exceeds the warning threshold but does not exceed the error threshold, Data Quality reports a warning alert. ■ If the fluctuation exceeds the error threshold, Data Quality reports an error alert. ■ If you do not specify the warning threshold, Data Quality reports error alerts or normal based on the monitoring result. ■ If you do not specify the error threshold, Data Quality reports warning alerts or normal based on the monitoring result. ■ If you specify neither the warning threshold nor the error threshold, Data Quality reports error alerts if it detects anomalies. However, you must specify at least one of the two thresholds. If you specify neither of them, Data Quality applies default values, namely, 10% for the warning threshold and 50% for the error threshold.

- **Click Quick Create.**

  Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Field	The fields to be monitored. You can select **All Fields in Table** or a specific field of a numeric type or non-numeric type.

Parameter	Description
Trigger	The trigger condition of the rule. If you select All Fields in Table for the Field parameter, **The number of rows is greater than 0** is selected by default.

3. Click **Batch Create**.

Create a custom rule

If template rules do not meet your requirements for monitoring the data quality, you can create custom rules.

1. Click **View Monitoring Rules** in the Actions column of a table or topic.
2. On the rule configuration page that appears, click the partition filter expression for which you want to configure a custom rule. Then, click **Create rules**. In the Create rules right-side pane, the **Template Rules** tab appears.
3. Click the **Custom Rules** tab. On the **Custom Rules** tab, click **Add Monitoring Rule** or **Quick Create** to create a custom rule.
   - **Click Add Monitoring Rule.**

     Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Field	The fields to be monitored. You can select **All Fields in Table**, **SQL Statement**, or a specific field. ■ If you select All Fields in Table or a specific field, you can specify the WHERE clause to customize filter conditions based on business requirements. ■ If you select SQL Statement, you can customize the SQL logic to set a rule. The return value is the value in a row of a column.
Rule Type	The type of the rule. Valid values: Rule Type and Soft. ■ If you select Rule Type, error alerts are reported and descendant nodes are blocked, whereas warning alerts are reported but descendant nodes are not blocked. ■ If you select Soft, error alerts are reported but descendant nodes are not blocked, whereas warning alerts are not reported and descendant nodes are not blocked.
Sampling Method	The statistical function. Valid values: **count** and **count/table_count**.
Filter	The filter condition of the rule. For example, if you need to query partitions of the table based on a specific data timestamp, you can specify `pt=$[yyyymmdd-1]` as the filter condition.
Check type	The threshold type of the rule. Valid values: **Numeric type** and **Fluctuation**.
Comparison Method	The comparison method of the rule. If you set Check type to Numeric type, the values that are optional for this parameter include **Greater Than**, **Greater Than or Equal To**, **Equal To**, **Unequal To**, **Less Than**, and **Less Than or Equal To**.
Verification Method	The verification method of the rule. If you set Check type to Numeric type, you can only set this parameter to **Compare with a specified value**.

Parameter	Description
Expected Value	The expected value of the rule.
Description	The description of the rule.

- **Click Quick Create.**

  Set parameters in the rule configuration section that appears, as described in the following table.

Parameter	Description
Rule Name	The name of the rule.
Trigger	The type of the rule. You can select only **Values Duplicated in Multiple Fields**.
Field	The fields to be monitored.

Associate a custom node with Data Quality monitoring rules

Before you associate a custom node with Data Quality monitoring rules, make sure that the custom node is created and committed to the production environment. For more information, see Create a custom node type.

You can use one of the following methods to associate a custom node with Data Quality monitoring rules:

- Associate a custom node with Data Quality monitoring rules on the Data Quality page.
  i. Log on to the DataWorks console.
  ii. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
  iii. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
  iv. Select the target data store from the Engine/Data Source drop-down list, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.
  v. On the rule configuration page that appears, click the partition filter expression for which monitoring rules are configured.
  vi. Click **Manage Linked Nodes**.
  vii. In the **Manage Linked Nodes** dialog box, select the target workspace, enter the ID or name of the custom node, and then click **Create**.
- Associate a custom node with Data Quality monitoring rules on the Operation Center page.
  i. Log on to the DataWorks console.
  ii. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Operation Center**.
  iii. In the left-side navigation pane, choose **Cycle Task Maintenance > Cycle Task**.
  iv. Find the target node and choose **More > Configure Data Quality Rules** in the Actions column.
  v. In the **Configure Data Quality Rules** dialog box, set the **Workspace**, **Table Name**, **Engine type**, **Engine instance**, and **Partition Expression** parameters, and click **Add**.

2.1.11.2.4. View monitoring results

The Node Query page displays the monitoring results of rules. After monitoring rules are triggered, you can go to the Node Query page to view the monitoring results of the rules.

Go to the Node Query page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click ☰ in the upper-left corner and choose **All Products > DataAnalysis**.
3. On the Data Quality page, click **Node Query** in the left-side navigation pane.

   On the **Node Query** page, you can set parameters, such as the **Engine/Data Source**, **Status**, and **My Subscriptions** parameters, to filter nodes and view the monitoring results.

View the monitoring results of E-MapReduce and MaxCompute tables

GUI element	Description
Engine/Data Source	The name of the compute engine. In this example, select **EMR** or **ODPS**.
Engine/Database Instance	The E-MapReduce instance or MaxCompute project where the desired tables reside.
Status	The monitoring result of rules. Pay attention to partitions that trigger alerts or blocks.
Data Timestamp	The data timestamp.
My Subscriptions	Specifies whether to display only monitoring results of tables that you subscribed to.
Run At	The time when rules were triggered.
Table Name	The name of the table whose monitoring results you want to view.
Node	The node that triggered rules.
Details	Click **Details** in the **Actions** column of a table. On the page that appears, you can perform the following operations on each rule configured for the table: • Click **View History Check Results** in the Actions column of a rule to view the monitoring result history of the rule. • Enter comments on a rule based on the execution status of the rule. Perform the following steps to enter comments on a rule: i. Click **Problem Handling** in the Actions column of the rule. ii. In the **Problem Handling** dialog box, set the **Handling Method** and **Comments** parameters. iii. Click **OK**. **Notice** You can only use the problem handling feature in DataWorks Enterprise Edition or higher. • Click **Handling Logs** in the Actions column of a rule to view the processing history of the rule.
Rules	Click **Rules** in the Actions column of a table to go to the rule configuration page for the table. On this page, you can view partition filter expressions and rules configured for the table, and modify the rules as required. For more information, see MaxCompute monitoring.
View Log	Click **View Log** in the Actions column of a table to view the operational logs of rules configured for the table.
View Statistics	Click **View Statistics** in the Actions column of a table to view rule execution information about the table, including the number of rows and the table size.

View the monitoring results of DataHub topics

GUI element	Description
Engine/Data Source	The name of the compute engine. In this example, select **Datahub**.
Configure a data source	The name of the DataHub connection.
Status	The monitoring result of rules. Pay attention to topics that trigger alerts or blocks.
Topic	The name of the topic whose monitoring results you want to view.
My Subscriptions	Specifies whether to display only monitoring results of topics that you subscribed to.
Clear	Click **Clear** to clear the filter conditions you specified.
View Log	Click **View Log** in the Actions column of a topic to view the operational logs of rules configured for the topic.
Alerts	Click **Alerts** in the Actions column of a topic. On the Alerts page, you can view details about alerts triggered by the topic. On the **Alerts** page, you can click **Close** in the Actions column of an alert. In the message that appears, click **OK** to disable the alert.

2.1.11.2.5. Report Template Management

On the **Report Template Management** page, you can create a template of data quality reports. DataWorks can periodically generate and send data quality reports based on the template.

Create a report template

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Quality**.
2. On the Data Quality page that appears, choose **Configuration > Report Template Management** in the left-side navigation pane. The Report Template Management page appears.
3. Click **Create Report Template**. On the **Create Report Template** page that appears, set required parameters.

Section	Parameter	Description
Basic settings	**Name**	The name of the report template.
	Sending Cycle	The interval at which reports are sent. Valid values: **Every Day**, **Every Week**, **Every Month**, and **Do Not Send**. If you set Sending Cycle to Every Week or Every Month, you also need to specify the specific day on which reports are sent.
	Timespan	The number of days before the current day. DataWorks generates reports based on the data of those days. The maximum value of this parameter is 30.

Section	Parameter	Description
Statistics of Rule Configuration The Statistics of Rule Configuration section displays metrics about rule configuration for offline data and real-time data. You can select metrics based on your needs.	**Offline data**	The metrics about rule configuration for tables in the workspace. The metrics include **Table count**, **Partition expression count**, **Count of rule on offline data**, and **Rule coverage on tables**. The Rule coverage on tables metric indicates the ratio of tables for which quality monitoring rules are configured.
	Realtime data	The metrics about rule configuration for topics in the workspace. The metrics include **Topic count**, **Count of rule on realtime data**, **Count of rule on cut off data**, **Rule coverage on topic**, **Count of rule on delayed data**, and **Count of customized rule**. The Rule coverage on topic metric indicates the ratio of topics for which quality monitoring rules are configured.
Statistics of Rule Execution The Statistics of Rule Execution section displays metrics about rule running for offline data and real-time data. You can select metrics based on your needs. Quality reports display the selected metrics in charts.	**Offline data**	The metrics about rule running for tables in the workspace. The metrics are classified into the following types: **About rules**, **About partitions**, and **About tables**.
	Realtime data	The metrics about rule running for topics in the workspace. The metrics are classified into the following types: **About messages**, **About alarms**, and **About cut-offs**.
Manage Subscriptions	**Subscription Method**	The method used to notify report subscribers of new reports. Currently, DataWorks sends emails to notify report subscribers of new reports.
	Recipient	The recipient of report notifications. You can add multiple recipients.
	Actions	The operations that you can perform on the subscription. You can click **Save** or **Cancel** in the Actions column of a subscription to save or cancel the subscription.
	Add Subscription	The button that allows you to add a subscription.

4. Click **Save** in the upper-right corner. A template of data quality reports is generated.

Preview a report template

After creating a report template, you can click **Preview** in the upper-right corner of the Create Report Template page to view the display format of reports generated based on this template.

> **Note** If report subscribers view reports through email notifications, they can only view the reports in tables. If they view reports on the Data Quality page, they can view reports in tables or charts.

2.1.11.2.6. Manage rule templates

In Data Quality, you can manage a set of custom rule templates and use the rule templates to improve the efficiency of rule configuration.

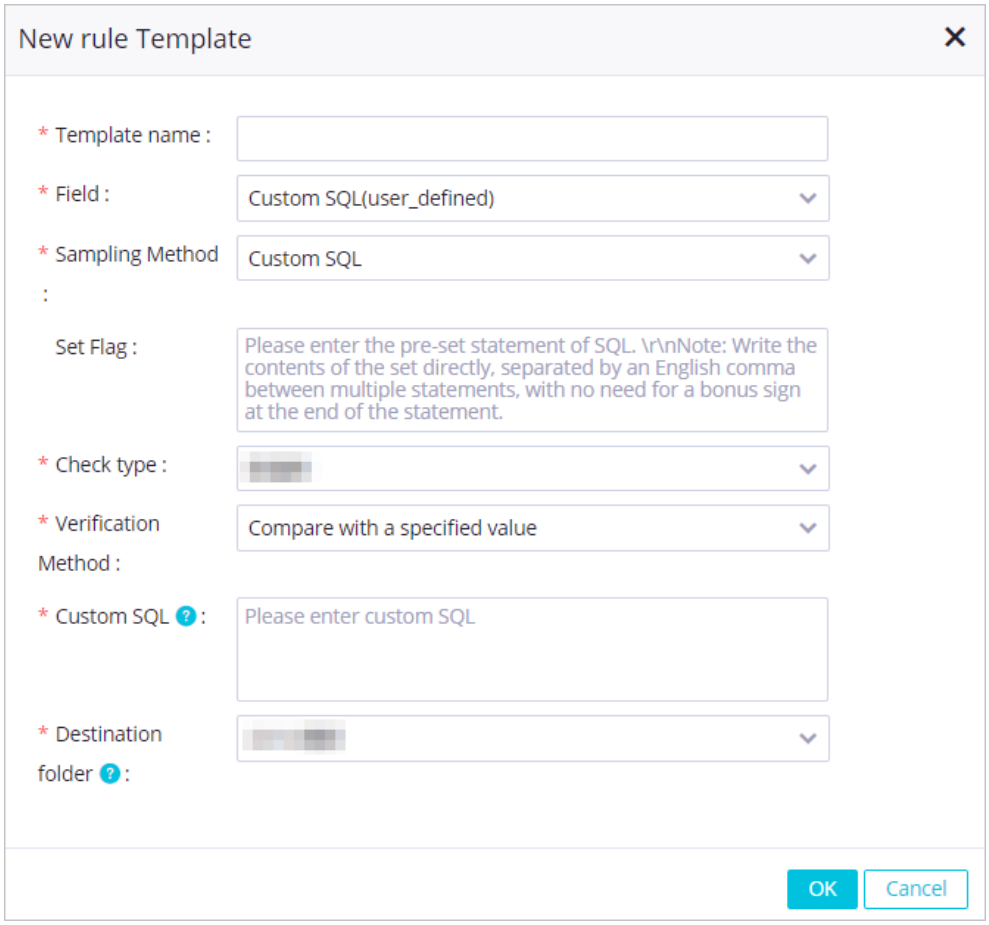
Context

You can create a rule template on the **Rule Templates** and **Monitoring Rules** pages. After the rule template is created, you can manage and use it.

Create a rule template on the Rule Template Management page

1. Log on to the DataWorks console.
2. On the DataStudio page, click in the upper-left corner and choose **All Products > Data Quality**.
3. On the Data Quality page, choose **Configuration > Rule Templates** in the left-side navigation pane.
4. On the Rule Templates page, click and select **Create Folder**.
5. In the **Create Folder** dialog box, set the **Name** and **Location** parameters and click **OK**.
6. Right-click the folder name and select **Create Rule Template**.

   You can also rename or delete a folder.
7. In the **Create Rule Template** dialog box, set relevant parameters.



Parameter	Description
Template Name	The name of the rule template.
Field	The fields to be monitored and the statistical function. You can only set the two parameters to **Custom SQL**.
Sampling Method	
Set Flag	The `SET` clause of the SQL statement for querying the field to be monitored. **Note** Separate multiple statements with commas (,). You do not need to add a semicolon (;) at the end of each statement.
Check type	The threshold type of the rule. Valid values: **Numeric type** and **Fluctuation**.

Parameter	Description
Verification Method	The verification method of the rule template. The verification methods that can be selected vary with the threshold type. ○ If you set the **Check type** parameter to **Numeric type**, you can only set this parameter to **Compare with a specified value**. ○ If you set the **Check type** parameter to **Fluctuation**, the values that are optional for this parameter include **Compare the current value with the average value of the last 7 days**, **Compare the current value with the average value of the last 30 days**, **Compare the current value with the value 1 day before**, **Compare the current value with the value 7 days before**, **Compare the current value with the value 30 days before**, **The variance between the current value and the value 7 days before**, **The variance between the current value and the value 30 days before**, **Compare with the value 1, 7, and 30 days before** and **Compare with the value of the previous cycle**.
Custom SQL	The custom SQL statement. You can use ${tableName} as the table name.
Location	The name of the folder to which you want to store the custom rule template.

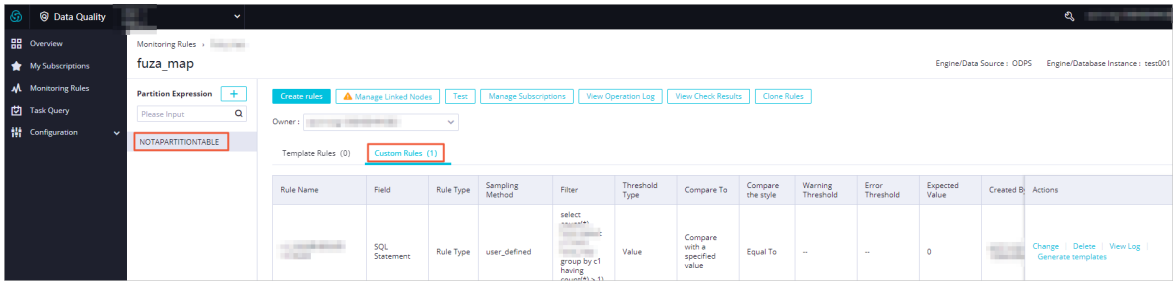
8. Click **OK**.

Create a rule template on the Monitoring Rules page

1. Go to the **Data Quality** page.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. On the Monitoring Rules page, select the compute engine or data store, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.

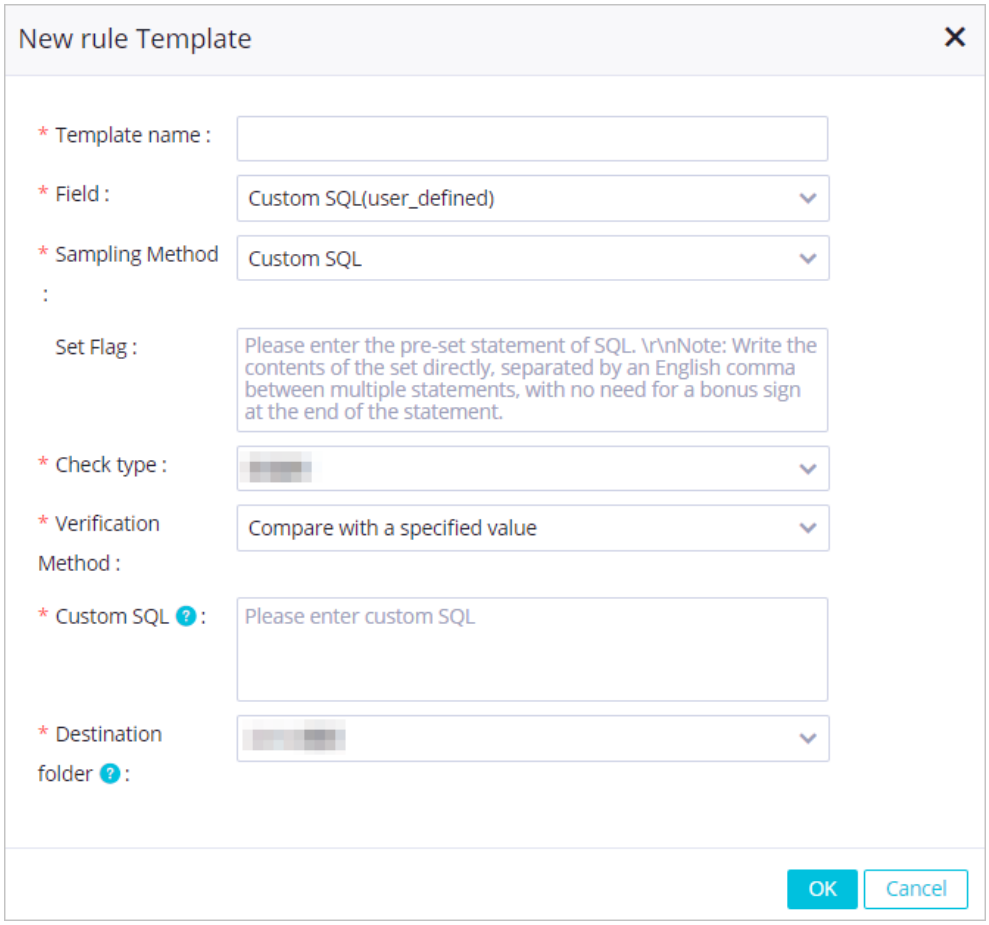
> **Note** This topic uses a MaxCompute table as an example.

4. Click a partition filter expression and then click the **Custom Rules** tab.



> **Note** For more information about how to create custom rules, see Custom rules.

5. On the Custom Rules tab, find the target custom rule and click **Generate Template** in the Actions column.
6. In the **Create Template** dialog box, set relevant parameters.



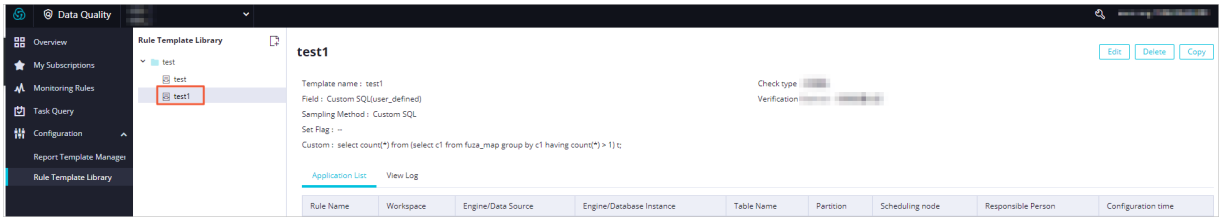
Parameter	Description
Template Name	The name of the rule template.
Field	The fields to be monitored and the statistical function. You can only set the two parameters to **Custom SQL**.
Sampling Method	
Set Flag	The `SET` clause of the SQL statement for querying the field to be monitored. **Note** Separate multiple statements with commas (,). You do not need to add a semicolon (;) at the end of each statement.
Check type	The threshold type of the rule. Valid values: **Numeric type** and **Fluctuation**.

Parameter	Description
Verification Method	The verification method of the rule template. The verification methods that can be selected vary with the threshold type. ○ If you set the **Check type** parameter to **Numeric type**, you can only set this parameter to **Compare with a specified value**. ○ If you set the **Check type** parameter to **Fluctuation**, the values that are optional for this parameter include **Compare the current value with the average value of the last 7 days**, **Compare the current value with the average value of the last 30 days**, **Compare the current value with the value 1 day before**, **Compare the current value with the value 7 days before**, **Compare the current value with the value 30 days before**, **The variance between the current value and the value 7 days before**, **The variance between the current value and the value 30 days before**, **Compare with the value 1, 7, and 30 days before** and **Compare with the value of the previous cycle**.
Custom SQL	The custom SQL statement. You can use ${tableName} as the table name.
Location	The name of the folder to which you want to store the custom rule template.

7. Click **OK**.
8. In the left-side navigation pane, choose **Configuration > Rule Templates** to view the created rule template.

Manage an existing rule template

On the Rule Templates page, you can click the name of a rule template to go to the template details page. On this page, you can view, edit, delete, or copy the rule template.



Action	Description
View	You can view the parameter configuration, the rules that use the rule template, and logs of the rule template: • The **Application List** tab displays the rules that use the rule template. • The **View Log** tab displays the logs of operations performed on the rule template, including the user who performed each operation, the time when each operation was performed, and the operation details.
Edit	Click **Edit** in the upper-right corner. In the **Edit Rule Template** dialog box, modify the required parameters, and click **OK**.
Delete	Click **Delete** in the upper-right corner. In the **Delete Template** message, click **OK**.
Copy	Click **Copy** in the upper-right corner. In the **Copy Rule Template** dialog box, set the **Template Name** and **Location** parameters and click **OK**.

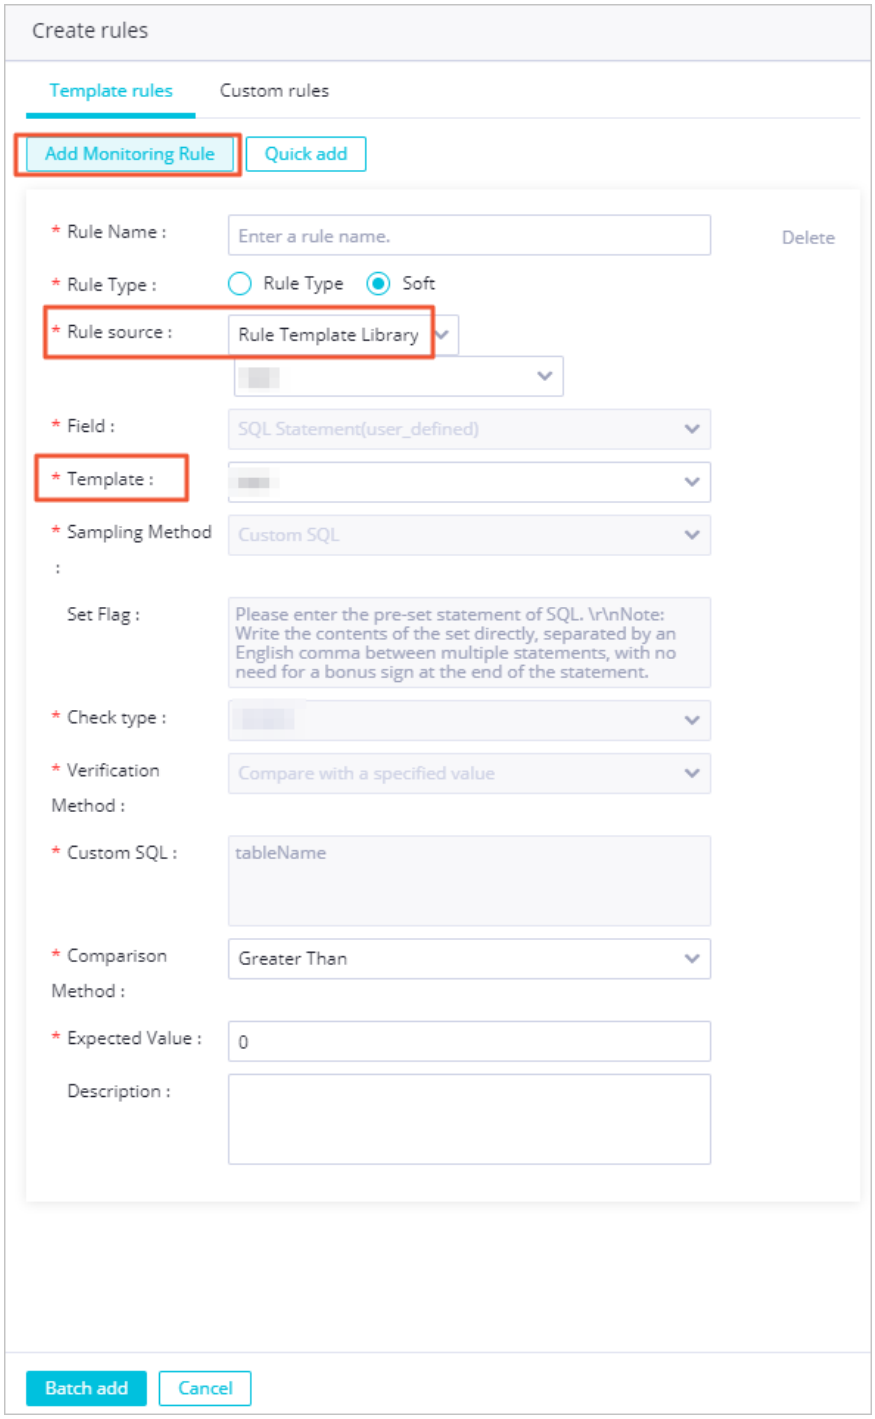
Use a rule template

When you create a monitoring rule, you can select a custom rule template to create the rule based on the rule template.

1. Go to the **Data Quality** page.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. On the Monitoring Rules page, select the compute engine or data store, find the target table or topic, and then click **View Monitoring Rules** in the Actions column.

   > **Note** This topic uses a MaxCompute table as an example.

4. Click a partition filter expression and click the **Custom Rules** tab.
5. On the **Template Rules** tab of the **Create rules** right-side pane, click **Add Monitoring Rule**.
6. Set the parameters for the rule. Specifically, set the **Rule Source** parameter to **Rule Templates** and select a rule template. For more information about the parameter description, see Rules.



7. Click **Batch Create**.

2.1.11.3. User guide

2.1.11.3.1. Configure monitoring rules for MaxCompute

The Monitoring Rules page is the most important part of Data Quality, where you can configure rules to monitor data in E-MapReduce, MaxCompute, and DataHub. This topic describes how to configure monitoring rules for MaxCompute.

Add a MaxCompute connection

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration**.
3. On the Data Integration page, click **Connection** in the left-side navigation pane. The **Data Source** page appears.
4. Click **Add Connection** in the upper-right corner to add a MaxCompute connection.

Select the MaxCompute connection

1. On the current page, click ☰ in the upper-left corner and choose **All Products > Data Quality**.
2. On the Data Quality page, click **Monitoring Rules** in the left-side navigation pane.
3. Select **ODPS** from the **Engine/Data Source** drop-down list to display all tables in the MaxCompute data store.

   You can search for a table by table name. Fuzzy search based on the initial letters of a table name is supported.
4. Find the target table and click **View Monitoring Rules** in the Actions column.

Configure a partition filter expression

In Data Quality, you must configure rules based on a partition filter expression:

- To configure rules for a non-partitioned table, you can specify NOTAPARTITIONTABLE as the partition filter expression.
- To configure rules for a partitioned table, you can specify a data timestamp expression, such as $[yyyymmdd], or a regular expression as the partition filter expression.

On the rule configuration page of a table, click **+** next to **Partition Expression** to add a partition filter expression.

You can create a partition filter expression or select a recommended partition filter expression.

- Create a partition filter expression

  In the **Add Partition** dialog box, enter a partition filter expression that conforms to the syntax as required. For a non-partitioned table, select **NOTAPARTITIONTABLE** from the recommended partition filter expressions.

  - For a table with only one partition, follow the format: Partition key=Partition value. The partition value can be either a constant or a system parameter. You must configure partition expressions by using the last partition.
  - For a table with multiple partitions, follow the format: Partition key 1\=Partition value/Partition key 2=Partition value/Partition key N=Partition value. Each partition value can be either a constant or a system parameter. You must use brackets [ ] to indicate a parameter, such as $[yyyymmdd-N].

  The data timestamp configured in a partition filter expression also determines the recurrence of the partition filter expression. For example, if the data timestamp is the date of five days ago, the partition filter expression is triggered every five days. The following table describes supported partition filter expressions.

Partition filter expression	Description
dt=$[yyyymmdd-N]	Indicates N days before.
dt=$[yyyymm01-1]	Indicates the first day of each month.
dt=$[yyyymm01-Nm]	Indicates the first day of the month that is N months before the current month.

Partition filter expression	Description
dt=$[yyyymmld-1]	Indicates the last day of each month.
dt=$[yyyymmld-1m]	Indicates the last day of the month that is N months before the current month.
dt=$[hh24miss-1/24]	Indicates one hour before the hour specified by the data timestamp.
dt=$[hh24miss-30/24/60]	Indicates half an hour before the hour specified by the data timestamp.
$[yyyymmdd]	Indicates the data timestamp.
$[yyyymmdd-1]	Indicates one day before the data timestamp of the current instance.
$[yyyymmddhh24miss]	Indicates the data timestamp of the current instance. Follow the `yyyymmddhh24miss` format by understanding the following format description: ○ yyyy indicates a four-digit year. ○ mm indicates a two-digit month. ○ dd indicates a two-digit day. ○ hh24 indicates a two-digit hour (24-hour clock). ○ mi indicates two-digit minutes. ○ ss indicates two-digit seconds.
NOTAPARTITIONTABLE	Indicates the partition filter expression of a non-partitioned table.

- Select a recommended partition filter expression

  This section uses the dt partition as an example to describe how to select a recommended partition filter expression. We recommend that you specify a regular expression as the partition filter expression for a dynamic partitioned table.

  i. In the **Add Partition** dialog box, click the Partition Expression field. A drop-down list appears to show you the partition filter expressions recommended by Data Quality.
     - Select a recommended partition filter expression if it meets your expectation.
     - Specify a custom partition filter expression if no recommended partition filter expressions meet your expectation.

  ii. After you enter a partition expression, click **Verify**. Data Quality uses the current time, that is, the data timestamp, to calculate data and verify the partition filter expression.

  iii. Click **OK**.

If you need to delete a partition filter expression, move the pointer over the partition filter expression and click the **Delete** icon to delete the partition filter expression. When you delete a partition filter expression, all rules configured based on the partition filter expression are also deleted.

Link a partition filter expression to a node

To monitor the quality of data involved in a node, you need to link a partition filter expression to the node.

- The Manage Linked Nodes dialog box lists all committed nodes. Data Quality allows you to link a partition filter expression to a node in another workspace.
- Before you link a partition filter expression to a node in another workspace, make sure that you are an administrator, a developer, or an administration expert in the two workspaces.

You can link a partition filter expression to one or more nodes. After nodes are linked, Data Quality can automatically monitor linked nodes.

> **Note** Data Quality allows you to flexibly link a partition filter expression to a node. You can select a node that is not related to your table.

1. On the rule configuration page of a table, click **Manage Linked Nodes**.
2. In **Manage Linked Nodes** dialog box, enter the name of the node that you want to link to the partition filter expression.
3. Click **Create**.

Create a rule

The Monitoring Rules page is the most important part of Data Quality, where you can create rules for your tables.

Data Quality allows you to create template rules and custom rules as needed. If you need to create a template rule or a custom rule, you can click **Add Monitoring Rule** or **Quick Create**. For more information, see Rules.

After rules are configured, you can click **Batch Create** to save all the configured rules for the current partition filter expression.

Creation method	Parameter	Description
Add Monitoring Rule	**Rule Name**	The name of the rule.
	Rule Type	The type of the rule. Valid values: • **Rule Type**: If a node reaches the error threshold, Data Quality reports an error alert and determines that the node fails. If a node reaches the warning threshold, Data Quality reports a warning alert and determines that the node is successful. • **Soft**: If a node reaches the error threshold, Data Quality reports an error alert and determines that the node is successful. If a node reaches the warning threshold, Data Quality does not report a warning alert and determines that the node is successful.
	Auto-Generated Threshold	You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.
	Rule Source	The source of the rule. Valid values: **Built-in Template** and **Rule Templates**.
	Field	The fields to be monitored. You can select **All Fields in Table** or a specific field. If you select a field, you can apply the rule to the specified field in the table. > **Note** In this example, select All Fields in Table and set other parameters for the table-specific rule.

Creation method	Parameter	Description
	Template	• If you set **Rule Source** to **Built-in Template**, the built-in table-specific rules appear. • If you set **Rule Source** to **Rule Templates**, you must set parameters, such as **Sampling Method** and **Set Flag**.
	Comparison Method	The comparison method of the rule. Valid values: **Absolute Value**, **Raise**, and **Drop**.
	Thresholds	The warning threshold and error threshold of the fluctuation. You can adjust the slider to specify thresholds or directly enter thresholds.
	Description	The description of the rule.
Quick Create	**Rule Name**	The name of the rule.
	Field	The fields to be monitored. You can select All Fields in Table or a specific field. If you select a field, you can apply the rule to the specified field in the table.
	Trigger	• The trigger condition of the rule. If you select All Fields in Table for the Field parameter, you can set this parameter to **The number of columns is greater than 0** or **Table row number dynamic threshold**. **Notice** You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher. • If you select a field for the Field parameter, you can select **The field value already exists**, **Null Field**, or **Unique value dynamic threshold**. **Notice** You can use the dynamic threshold feature only in DataWorks Enterprise Edition or higher.

Test rules

After rules are configured for a partition filter expression, you can test all these rules and view the test results.

Note You can manually run these rules to test their configuration and notification methods. We recommend that you test rules as required.

1. On the rule configuration page of a table, click **Test**.
2. In the **Test** dialog box, set the **Data Timestamp** parameter.

Parameter	Description

Parameter	Description
Partition	The partition filter expression for which rules are run. The actual partition key varies with the data timestamp. For a non-partitioned table, use NOPARTITIONTABLE as the partition filter expression.
Data Timestamp	The data timestamp for testing rules. The default value is the current time.

3. Click **Test**.
4. In the Test dialog box, click **The test is complete. Click to view the results** to view the test results on the **Node Query** page.

Manage subscriptions

By default, Data Quality sends notifications to the user who created a partition filter expression. You can add other users so that Data Quality sends notifications to them.

1. On the rule configuration page of a table, click **Manage Subscriptions**.
2. In the **Manage Subscriptions** dialog box, specify the notification method and notification receiver.

   Data Quality supports the following four methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.

   > **Note** Add a DingTalk chatbot and obtain a webhook URL. Then, copy the webhook URL to the Manage Subscriptions dialog box.

3. Click **Save**.

View operational logs

On the rule configuration page of a table, click **View Operation Log**. In the **Operations Logs** right-side pane, you can view the information about each operation, including the user who performed the operation, the time when the operation was performed, and the operation details.

The **Details** column displays the details of each operation performed on the current partition filter expression, including the rule configuration details.

View check results

On the rule configuration page of a table, click **View Check Results** to go to the **Node Query** page. On this page, you can view the check results for all rules under the current partition filter expression.

Clone rules

1. On the rule configuration page of a table, click **Clone Rules**.
2. In **Clone Rules** dialog box, set the **Target Expression** parameter.
3. Select **Clone Subscribers** or **Change Table Names in Custom Rules** as required.
4. Click **Clone**.

2.1.11.3.2. Configure monitoring rules for DataHub

The Monitoring Rules page is the most important part of Data Quality, where you can configure rules to monitor data in E-MapReduce (EMR), MaxCompute, and DataHub. This topic describes how to configure monitoring rules for DataHub.

Context

DataHub monitoring supports the following features:

- Templates for monitoring stream discontinuity and data latency
- Stream processing features, such as custom Flink SQL, dimension table JOIN, multi-stream JOIN, and window functions

Procedure

1. Add a DataHub data source.
   i. Log on to the DataWorks console.
   ii. On the **DataStudio** page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
   iii. On the Data Integration page, choose **Data Source > Data Stores**.
   iv. On the Data Source page, click **Add data source** in the upper-right corner to add a DataHub data source. For more information, see Configure monitoring rules for DataHub.
2. Select the DataHub data source.
   i. On the current page, click the icon in the upper-left corner and choose **All Products > Data governance > Data Quality**.
   ii. On the page that appears, click **Monitoring Rules** in the left-side navigation pane.

iii. On the Monitoring Rules page, select **Datahub** from the **Engine/Data Source** drop-down list and select the newly added DataHub data source from the Engine/Database Instance drop-down list. All the topics in the selected DataHub data source are displayed.

Parameter	Description
Configure Flink/SLS Resources	After you add a data source, click Configure Flink/SLS Resources to configure Realtime Compute and Log Service resources related to the data source.
Topics	The Topics tab lists all the topics in the DataHub data source. You can click the following buttons in the Actions column for a topic: ■ **View Monitoring Rules**: Click it to create rules for the topic. You can create template rules and custom rules. ■ **Manage Subscriptions**: Click it to view and modify subscribers to the topic, and change the notification method. You can use a DingTalk chatbot to receive notifications. The changed notification method takes effect for all subscribers to the topic.
Dimension Tables	When you create custom rules for a topic, you can create and join dimension tables. If the collected data streams lack some fields for a dimension table, you must supplement fields to data streams before data analysis and declare the dimension table in Data Quality. DataHub supports the dimension tables of ApsaraDB for HBase, Lindorm, ApsaraDB RDS, Tablestore, Taobao Distributed Data Layer (TDDL), and MaxCompute. Flink SQL does not design the data definition language (DDL) syntax for dimension tables. You can use the standard CREATE TABLE statement. However, you must add `period for system_time` to specify the period of a dimension table and declare that the dimension table stores time-varying data. **Note** When you declare a dimension table, you must specify the primary key. When you join a dimension table with another table, the ON condition must contain an equivalence condition for each primary key of the tables.

iv. Click the **Topics** tab. Find the topic for which you want to configure monitoring rules and click **View Monitoring Rules** in the Actions column.

3. On the rule configuration page of the topic, click **Create Rule**.
4. Create a monitoring rule.

   In Data Quality, you can create template rules and custom rules.

   - On the Template Rules tab of the Create rules panel, click **Create Template Rule**. Two templates are available: **Data Delay** and **Stream Discontinuity**.

     For example, you can select **Data Delay** for the Template Type parameter.

Parameter	Description
Rule Name	The name of the rule. The name can be a maximum of 255 characters in length.
Field Type	The fields to be monitored. By default, this parameter is set to All Fields in Table.

Parameter	Description
Template Type	■ **Data Delay**: monitors the interval between the time when data is generated and the time when data is written to DataHub based on the data timestamp field. If the interval exceeds a specified threshold, an alert is generated. Note ■ Before you configure a stream discontinuity rule, you must activate Realtime Compute in Flink and create a project. ■ The data timestamp field supports two data types: TIMESTAMP and STRING (yyyy -MM -dd H dd HH:mm:ss). ■ **Stream Discontinuity**: monitors the period during which no data is written to DataHub. If the period exceeds a specified threshold, an alert is generated.
Alerts Threshold	The maximum number of alerts generated for data latency. Data Quality reports an alert when the number of alerts generated for data latency exceeds this threshold. This parameter is displayed only when you select Data Delay for the Template Type parameter.
Data Timestamp Field	The data timestamp field of the topic for which the rule is created. This field supports two data types: TIMESTAMP and STRING (yyyy-MM-dd HH:mm:ss). This parameter is displayed only when you select Data Delay for the Template Type parameter.
Alert Frequency	The interval at which alerts are reported. You can set the alert interval to 10 minutes, 30 minutes, 1 hour, or 2 hours.
Warning Threshold	The warning threshold, in seconds. The value must be an integer and less than the error threshold.
Error Threshold	The error threshold, in seconds. The value must be an integer and greater than the warning threshold.

- If template rules do not meet your requirements for monitoring the data quality of DataHub topics, you can create a custom rule. On the Custom Rules tab of the Create rules panel, click **Create Custom Rule**.

Note
- The field in the SELECT clause must be a column. Make sure that you can compare the field values with the warning threshold and error threshold.
- The FROM clause must include the current topic and all its columns.

Parameter	Description
Rule Name	The name of the rule. The name must be unique in the topic and can be a maximum of 20 characters in length.

Parameter	Description

Script	The custom SQL script that is used to set a rule. The return value of the SELECT clause must be unique. You can refer to the following sample statements:
	■ Use a simple SQL statement.
	`select id as a from zmr_tst02;`
	■ Join the topic and a dimension table named test_dim.
	`select e.id as eid`
	`from zmr_test02 as e`
	`join test_dim for system_time as of proctime() as w`
	`on e.id=w.id`
	■ Join the topic and another topic named dp1test_zmr01.
	`select count(newtab.biz_date) as aa`
	`from (select o.*`
	`from zmr_test02 as o`
	`join dp1test_zmr01 as p`
	`on o.id=p.id)newtab`
	`group by id.biz_date,biz_date_str,total_price,'timestamp'`

Warning Threshold	The warning threshold, in minutes. The value must be an integer and less than the error threshold.
Error Threshold	The error threshold, in minutes. The value must be an integer and greater than the warning threshold.
Minimum Alert Interval	The minimum interval at which alerts are reported, in minutes.
Description	The description of the rule.

5. Click **Batch Create**. After rules are created for the topic, you can perform the following operations:
   - **View Log**: Click it to view the operational logs of the rules.
   - **Manage Subscriptions**: Click it to view and modify subscribers to the rules, and change the notification method. The changed notification method takes effect for all the subscribers of the rules.

     Data Quality supports the following methods: **Email**, **Email and SMS**, **DingTalk Chatbot**, and **DingTalk Chatbot @ALL**.

     > **Note** Add a DingTalk chatbot and obtain the webhook address of the chatbot. Then, copy the webhook address to the Manage Subscriptions dialog box.

2.1.12. Data Map

2.1.12.1. Overview

Data Map is developed based on Data Management and uses roles to control the permissions for using different features, such as the permissions for creating and previewing data. Data Map helps you build a better enterprise-level knowledge base.

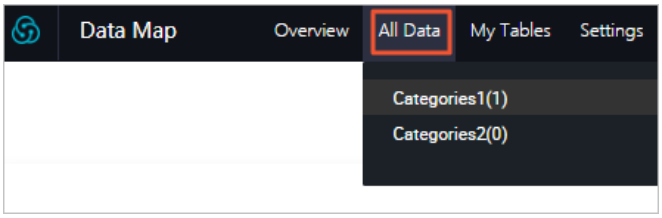
On the homepage of Data Map, you can enter keywords to search for tables by name. You can also click a table in one of the following sections to view the table data: **Recently Viewed Tables**, **Recently Read Tables**, **Most Viewed Tables**, or **Most Read Tables**.

- If you prefer a powerful search engine, go to the homepage to search for data.

  > **Note** The homepage appears when you go to the **Data Map** page. To return to the homepage from other pages, click **Data Map** in the upper-left corner.

- If you want to find tables by workspace or cluster, click **All Data** in the top navigation bar. On the page that appears, you can view tables on different tabs, such as **MaxCompute** or **EMR**. You can also find a table and perform the following operations on it: **Add to Favorites**, **Apply for Permission**, **View Lineage**, or **View DDL Statement**.

  If you have added tables to categories, move the pointer over **All Data** in the top navigation bar and select a category. Tables in the category appear. For more information, see Manage categories of and permissions on MaxCompute tables.

- If you want to view the overall data of the current tenant, click **Overview** in the top navigation bar. For more information, see View overall data.
- If you want to modify tables that are owned by your account, click **My Data** in the top navigation bar. For more information, see View and manage tables and data permissions.
- If you are a category administrator or workspace administrator and want to modify the workspace configurations or global categories, click **Configuration Management** in the top navigation bar. For more information, see Manage categories of and permissions on MaxCompute tables.

2.1.12.2. Configure whitelists and category management permissions

If you want to view MaxCompute table data or collect metadata in Data Map, you must configure a whitelist for your MaxCompute project or the desired data source. Then, add the Classless Inter-Domain Routing (CIDR) blocks of the region where your DataWorks workspace resides to the whitelist. If you want to manage categories in Data Map, you must grant the related permissions to the account you use. This topic describes how to configure the whitelists and grant category management permissions.

Context

- Data Map provides a platform to manage both metadata and the data assets of enterprises. This platform allows you to search global data, view metadata details, preview data, view data lineages, and manage data categories. Data Map helps you search for, understand, and use data. If you want to use Data Map to view the table data in a MaxCompute project, check whether a whitelist is configured for the project. If a whitelist is configured, make sure that the CIDR blocks of the region where your DataWorks workspace resides are in the whitelist. Otherwise, you cannot view the table data in Data Map. Therefore, to ensure that Data Map can access MaxCompute projects, you must configure whitelists for the projects in advance.

  > **Note** Only MaxCompute requires whitelist configuration. For other products, you can directly view data in Data Map.

- The metadata collection feature allows you to collect metadata from different data sources. This way, you can manage the metadata in a centralized manner. After the metadata of a data source is collected, you can view the metadata in Data Map. Before you collect metadata from the data source, check whether a whitelist is configured for the data source. If a whitelist is configured, make sure that the CIDR blocks of the region where your DataWorks workspace resides are in the whitelist.
- The category management feature allows you to effectively organize and manage tables by category. For more information, see Manage categories of and permissions on MaxCompute tables. Before you use this feature, make sure that you have the required permissions.
  - If you use an Alibaba Cloud account to manage categories, you have the permissions by default.
  - If you use a RAM user to manage categories, you must attach the **AliyunDataWorksFullAccess** policy to the RAM user.

Configure a whitelist for a MaxCompute project to allow Data Map to access the project

1. Check whether a whitelist is configured for your MaxCompute project. For more information, see *View an IP address whitelist* in the MaxCompute documentation.

   If a whitelist is not configured for the project, Data Map can access the table data in the project. If a whitelist is configured, proceed to the next step.

2. Configure the whitelist.

   Add the desired CIDR blocks of the region where your DataWorks workspace resides to the whitelist. The following table lists the CIDR blocks of each region. For more information about how to configure a whitelist, see *Configure IP address whitelists*.

Region	CIDR block or IP address
China (Hangzhou)	100.64.0.0/10,11.193.102.0/24,11.193.215.0/24,11.194.110.0/24,11.194.73.0/24,118.31.157.0/24,47.97.53.0/24,11.196.23.0/24,47.99.12.0/24,47.99.13.0/24,114.55.197.0/24,11.197.246.0/24,11.197.247.0/24
China (Shanghai)	11.193.109.0/24,11.193.252.0/24,47.101.107.0/24,47.100.129.0/24,106.15.14.0/24,10.117.28.203,10.143.32.0/24,10.152.69.0/24,10.153.136.0/24,10.27.63.15,10.27.63.38,10.27.63.41,10.27.63.60,10.46.64.81,10.46.67.156,11.192.97.0/24,11.192.98.0/24,11.193.102.0/24,11.218.89.0/24,11.218.96.0/24,11.219.217.0/24,11.219.218.0/24,11.219.219.0/24,11.219.233.0/24,11.219.234.0/24,118.178.142.154,118.178.56.228,118.178.59.233,118.178.84.74,120.27.160.26,120.27.160.81,121.43.110.160,121.43.112.137,100.64.0.0/10,10.117.39.238

Configure a whitelist for metadata collection from a data source

1. Check whether a whitelist is configured for the data source.

   Data Map allows you to collect metadata from the following types of data sources:

- Collect metadata from an EMR data source
- Collect metadata from an AnalyticDB for PostgreSQL data source
- Collect metadata from a MySQL data source
- Collect metadata from a PostgreSQL data source
- Collect metadata from an SQL Server data source
- Collect metadata from an Oracle data source
- Collect metadata from an AnalyticDB for MySQL 2.0 data source
- Collect metadata from an AnalyticDB for MySQL 3.0 data source
- Collect metadata from a Hologres data source

The method used to check whether a whitelist is configured varies based on the data source type. You can consult technical support personnel.

If a whitelist is not configured for the data source, you can directly use Data Map to collect metadata from the data source. If a whitelist is configured, proceed to the next step.

2. Configure the whitelist.

   Add the desired CIDR blocks of the region where your DataWorks workspace resides to the whitelist. The following table lists the CIDR blocks of each region. The position where the CIDR blocks are added varies based on the data source type. You can consult technical support personnel.

Region	CIDR block or IP address
China (Shanghai)	100.104.189.64/26,11.115.110.10/24,11.115.109.9/24,47.102.181.128/26,47.102.181.192/26,47.102.234.0/26,47.102.234.64/26,100.104.38.192/26
China (Hangzhou)	100.104.135.128/26,11.193.215.233/24,11.194.73.32/24,118.31.243.0/26,118.31.243.64/26,118.31.243.128/26,118.31.243.192/26,100.104.242.0/26
China (Shenzhen)	100.104.46.128/26,11.192.91.119/24,120.77.195.128/26,120.77.195.192/26,120.77.195.64/26,47.112.86.0/26,100.104.138.128/26
China (Beijing)	100.104.37.128/26,11.193.82.20/24,11.197.254.171/24,39.107.223.0/26,39.107.223.64/26,39.107.223.128/26,39.107.223.192/26,100.104.152.128/26
China (Chengdu)	100.104.88.64/26,11.195.57.28/24,47.108.46.0/26,47.108.46.64/26,47.108.46.128/26,47.108.46.192/26,100.104.248.128/26
China (Zhangjiakou)	100.104.197.0/26,11.193.236.121/24,47.92.185.0/26,47.92.185.64/26,47.92.185.128/26,47.92.185.192/26,100.104.75.64/26

Configure category management permissions for a RAM user

If you use a RAM user to manage categories, you must attach the **AliyunDataWorksFullAccess** policy to the RAM user.

What's next

After the whitelists and category management permissions are configured, you can view MaxCompute table data, collect metadata, or manage categories in Data Map.

2.1.12.3. View overall data

This topic describes how to view the overall data of a tenant on the Overview page.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
3. In the top navigation bar, click **Overview**.

   The **Overview** page displays the offline statistics of the current tenant.

   > **Note** The data on the Overview page is generated on the previous day.

Section	Description
Total Number of Projects	The total number of projects of the specified type for the current tenant.
Total Number of Tables	The total number of tables in the destination project or destination database for the current tenant.
Storage	The total storage space that is occupied by all the tables in the destination MaxCompute project for the current tenant.
Storage trend chart	The offline statistics on the trend of storage usage.
Top Projects by Table Storage	The top projects that occupy the most storage space for the current tenant.
Top Tables by Occupied Storage	The top tables that occupy the most storage space for the current tenant. You can click a table name to go to the details page of the table. **Note** The logical storage space that is occupied by projects and tables is calculated in a T+1 manner. The numbers next to the project and table names indicate the sizes of the occupied logical storage space. The project storage volume includes not only the table storage volume but also the storage volumes of resources, data in the recycle bin, and other system files. Therefore, the project storage volume is larger than the table storage volume. You are charged for the logical storage volume of a table rather than the physical storage volume of a table.
Most Frequently Used Tables	The most frequently referenced tables for the current tenant. You can click a table name to go to the details page of the table.

2.1.12.4. View and manage tables and data permissions

This topic describes how to view and manage tables on the Owned by Me, Managed by Me, Managed by Tenant Account, and My Favorites pages. This topic also describes how to view and manage data permissions.

Context

Data Map updates data one day after the data is generated. If you want to query real-time data, we recommend that you use SQL statements.

Go to the Owned by Me page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data**

governance > DataMap(Data Management).

3. In the top navigation bar, click **My Data**. The **Owned by Me** page appears.

View and manage tables on the Owned by Me page

On the **Owned by Me** page, you can search for your desired table by keyword, environment, project or data source, and visibility. You can also view the details about a table and perform operations on the table.

Parameter	Description
Table Name	The name of the table. You can click a table name to go to the details page of the table.
Display Name	The display name of the table. You can click the icon in the **Display Name** column of a table to modify the display name of the table.
Project/Data Store	The name of the project or data source to which the table belongs. The suffix of the name varies based on the environment where the table resides. For example, **_dev** indicates that the table resides in the development environment.
Hide or Show	You can click the icon in the Hide or Show column of a table to display or hide the table. Valid values: **Show**, **Hide**, and **Within the Project Only**.
TTL (Days)	The TTL of the table. The value is the same as that you set when you created the table.
Environment	The environment where the table resides. Valid values: **Development** and **Production**.
Storage	The volume of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.
Actions	The operations that you can perform on the table. You can click **Delete** or **Change Category** in the Actions column of a table to delete the table or change the category of the table.
Edit, Change Owner, Delete, and Change Category	The operations that you can perform on multiple tables at a time. You can select tables and click **Edit**, **Change Owner**, **Delete**, or **Change Category** to modify the tables, change the owners of the tables, delete the tables, or change the categories of the tables.

View and manage tables on the Managed by Me page

In the left-side navigation pane, click **Managed by Me**. On the page that appears, you can search for your desired table by keyword, project or data source, and environment. You can also view the details about a table and perform operations on the table.

Parameter	Description
Table Name	The name of the table. You can click a table name to go to the details page of the table.

Parameter	Description
Display Name	The display name of the table. You can click the icon in the **Display Name** column of a table to modify the display name of the table.
Project/Data Store	The name of the project or data source to which the table belongs. The suffix of the name varies based on the environment where the table resides. For example, **_dev** indicates that the table resides in the development environment.
TTL (Days)	The TTL of the table. The value is the same as that you set when you created the table.
Environment	The environment where the table resides. Valid values: **Development** and **Production**.
Storage	The volume of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.
Views in Last 30 Days	The number of times that users view the table in the last 30 days.
Created At	The time when the table was created.
Actions	The operations that you can perform on the table. You can click **Delete** or **Change Category** in the Actions column of a table to delete the table or change the category of the table.
Edit, Change Owner, Delete, and Change Category	The operations that you can perform on multiple tables at a time. You can select tables and click **Edit**, **Change Owner**, **Delete**, or **Change Category** to modify the tables, change the owners of the tables, delete the tables, or change the categories of the tables.

View and manage tables on the Managed by Tenant Account page

In the left-side navigation pane, click **Managed by Tenant Account**. On the page that appears, you can search for your desired table by keyword and project or data source and view the details about a table.

Parameter	Description
Table Name	The name of the table. You can click a table name to go to the details page of the table.
Display Name	The display name of the table.
Project/Data Store	The name of the project or data source to which the table belongs. You can click a project or data source name in the Project/Data Store column of a table to go to the details page of the project or data source.
TTL (Days)	The TTL of the table. The value is the same as that you set when you created the table.
Environment	The environment where the table resides. Valid values: **Development** and **Production**.
Storage	The volume of data that is stored in the table.
Favorites	The number of times that users add the table to favorites.

Parameter	Description
Views in Last 30 Days	The number of times that users view the table in the last 30 days. You can click the icon to arrange the tables by the number of views in ascending or descending order.
Created At	The time when the table was created.

View tables on the Tables of Other Tenants page

In the left-side navigation pane, click **Tables of Other Tenants**. On the page that appears, you can search for your desired table by table name and project or data source name and view the details about a table.

Parameter	Description
Table Name	The name of the table. You can click a table name to go to the details page of the table.
Display Name	The display name of the table.
Project/Data Store	The name of the project or data source to which the table belongs. You can click a project or data source name in the Project/Data Store column of a table to go to the details page of the project or data source.
Physical Storage	The volume of data that is stored in the table.
TTL (Days)	The TTL of the table. The value is the same as that you set when you created the table.
Created At	The time when the table was created.

View and manage tables on the My Favorites page

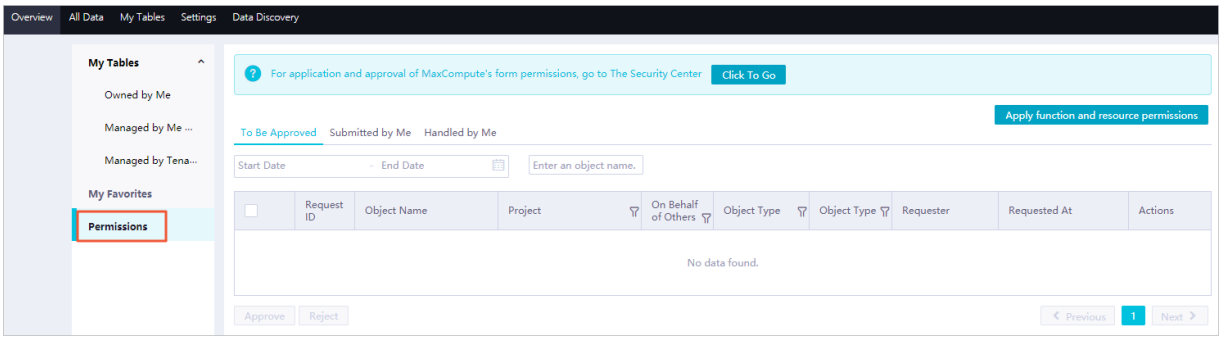
In the left-side navigation pane, click **My Favorites**. On the page that appears, you can view the tables that you have added to favorites. You can specify the following conditions to search for the tables that you have added to favorites: **Data Type**, **Project/Data Store**, and **Table Name**.

You can click **Remove from Favorites** in the Actions column of a table to remove the table from your favorites.

View and manage data permissions

In the left-side navigation pane, click **Permission Management**. On the page that appears, you can view and manage data permissions.

You can click **Apply for Function and Resource Permissions** in the upper-right corner of the **Permission Management** page to request permissions. You can also view permission request details on the **To Be Approved**, **Submitted by Me**, and **Handled by Me** tabs.



- **Apply for Function and Resource Permissions**
  i. On the Permission Management page, click **Apply for Function and Resource Permissions** in the upper-right corner.
  ii. In the **Apply for Function and Resource Permissions** dialog box, configure the parameters. The following table describes the parameters.

Parameter	Description
Object Type	The type of the object on which you want to request permissions. Valid values: **Functions** and **Resources**.
Grant To	The account to which permissions will be granted. Valid values: **Current Account** and **Specified Account**. ■ If you select **Current Account**, permissions will be granted to you after the request is approved. ■ If you select **Specified Account**, you must also set the **Username** parameter. Permissions will be granted to the specified account after the request is approved.
Project Name	The name of the MaxCompute project that contains the function or resource on which you want to request permissions. Fuzzy match is supported.
Function Name	The name of the function or resource in the project. If the resource is a file, enter the full name of the file, including the file name extension, such as my_mr.jar.
Validity Period	The validity period of the permissions, in days. If this parameter is not specified, the permissions are permanently valid. After the validity period is exceeded, the system automatically revokes the permissions.
Reason	The reason why you request the permissions.

- **To Be Approved**

  If you are the workspace administrator, you can view and approve the requests for permissions on all objects such as tables, resources, and functions in the workspace on the **To Be Approved** tab.

- **Submitted by Me**

  On the **Permission Management** page, click the **Submitted by Me** tab.

  On the **Submitted by Me** tab, you can view the permission requests that you have submitted.

- **Handled by Me**

  On the **Permission Management** page, click the **Handled by Me** tab.

  If you are the workspace administrator, you can view the permission requests that you have handled for all objects such as tables, resources, and functions in the workspace on the **Handled by Me** tab.

Manually synchronize a table

1. In the left-side navigation pane, choose **My Tools > Manually Sync Table** to go to the **Manually Sync Table** page.
2. Enter a table GUID in the **Table GUID** field. Then, click **Manually Sync Table** to synchronize the table.

2.1.12.5. Manage categories of and permissions on MaxCompute tables

This topic describes how to manage categories of and permissions on MaxCompute tables that are in your owned or managed workspaces on the Configuration Management page of Data Map.

Go to the Configuration Management page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
3. On the Data Map page, click **Configuration Management** in the top navigation bar. The **Manage Categories** tab is displayed.

   The Configuration Management page allows you to manage categories and permissions on MaxCompute tables in a workspace.

Manage categories

On the **Manage Categories** page, you can perform the following steps to create a category and add tables to and remove tables from the category.

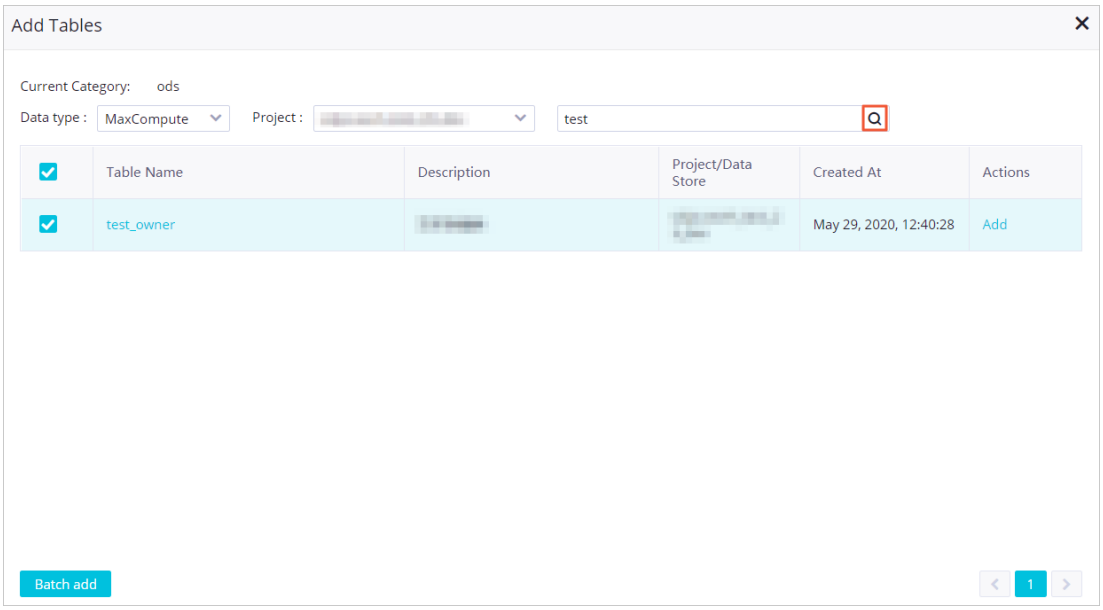
1. On the **Manage Categories** page, move the pointer over **Categories** and click the + icon. In the field that appears, enter a category name and press Enter to create a level-1 category.
2. Move the pointer over the level-1 category and click the + icon. In the field that appears, enter a category name and press Enter to create a level-2 category.

   
   Use the same method to create more categories. DataWorks allows you to create a maximum of four levels of categories. You can click the icon to edit a category or click the icon to delete a category.

3. Add tables to and remove tables from a category.

   
   - Add tables to a category
     a. Select the category and click **Add Tables** in the upper-right corner.

b. In the **Add Tables** dialog box, specify the table type and project, enter a table name or keyword, and then click the icon to search for tables.



c. If you want to add a table to the category, find the table and click **Add** in the Actions column.

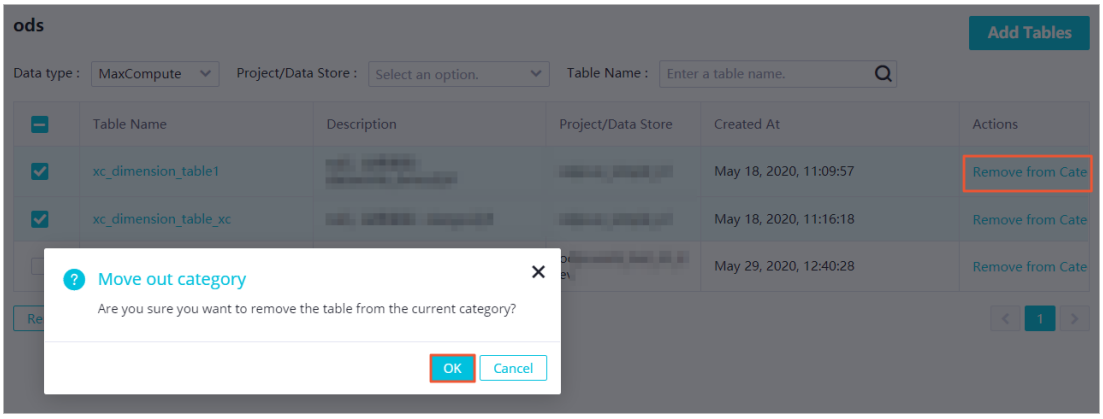
If you want to add multiple tables at a time, select the tables and click **Batch add**.

- Remove tables from a category

a. Select the category. If you want to remove a table from the category, find the table and click **Remove** in the Actions column.

If you want to remove multiple tables at a time, select the tables and click **Remove from Category**.

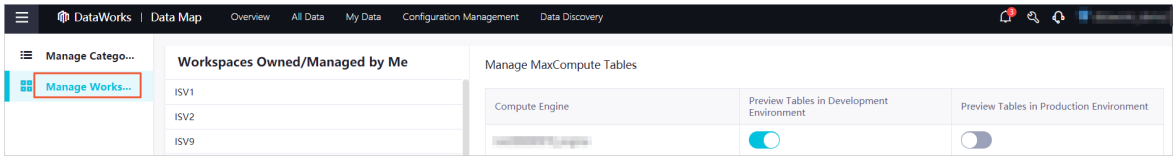
b. In the **Move out category** message, click **OK**.



Manage permissions on MaxCompute tables

On the **Manage Workspaces** page, you can specify whether MaxCompute tables can be previewed in a compute engine in the development and production environments.

1. In the left-side navigation pane, click **Manage Workspaces**.
2. In the **Workspaces Owned/Managed by Me** section, click the workspace for which you want to manage permissions on MaxCompute tables.
3. In the **Manage MaxCompute Tables** section, turn on or off the switch in the **Preview Tables in Development Environment** or **Preview Tables in Production Environment** column.



4. Turn on the switch in the **Preview Tables in Production Environment** column. In the **Attention** message, click **I already know that I am sure to open it**.

> **Note**
> - If you use a workspace in basic mode, you can turn on or off only the switch in the **Preview Tables in Production Environment** column.
> - After the switch in the **Preview Tables in Production Environment** column is turned on, all members of the workspace can preview MaxCompute tables in the production environment without requesting permissions. This may cause the leak of sensitive data. Therefore, exercise caution before you turn on the switch.

2.1.12.6. Table details

2.1.12.6.1. View the details of a table

This topic describes how to go to the details page of a table and view the details about the table, such as the basic information, output information, and lineage information.

Go to the details page of a table

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
3. In the top navigation bar, click **All Data**.
4. On the All Data page, click a tab as required, such as MaxCompute.
5. On the tab that appears, click the name of the table that you want to view.

   On the details page that appears, you can view the basic information, business information, permission information, technical information, detailed information, output information, lineage information, reference records, and usage notes of the table. You can also preview data in the table.

View basic information

In the **Basic Information** section, you can view the numbers of times that the table is read, the table is added to favorites, and the table is viewed. You can also view the number and code of the output nodes, MaxCompute project name, region where the current workspace resides, region to which the engine belongs, owner, creation time, time-to-live (TTL), storage capacity, description, and tags of the table. You can also check whether the table is a partitioned table.

You can perform the following operations in the **Basic Information** section:

- View the code of an output node of the table: Click **View Code** next to **Output Node**. On the **Operation Center** page, view the node code.
- View the details of a MaxCompute project: Click the MaxCompute project name. On the page that appears, view the details of the MaxCompute project to which the table belongs.
- Edit the description of the table: Click the icon next to **Description**, edit the description, and then click the icon.

- Add a tag to the table: Click the + icon next to **Tags**, enter a tag name, and then press **Enter**.

  To remove a tag from the table, move the pointer over the tag and click the x icon.

View business information

In the **Business Information** section, you can view the DataWorks workspace name, environment type, category, and display name of the table.

You can perform the following operations in the **Business Information** section:

- View the details about the workspace: Click the DataWorks workspace name. On the page that appears, view the details about the DataWorks workspace to which the table belongs.
- Edit the display name of the table: Click the icon next to **Display Name**, edit the display name, and then click the icon.

View permission information

In the **Permission Information** section, you can view your permissions on the table.

To modify your permissions on the table, perform the following steps:

1. Click **View More** in the upper-right corner of the **Permission Information** section. Then, the Permission application tab of the Data access control page appears.
2. On the **Permission application** tab, specify **User**, **Application duration**, and **Reason for application** in the Application Information section.

   > **Note** If you do not specify **Application duration**, the permissions that you request will be permanently valid after your request is approved.

3. Click **Apply for permission**.

View technical information

In the **Technical Information** section, you can view the technical type, time when the data definition language (DDL) statement was last modified, time when data was last modified, time when data was last viewed, and compute engine information.

In the **Technical Information** section, you can click **View** next to **Compute Engine Information**. In the **Compute Engine Information** dialog box, you can view or copy the information about the compute engine.

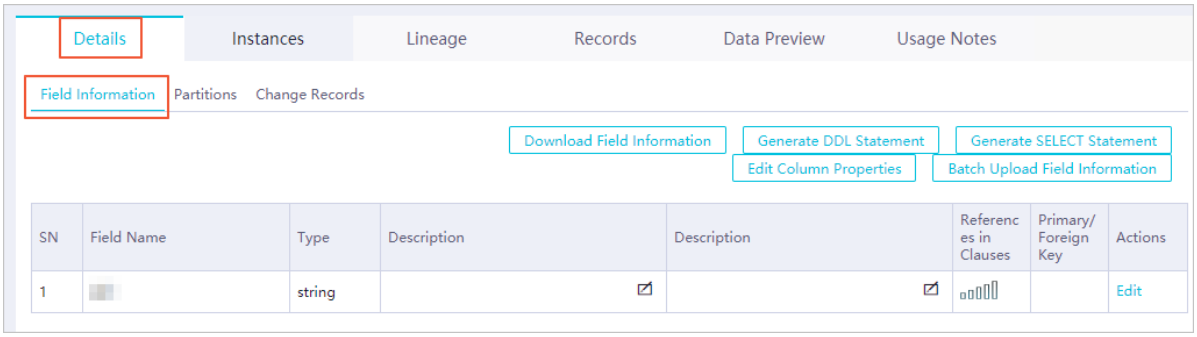
> **Note** By default, the time format yyyy-MM-dd HH:mm:ss is used to describe the compute engine.

View detailed information

The **Details** tab contains the following subtabs: **Field Information**, **Partitions**, and **Change Records**.

- **Field Information** subtab

On the **Field Information** subtab, you can view the name, data type, description, business description, and popularity of fields. You can also check whether a field is a primary key or a foreign key.



Button	Description
Edit	Click this button, modify the field description and business description, determine whether to select the Primary Key check box for the field, and then click **Saved** or **Cancel**.
Upload	Click this button and drag the file that you want to upload from your on-premises machine to the **Batch Upload Field Information** dialog box.
Download	Click this button to download the field information of the current table.
Generate DDL Statement	Click this button. In the **Generate DDL Statement** dialog box, view or copy the DDL statement used to create the current table.
Generate SELECT Statement	Click this button. In the **Generate SELECT Statement** dialog box, view or copy the `SELECT` statement used to query data in the current table.

- **Partitions** subtab

  On the **Partitions** subtab, you can view the name, number of records, storage capacity, creation time, and last update time of each partition in the current table.

- **Change Records** subtab

  On the **Change Records** subtab, you can view the description, type, granularity, time, and operator of changes performed on the current table.

  On this subtab, you can also select a change type from the drop-down list in the upper-left corner to filter the table changes.

  Change types include **Create Table**, **Modify Table**, **Delete Table**, **Create Partition**, **Delete Partition**, **Change Owner**, and **Change TTL**.

View output information

If the table data periodically changes with the related node, you can view the change status and data that is continuously updated on the **Instances** tab.

On this tab, you can also click **View Code** or **View** in the Actions column of a node to view the code or logs of the node.

View lineage information

On the Lineage tab, you can view the source and destination of data and manage the lineage information with ease.

The **Lineage** tab contains the following subtabs: **Table Lineage**, **Field Lineage**, and **Impact Analysis**.

- The **Table Lineage** subtab consists of the **Graph Analysis** and **View by Level** parts.

- **Graph Analysis**: displays the ancestor and descendant tables of a specific number of levels for the current table and the number of ancestor and descendant tables for each table.
- **View by Level**: displays the ancestor and descendant tables of a single level for the current table by default. You can search for the ancestor and descendant tables based on the globally unique identifier (GUID).

- On the **Field Lineage** subtab, you can select a field from the **Field Name** drop-down list to view the lineage information of the field.
- On the **Impact Analysis** subtab, you can query the node that generates a lineage and the full link of the lineage based on information such as the lineage level, field, node type, table name, workspace name, and table owner.

  You can click **Manual update** to rerun the impact analysis. You can also download the impact analysis result or send the impact analysis result to the owners of descendant tables of the current table by email.

View reference records

The **Records** tab contains the following subtabs: **Foreign Key References** and **Access Statistics**.

- **Foreign Key References** subtab: On this subtab, you can check the number of users who reference the current table.
- **Access Statistics** subtab: On this subtab, you can view the reference records in a line chart.

Preview data

On the **Data Preview** tab, you can preview the data of the current table.

> **Notice** Only authorized users can preview tables in the production environment. If you do not have the required permissions, click **Apply Now**.

View usage notes

On the **Usage Notes** tab, you can edit usage notes, check the historical versions of the usage notes, and view the business description of data.

2.1.12.6.2. Request permissions on tables

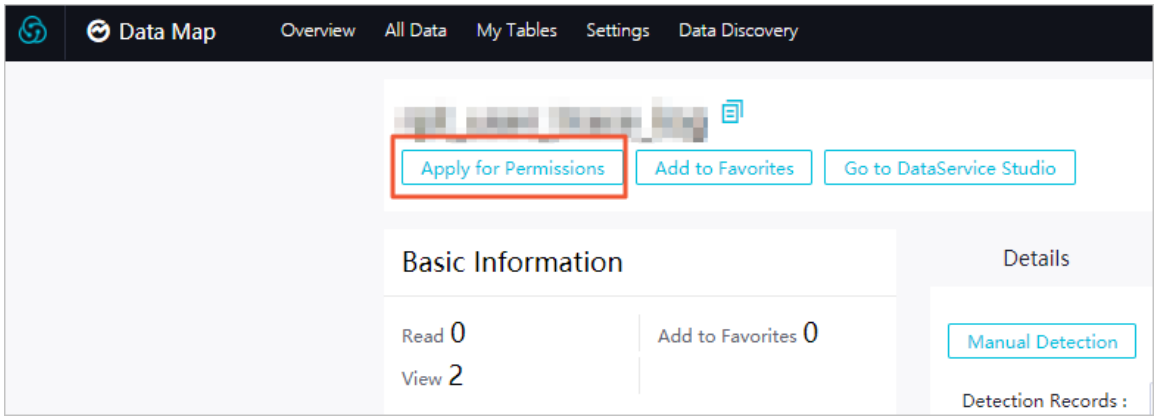
This topic describes how to request permissions on tables in Security Center or Data Map.

Go to the details page of a table

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
3. In the top navigation bar, click **All Data**.
4. On the All Data page, click a tab based on your business requirements, such as MaxCompute.
5. On the tab that appears, click the name of the table on which you want to request permissions.

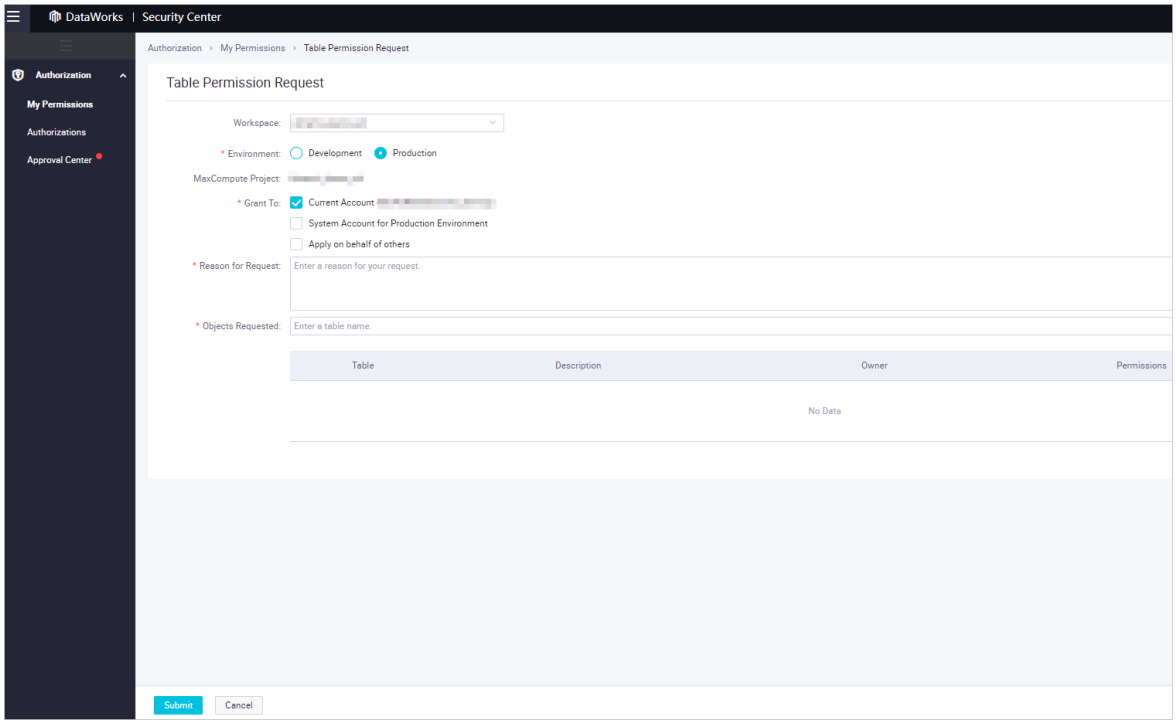
Request permissions on tables in Security Center

1. On the table details page, click **Apply for Permission**.



> **Note** If the table is hidden, the **Apply for Permission** button does not appear on the details page of the table.

2. On the **Table Permission Request** page, configure the parameters.



Parameter	Description
Workspace	The workspace to which the table belongs.
Environment	The environment to which the table belongs. For a workspace in standard mode, you can request permissions on the table in both the development environment and production environment. For a workspace in simple mode, you can request permissions on the table only in the production environment.
MaxCompute Project	The name of the MaxCompute project that is associated with the DataWorks workspace you selected. The value is automatically generated and cannot be changed.
Grant To	The account for which you request permissions on the table. Valid values: **Current Account** and **System Account for Production Environment**.

Parameter	Description
Valid Until	The validity period of the permissions on the table. Valid values: **1 Month**, **3 Months**, **6 Months**, **1 Year**, **Permanent**, and **Others**.
Reason for Request	The reason why you want to request permissions on the table. Enter a reason for faster approval.
Objects Requested	The name of the table.

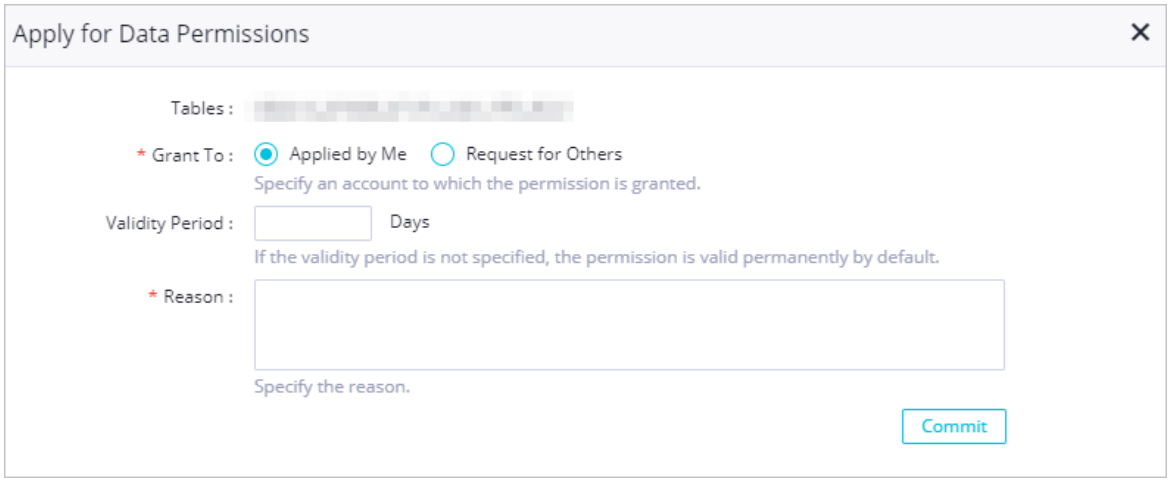
3. Click **Submit**.

Request permissions on tables in Data Map

1. On the table details page, click **Apply for Permission**.

> **Note** If the table is hidden, the **Apply for Permission** button does not appear on the details page of the table.

2. In the **Apply for Permission** dialog box, configure the parameters.



Parameter	Description
Table	The name of the table on which you want to request permissions. The value is automatically generated and cannot be changed.
Grant To	Specifies whether you want to request permissions on the table for the current account or another account. Valid values: **Current Account** and **Specified Account**.
Username	The username of the account for which you request permissions on the table. **Note** This parameter is available only when you set the **Grant To** parameter to **Specified Account**.
Validity Period	The validity period of the permissions on the table. If you do not set this parameter, the permissions are permanently valid.
Reason	The reason why you want to request permissions on the table. Enter a reason for faster approval.

3. Click **Submit**.

View the request status

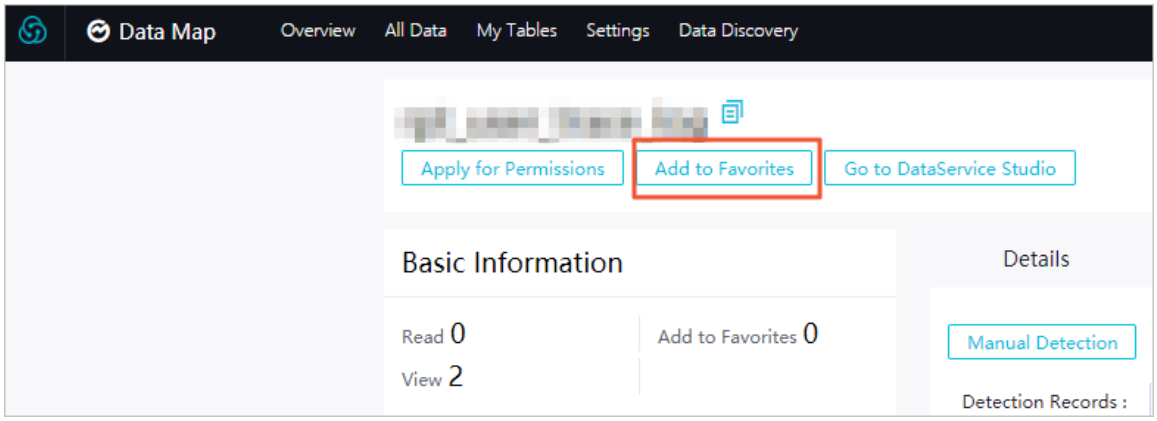
1. In the top navigation bar, click **My Data**.
2. On the My Data page, click **Permission Management** in the left-side navigation pane.
3. On the page that appears, click the **Submitted by Me** tab.
4. Find the required request record and click **View** in the Actions column to view the request status.

2.1.12.6.3. Add a table to favorites

This topic describes how to add a table to favorites, remove a table from favorites, and view the tables added to favorites.

Procedure

1. Go to the details page of a table.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **All Data**.
   iv. On the **All Data** page, click a tab based on your business requirements, such as MaxCompute.
   v. On the tab that appears, click the name of the table that you want to add to favorites.
2. On the table details page, click **Add to Favorites**.



3. In the top navigation bar, click **My Data**.
4. On the **My Data** page, click **My Favorites** in the left-side navigation pane.

   On the page that appears, you can view all the tables that you have added to favorites and remove tables from favorites. To remove a table from favorites, find the table that you want to remove and click **Remove from Favorites** in the Actions column.

2.1.12.6.4. Go to DataService Studio to create an API

This topic describes how to go to DataService Studio from the details page of a table to create an API.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data**

governance > DataMap(Data Management).

3. In the top navigation bar, click **All Data**.
4. On the **All Data** page, click a tab based on your business requirements, such as MaxCompute.
5. On the details page of the table, click **Create API in DataService Studio**.
6. On the **DataService Studio** page, create an API based on tables or register the existing API as required. For more information, see Overview.

2.1.12.7. Data discovery

2.1.12.7.1. Collect metadata from an EMR data source

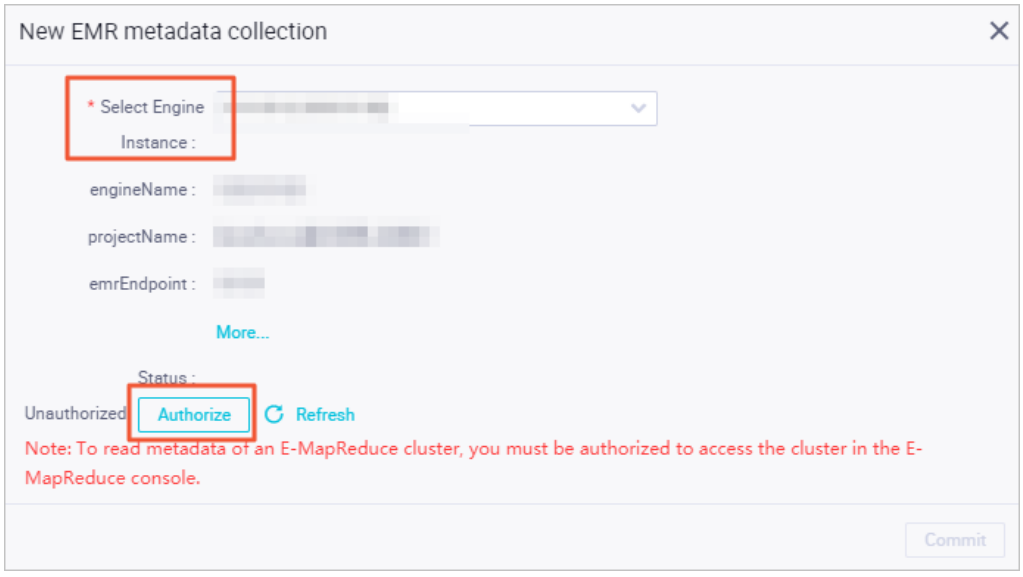
This topic describes how to create a crawler to collect metadata from an E-MapReduce (EMR) data source to DataWorks. You can view the collected metadata in Data Map.

Prerequisites

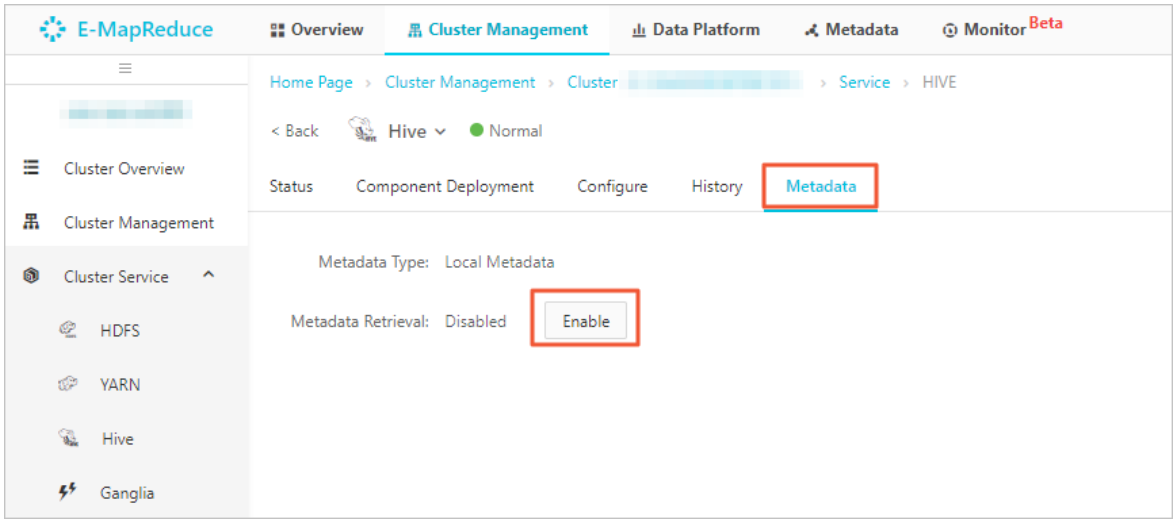
An EMR cluster is associated with your DataWorks workspace.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. On the Data Map page, click **Data Discovery** in the top navigation bar.
2. On the **E-MapReduce Metadata Crawler** page, click **Create Crawler**.
3. In the **Create Crawler** dialog box, select the associated EMR cluster from the **Select a cluster** drop-down list and click **Authorize**.



4. On the page that appears, click the **Metadata** tab and click **Enable**.



5. In the **Confirm Operation** message, click **OK**.
6. Return to the **Create Crawler** dialog box on the **E-MapReduce Metadata Crawler** page and click **Refresh**.
7. After the authorization status changes to **Authorized**, click **Commit**.
8. On the **E-MapReduce Metadata Crawler** page, find the newly created crawler and click **Obtain All** in the Actions column.

   Click **Refresh** in the upper-right corner of the page and verify that the value in the **Running Status** column of the created crawler changes to **Collected**.

   > **Note** After full metadata from the EMR data source is collected, the system automatically synchronizes new metadata from the data source.

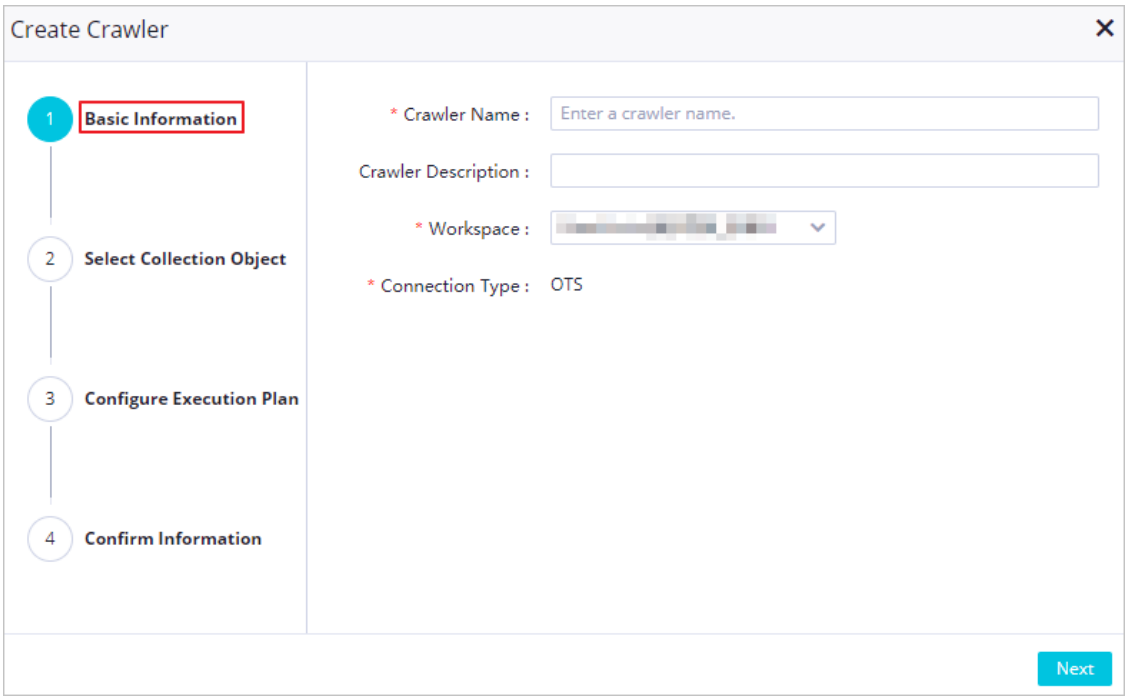
   If you want to delete the created crawler, click **Delete** in the Actions column. In the **Delete Instance** message, click **OK**.
9. View the metadata collected from the EMR data source.
   i. In the top navigation bar, click **All Data**.
   ii. Click the **E-MapReduce** tab.
   iii. On the **E-MapReduce** tab, click the name of the table that stores the collected metadata and view the table details.

2.1.12.7.2. Collect metadata from a Tablestore data source

You can collect information about the schema and lineage of a table to Data Map. This way, the inner structure and association relationships of the table can be clearly displayed. This topic describes how to create a crawler and collect metadata from a Tablestore data source to DataWorks. You can view the collected metadata in Data Map.

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. On the Data Map page, click **Data Discovery** in the top navigation bar.
2. In the left-side navigation pane, click **OTS**.
3. On the **OTSMetadata Crawler** page, click **Create Crawler**.

4. In the **Create Crawler** dialog box, perform the following steps:
   i. In the **Basic Information** step, configure the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must specify a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of data source from which you want to collect metadata. The default value is **OTS** and cannot be changed.

   ii. Click **Next**.
   iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

   If no data source is available, click **Create** to go to the **Data Source** page and add a Tablestore data source. For more information, see Configure a Tablestore connection.
   iv. Click Start Testing next to **Test Crawler Connectivity**.
   v. If the message **The connectivity test is successful** appears, click **Next**.

   If the message **The connectivity test failed** appears, check whether you have configured a valid data source.
   vi. In the **Configure Execution Plan** step, specify **Execution Plan**.

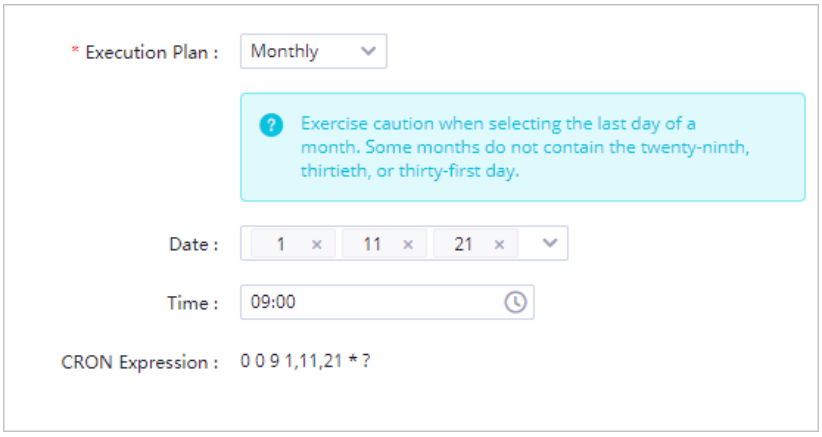
   Valid values of the **Execution Plan** parameter: **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The running plan that is generated varies based on the running cycle. The system collects metadata from the Tablestore data source based on the running cycle that you specify. The following descriptions explain each value and provide examples:

   - On-demand Execution: The system collects metadata from the Tablestore data source based on your business requirements.

- Monthly: The system automatically collects metadata from the Tablestore data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In this case, the system does not collect metadata from the Tablestore data source on these dates. We recommend that you do not select the last day of a month.

  The following figure shows that the system automatically collects metadata from the Tablestore data source once at 09:00 on the 1st, 11th, and 21th days of each month. **Cron Expression** is automatically generated based on the values of Date and Time.

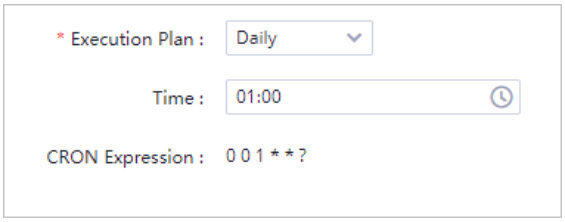
- Weekly: The system automatically collects metadata from the Tablestore data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the Tablestore data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not specified, the system automatically collects Tablestore metadata once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the Tablestore data source once at a specific time of each day.

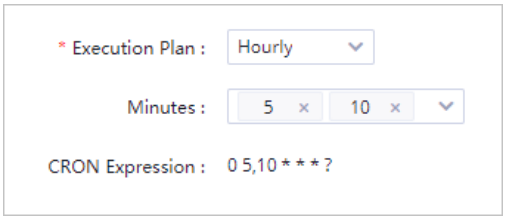
  The following figure shows that the system automatically collects metadata from the Tablestore data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the Tablestore data source once from the `N × 5` th minute of each hour.

  > **Note** For a Tablestore metadata collection task that runs each hour, you can configure the time to a multiple of 5 minutes.

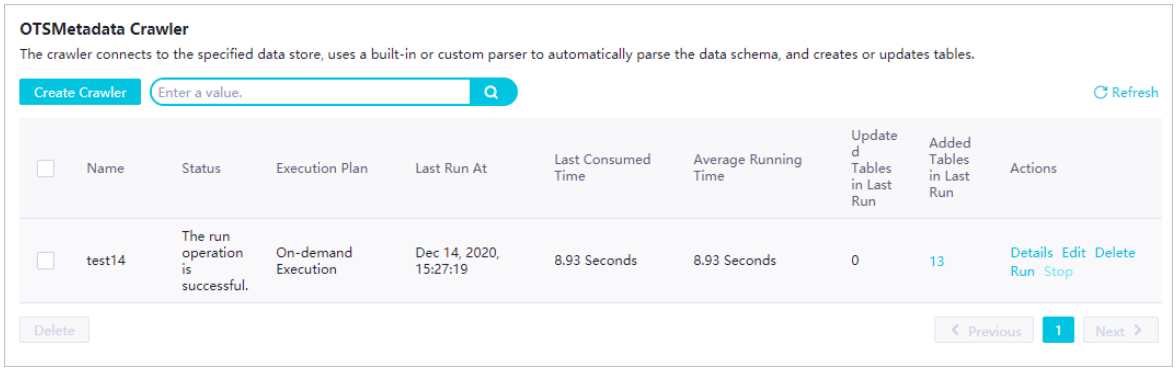
  The following figure shows that the system automatically collects metadata from the Tablestore data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **OTSMetadata Crawler** page, you can view the information about your crawler and manage your crawler.



The following descriptions show the information that you can view and the operations that you can perform:

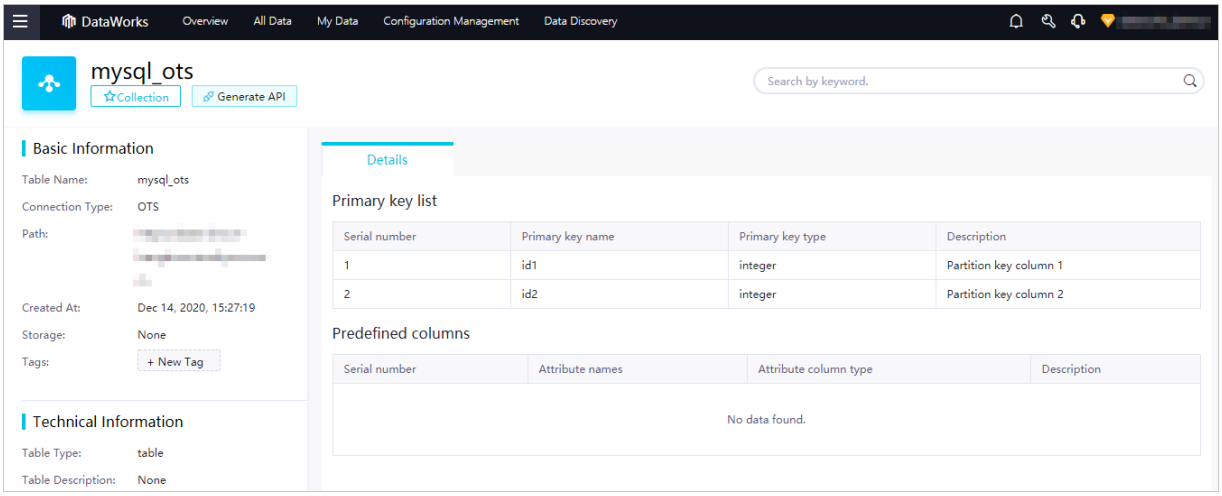
- You can view **Status**, **Execution Plan**, **Last Run At**, **Last Consumed Time**, **Average Running Time**, Updated Tables in Last Run, and Added Tables in Last Run of your crawler.
- You can click **Details**, **Edit**, **Delete**, **Run**, or **Stop** in the **Actions** column to perform the desired operation.
  - **Details**: View **Crawler Name**, **Data Source Type**, and **Execution Plan** configured for the crawler.
  - **Edit**: Modify the configurations of the crawler.
  - **Delete**: Delete the crawler.
  - **Run**: Run the task to collect metadata from the Tablestore data source. The **Run** entry point is available only when **Execution Plan** is set to **On-demand Execution**.
  - **Stop**: Stop running the crawler.

Result

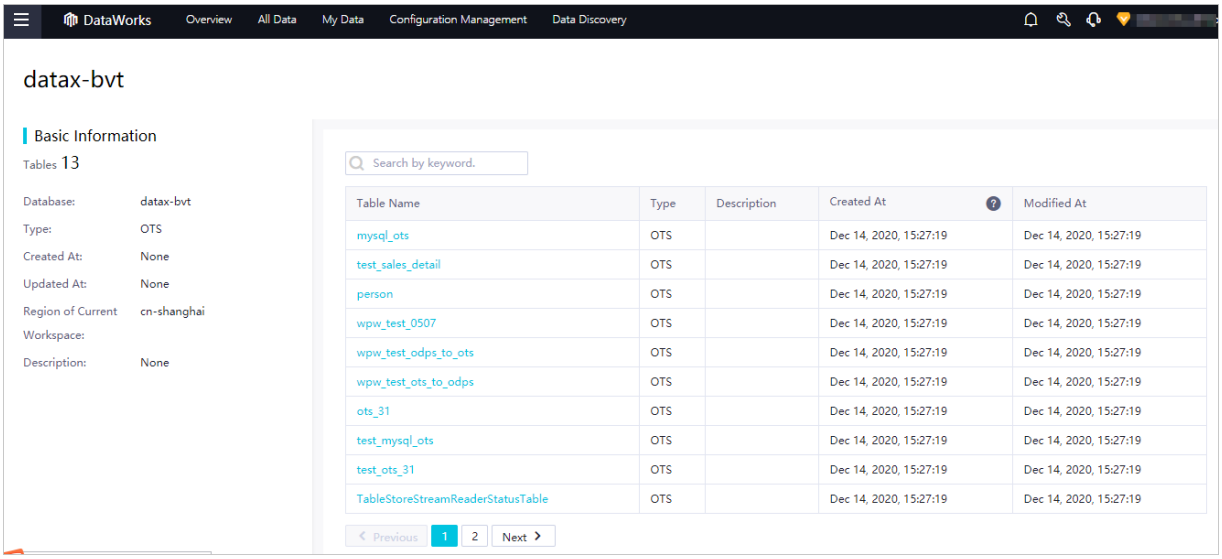
After the metadata in the Tablestore data source is collected, switch back to the previous page and click **All Data** in the top navigation bar. On the page that appears, click the **OTS** tab in the upper part. On the OTS tab, you can view the table that stores the collected Tablestore metadata.

Click the **table name**, **workspace**, or **database** to view the related details.

Example 1: View the details of the *mysql_ots* table.



Example 2: View all tables in the *datax-bvt* database.



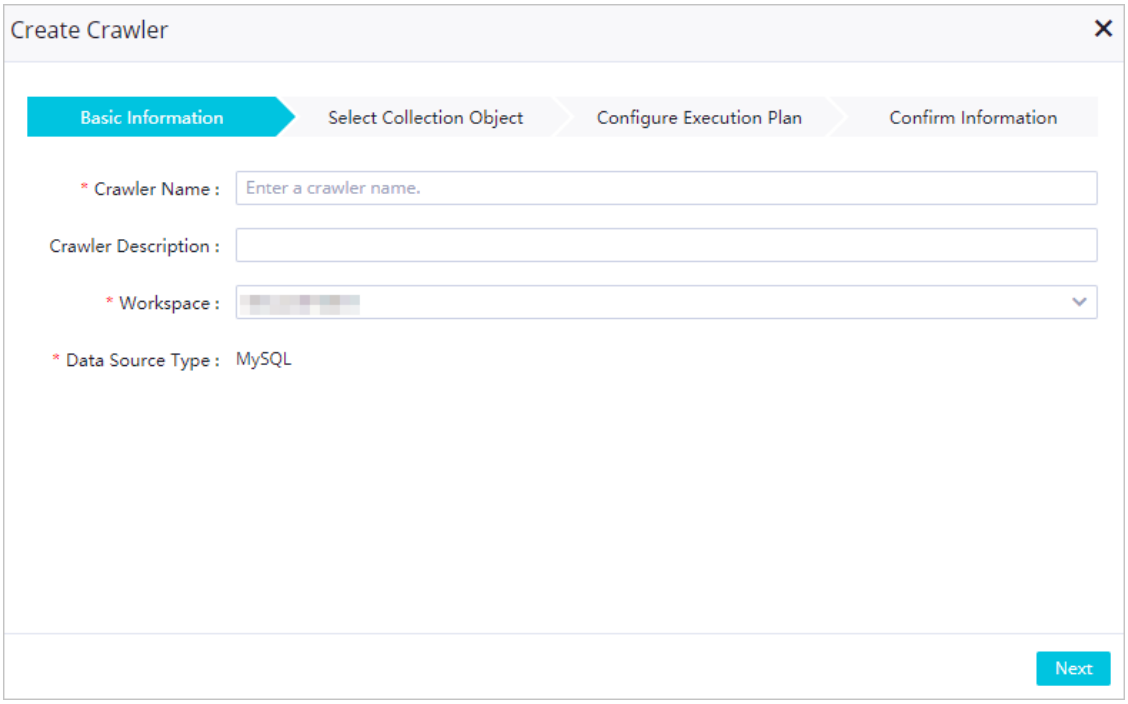
2.1.12.7.3. Collect metadata from a MySQL data source

This topic describes how to create a crawler to collect metadata from a MySQL data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **MySQL**.
3. On the **MySQLMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **MySQL** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add a MySQL data source. For more information, see Configure a MySQL connection.

> **Note** You can select an ApsaraDB RDS for MySQL instance or a MySQL data source that is accessible from the Internet by using a Java Database Connectivity (JDBC) connection string.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

vi. In the **Configure Execution Plan** step, configure an execution plan.

Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**.

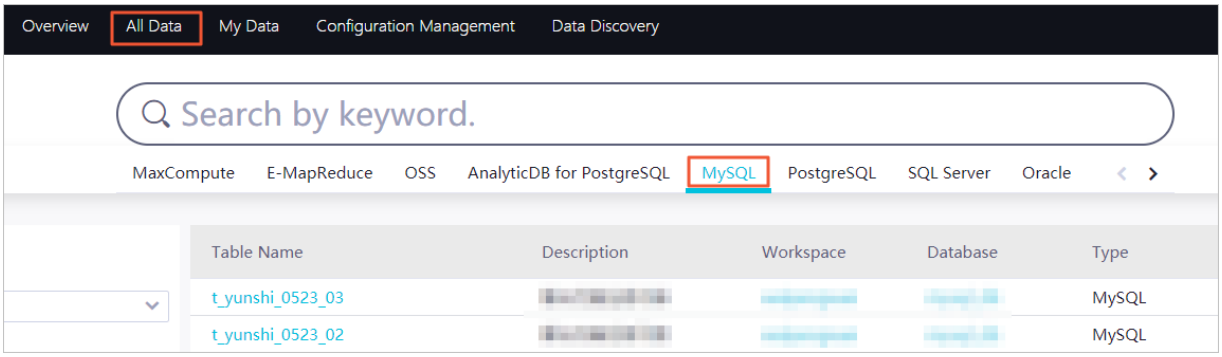
vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

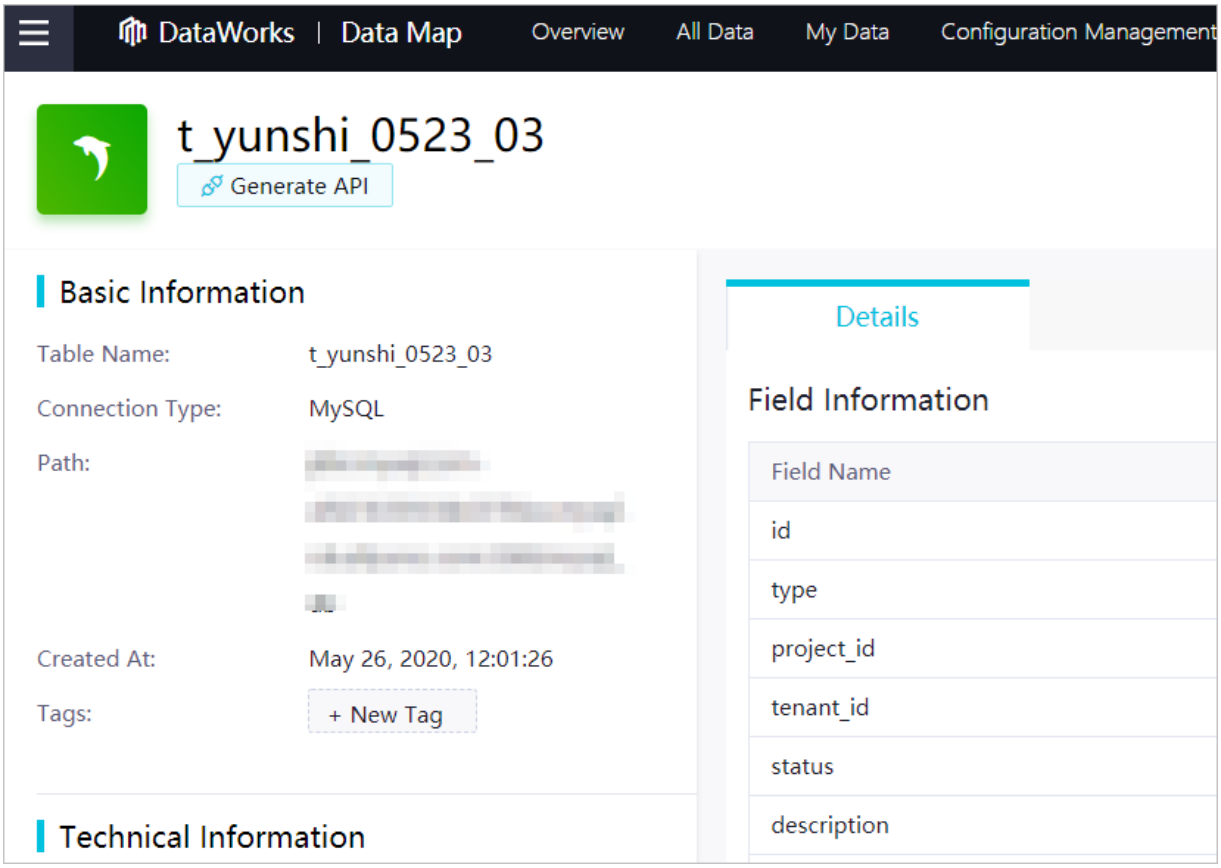
5. On the **MySQLMetadata Crawler** page, find the created crawler and click **Run** in the Actions column.

Result

After the metadata in the MySQL data source is collected, click **All Data** in the top navigation bar. Select **MySQL** from the options in the upper part of the page. You can view the tables that store the collected MySQL metadata.



Click the name of the table to view the table details.



2.1.12.7.4. Collect metadata from an SQL Server data source

This topic describes how to create a crawler to collect metadata from an SQL Server data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

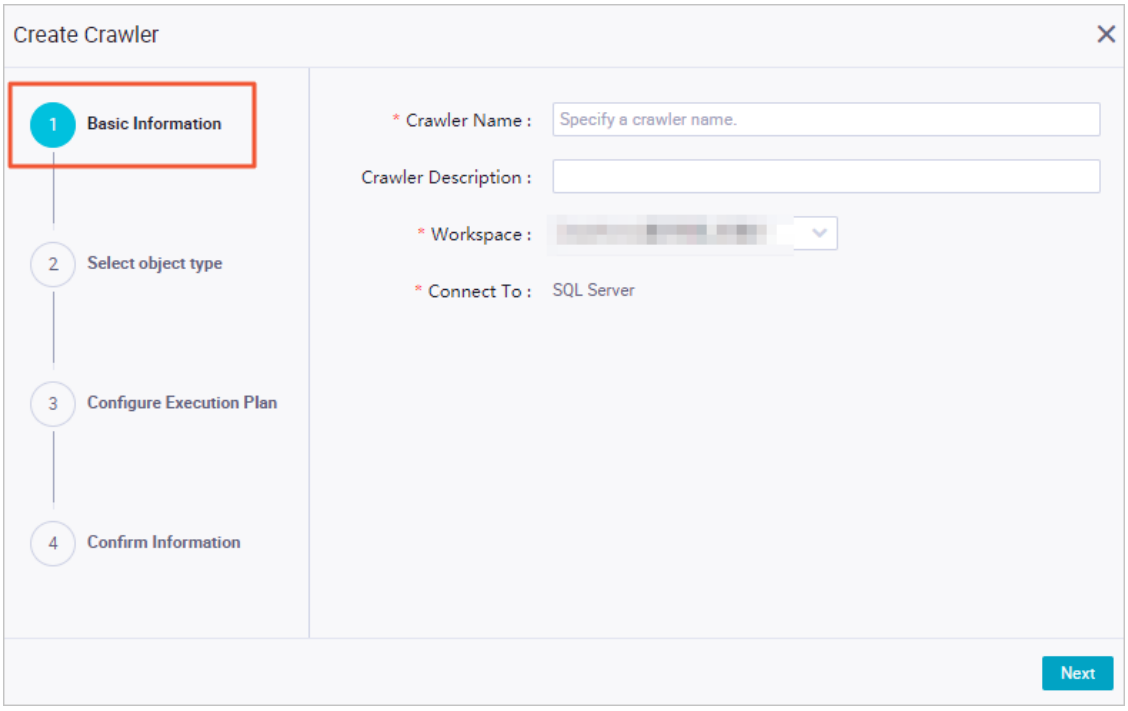
1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.

ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.

iii. In the top navigation bar, click **Data Discovery**.

2. In the left-side navigation pane, click **SQL Server**.
3. On the **SQL ServerMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **SQL Server**.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add an SQL Server data source. For more information, see Configure an SQL Server data source.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

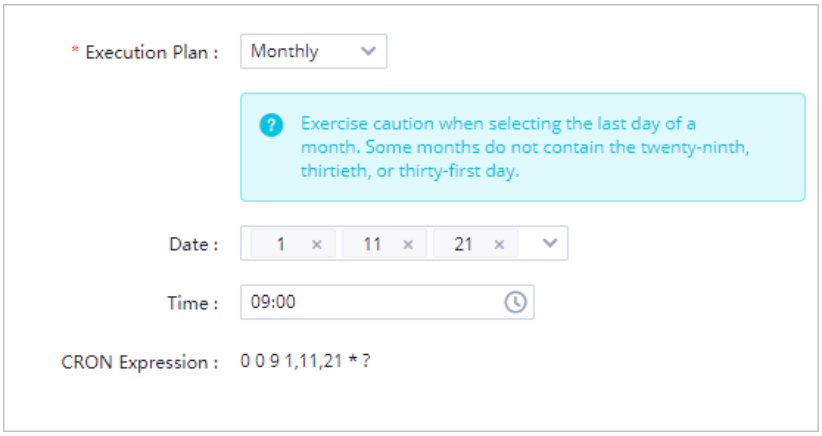
vi. In the **Configure Execution Plan** step, configure an execution plan.

Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the SQL Server data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: The system collects metadata from the SQL Server data source based on your business requirements.
- Monthly: The system automatically collects metadata from the SQL Server data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the SQL Server data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the SQL Server data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

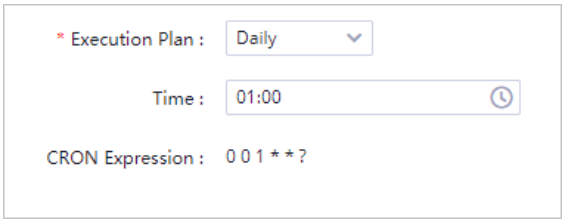
- Weekly: The system automatically collects metadata from the SQL Server data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the SQL Server data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not set, the system automatically collects metadata from the SQL Server data source once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the SQL Server data source once at a specific time of each day.

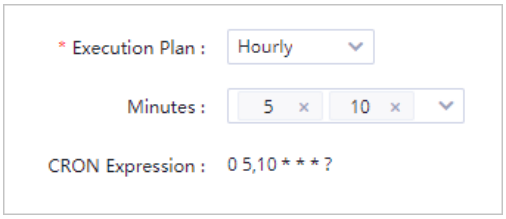
  The following figure shows that the system automatically collects metadata from the SQL Server data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the SQL Server data source once from the `N × 5` th minute of each hour.

  > **Note** For an SQL Server metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the SQL Server data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **SQL ServerMetadata Crawler** page, find the created crawler and click **Run** in the Actions column.

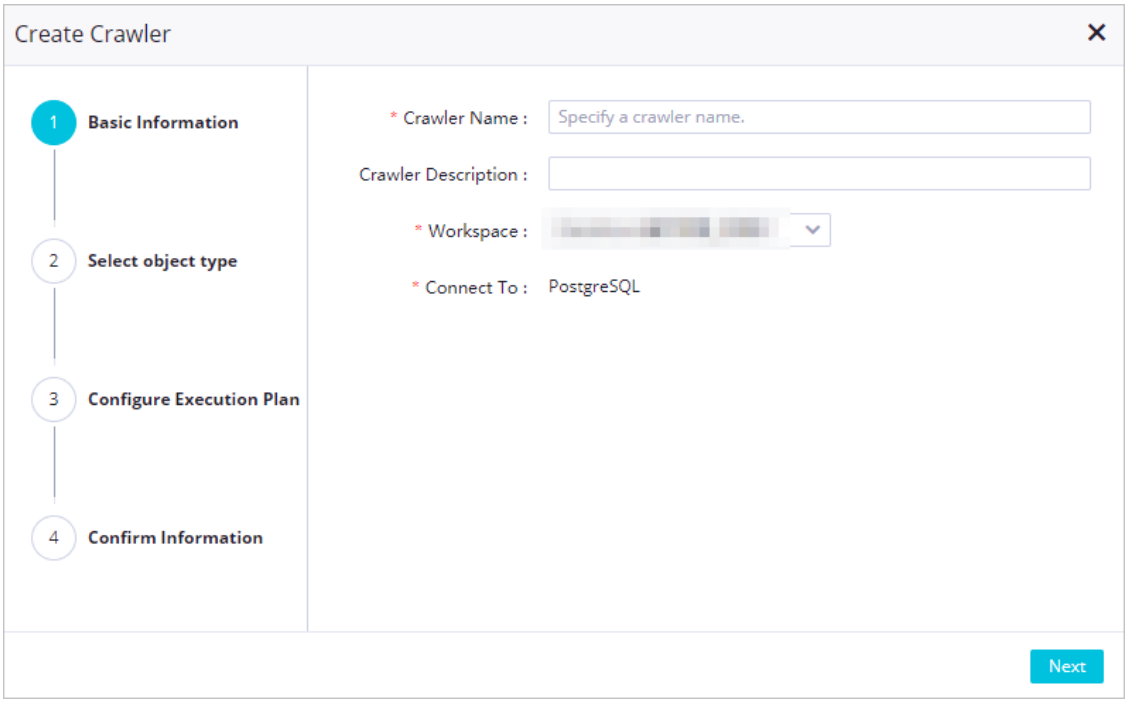
2.1.12.7.5. Collect metadata from a PostgreSQL data source

This topic describes how to create a crawler to collect metadata from a PostgreSQL data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **PostgreSQL**.
3. On the **PostgreSQLMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **PostgreSQL** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add a PostgreSQL data source. For more information, see Configure a PostgreSQL connection.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

vi. In the **Configure Execution Plan** step, configure an execution plan.

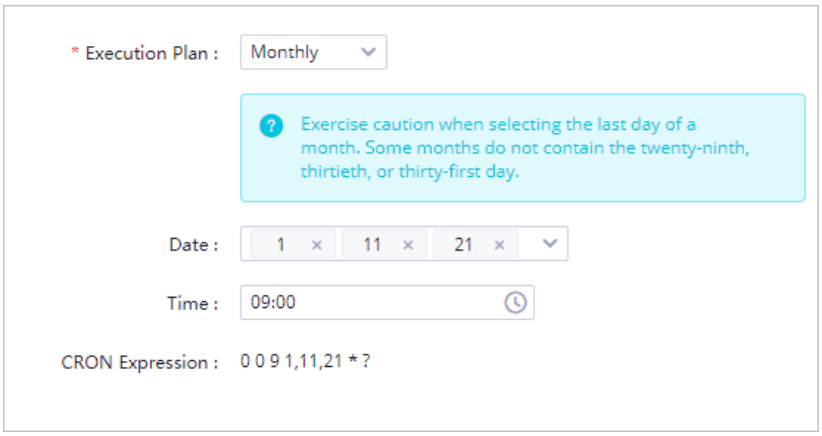
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the PostgreSQL data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: The system collects metadata from the PostgreSQL data source based on your business requirements.

- Monthly: The system automatically collects metadata from the PostgreSQL data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the PostgreSQL data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the PostgreSQL data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

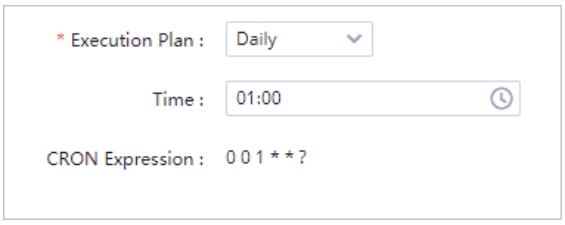
- Weekly: The system automatically collects metadata from the PostgreSQL data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the PostgreSQL data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not set, the system automatically collects metadata from the PostgreSQL data source once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the PostgreSQL data source once at a specific time of each day.

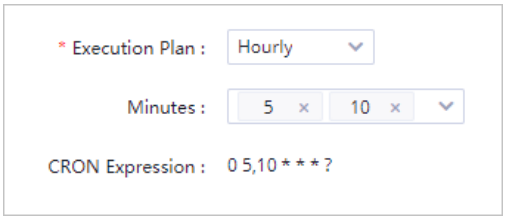
  The following figure shows that the system automatically collects metadata from the PostgreSQL data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the PostgreSQL data source once from the `N × 5` th minute of each hour.

  > **Note** For a PostgreSQL metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the PostgreSQL data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **PostgreSQLMetadata Crawler** page, find the created crawler and click **Run** in the Actions column.

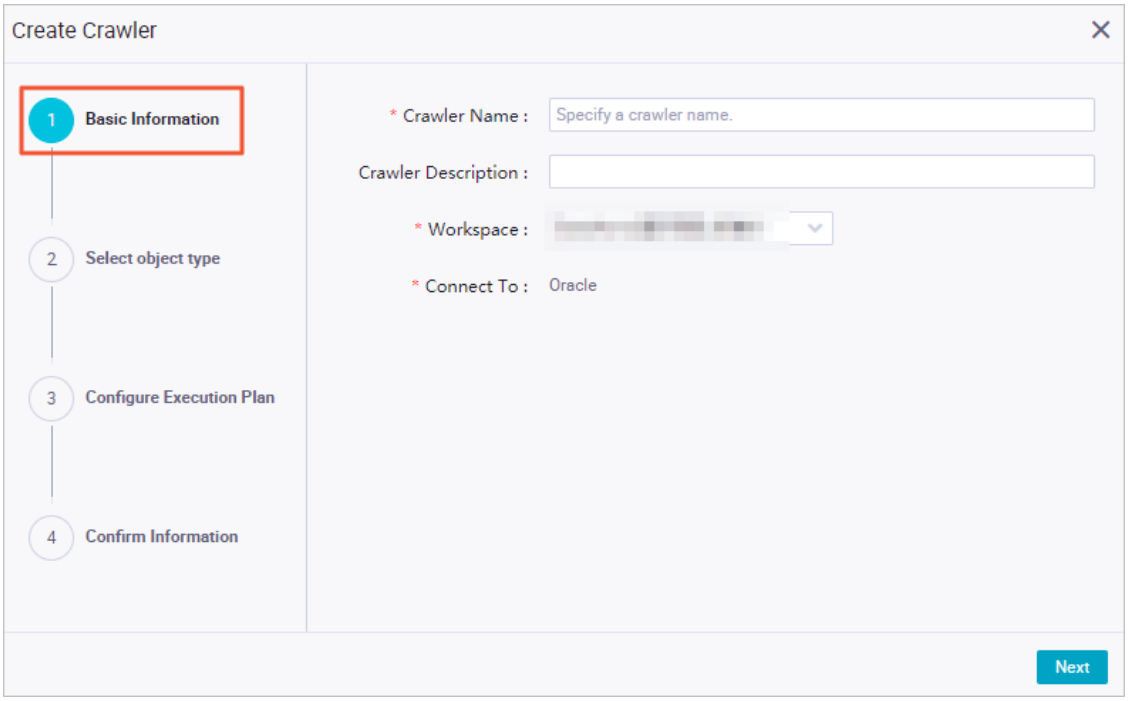
2.1.12.7.6. Collect metadata from an Oracle data source

This topic describes how to create a crawler to collect metadata from an Oracle data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **Oracle**.
3. On the **OracleMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **Oracle** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add an Oracle data source. For more information, see Configure an Oracle connection.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

vi. In the **Configure Execution Plan** step, configure an execution plan.

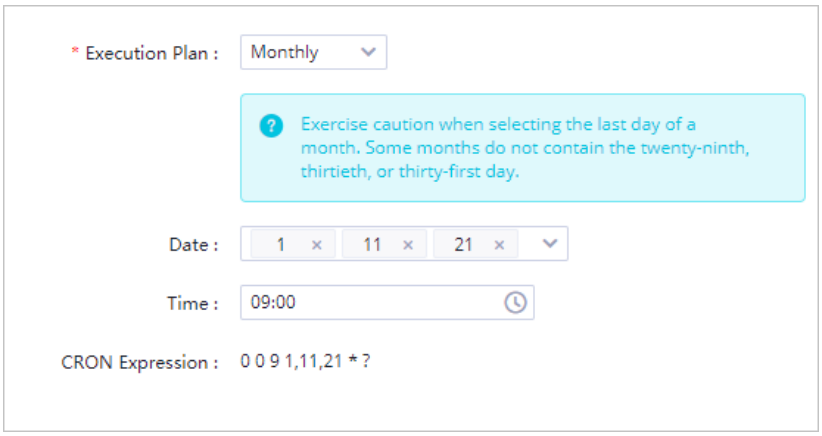
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the Oracle data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: The system collects metadata from the Oracle data source based on your business requirements.

- Monthly: The system automatically collects metadata from the Oracle data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the Oracle data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the Oracle data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

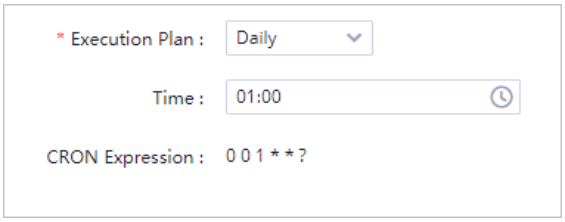
- Weekly: The system automatically collects metadata from the Oracle data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the Oracle data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not specified, the system automatically collects Oracle metadata once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the Oracle data source once at a specific time of each day.

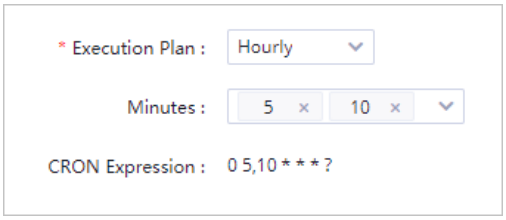
  The following figure shows that the system automatically collects metadata from the Oracle data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the Oracle data source once from the `N × 5` th minute of each hour.

  > **Note** For an Oracle metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the Oracle data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **OracleMetadata Crawler** page, find the created crawler and click **Run** in the Actions column.

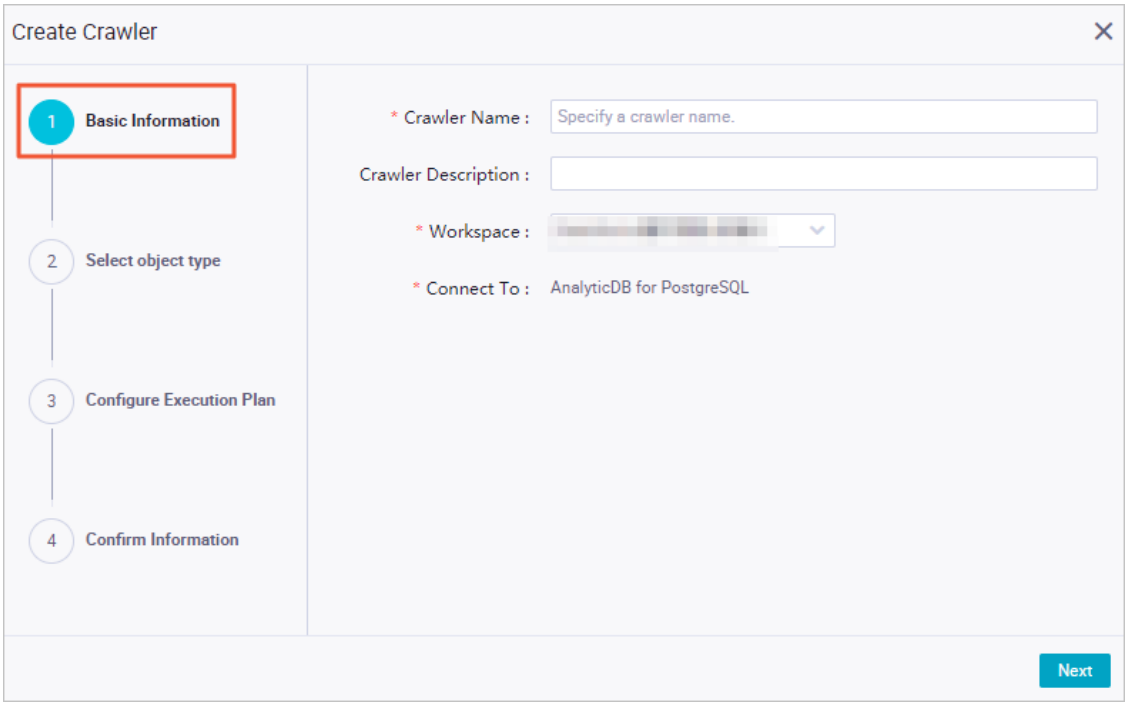
2.1.12.7.7. Collect metadata from an AnalyticDB for PostgreSQL data source

This topic describes how to create a crawler to collect metadata from an AnalyticDB for PostgreSQL data source to DataWorks. You can view the collected metadata in Data Map.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the ☰ icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **AnalyticDB for PostgreSQL**.
3. On the **AnalyticDB for PostgreSQLMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **AnalyticDB for PostgreSQL** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add an AnalyticDB for PostgreSQL data source.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

5. On the **AnalyticDB for PostgreSQLMetadata Crawler** page, find the created crawler and click **Run** in the Actions column.

After the crawler is run, click the number in the **Tables found during Last Run** column to view the details of the updated or created tables.

> **Notice** The **Run** button is available only in the Actions column of a crawler that needs to be manually triggered.

You can also perform the following operations on the AnalyticDB for PostgreSQLMetadata Crawler page:

- Click **Details** in the Actions column that corresponds to a crawler. In the **Crawler Details** dialog box, view the detailed information about the crawler.
- Click **Edit** in the Actions column that corresponds to a crawler. In the **Edit Crawler** dialog box, modify the configurations of the crawler.
- Click **Delete** in the Actions column that corresponds to a crawler. In the **Confirm** message, click **Ok** to delete the crawler.
- Find a crawler that is running and click **Stop** in the **Actions** column to stop the crawler.

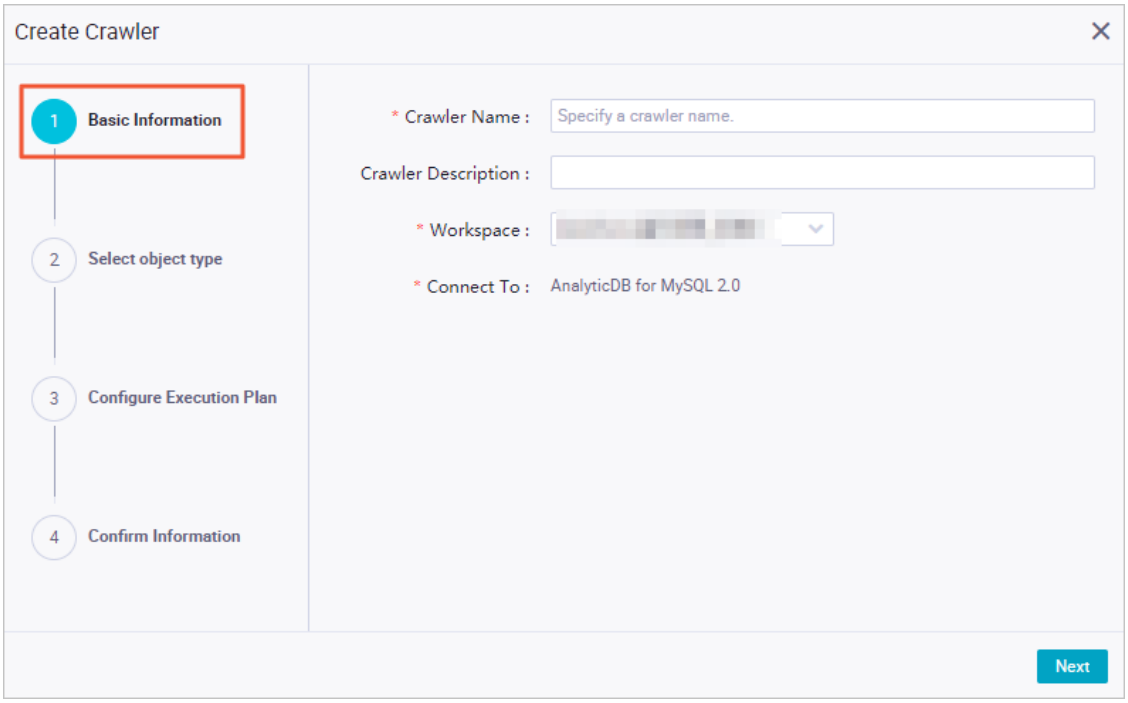
2.1.12.7.8. Collect metadata from an AnalyticDB for MySQL 2.0 data source

This topic describes how to create a crawler to collect metadata from an AnalyticDB for MySQL 2.0 data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **AnalyticDB for MySQL 2.0**.
3. On the **AnalyticDB for MySQL 2.0Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **AnalyticDB for MySQL 2.0** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add an AnalyticDB for MySQL V2.0 data source.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

vi. In the **Configure Execution Plan** step, configure an execution plan.

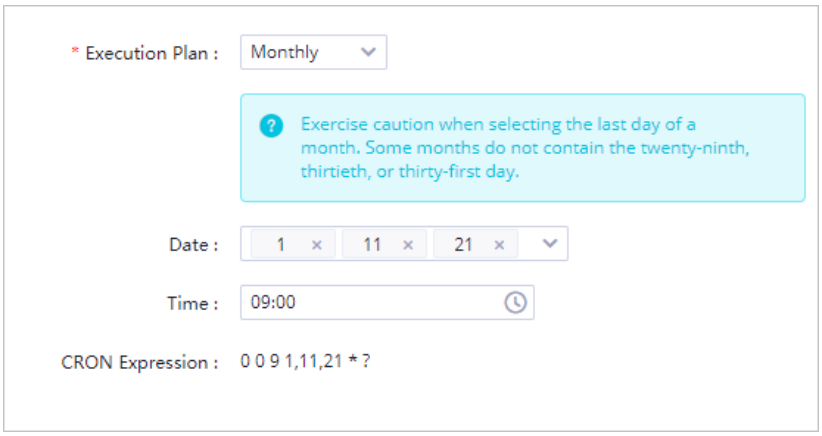
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the AnalyticDB for MySQL V2.0 data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: The system collects metadata from the AnalyticDB for MySQL V2.0 data source based on your business requirements.

- Monthly: The system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the AnalyticDB for MySQL V2.0 data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

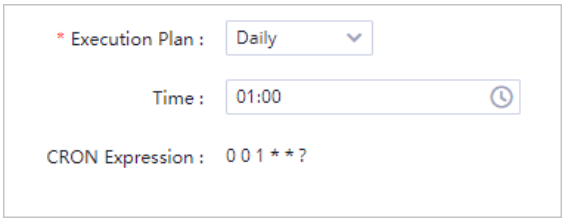
- Weekly: The system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not specified, the system automatically collects AnalyticDB for MySQL V2.0 metadata once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once at a specific time of each day.

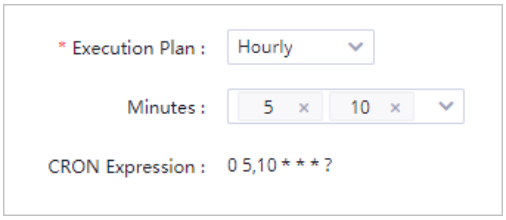
  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source once from the `N × 5` th minute of each hour.

  > **Note** For an AnalyticDB for MySQL V2.0 metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL V2.0 data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **AnalyticDB for MySQL 2.0Metadata Crawler** page, find the created crawler and click **Run** in the Actions column.

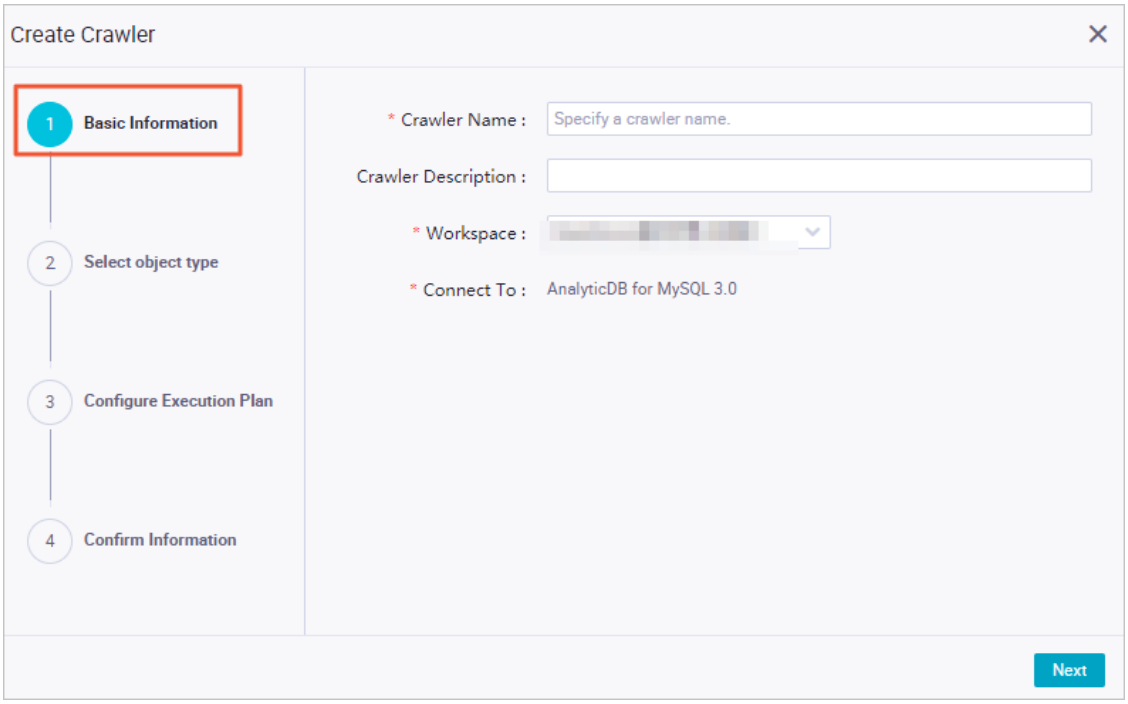
2.1.12.7.9. Collect metadata from an AnalyticDB for MySQL 3.0 data source

This topic describes how to create a crawler to collect metadata from an AnalyticDB for MySQL 3.0 data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **AnalyticDB for MySQL 3.0**.
3. On the **AnalyticDB for MySQL 3.0Metadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **AnalyticDB for MySQL 3.0** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

If no data sources are available, click **Create** to go to the **Data Source** page and add an AnalyticDB for MySQL V3.0 data source.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

vi. In the **Configure Execution Plan** step, configure an execution plan.

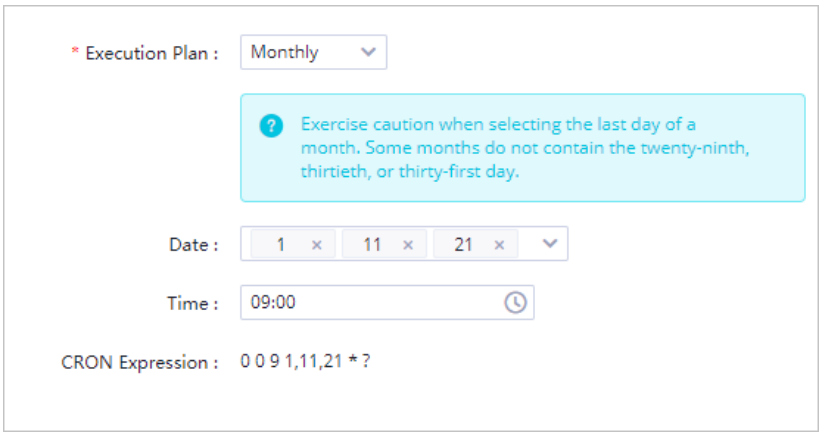
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the AnalyticDB for MySQL 3.0 data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: The system collects metadata from the AnalyticDB for MySQL 3.0 data source based on your business requirements.

- Monthly: The system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the AnalyticDB for MySQL 3.0 data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

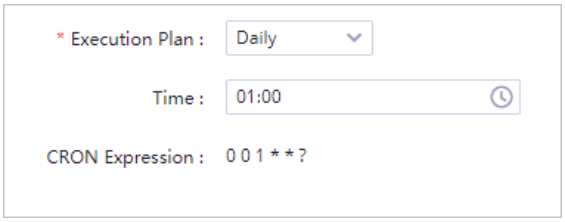
- Weekly: The system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not specified, the system automatically collects AnalyticDB for MySQL 3.0 metadata once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once at a specific time of each day.

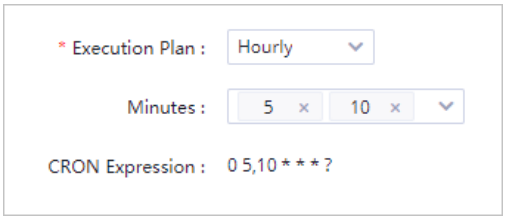
  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source once from the `N × 5` th minute of each hour.

  > **Note** For an AnalyticDB for MySQL 3.0 metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the AnalyticDB for MySQL 3.0 data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **AnalyticDB for MySQL 3.0Metadata Crawler** page, find the created crawler and click **Run** in the Actions column.

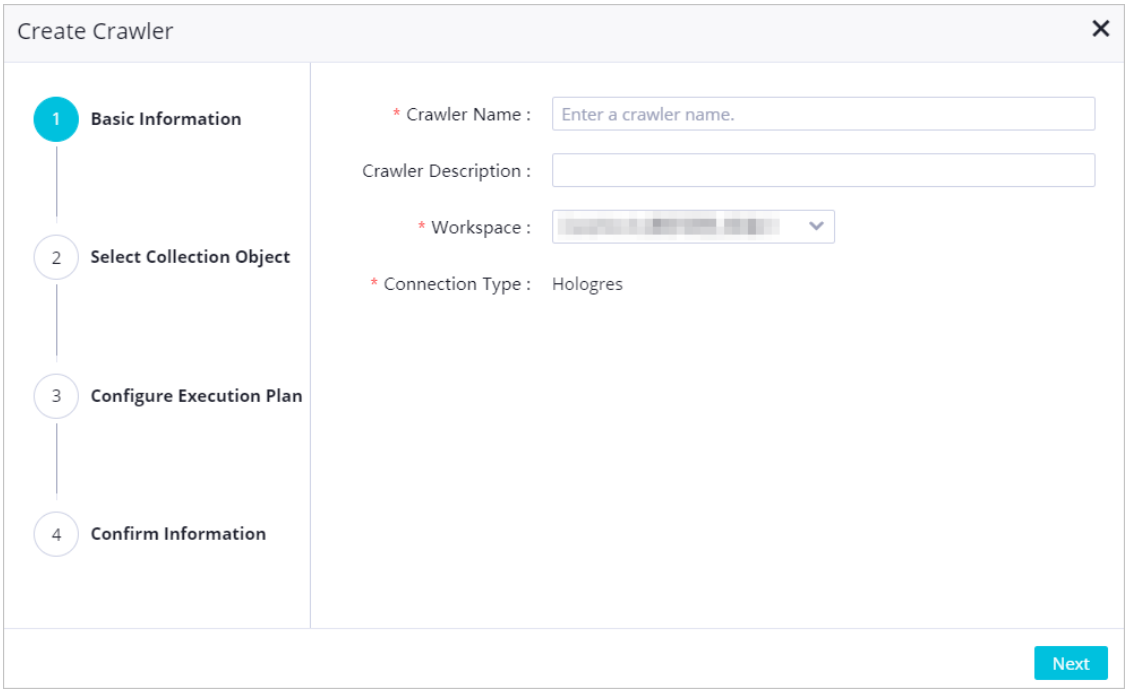
2.1.12.7.10. Collect metadata from a Hologres data source

This topic describes how to create a crawler to collect metadata from a Hologres data source to DataWorks. You can view the collected metadata on the Data Map page.

Procedure

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. In the left-side navigation pane, click **Hologres**.
3. On the **HologresMetadata Crawler** page, click **Create Crawler**.
4. In the **Create Crawler** dialog box, set the parameters in each step.

i. In the **Basic Information** step, set the parameters.



Parameter	Description
Crawler Name	Required. The name of the crawler. You must set a unique name.
Crawler Description	The description of the crawler.
Workspace	The workspace of the data source from which you want to collect metadata.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is **Hologres** and cannot be changed.

ii. Click **Next**.

iii. In the **Select Collection Object** step, select a data source from the **Data Source** drop-down list.

iv. Click Start Testing next to **Test Crawler Connectivity**.

v. If the message **The connectivity test is successful** appears, click **Next**.

If the message **The connectivity test of the data source failed, and the data source cannot be connected to the resource group** appears, check whether you have configured a valid data source.

vi. In the **Configure Execution Plan** step, configure an execution plan.

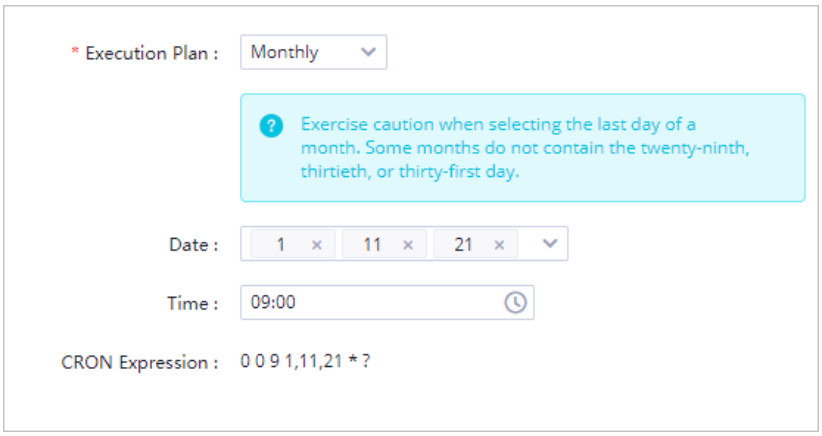
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, and **Hourly**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the Hologres data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: The system collects metadata from the Hologres data source based on your business requirements.

- Monthly: The system automatically collects metadata from the Hologres data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the Hologres data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the Hologres data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

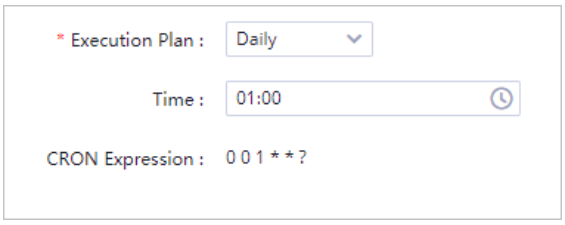
- Weekly: The system automatically collects metadata from the Hologres data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the Hologres data source once at 03:00 on Sunday and Monday of each week.

  
  If the **Time** parameter is not specified, the system automatically collects Hologres metadata once at 00:00:00 on the specific days of each week.

- Daily: The system automatically collects metadata from the Hologres data source once at a specific time of each day.

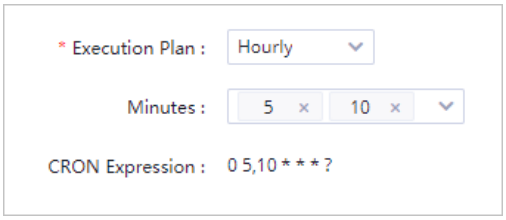
  The following figure shows that the system automatically collects metadata from the Hologres data source once at 01:00 each day.

- Hourly: The system automatically collects metadata from the Hologres data source once from the N × 5 th minute of each hour.

  > **Note** For a Hologres metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the Hologres data source from the 5th and 10th minutes of each hour.

vii. Click **Next**.

viii. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

5. On the **HologresMetadata Crawler** page, find the created crawler and click **Run** in the Actions column.

2.1.12.7.11. Collect metadata from a CDH Hive data source

DataWorks allows you to collect metadata that includes the table schema and the linage information of tables in Data Map. You can view the schema of a table and the relationships between tables. This topic describes how to create a crawler to collect metadata from a CDH Hive data source to DataWorks. You can view the collected metadata on the Data Map page.

Prerequisites

A CDH cluster is associated with the current DataWorks workspace. For more information, see Associate a CDH cluster with a workspace.

Limits

You cannot collect metadata across regions. You must create a crawler in the region where the source metadata resides to collect the metadata.

Create a crawler

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the ☰ icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. Create a crawler.
   i. In the left-side navigation pane, click **CDH Hive**.
   ii. On the **CDH Hive Metadata Crawler** page, click **Create Crawler**.
3. Configure the crawler.
   i. Select a CDH cluster.

   In the **Create Crawler** dialog box, select the cluster from which you want to collect metadata from the drop-down list.

   ii. Configure Execution Plan

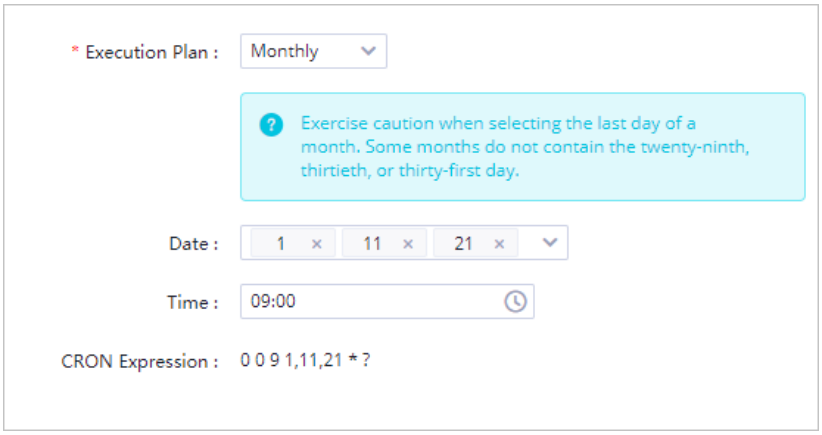
In the **Create Crawler** dialog box, specify a value for the **Execution Plan** parameter from the drop-down list.

Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, **Hourly**, and **Customize**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the CDH Hive data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: You need to manually run the crawler. The system collects metadata from the CDH Hive data source based on your business requirements.
- Monthly: The system automatically collects metadata from the CDH Hive data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the CDH Hive data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the CDH Hive data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

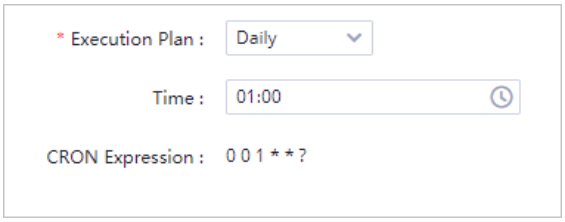
- Weekly: The system automatically collects metadata from the CDH Hive data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the CDH Hive data source once at 03:00 on Sunday and Monday of each week. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

  
  If the **Time** parameter is not set, the system automatically collects metadata from the CDH Hive data source once at `00:00:00` on the specific days of each week.

- Daily: The system automatically collects metadata from the CDH Hive data source once at a specific time of each day.

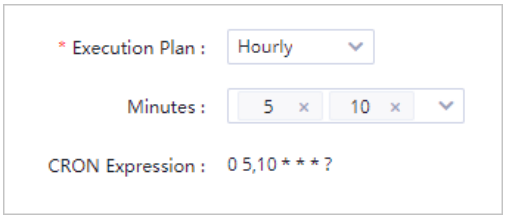
  The following figure shows that the system automatically collects metadata from the CDH Hive data source once at 01:00 each day. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

- Hourly: The system automatically collects metadata from the CDH Hive data source once from the `N × 5` th minute of each hour.

  > **Note** For a CDH Hive metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the CDH Hive data source from the 5th and 10th minutes of each hour. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

- Customize: You can enter a cron expression in the field of the Cron Expression parameter. The system automatically collects metadata based on the time configuration that matches the corn expression.

iii. Click **OK**.

Manage the crawler

On the **CDH Hive Metadata Crawler** page, you can view, edit, and delete the created crawler.

Area No.	Description
1	In this area, you can enter the name of a crawler to find the crawler. > **Note** The fuzzy match is supported. If you enter keywords in the search box, crawlers whose names contain the keywords are displayed.

Area No.	Description
2	In this area, you can view the details of a crawler in the **Status**, **Execution Plan**, **Last Run At**, **Last Consumed Time**, and **Average Running Time** columns. You can also perform the following operations on the crawler: • **Details**: View the CDH cluster and the execution plan that are configured for the crawler. • **Edit**: Modify the CDH cluster and the execution plan that are configured for the crawler. • **Delete**: Delete the crawler. • **Run**: Run the crawler to collect metadata based on the configurations. • **Stop**: Stop the crawler. **Note** **Run** and **Stop** are displayed in the **Actions** column only if the **Execution Plan** parameter is set to **On-demand Execution**.

What's next

After the metadata is collected, you can view the details of the collected metadata on the **All Data** page of Data Map.

2.1.12.7.12. Collect metadata from an HBase data source

DataWorks allows you to collect metadata that includes the table schema and the linage information of tables in Data Map. You can view the schema of a table and the relationships between tables. This topic describes how to create a crawler to collect metadata from an HBase data source to DataWorks. You can view the collected metadata on the Data Map page.

Prerequisites

A Cloudera Distribution Hadoop (CDH) cluster is associated with the current DataWorks workspace. For more information, see Associate a CDH cluster with a workspace.

Limits

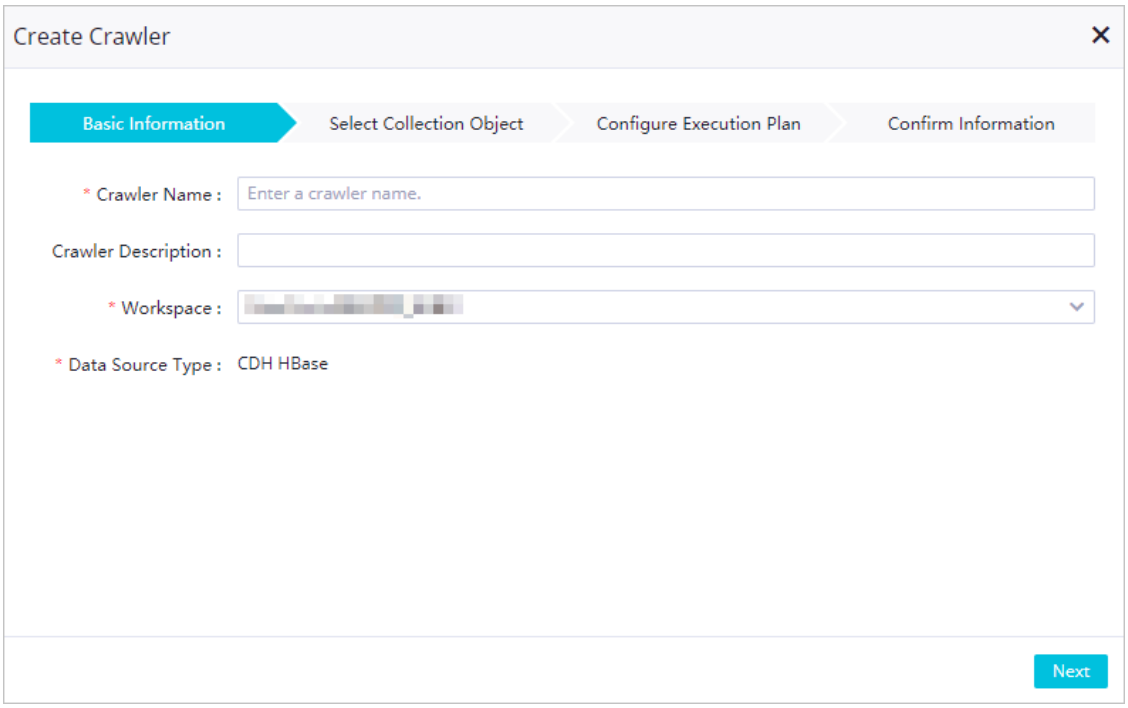
You cannot collect metadata across regions. You must create a crawler in the region where the source metadata resides to collect the metadata.

Create a crawler

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. Create a crawler.
   i. In the left-side navigation pane, click **CDH HBase**.
   ii. On the **CDH HBaseMetadata Crawler** page, click **Create Crawler**.
3. Configure the crawler.

i. Configure the basic information.

In the **Basic Information** step of the **Create Crawler** dialog box, set the parameters.



Parameter	Description
Crawler Name	The name of the crawler.
Crawler Description	The description of the crawler.
Workspace	The workspace in which the crawler resides.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is CDH HBase.

ii. Click **Next**.

iii. Select an HBase data source.

In the **Select Collection Object** step, select a data source and a resource group from the drop-down lists, and click **Start Testing** to test the connectivity between the data source and the resource group.

> **Note** If no data sources are available, click **Create** to add an HBase data source on the Data Source page.

iv. Configure an execution plan.

In the **Configure Execution Plan** step, configure an execution plan.

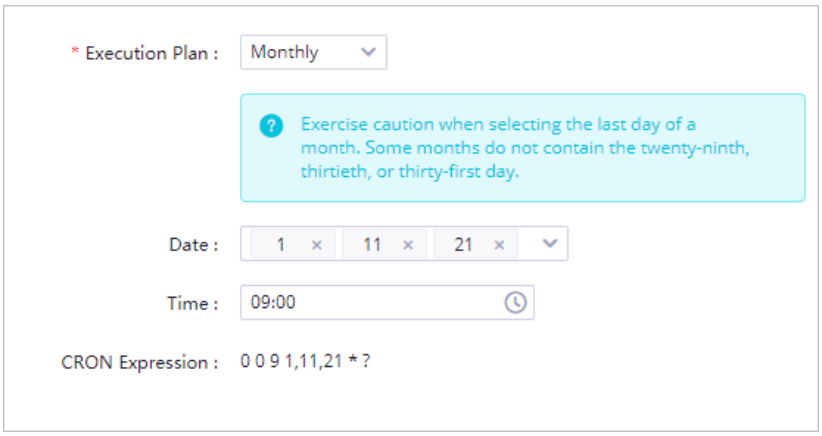
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, **Hourly**, and **Customize**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the HBase data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: You need to manually run the crawler. The system collects metadata from the HBase data source based on your business requirements.

- Monthly: The system automatically collects metadata from the HBase data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the HBase data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the HBase data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

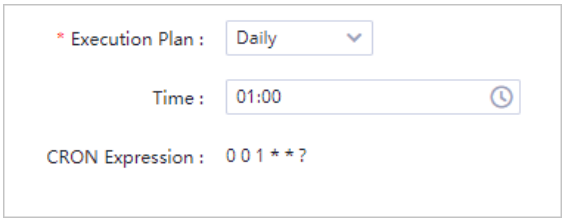
- Weekly: The system automatically collects metadata from the HBase data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the HBase data source once at 03:00 on Sunday and Monday of each week. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

  
  If the **Time** parameter is not set, the system automatically collects metadata from the HBase data source once at `00:00:00` on the specific days of each week.

- Daily: The system automatically collects metadata from the HBase data source once at a specific time of each day.

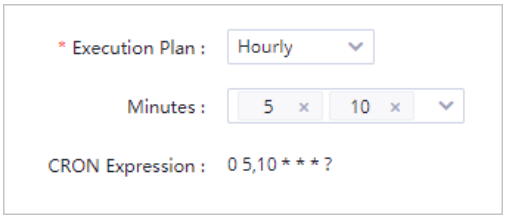
  The following figure shows that the system automatically collects metadata from the HBase data source once at 01:00 each day. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

- Hourly: The system automatically collects metadata from the HBase data source once from the `N ×` `5` th minute of each hour.

  > **Note** For an HBase metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the HBase data source from the 5th and 10th minutes of each hour. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

- Customize: You can enter a cron expression in the field of the Cron Expression parameter. The system automatically collects metadata based on the time configuration that matches the corn expression.

v. Click **Next**.

vi. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

Manage the crawler

On the **CDH HBaseMetadata Crawler** page, you can view, edit, and delete the created crawler.

Area No.	Description
1	In this area, you can enter the name of the crawler or the name of the data source in the search boxes to find the crawler. > **Note** The fuzzy match is supported. If you enter keywords in the search boxes, crawlers whose names or data source names contain the keywords are displayed.
2	In this area, you can view the details of the crawler in the **Status**, **Environment**, **Network Connectivity**, **Execution Plan**, **Last Run At**, **Last Consumed Time**, and **Average Running Time** columns. You can also perform the following operations on the crawler: • **Details**: View the configurations of the crawler. • **Edit**: Modify the configurations of the crawler. For example, you can modify the resource group and the execution plan of the crawler. • **Delete**: Delete the crawler. • **Run**: Run the crawler.

What's next

After the metadata is collected, you can view the details of the collected metadata on the **All Data** page of Data Map.

2.1.12.7.13. Collect metadata from a Kudu data source

DataWorks allows you to collect metadata that includes the table schema and the linage information of tables in Data Map. You can view the schema of a table and the relationships between tables. This topic describes how to create a crawler to collect metadata from a Kudu data source to DataWorks. You can view the collected metadata on the Data Map page.

Prerequisites

A CDH cluster is associated with the current DataWorks workspace. For more information, see Associate a CDH cluster with a workspace.

Limits

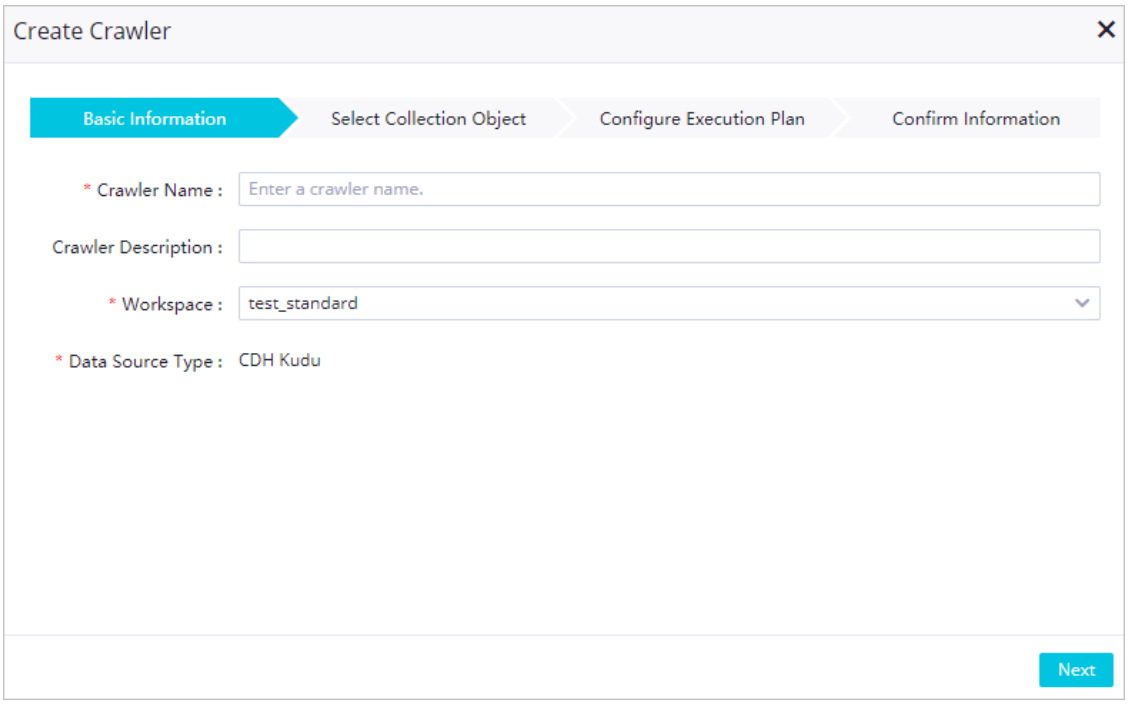
You cannot collect metadata across regions. You must create a crawler in the region where the source metadata resides to collect the metadata.

Create a crawler

1. Go to the **Data Discovery** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > DataMap(Data Management)**.
   iii. In the top navigation bar, click **Data Discovery**.
2. Create a crawler.
   i. In the left-side navigation pane, click **CDH Kudu**.
   ii. On the **CDH KuduMetadata Crawler** page, click **Create Crawler**.
3. Configure the crawler.

i. Configure the basic information.

In the **Basic Information** step of the **Create Crawler** dialog box, set the parameters.



Parameter	Description
Crawler Name	The name of the crawler.
Crawler Description	The description of the crawler.
Workspace	The workspace in which the crawler resides.
Data Source Type	The type of the data source from which you want to collect metadata. The default value is CDH Kudu.

ii. Click **Next**.

iii. Select a Kudu data source.

In the **Select Collection Object** step, select a data source and a resource group from the drop-down lists, and click **Start Testing** to test the connectivity between the data source and the resource group.

> **Note** If no data sources are available, click **Create** to add a Kudu data source on the Data Source page.

iv. Configure an execution plan.

In the **Configure Execution Plan** step, configure an execution plan.

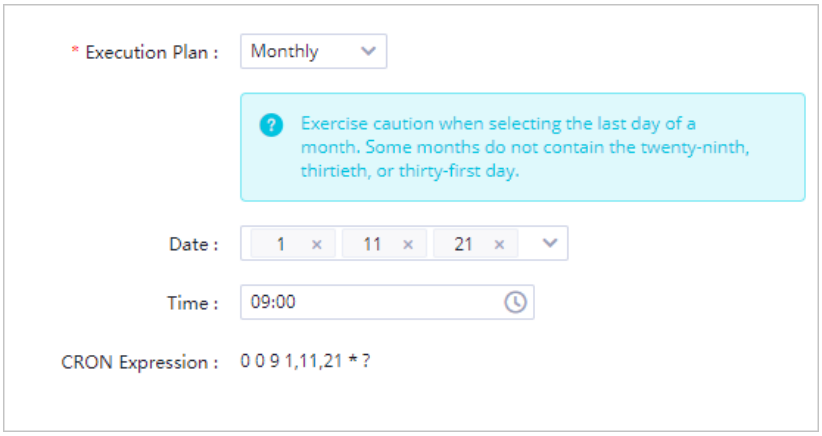
Valid values of the **Execution Plan** parameter are **On-demand Execution**, **Monthly**, **Weekly**, **Daily**, **Hourly**, and **Customize**. The execution plan that is generated varies based on the execution cycle. The system collects metadata from the Kudu data source based on the execution cycle that you specify. The following descriptions explain each value and provide examples:

- On-demand Execution: You need to manually run the crawler. The system collects metadata from the Kudu data source based on your business requirements.

- Monthly: The system automatically collects metadata from the Kudu data source once at a specific time on several specific days of each month.

  > **Notice** Some months do not have the 29th, 30th, or 31st day. In these months, the system does not collect metadata from the Kudu data source on these dates. We recommend that you do not select the last days of a month.

  The following figure shows that the system automatically collects metadata from the Kudu data source once at 09:00 on the 1st, 11th, and 21st days of each month. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

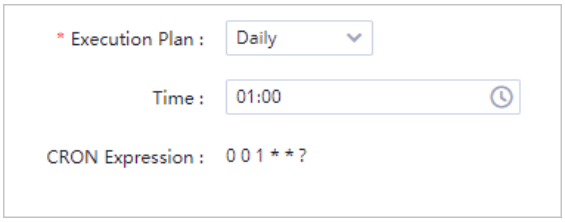
- Weekly: The system automatically collects metadata from the Kudu data source once at a specific time on several specific days of each week.

  The following figure shows that the system automatically collects metadata from the Kudu data source once at 03:00 on Sunday and Monday of each week. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

  
  If the **Time** parameter is not set, the system automatically collects metadata from the Kudu data source once at `00:00:00` on the specific days of each week.

- Daily: The system automatically collects metadata from the Kudu data source once at a specific time of each day.

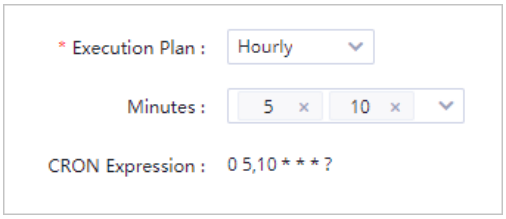
  The following figure shows that the system automatically collects metadata from the Kudu data source once at 01:00 each day. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

- Hourly: The system automatically collects metadata from the Kudu data source once from the `N` × `5` th minute of each hour.

  > **Note** For a Kudu metadata collection task that is run each hour, you can set the time to a multiple of 5 minutes.

  The following figure shows that the system automatically collects metadata from the Kudu data source from the 5th and 10th minutes of each hour. An expression is automatically generated for the **Cron Expression** parameter based on the values of the Date and Time parameters.

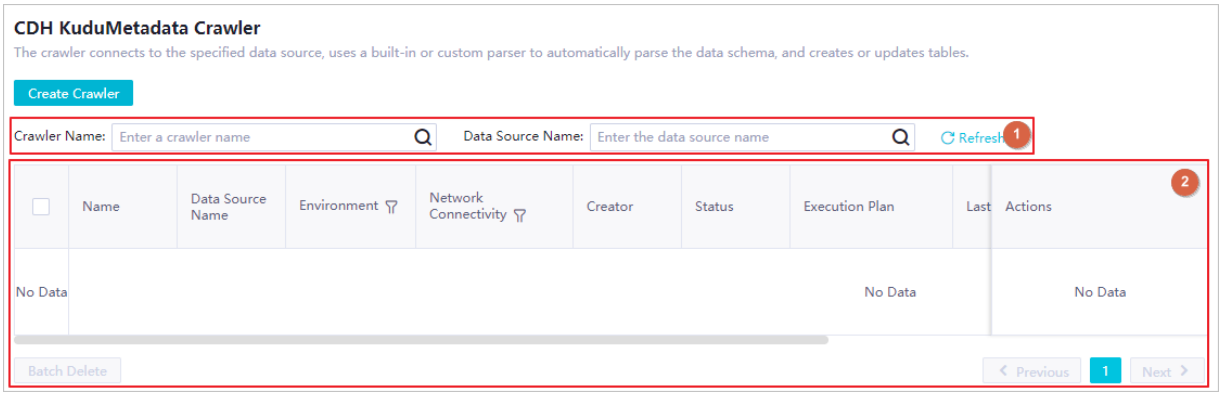
- Customize: You can enter a cron expression in the field of the Cron Expression parameter. The system automatically collects metadata based on the time configuration that matches the corn expression.

v. Click **Next**.

vi. In the **Confirm Information** step, check the information that you specified and click **Confirm**.

Manage the crawler

On the **CDH KuduMetadata Crawler** page, you can view, edit, and delete the created crawler.



Area No.	Description
1	In this area, you can enter the name of the crawler or the name of the data source in the search boxes to find the crawler. **Note** The fuzzy match is supported. If you enter keywords in the search boxes, crawlers whose names or data source names contain the keywords are displayed.

Area No.	Description
2	In this area, you can view the details of the crawler in the **Status**, **Environment**, **Network Connectivity**, **Execution Plan**, **Last Run At**, **Last Consumed Time**, and **Average Running Time** columns. You can also perform the following operations on the crawler: • **Details**: View the configurations of the crawler. • **Edit**: Modify the configurations of the crawler. For example, you can modify the resource group and the execution plan of the crawler. • **Delete**: Delete the crawler. • **Run**: Run the crawler.

What's next

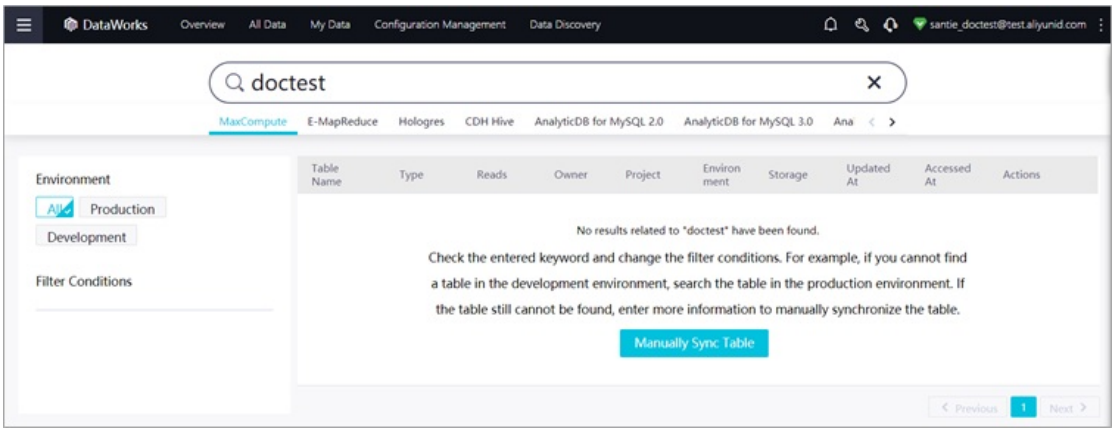
After the metadata is collected, you can view the details of the collected metadata on the **All Data** page of Data Map.

2.1.12.8. What do I do if no search results are returned when I query a newly created table in the Data Map service of DataWorks?

The Data Map service of DataWorks allows you to query tables on the homepage of Data Map by using a keyword. It also allows you to view the tables that you have recently browsed or read. If no search results are returned when you query a newly created table in the Data Map service of DataWorks, the possible cause is a latency of DataWorks in obtaining metadata. This topic describes how to address this issue.

Problem description

When I query a newly created table on the **All Data** page of Data Map by using a keyword, the **No data found.** message is displayed.



Possible causes

Possible causes:

- Possible cause 1: You entered an invalid keyword and no tables that match the keyword can be found.
- Possible cause 2: The table that you want to query has just been created, and no search results can be returned because of a latency of DataWorks in obtaining metadata.

Solution

1. Check the keyword that you have entered.

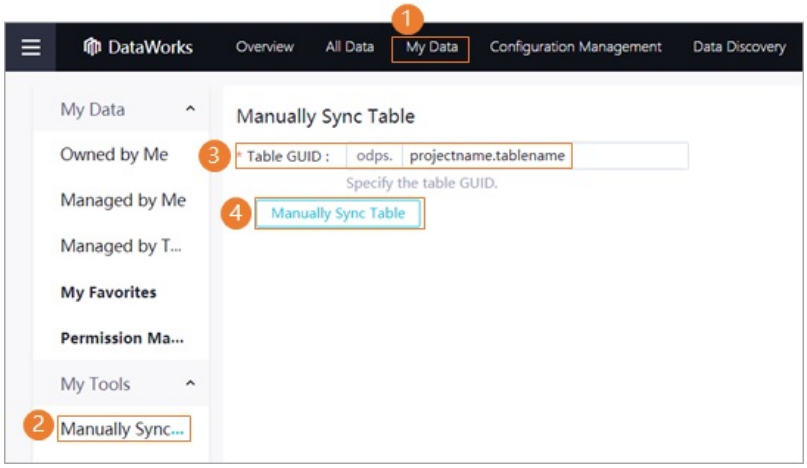
   Make sure that the keyword that you have entered is valid and matches the table that you want to query.

2. Manually synchronize the table.

   If the table that you want to query exists and the keyword that you have entered is correct, the possible cause is that the metadata of the newly created table has not been synchronized. In this case, you need to manually synchronize the table. Use one of the following methods to synchronize the table:

   - Click **Manually Sync Table** on the query result page.

   - Choose **My Data > Manually Sync Table** in Data Map of the DataWorks console. On the page that appears, `set Table GUID to a value in the format of Project name.Table name, and click Manually Sync Table.`



After you complete the preceding steps, query the table on the All Data page of Data Map by using the keyword again.

2.1.13. Data Asset Management

2.1.13.1. Go to the Data Asset Management page

Data Asset Management provides you with an overview of your data assets. Data Asset Management requires that data be synchronized by using Data Integration and processed by using DataStudio before you manage your tables and APIs stored in your business system and DataWorks.

Context

Data Asset Management controls the permissions of users independently. You must grant the permissions on the Project Management page because Data Asset Management is a tenant-level feature.

Data Asset Management allows you to view the metadata collected in Data Map. You can also perform basic management operations on the metadata. For example, you can change the business classes and add business descriptions for metadata tables.

Procedure

1. Log on to the DataWorks console.
2. Click ☰ in the upper-left corner and choose **All Products > Project Management**. The Project Management page appears.
3. In the left-side navigation pane, click **Member Management**.

   On the Member Management page, you can assign the following roles to members: **Data Asset Management-Asset Manager**, **Data Asset Management-Class Manager**, and **Data Asset Management-Home Visitor**.
4. Click ☰ in the upper-left corner and choose **All Products > Data Asset Management** to manage data assets in Data Asset Management.

   The following table describes the permissions of each role.

Role	Permission
Data Asset Management-Asset Manager	In the top navigation bar of the **Data Asset Management** page, click the **Assets** tab. On the Assets tab, you can manage data assets, such as adding business units and classes. You can also add data assets to a class.
Data Asset Management-Class Manager	In the top navigation bar of the **Data Asset Management** page, click the **Classes** tab. On the Classes tab, you can view the data assets of each class.
Data Asset Management-Home Visitor	In the top navigation bar of the **Data Asset Management** page, click the **Home** tab. On the Home tab, you can view the statistics of data assets of different classes and business units.

2.1.13.2. Asset manager

Asset managers can view the information about data assets.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Home** page that appears, enter keywords in the search box and click **Search**.
4. On the search results page that appears, click the **Tables**, **File**, or **API** tab to view details and apply for permissions.

   You can click the **Classes** tab in the top navigation bar to filter data assets by class.

2.1.13.3. Asset user

Asset users can access Data Asset Management to perform operations such as searching for assets, applying for permissions, and using assets.

1. Log on to the DataWorks console.

2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Home** page that appears, enter keywords in the search box and click **Search**.
4. On the search results page that appears, click the **Tables**, **File**, or **API** tab to view details and apply for permissions.

   You can click the **Classes** tab in the top navigation bar to filter data assets by class.

2.1.13.4. Asset administrator

Asset administrators can manage assets and authorizations in Data Asset Management.

> **Note** You can submit a ticket to apply for the asset administrator role.
>
> An administrator can grant the administrator role to common users. An administrator can perform any operations in Data Asset Management, and no approval is required.

Go to the Assets tab

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. In the top navigation bar, click the **Assets** tab.

   Under the **Assets** tab, you can click **Data Management**, **Classes**, or **Business Management** in the left-side navigation pane to manage your data assets accordingly.

Manage data

In the left-side navigation pane, you can click **Data Management** and then **Tables**, **Files**, or **APIs** to manage tables, files, or APIs.

- **Manage tables**

  In the left-side navigation pane, choose **Data Management > Tables** to go to the **Tables** page.

  On the Tables page, you can view, edit, publish, or delete a table.

  - Click the name of a table to view table details.
  - Click **Edit** in the Actions column of a table. In the Edit dialog box that appears, you can edit the configuration of the table.
  - Move the pointer over **Publish** in the Actions column of a table. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

    > **Note** You can search for a published table in Data Asset Management.

  - Move the pointer over **Delete** in the Actions column of a table. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

    > **Note** You cannot search for a deleted table in Data Asset Management.

- **Manage files**

  In the left-side navigation pane, choose **Data Management > Files** to go to the **Files** page.

On the **File Management** page that appears, you can upload a file. Then, you can view, edit, download, or delete the file.

- In the upper-right corner, click **Upload File**. In the **Upload File** dialog box that appears, click **Add File**. In the Add dialog box that appears, select the file to be uploaded and click **Open**. Alternatively, you can drag and drop a file to the **Upload File** dialog box. Then, click **Next**.

  > **Note**
  > - To upload a file, make sure that the size of the file does not exceed 50 MB.
  > - You can only upload a file with one of the following file name extensions:
  >
  >   3DX, 7Z, A3D, ATX, AVI, BMP, SV, DBF, DOC, DOCX, DWG, EPS, ESP, FREELIST, GDB, GDBINDEXES, GDBTABLE, GDBTABLX, GIF, GZ, HTM, HTML, IVE, JPEG, JPG, LOCK, LSP, LST, MP3, MP4, MPJ, OSG, OSGB, PDF, PNG, PPT, PPTX, PRJ, PSD, RAR, S3C, SBN, SBX, SCP, SHP, SPX, TFW, TIF, TIFF, TTF, TXT, WAV, WL, WP, WT, XLS, XLSX, ZIP, XML, SHX, and SKP

- Click the name of a file to view file details.
- Click **Edit** in the Actions column of a file. In the Edit dialog box that appears, you can edit the configuration of the file.
- Move the pointer over **Publish** in the Actions column of a file. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

  > **Note** You can search for a published file in Data Asset Management.

- Move the pointer over **Delete** in the Actions column of a file. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

  > **Note** You cannot search for a deleted file in Data Asset Management.

- Click **Download** in the Actions column of a file to download the file.

  > **Note** Before downloading a file, apply for the download permission.

- **Manage APIs**

  In the left-side navigation pane, choose **Data Management > APIs** to go to the **APIs** page.

  On the **APIs** page, you can edit, publish, or delete an API.

  - Click **Edit** in the Actions column of an API. In the **Edit** dialog box that appears, you can edit the configuration of the API. Then, click **Submit**.
  - Move the pointer over **Publish** in the Actions column of an API. In the dialog box that appears, click **Publish**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

    > **Note** You can search for a published API in Data Asset Management.

  - Move the pointer over **Delete** in the Actions column of an API. In the dialog box that appears, click **Delete**. After the request is submitted, click the **Permissions** tab in the top-navigation bar. In the left-side navigation pane, click **Submitted by Me** to view the request you submitted.

    > **Note** You cannot search for a deleted API in Data Asset Management.

Manage classes

1. In the left-side navigation pane, click **Classes** to go to the **Classes** page.

   On the Classes page, you can import or export a class.

2. Click the icon. In the **Add Class** dialog box that appears, set relevant parameters and click **OK** to add a level-1 class

Parameter	Description
Name	The name of the class, which can be up to 128 characters in length.
Code	The code of the class. This parameter cannot be left empty.
Description	The description of the class.
Confidential	Specifies whether the class is confidential. Valid values: **Yes** and **No**.
Share	Specifies whether to share the class. Valid values: **Yes**, **Conditional**, and **No**.

   To create a subclass under a class, click the icon next to the class.

3. Click a class. On the page that appears, click the **Tables** tab.
4. Click **Add Table**. In the **Add Table** dialog box that appears, select the tables to be added to the class and click **OK**.

   You can add files and APIs to a class in the same way.

   To change the class of a table, click **Modify Class** in the Actions column. In the **Change Class** dialog box that appears, change the class as needed.

Manage business

In the left-side navigation pane, you can click **Business Management** and then **Business Units**, **Business Systems**, or **Connections** to manage business units, business systems, or connections.

> **Note** Connections belong to a business system, and business systems belong to a business unit.
> - A business system with connections cannot be deleted.
> - A business unit with business systems cannot be deleted.

- **Manage business units**

  In the left-side navigation pane, choose **Business Management > Business Units** to go to the **Business Units** page.

  Click the icon. In the **Add Business Unit** dialog box that appears, set relevant parameters and click **OK** to add a business unit.

Parameter	Description
Name	The name of the business unit. This parameter cannot be left empty.

Parameter	Description
Code	The code of the business unit. By default, the code cannot be modified.
Description	The description of the business unit.
Confidential	Specifies whether the business unit is confidential. Valid values: **Yes** and **No**.
Share	Specifies whether to share the business unit. Valid values: **Yes**, **Conditional**, and **No**.
Business system included	Select the business systems to be added to the business unit and click the > icon.

To create a sub-business unit under a business unit, click the icon next to the business unit.

- **Manage business systems**

  In the left-side navigation pane, choose **Business Management > Business Systems** to go to the **Business Systems** page.

  On the Business Systems page, you can add a business system. Then, you can view, edit, or delete the business system.

  - Click **Add Business System**. In the **Basic information** dialog box that appears, set relevant parameters and click **Submit**.
  - Click **View** in the Actions column of a business system to view its details.
  - Click **Edit** in the Actions column of a business system. In the **Business System Properties** dialog box that appears, you can edit the configuration of the business system.
  - Click **Delete** in the Actions column of a business system. In the **Delete business system** dialog box that appears, click **OK** to delete the business system.

- **Manage connections**

  In the left-side navigation pane, choose **Business Management > Connections** to go to the **Connections** page.

  On the **Connections** page, you can view the information of connections. The connection information includes the connection name, the number of tables, the owner, the business system to which the connection belongs, the data type, and the update time. You can also edit the configuration of a connection.

2.1.13.5. Manage authorizations

Under the Permissions tab, you can view permissions in different states on the Submitted by Me, To Be Handled, Handled by Me, and My Permissions pages respectively.

Go to the Permissions tab

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. In the top navigation bar, click the **Permissions** tab.

   Under the **Permissions** tab, you can view permissions in different states on the **Submitted by Me**, **To Be Handled**, **Handled by Me**, and **My Permissions** pages respectively.

Submitted by Me

In the left-side navigation pane, click **Submitted by Me**.

On the **Submitted by Me** page, you can view request details or cancel requests submitted by you. To resubmit a request that was not approved, find the target request and click **Reapply**.

To Be Handled

In the left-side navigation pane, click **To Be Handled**. On the To Be Handled page, you can view request details and approve or reject requests.

Handled by Me

In the left-side navigation pane, click **Handled by Me** to view requests handled by you.

My Permissions

In the left-side navigation pane, click **My Permissions**. On the My Permissions page, you can view your permissions on tables, files, and APIs respectively.

2.1.13.6. Perform cross-tenant authorization

This topic describes how to perform cross-tenant authorization.

Authorization logic

DataWorks performs authorization within a tenant and cross-tenant authorization based on the following logic:

- Authorization within a tenant: An access control list (ACL) is used for authorization. You must add the applicant to the corresponding workspace and then grant permissions to the applicant as requested.
- Cross-tenant authorization: A package is used for authorization. First, check whether the workspace where the requested resources reside has a package.
  - If the workspace does not have a package, create a package and add the requested resources to the package. Then, install the package in the workspace where the requested resources are used.

    After that, use an ACL to grant permissions to the applicant as requested.
  - If the workspace has a package, add the requested resources to the package.

  If the requested resources must be shared with multiple workspaces, install the package in all these workspaces. If the workspace where the requested resources reside has multiple packages, install all of them in the workspaces where the requested resources are used.

Procedure

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Data Asset Management**.
3. On the **Asset Portal** tab, enter the name of the table that belongs to another tenant in the search box and click **Search**.
4. On the **Asset Category** tab that appears, click the name of the found table on the **Tables** tab. The details page of the table appears.

   On the details page, you can view details about the table, including the basic information, business information, physical information, and field information.
5. Click **Request Permission** in the upper-right corner. The **Table Permission Request** page appears.
6. Set parameters on the **Table Permission Request** page.

Parameter	Description
Target Workspace	The workspace where the table is to be used.

Parameter	Description
Environment	The type of the environment where the table is to be used. If the selected workspace is in standard mode, you must set this parameter to Development or Production.
Home Workspace	The workspace where the table resides. This parameter is automatically set.
Home Tenant	The tenant to which the table belongs. This parameter is automatically set.
Grant To	The account to which the permissions are granted. Valid values: **Current Account** and **System Account for Production Environment**.
Requested Period	The period in which the requested permissions are valid.
Reason for Request	The reason why you request the permissions. We recommend that you describe the reason in detail for faster approval.
Objects Requested	The tables you want to use. By default, the current table is selected. You can select other tables.

7. After the configuration is complete, click **Submit**.

   After you submit the request, click **Approval Management** in the top navigation bar and then click **Submitted by Me**. You can view the review progress on the page that appears.

   - If you need to revoke a request, click **Revoke** in the Actions column of the request.
   - If you need to submit a revoked or rejected request again, click **Reapply** in the Actions column of the request.

8. Log on to the DataWorks console as the table owner, go to the **Approval Management** tab and click **To Be Handled**. On the page that appears, review the request information and click **Agree**.

   After you click **Agree**, click **Approval Management** in the top navigation bar and click **Handled by Me**. On the page that appears, you can view your authorization records and revoke specific authorizations.

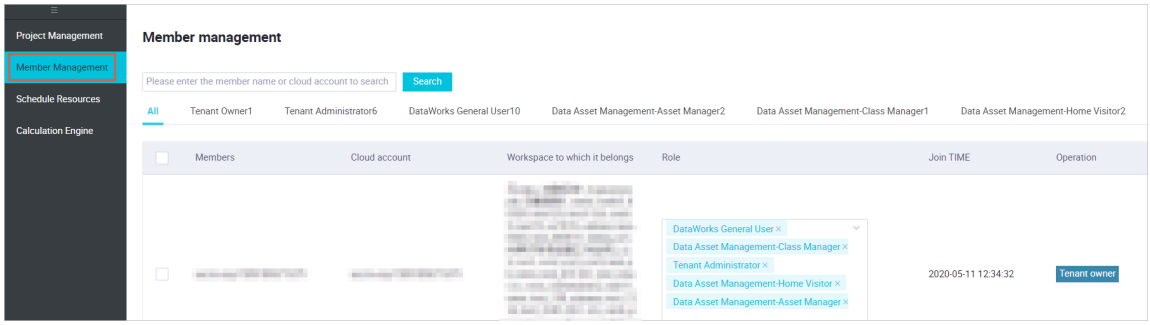
2.1.14. Organization management

2.1.14.1. Manage members

On the Member Management page of a workspace, you can manage and configure members in the workspace.

1. Log on to the DataWorks console as a workspace administrator.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**.
3. In the left-side navigation pane, click **Member Management**.
4. Enter a member name or logon name in the search box to search for a member. You can assign a role to the member found or remove the member from the current workspace.
   - Assign a role to a member

To assign a role to a member, find the member in the member list and select the role from the drop-down list in the **Roles** column.



To revoke a role from a member, click **x** next to the role in the Roles column.

- Remove a member from the workspace

  To remove a member from the current workspace, find the member in the member list, click **Delete** in the Actions column, and then click **OK** in the **Remove from Tenant** message.

2.1.14.2. Resource groups

2.1.14.2.1. Go to the page for managing scheduling resources

Scheduling resources are managed at the tenant level. An exclusive scheduling resource can consist of multiple physical machines for running nodes.

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**.
3. In the left-side navigation pane, click **Schedule Resources**. On the Schedule Resources page, manage scheduling resources as required.

   > **Note** If you are the tenant administrator, you can modify existing scheduling resources on the **Schedule Resources** page.

2.1.14.2.2. Change the workspace to which a scheduling resource belongs

After you create and configure an exclusive scheduling resource, you can change the workspace to which the resource belongs.

Procedure

1. Log on to the DataWorks console as the tenant administrator.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**.
3. On the page that appears, click **Schedule Resources** in the left-side navigation pane. On the **Schedule Resources** page, enter a keyword in the search box in the upper-left corner. DataWorks searches for the scheduling resources whose names contain the keyword in fuzzy match mode.
4. Find the target scheduling resource and click **Modify attribution**.
5. In the **Modify attribution** dialog box, select the workspace to which the exclusive scheduling resource will be bound.
6. Click **OK**.

2.1.14.3. Configure the compute engine

DataWorks supports only MaxCompute as its compute engine. All workflows and nodes in a workspace are run on the MaxCompute compute engine associated with the workspace.

Background information

You can modify the compute engine that has been configured for a workspace as the tenant administrator. You can modify the following settings of the compute engine: description, whether to use the account to which the MaxCompute project belongs to run nodes, account that is used to run nodes, and AccessKey pair of the account.

For example, if the owner of a MaxCompute project resigns, but Run Nodes Using MaxCompute Owner Account is not selected for the corresponding nodes, you must specify another account and the corresponding AccessKey pair for running those nodes in time.

Procedure

To change the account for running nodes and its AccessKey pair, perform the following steps:

1. Log on to the DataWorks console as the tenant administrator.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > Project Management**.
3. On the page that appears, click **Calculation Engine** in the left-side navigation pane. On the **Calculation Engine** page, enter a keyword in the search box in the upper-left corner. DataWorks searches for the compute engines whose names contain the keyword in fuzzy match mode.
4. Find the target compute engine and click **Configuration** in the Operation column.
5. In the **Configure MaxCompute Compute Engine** dialog box, set the Tenant Account for Running Nodes, Access Id, and Access Key parameters as required.

   > **Note** As the tenant administrator, you can select Run Nodes Using MaxCompute Owner Account or create an account and set the Tenant Account for Running Nodes parameter to this account.

6. Click **OK**.

2.1.15. Data Service

2.1.15.1. Overview

With Data Service, you can manage all your table APIs after you create new APIs or register existing APIs. You can also easily publish your APIs to API Gateway. Together with API Gateway, Data Service provides a secure, stable, low-cost, and easy-to-use data sharing service.

Data Service adopts a serverless architecture and allows you to develop table APIs without thinking about infrastructure such as compute resources. Data Service supports automatic scaling for compute resources, which significantly reduces your OPEX.

Create an API

In Data Service, you can quickly create APIs based on tables in relational databases or NoSQL databases using a visual wizard. It takes only a few minutes to configure a data API, and coding is not required. You can also create APIs by specifying SQL scripts. The script mode supports advanced functions such as associative tables, complex criteria, and aggregate functions.

Register an API

You can register existing RESTful APIs to Data Service for unified API management. Four request methods and three data formats are supported. The four request methods are GET, POST, PUT, and DELETE. The three data formats are tables, JSON, and XML.

API Gateway

API Gateway provides API lifecycle management services, including API publishing, management, maintenance, and monetization. It enables low-risk, simple, cost-effective, and fast microservice integration, front and back end separation, and system integration. You can use API Gateway to share functions and data with your partners and third-party developers.

API Gateway supports authorization, authentication, flow control, and billing for Data Service.

2.1.15.2. Terms

This section introduces terms of Data Service.

Name	Description
Data source	Indicates database links. Data Service accesses data through data sources. Data sources are configured in Data Integration.
Create an API	Creates APIs based on data tables.
Register an API	Registers existing APIs to Data Service for unified management.
Wizard mode	Guides you through the procedure of API creation. This method is suitable for beginners who want to create simple APIs. You do not need to write any code.
Script mode	Allows you to create APIs by writing SQL scripts. This method supports associative tables, complex queries, and aggregate functions. This method is suitable for experienced developers who want to create complex APIs.
API group	Indicates a set of APIs for a specific scenario or for consuming a specific service. An API group is the smallest group unit in Data Service, and the smallest unit for API Gateway management. API groups are published in Alibaba Cloud API Marketplace as API products.
API Gateway	Indicates a hosted service provided by Alibaba Cloud to manage APIs. API Gateway supports API lifecycle management, permission management, access management, and traffic control.

2.1.15.3. Manage tags

This topic describes how to create, add, view, and remove tags for an API.

DataService Studio allows you to add tags to APIs when you manage workflows and create, register, and deploy APIs. This topic uses the scenario of creating an API in the codeless UI as an example. Tags allow you to efficiently classify and search for APIs. You can maintain only one tag list in a workspace, and cannot use the tag list of a workspace in another workspace.

> **Note**
>
> - Each API supports zero to five tags. That is, you can add no tags to an API at all or add a maximum of five tags to an API.
> - The name of a tag can contain letters, digits, and underscores (_), and cannot exceed 20 characters in length.

Create a tag for an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the Service Development tab, move the pointer over and choose **API > Generate API**.
3. In the **Generate API** dialog box, set the API mode parameter to Wizard Mode and enter a tag in the **Label** field.

   If the tag you entered does not exist in the current workspace, Add <Tag> appears in the drop-down list. Click Add <Tag> to create the tag for the API.
4. Set other parameters and click **OK**. The tag is created for the API and appears in the tag list of the current workspace.

Add an existing tag to an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the Service Development tab, move the pointer over and choose **API > Generate API**.
3. In the **Generate API** dialog box, set the API mode parameter to Wizard Mode and click a blank area or the downward arrow in the **Label** field. Tags in the current workspace appear in a drop-down list.
4. Click the required tag, set other parameters, and then click **OK**. The tag is added to the API.

View tags of an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the **Service Development** tab, double-click the name of the target API in the API list.
3. In the right-side navigation pane, click **Properties**. Then you can view the tags of the API in the **Label** column.

   > **Note** You can also create, add, and remove tags for the API in the Properties pane.

   If an API is published, you can also perform the following steps to view the tags of the API:

   i. In DataService Studio, click **Service Management** in the upper-right corner.

   ii. Click **Manage APIs** in the left-side navigation pane. On the page that appears, click the **APIs of Published** tab and click the name of the target API. The **API Details** page appears.

   iii. View the tags of the API under **Label** in the **API Basic Information** section.

Remove a tag from an API

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All Products > Data Service**.
2. On the **Service Development** tab, double-click the name of the target API in the API list.
3. In the right-side navigation pane, click **Properties**. Then, you can view the tags of the API in the **Label** column.
4. Click next to the tag to remove.
5. Click **Publish** in the upper-right corner. The tag is removed from the API.

Search for APIs by tag

1. Log on to the DataWorks console, click the DataWorks icon in the upper-left corner, and then choose **All**

Products > Data Service.

2. On the **Service Development** tab, click **Service Management** in the upper-right corner.
3. Click **Manage APIs** in the left-side navigation pane. On the page that appears, click the **APIs of Published** tab and view the tags of each API in the **Label** column.

   If an API has multiple tags and some of them are hidden, click **...** to show all the tags.
4. On the **APIs of Published** tab, click **Advanced Search**.
5. Enter a tag in the **Label** field to search for all APIs associated with the tag.

> **Note** You can search for APIs based on multiple tags.

2.1.15.4. Manage business processes and objects under business processes

2.1.15.4.1. Manage business processes

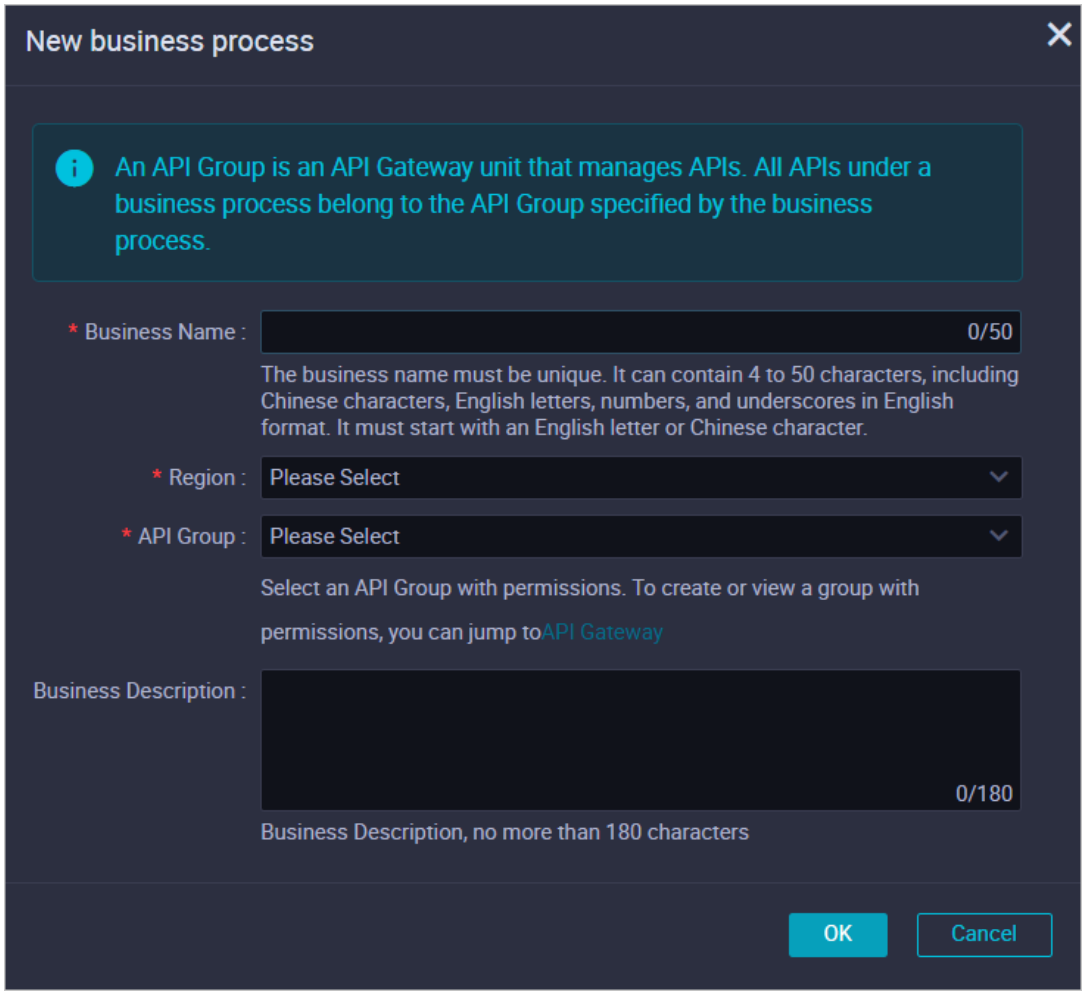
This topic describes how to create, modify, and delete a business process.

Context

DataWorks allows you to organize different types of resources in a business process. This helps you analyze data by business. Each business process contains the following categories: API, function, and workflow.

Create a business process

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Development > Data Service**.
3. On the **Service Development** page, move the pointer over the icon and select **Workflows**.
4. In the **Create Workflow** dialog box, configure the parameters.



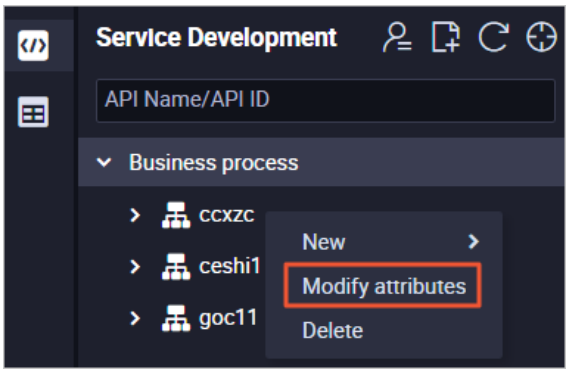
Parameter	Description
Business Name	The name of the business process. ○ The name can contain letters, digits, and underscores (_). ○ The name must start with a letter. ○ The name must be 4 to 50 characters in length. ○ The name must be unique in the workspace to which the business process belongs.
Region	The region. After you select a region, you can publish APIs to this region. You can set this parameter to a region that is associated with the level-1 organization to which your account belongs in the Apsara Uni-manager Management Console.
API Group	The API group to which the APIs in the business process belong. An API group is the API management unit of API Gateway. You can select an API group from the **API Group** drop-down list. We recommend that you select an API group on which you have permissions in the Apsara Uni-manager Management Console. If you want to view existing API groups or create an API group, go to the API Gateway console.
Business Description	The description of the business process, which cannot exceed 180 characters in length.

5. Click **OK**.

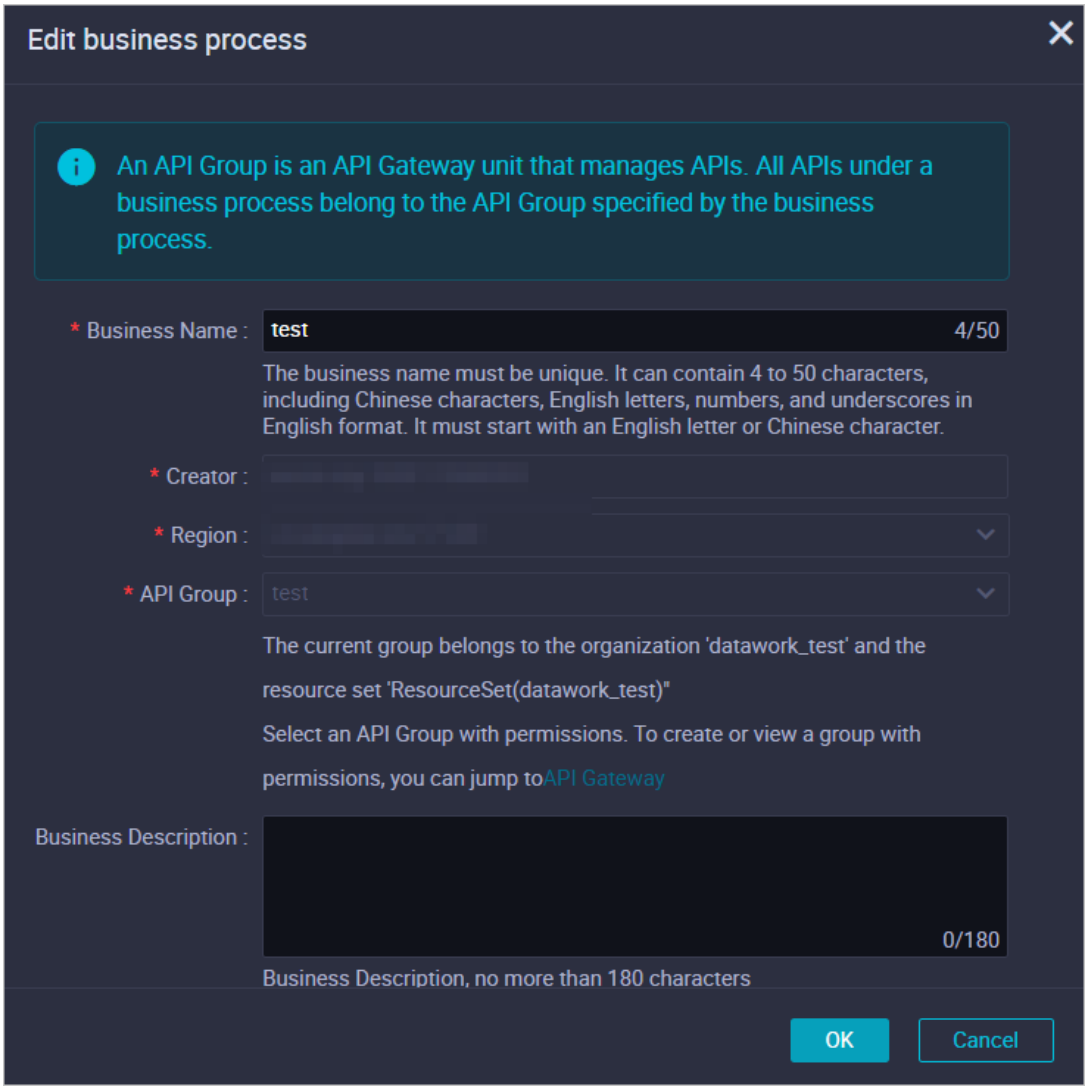
   After the business process is created, you can view it in the business process list.

Modify a business process

1. On the **Service Development** page, right-click the name of the business process that you want to modify and select **Modify attributes**.



2. In the **Edit business process** dialog box, modify the **Business Name** and **Business Description** parameters as required.

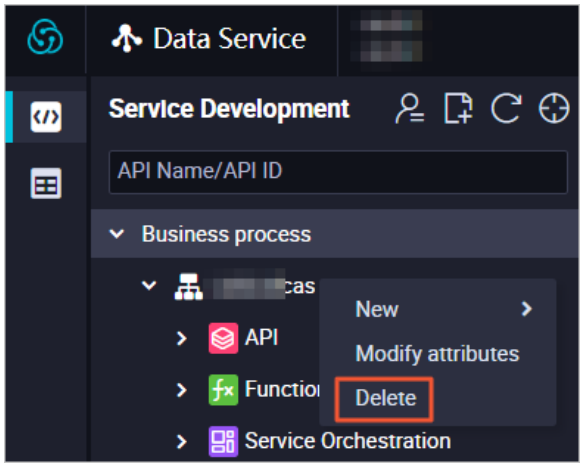


> **Note** You cannot modify the **Creator** or **API Group** parameter of a business process.

3. Click **OK**.

Delete a business process

1. On the **Service Development** page, right-click the name of the business process that you want to delete and select **Delete**.



2. In the Notes message, click **OK**.

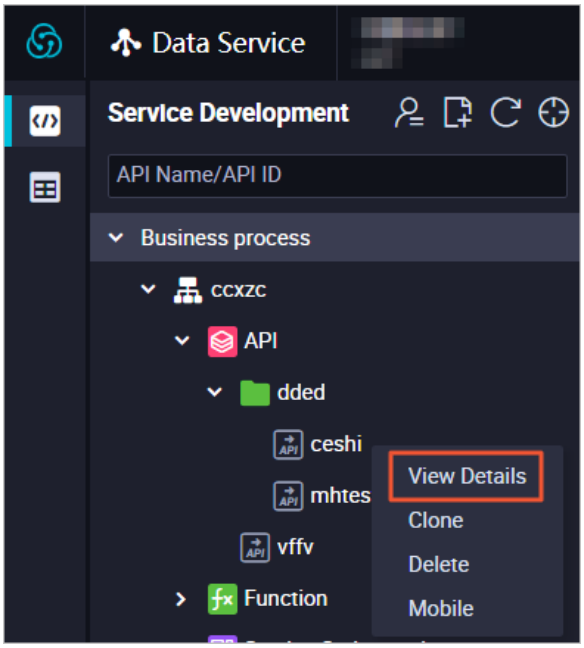
> **Note**
> - You can delete only business processes that do not contain objects such as folders, APIs, functions, or workflows.
> - If you want to delete a business process that contains such objects, delete the objects before you delete the business process.

2.1.15.4.2. Manage APIs

This topic describes how to view, clone, delete, and move APIs.

View an API

1. Log on to the DataWorks console.
2. Click ☰ in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, right-click the name of the target API and select **View Details**.

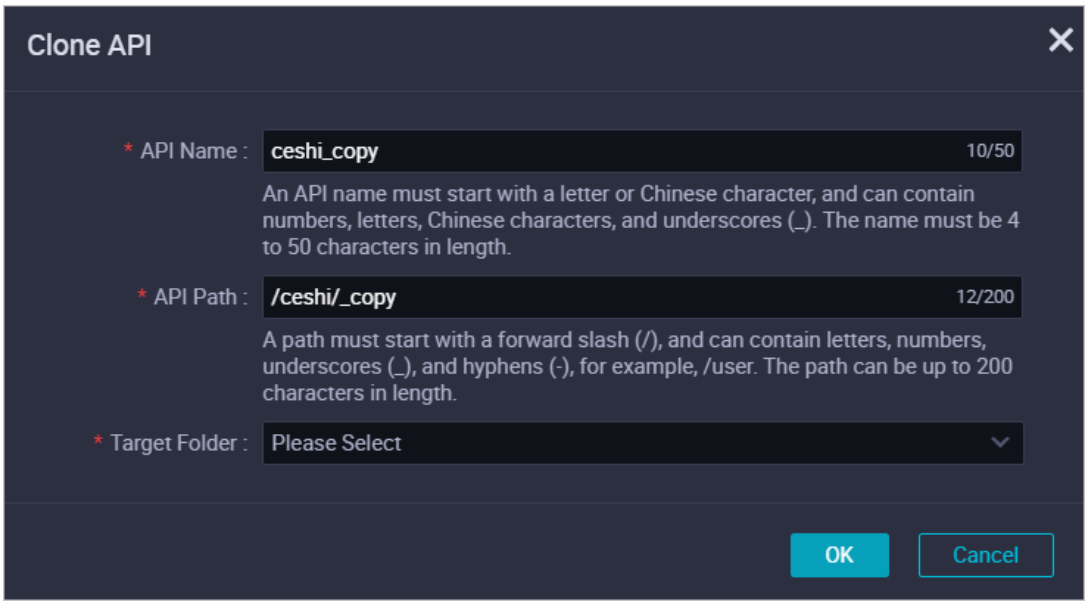


Note The **View Details** option appears only in the shortcut menu of an API that has been published. If an API has not been published, double-click the API to go to the configuration tab of the API. Then, click **Properties** in the right-side navigation pane to view its basic information.

Clone an API

You can clone an API to a specified directory in the directory tree.

1. On the **Service Development** tab, right-click the name of the target API and select **Clone**.
2. In the **Clone API** dialog box, set the parameters as required.



Parameter	Description
API Name	The name of the cloned API. It must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.

Parameter	Description
API Path	The path for storing the cloned API, for example, */user*. The path can contain letters, digits, underscores (_), and hyphens (-). It must start with a forward slash (/) and can be up to 200 characters in length.
Target Folder	The directory for storing the cloned API.

3. Click **OK**.

Delete an API

You can delete only APIs that have not been published. To delete APIs that have been published, you must unpublish them first.

1. Optional. Unpublish the target API.

   If the API to be deleted is in the Unpublished state, skip this step.

   i. Go to the **Service Development** tab and click **Service Management** in the upper-right corner.

   
   ii. On the page that appears, click the **APIs of Published** tab, find the target API, and then click **Unpublish** in the Actions column.

   iii. In the **Unpublish API** message, click **OK**.

   iv. Click **Service Development** in the upper-right corner to return to the **Service Development** tab.

2. On the **Service Development** tab, right-click the name of the target API and select **Delete**.
3. In the **Delete API** message, click **OK**.

> **Note** Deleted APIs cannot be recovered. Use caution when you delete an API.

Move an API to another directory

You can move only APIs that have not been published. To move APIs that have been published, you must unpublish them first.

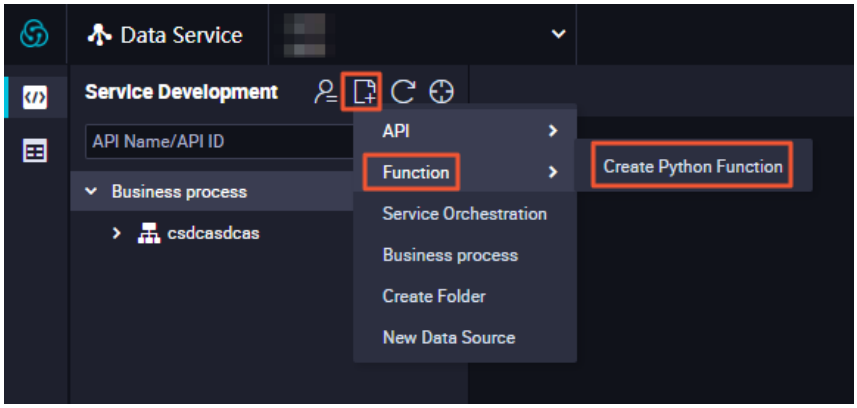
1. On the **Service Development** tab, right-click the name of the target API and select **Mobile**.
2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.1.15.4.3. Manage functions

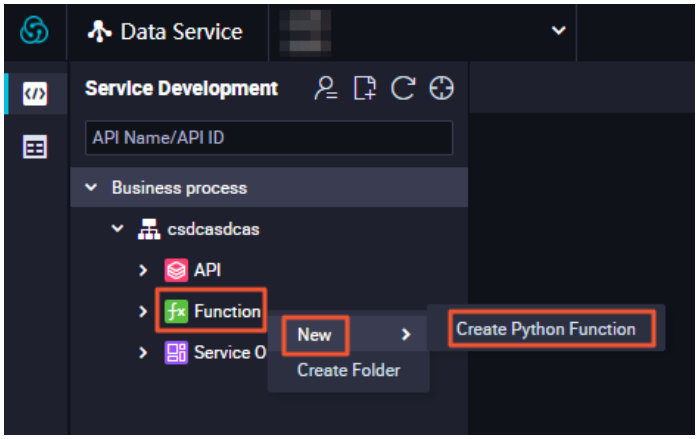
This topic describes how to create, clone, delete, and move Python functions.

Create a function

1. Log on to the DataWorks console.
2. Click ☰ in the upper-left corner and choose **All Products > Data Service**.
3. Move the pointer over and choose **Function > Create Python Function**.

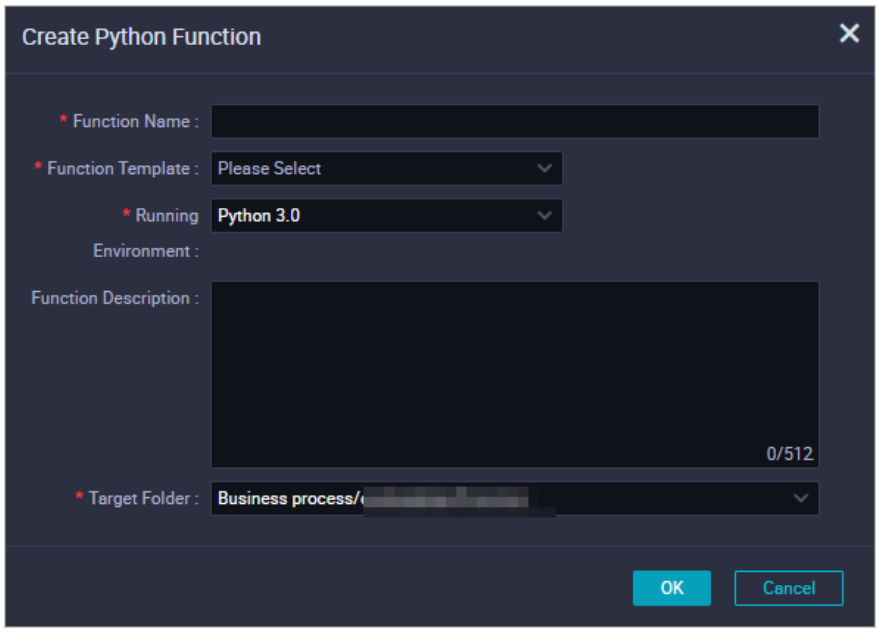


You can also click a business process, right-click **Function**, and then choose **New > Create Python Function**.



> **Notice** DataService Studio allows you to create only Python functions.

4. In the **Create Python Function** dialog box, set the parameters as required.

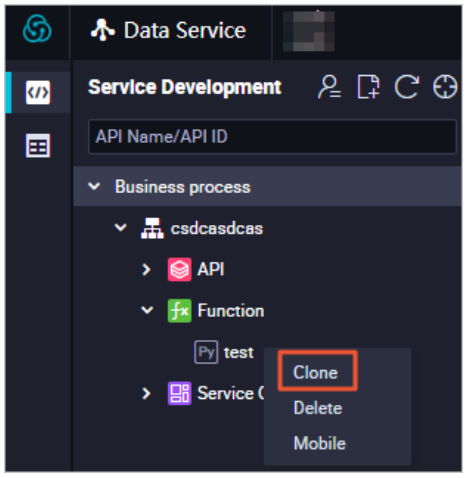


Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function. The description can be up to 512 characters in length.
Target Folder	The directory for storing the function.

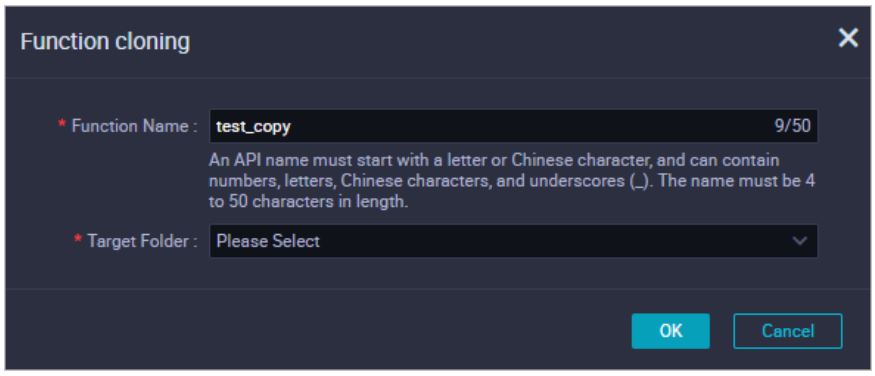
5. Click **OK**.
6. On the configuration tab of the function, configure the function.
   i. In the **Edit Code** section, enter the function code.
   ii. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.
7. Click Save icon in the toolbar.

Clone a function

1. On the **Service Development** tab, right-click the name of the target function and select **Clone**.



2. In the **Function cloning** dialog box, set the **Function Name** and **Target Folder** parameters.

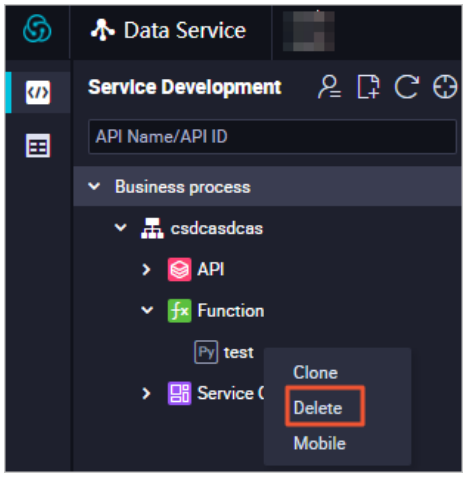


> **Note** The name of the function must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.

3. Click **OK**.

Delete a function

1. On the **Service Development** tab, right-click the name of the target function and select **Delete**.

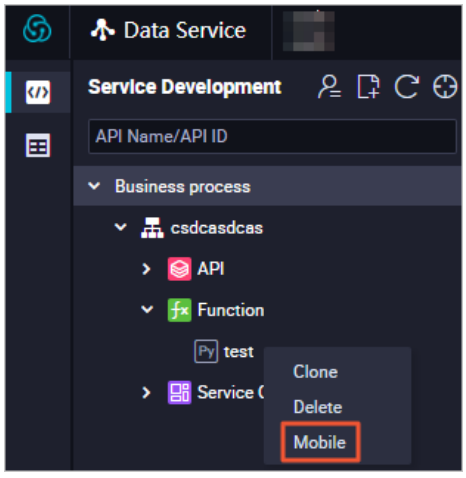


2. In the message that appears, click **OK**.

> **Note** You can delete only functions that are not referenced by APIs. You must remove the function from the filters of the APIs that reference the function before you can delete the function.

Move a function to another directory

1. On the **Service Development** tab, right-click the name of the target function and select **Mobile**.



2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.1.15.4.4. Manage workflows

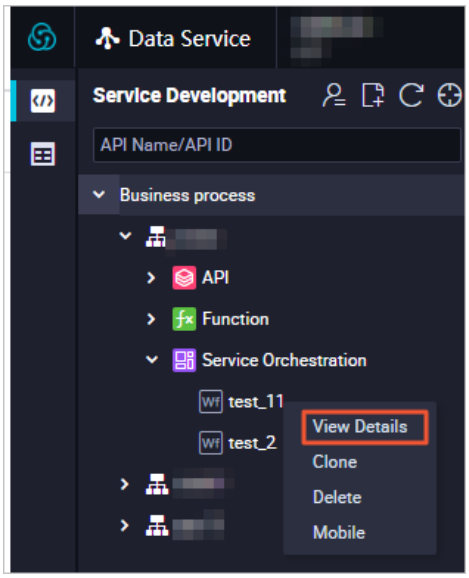
This topic describes how to view, clone, delete, and move a workflow.

Prerequisites

Workflows are created and published. For more information, see Use workflows.

View a workflow

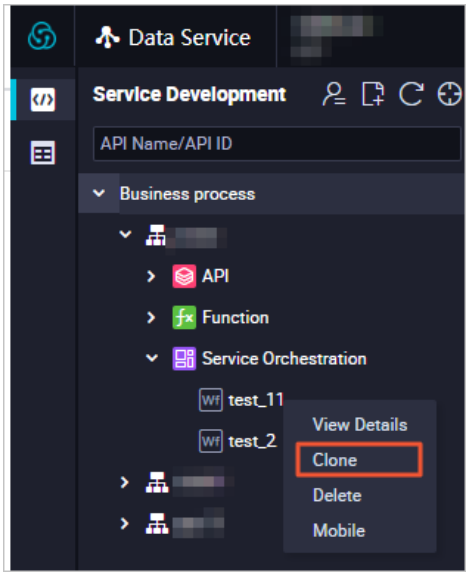
1. Log on to the DataWorks console.
2. Click ☰ in the upper-left corner and choose **All Products > Data Service**.
3. On the Service Development tab, right-click the name of the target workflow and select **View Details**.



> **Note** The View Details option appears only in the shortcut menu of a workflow that has been published. If a workflow has not been published, double-click the workflow to go to the configuration tab of the workflow. Then, click **Properties** in the right-side navigation pane to view its basic information.

Clone a workflow

1. On the **Service Development** tab, right-click the name of the target workflow and select **Clone**.



2. In the **Clone API** dialog box, set the parameters as required.

Parameter	Description
API Name	The name of the cloned workflow. It must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the cloned workflow, for example, */user*. The path can contain letters, digits, underscores (_), and hyphens (-). It must start with a forward slash (/) and can be up to 200 characters in length.
Target Folder	The directory for storing the cloned workflow.

3. Click **OK**.

Delete a workflow

You can delete only workflows that have not been published. To delete workflows that have been published, you must unpublish them first.

1. Optional. Unpublish the target workflow.

   If the workflow to be deleted is in the Unpublished state, skip this step.

   i. Go to the **Service Development** tab and click **Service Management** in the upper-right corner.

   
   ii. On the page that appears, click the **APIs of Published** tab, find the target API, and then click **Unpublish** in the Actions column.

   iii. In the **Unpublish API** message, click **OK**.

   iv. Click **Service Development** in the upper-right corner to return to the **Service Development** tab.

2. On the **Service Development** tab, right-click the name of the target workflow and select **Delete**.
3. In the **Delete API** message, click **OK**.

> **Note** Deleted workflows cannot be recovered. Use caution when you delete a workflow.

Move a workflow to another directory

You can move only workflows that have not been published. To move workflows that have been published, you must unpublish them first.

1. On the **Service Development** tab, right-click the name of the target workflow and select **Mobile**.
2. In the **Modify file path** dialog box, set the **Target Folder** parameter.
3. Click **OK**.

2.1.15.5. Create an API

In Data Service, you can quickly create APIs based on tables in relational databases or NoSQL databases using a visual wizard. It takes only a few minutes to configure a data API, and coding is not required.

You can also create APIs by specifying SQL scripts. The script mode supports advanced functions such as associative tables, complex criteria, and aggregate functions.

The differences between the wizard mode and script mode are described as follows:

Differences between the wizard mode and script mode

Category	Description	Wizard mode	Script mode
Query object	Queries a single table from one data source	Supported	Supported
	Queries associative tables from one data source	Not supported	Supported
Search condition	Searches for an exact number	Supported	Supported
	Searches for a range of numbers	Not supported	Supported
	Matches an exact string	Supported	Supported
	Performs fuzzy search for strings	Supported	Supported
	Sets required and optional parameters	Supported	Supported
Query result	Returns the field value	Supported	Supported
	Performs a mathematical calculation for field values	Not supported	Supported
	Performs an aggregate operation on field values	Not supported	Supported
	Displays results with pagination	Supported	Supported

2.1.15.5.1. Configure a data source

You can configure data sources for DataService Studio to read table schemas and process API query requests.

Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Aggregation > Data Integration**.
3. On the page that appears, click **Connection** in the left-side navigation pane. The **Data Source** page appears.

   You can configure a data source on this page. The following table lists the supported data sources.

Data source	Generate an API in wizard mode	Generate an API in script mode
PolarDB-X	Supported	Supported
MySQL	Supported	Supported
PostgreSQL	Supported	Supported
SQL Server	Supported	Supported

Data source	Generate an API in wizard mode	Generate an API in script mode
Oracle	Supported	Supported
AnalyticDB for MySQL 2.0	Supported	Supported
AnalyticDB for PostgreSQL	Supported	Supported
Tablestore	Supported	Not supported
MongoDB	Supported	Not supported
Hologres	Supported	Supported

> **Note** DataService Studio cannot directly read data from MaxCompute. You can add a Hologres data source and use the accelerated query feature of Hologres to allow DataService Studio to query data in MaxCompute.
>
> Hologres is compatible with PostgreSQL. PostgreSQL does not support the DATETIME data type. If your MaxCompute project contains data of the DATETIME type, Hologres converts the data from the DATETIME type to the TIMESTAMP type that PostgreSQL supports for DataService Studio to query.

2.1.15.5.2. Create an API in the codeless UI

DataWorks allows you to create APIs by setting parameters in the codeless UI without the need to write code. This topic describes how to create an API in the codeless UI.

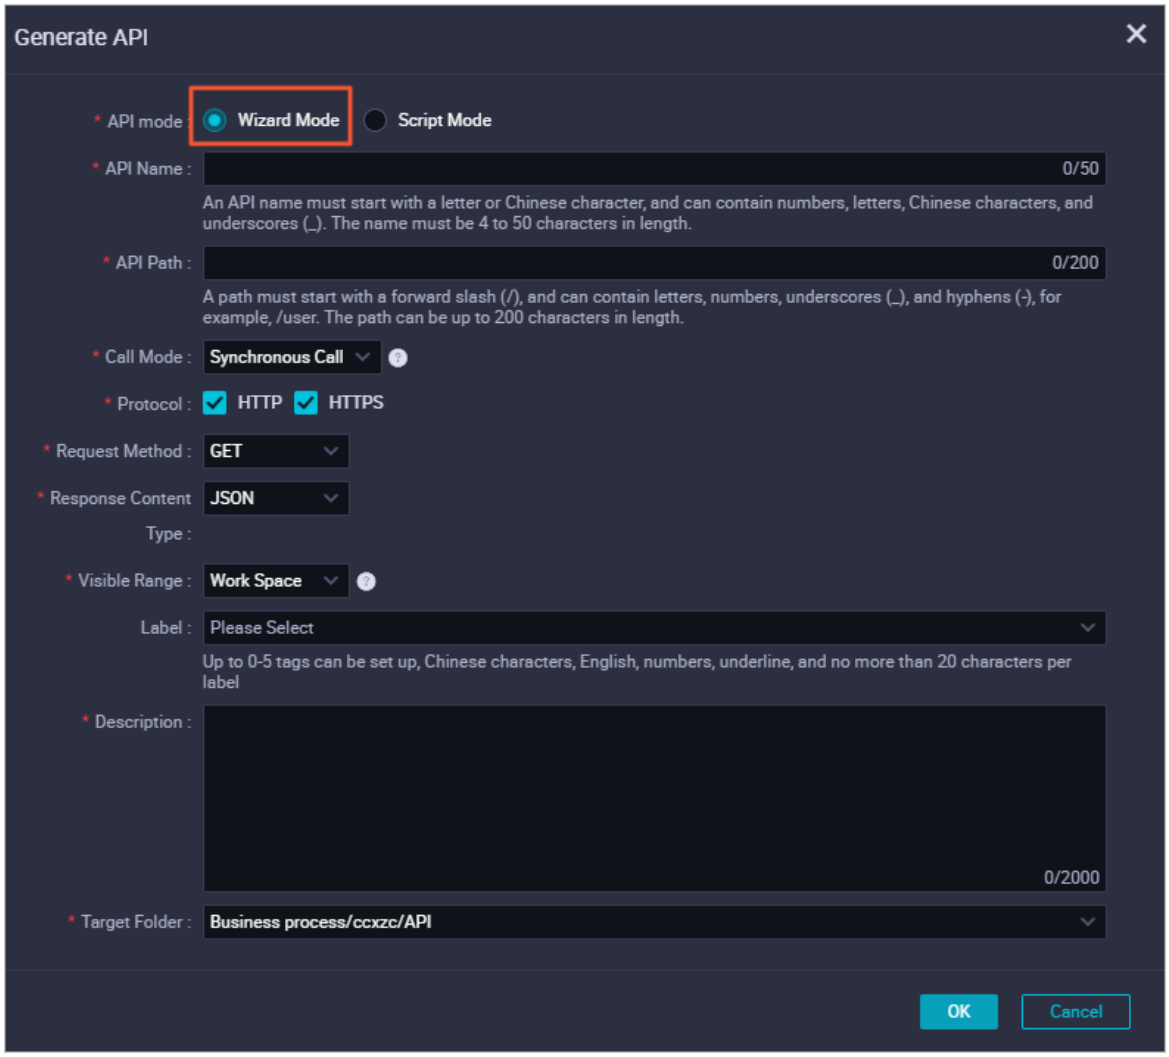
Prerequisites

Connections are configured on the **Data Source** page. For more information, see Configure data sources.

Create an API

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over and choose **API > Generate API**.

   You can also click a business process, right-click **API**, and then choose **New > Generate API**.
4. In the **Generate API** dialog box, set the parameters as required.



Parameter	Description
API mode	The mode for creating the API. Valid values: **Wizard Mode** and **Script Mode**. In this example, select **Wizard Mode**.
API Name	The name of the API. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the API, for example, */user*.
Call Mode	The mode for calling the API. Valid values: **Synchronous Call** and **Asynchronous Call**. ◦ If you set this parameter to **Synchronous Mode**, the API returns results immediately after it is called. The synchronous mode is most commonly used. ◦ If you set this parameter to **Asynchronous Mode**, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: **HTTP** and **HTTPS**.
Request Method	The request method used by the API. Valid values: **GET** and **POST**.

Parameter	Description
Response Content Type	The return type of the API. Set the value to **JSON**.
Visible Range	The visibility of the API. Valid values: ○ **Work Space**: The API is visible to all members in the current workspace. ○ **Private**: The API is visible only to its owner and permissions on the API cannot be granted to other users. **Note** If you set the Visible Range parameter to Private, the API is visible only to you in the directory tree. It is hidden to other members of the workspace.
Label	The tag of the API. Select one or more tags from the drop-down list. For more information, see Manage tags. **Note** You can set at most five tags for an API.
Description	The description of the API, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the API.

5. Click **OK**.

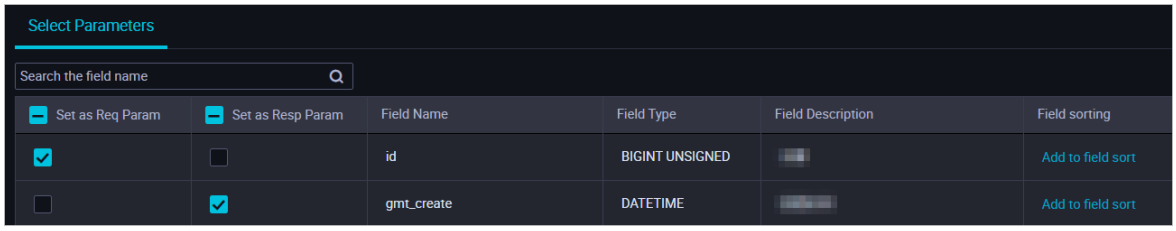
Configure the API

1. Double-click the API in the directory tree. On the configuration tab that appears, set the **Datasource Type**, **Datasource Name**, and **Table Name** parameters in the **Select Table** section.

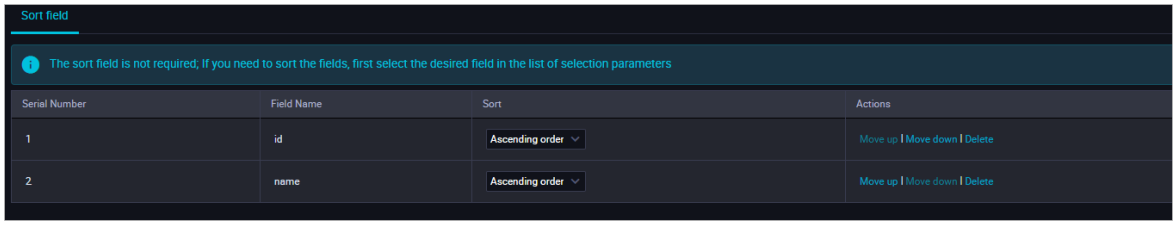
   Note
   - Before you select a table for an API, you must configure a connection in Data Integration. You can enter a table name in the Table Name field to search for the desired table.
   - After you create an API, the table configuration tab automatically appears for you to select a table for the API.

2. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.
3. In the **Select Parameters** section, set the request and response parameters for the API.

   After you select a table in the Select Table section, all fields in the table appear in the **Select Parameters** section. Select the required fields and select the check boxes in the **Set as Req Param** and **Set as Resp Param** columns as required.

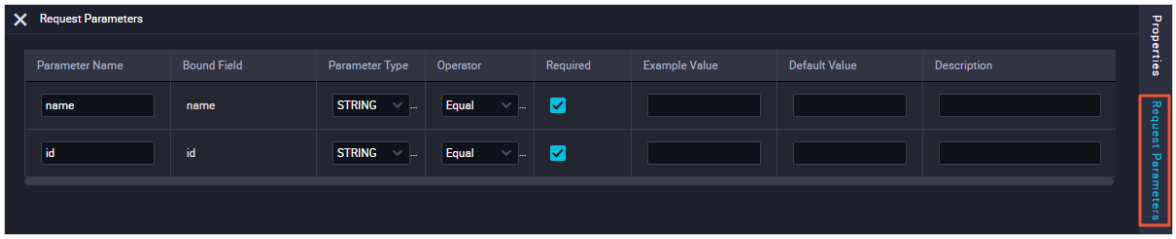


To sort the data returned by the API based on a field, click **Add to field sort** in the Actions column of the field to add it to the **Sort field** section.



The sorting feature allows you to specify the fields based on which the parameters returned by the API are sorted. A field with a smaller sequence number in the Sort field section has a higher priority in sorting. You can click **Move up** or **Move down** to adjust the sequence of a field. You can specify the sorting mode for each field by selecting **Ascending order** or **Descending order** in the Sort column.

4. In the right-side navigation pane, click **Request Parameters**. In the Request Parameters pane, set the parameters as required.



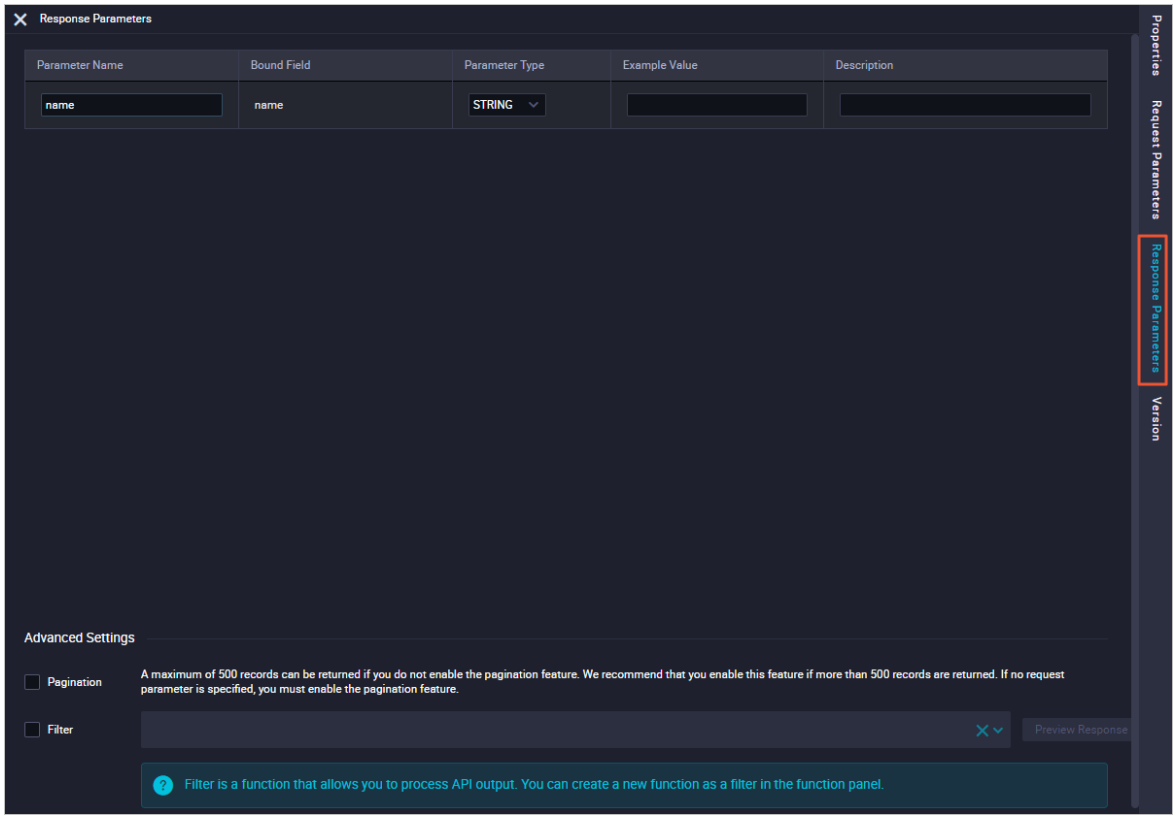
Parameter	Description
Parameter Name	The name of the request parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Bound Field	The field to be bound to the request parameter. You cannot change the value.
Parameter Type	The type of the request parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Operator	The operator that is used to associate or compare the value of the request parameter with the specified value. You can select one of the following operators: ○ **Equal**: The value of the request parameter is equal to the specified value. ○ **LIKE**: The value of the request parameter matches the specified pattern. ○ **IN**: The value of the request parameter is in the specified range. ○ **NOT IN**: The value of the request parameter is out of the specified range. ○ **NOT LIKE**: The value of the request parameter does not match the specified pattern. ○ **! =**: The value of the request parameter is not equal to the specified value. ○ **>**: The value of the request parameter is greater than the specified value. ○ **<**: The value of the request parameter is less than the specified value. ○ **>=**: The value of the request parameter is greater than or equal to the specified value. ○ **<=**: The value of the request parameter is less than or equal to the specified value.
Required	Specifies whether the request parameter is required.

Parameter	Description
Example Value	The sample value of the request parameter.
Default Value	The default value of the request parameter.
Description	The description of the request parameter.

To preprocess the request parameters of the API, select **Use prefilter** in the **Advanced Settings** section. For more information, see Use prefilters.

> **Note**
>
> - To enhance the matching efficiency, set an indexed field as a request parameter.
> - To make it easier for API callers to know the details about the API, we recommend that you specify information such as the sample value, default value, and description for each parameter of the API.

5. In the right-side navigation pane, click **Response Parameters**. In the Response Parameters pane, set the parameters as required.



Parameter	Description
Parameter Name	The name of the response parameter. The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and can be up to 64 characters in length.
Bound Field	The field to be bound to the response parameter. You cannot change the value.

Parameter	Description
Parameter Type	The type of the response parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Example Value	The sample value of the response parameter.
Description	The description of the response parameter.

You can select **Pagination** and **Filter** in the **Advanced Settings** section.

Select Pagination based on your needs.

- If you do not select **Pagination**, the API returns a maximum of 2,000 records by default.
- If the API may return more than 2,000 records, we recommend that you select **Pagination**.

The following common parameters are available when Pagination is selected:

- Common request parameters
  - pageNum: the number of the page to return.
  - pageSize: the number of entries to return on each page.
- Common response parameters
  - pageNum: the page number of the returned page.
  - pageSize: the number of entries returned per page.
  - totalNum: the total number of returned entries.

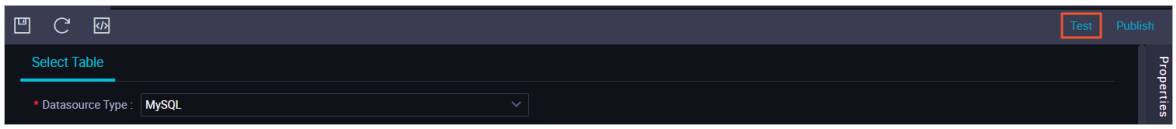
If you need to process the query results returned by the API, select **Filter**.

> **Note**
> - Field values are returned in the response as they are in the table.
> - Request parameters are optional for an API. If you do not specify any request parameters for an API, you must select **Pagination**.

6. Click Save icon in the toolbar.

Test the API

1. After you save the settings of the API, click **Test** in the upper-right corner.



2. In the **Test APIs** dialog box, click **Test** to send an API request.

   The request and response details appear on the right. If the API fails the test, check the error message, modify the API settings accordingly, and test the API again.

   You can select **Save the correct response example automatically** as required.

> **Note**
>
> - The system automatically generates sample failure responses and error codes when it tests an API. However, the system does not automatically generate sample success responses.
>
> To allow the system to save the success test result as a sample success response, you must select **Save the correct response example automatically** before you perform the test. If the response contains sensitive data that must be de-identified, you can manually edit the response.
> - The sample success response is an important reference for API callers, and therefore must be configured.
> - The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

3. After the API is tested, close the **Test APIs** dialog box and click **Publish** in the upper-right corner of the configuration tab.

Switch from the codeless UI to the code editor

On the configuration tab of an API, you can switch from the codeless UI to the code editor.

1. Go to the **Service Development** tab and double-click the target API. The configuration tab of the API appears.
2. Click in the toolbar.
3. In the message that appears, click **OK**. Then, you can view the SQL statements of the API in the **Edit query SQL** section.

> **Notice**
>
> - DataService Studio allows you to switch only from the codeless UI to the code editor.
> - After you switch from the codeless UI to the code editor, you cannot switch back to the codeless UI.

2.1.15.5.3. Create an API in the code editor

To meet the requirements of advanced data queries, DataService Studio allows you to create an API by writing an SQL script in the code editor. DataService Studio supports table join queries, complex queries, and aggregate functions. This topic describes how to create an API in the code editor.

Prerequisites

Data sources are configured on the **Data Source** page in **Workspace Management**. For more information about how to configure a data source, see Configure a data source.

Create an API

1. Log on to the DataWorks console.
2. On the DataStudio page, click the  icon in the upper-left corner and choose **All Products > Data Development > Data Service**.
3. On the **Service Development** page, move the pointer over the  icon and choose **API > Generate API**.

   You can also select a required business process, right-click **API**, and then choose **New > Generate API**.
4. In the **Generate API** dialog box, configure the parameters as required.

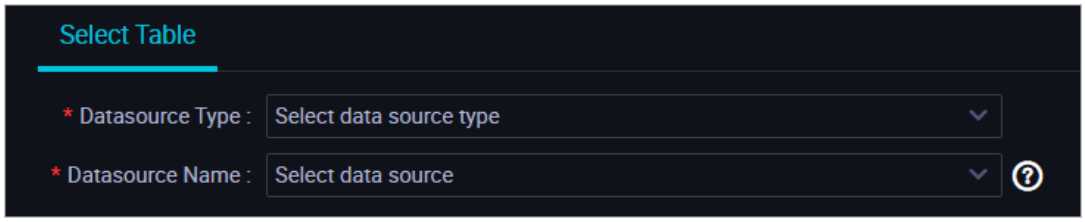
Parameter	Description
API mode	The mode used to create an API. Valid values: **Wizard Mode** and **Script Mode**. In this example, select **Script Mode**.
SQL Mode	The SQL mode. Valid values: **Basic SQL** and **Advanced SQL**. ○ **Basic SQL**: Use basic SQL statements to implement the query logic. This mode provides the SQL capability the same as that in earlier versions. ○ **Advanced SQL**: Use SQL statements with MyBatis tags to implement the query logic. This mode supports the following tag types: if, choose, when, otherwise, trim, foreach, and where.
API Name	The name of the API. The name must be 4 to 50 characters in length, and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path in which the API is stored, such as */user*.
Call Mode	The mode used to call the API. Valid values: **Synchronous Call** and **Asynchronous Call**. ○ If you set this parameter to **Synchronous Call**, the API returns results immediately after it is called. The synchronous mode is most commonly used. ○ If you set this parameter to **Asynchronous Call**, the API returns the request ID immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol. Valid values: **HTTP** and **HTTPS**.
Request Method	The request method. Valid values: **GET** and **POST**.
Response Content Type	The format of the data returned by the API. Set the value to **JSON**.
Visible Range	The range of users to whom the API is visible. Valid values: ○ **Work Space**: The API is visible to all members in the current workspace. ○ **Private**: The API is visible only to its owner and permissions on the API cannot be granted to other members. **Note** If you set this parameter to Private, other members in the workspace cannot view the API in the API list.
Label	The tag of the API. Select one or more tags from the drop-down list. For more information about tags, see Manage tags. **Note** You can set a maximum of five tags for an API.
Description	The description of the API, which cannot exceed 2,000 characters in length.
Target Folder	The folder that stores the API.

5. Click **OK**.

Configure the API

1. Double-click the API in the API list. On the tab that appears, specify **Datasource Type** and **Datasource**

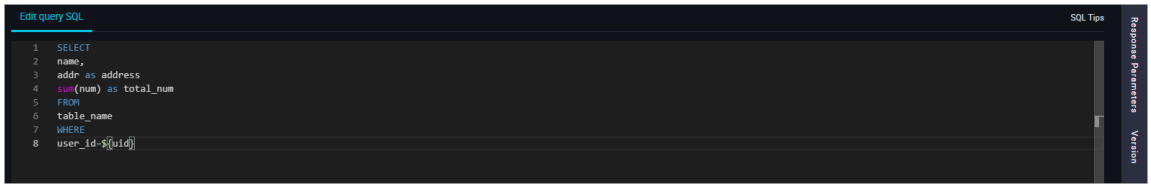
Name in the **Select Table** section.



> **Note** A data source must be selected first, and only table join queries in the same data source are supported.

2. In the **Environment Configuration** section, specify **Memory** and **Function Timeout**.

3. In the **Edit query SQL** section, enter an SQL statement for querying data.
   - If you set the SQL Mode parameter to **Basic SQL**, you can enter only a basic SQL statement.



> **Note** The SELECT statement specifies the parameters that the API returns. The WHERE clause specifies the request parameters of the API. You must use ${} to interpolate a request parameter.

Follow these rules when you enter an SQL statement:

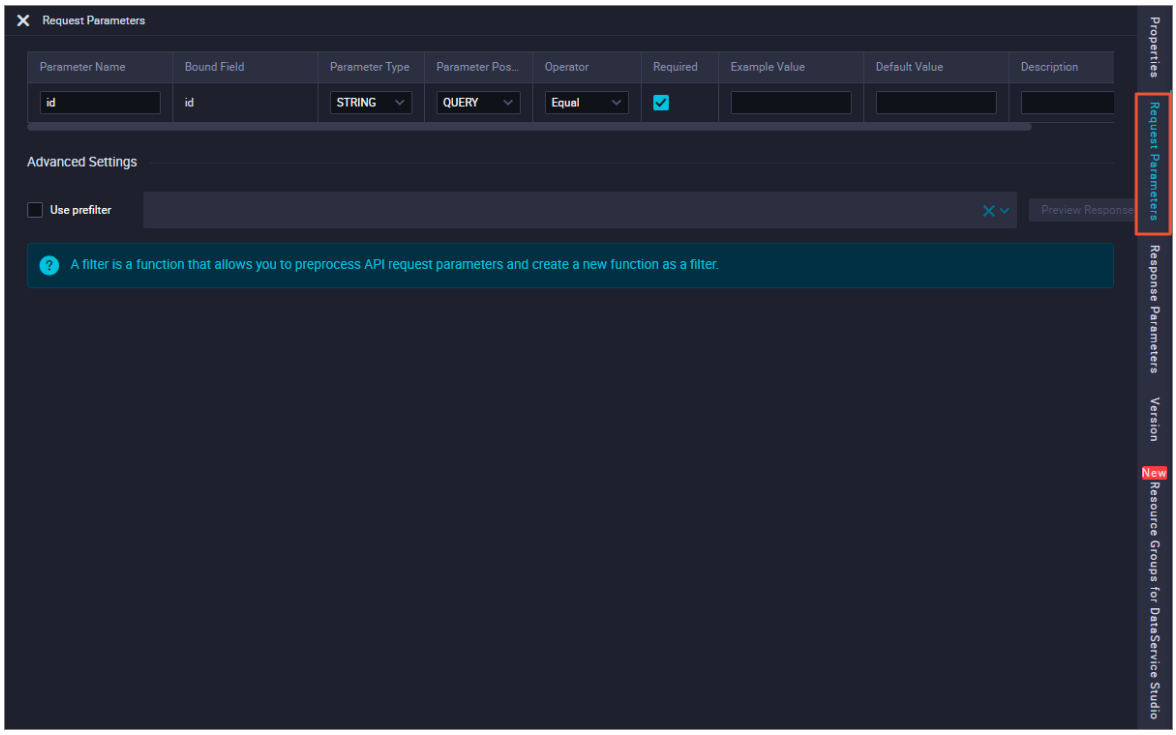
- Single-table queries, table join queries, and nested queries in the same data source are supported.
- Only a SELECT statement is supported. You cannot add comments before the SELECT statement. Other statements such as INSERT, UPDATE, and DELETE are not supported.
- `SELECT *` is not supported. You must specify the columns to be queried.
- If the name of a column to be queried is prefixed with a table name (example: t.name) or you use an aggregate function, such as min, max, sum, or count in the column name, you must create an alias for the corresponding response parameter. Examples: t.name as name and sum(num) as total_num.
- The ${param} variable in an SQL statement is regarded as a request parameter and is replaced with an actual value. The variable cannot be replaced with a column name.
- ${param} cannot be enclosed in single quotation marks (' '). For example, `'${id}'` and `'abc${xyz}123'` are not allowed. If necessary, you can use `concat('abc', ${xyz}, '123')` instead.
- ${param} is not allowed in comments. For example, --${id} is not allowed.
- If a request parameter is set as optional and is not specified when you call an API, a null value is used for this parameter in an SQL statement that is executed.

   - If you set the SQL Mode parameter to **Advanced SQL**, you can enter an SQL statement with MyBatis tags.

     This mode supports the following MyBatis tag types: if, choose, when, otherwise, trim, foreach, and where.

4. In the right-side navigation pane, click **Request Parameters**. In the Request Parameters pane, configure the parameters as required.

   If you set the SQL Mode parameter to **Advanced SQL**, you must manually add all request parameters that are specified in the SQL statement to the parameter list. This ensures that the parameters that are described in the API details are consistent with the parameters that are actually used.



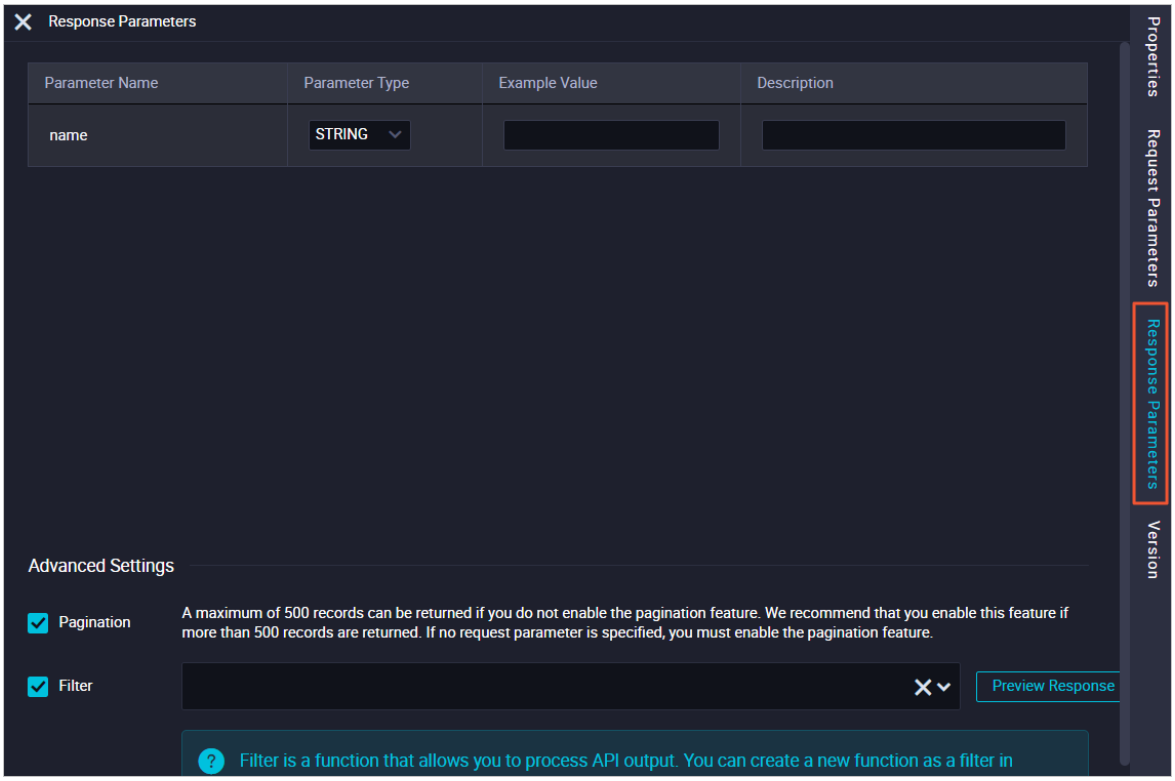
Parameter	Description
Parameter Name	The name of the request parameter. The name cannot exceed 64 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter.
Parameter Type	The type of the request parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Required	Specifies whether the request parameter is required.
Example Value	The example value of the request parameter.
Default Value	The default value of the request parameter.
Description	The description of the request parameter.

To preprocess the request parameters of the API, select **Use prefilter** in the **Advanced Settings** section. For more information, see Use prefilters.

> **Note**
>
> - To enhance the match efficiency, set an indexed field as a request parameter.
> - To make it easier for API callers to know the details about the API, we recommend that you specify information such as the example value, default value, and description for each parameter of the API.

5. In the right-side navigation pane, click **Response Parameters**. In the Response Parameters pane, configure the parameters as required.

   If you set the SQL Mode parameter to **Advanced SQL**, you must manually add all response parameters that are specified in the SQL statement to the parameter list. This ensures that the parameters that are described in the API details are consistent with the parameters that are actually used.



Parameter	Description
Parameter Name	The name of the response parameter. The name cannot exceed 64 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter.
Parameter Type	The type of the response parameter. Valid values: **STRING**, **INT**, **LONG**, **FLOAT**, **DOUBLE**, and **BOOLEAN**.
Example Value	The example value of the response parameter.
Description	The description of the response parameter.

You can select **Pagination** and **Filter** in the **Advanced Settings** section.

Select Pagination based on your needs.

- If you do not select **Pagination**, the API returns a maximum of 2,000 records.
- If the API may return more than 2,000 records, we recommend that you select **Pagination**.

The following common parameters are available when you select Pagination:

- Common request parameters
  - pageNum: the number of the page to return.
  - pageSize: the number of entries to return on each page.
- Common response parameters

- pageNum: the page number of the returned page.
- pageSize: the number of entries returned per page.
- totalNum: the total number of returned entries.

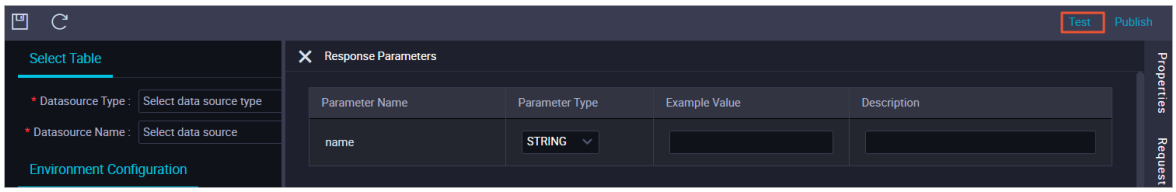
If you want to process the query results returned by the API, select **Filter**.

> **Note**
> - Field values are returned in the response as they are in the table.
> - Request parameters are optional for an API. If you do not specify request parameters for an API, you must select **Pagination**.

6. Click in the toolbar.

Test the API

1. After you save the settings of the API, click **Test** in the upper-right corner.



2. In the **Test APIs** dialog box, click **Test** to send an API request.

   The request and response details appear on the right. If the API fails to pass the test, check the error message, modify the API settings accordingly, and test the API again.

   You can select **Save the correct response example automatically** as required.

> **Note**
> - The system automatically generates sample failure responses and error codes when it tests an API. However, the system does not automatically generate sample success responses.
>
>   To allow the system to save the success test result as a sample success response, you must select **Save the correct response example automatically** before you perform the test. If the response contains sensitive data that must be de-identified, you can manually edit the response.
> - The sample success response must be configured because it is an important reference for API callers.
> - The API call latency is the latency of the current API request. The latency is used to evaluate the API performance. If the latency is long, consider whether to optimize the database.

3. After the API is tested, close the **Test APIs** dialog box and click **Publish** in the upper-right corner.

2.1.15.5.4. Use filters

2.1.15.5.4.1. Use prefilters

A prefilter is a function that is used to process request parameters of APIs. You can specify one or more prefilters to customize the request content for APIs. This topic describes the limits of prefilters, the built-in function template provided by the system, and how to create functions and use them as prefilters.

Context

Prefilters have the following limits:

- Only Python 3.0 functions can be used as prefilters.
- Prefilters support importing only the following modules: json, time, random, pickle, re, and math.
- The function name of a prefilter must be `def handler(event,context):` .

Function template

The system provides the following built-in function template:

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
# do not modify function name
import json
def handler(event,context):
# load str to json object
obj = json.loads(event) # Convert the string specified by the event parameter to a JSON object.
# add your code here
# end add
return obj
```

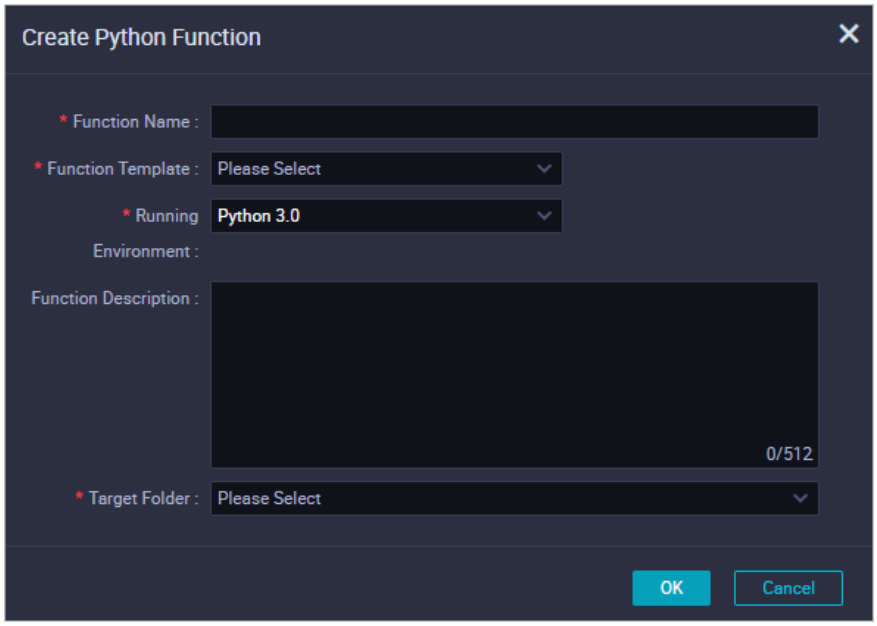
You can modify the function template to write your own function. You can modify the names of the input parameters as needed.

```
Parameter 1 [context]: the context of calling APIs. The value is of the STRING type. This parameter
is not in use and is left empty.
Parameter 2 [event]: the result data returned by APIs or the preceding filter. The value is of the S
TRING type.
```

Create a Python function

1. Log on to the DataWorks console.
2. Click in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over and choose **Function > Create Python Function**.

   You can also click a workflow, right-click **Function**, and then choose **New > Create Python Function**.
4. In the **Create Python Function** dialog box, set the parameters as required.

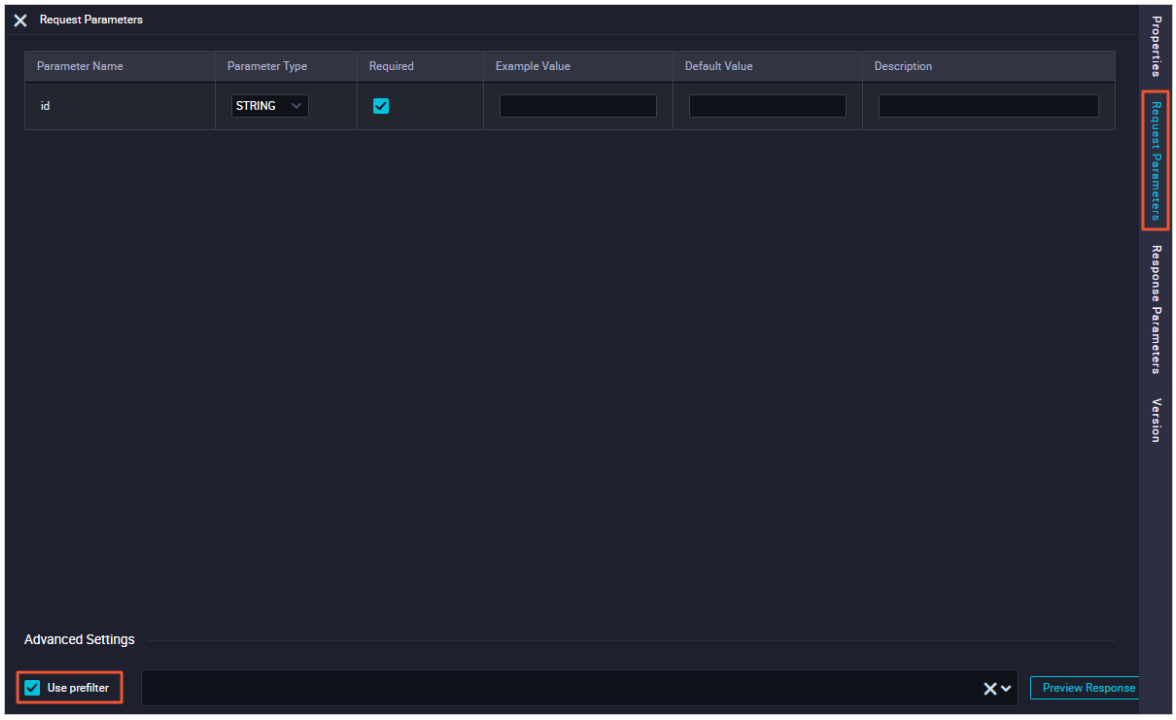


Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function.
Target Folder	The directory for storing the function.

5. Click **OK**.

Use prefilters

1. On the **Service Development** tab, double-click the target API.
2. On the configuration tab that appears, click **Request Parameters** in the right-side navigation pane.
3. In the **Request Parameters** pane, select **Use prefilter** in the **Advanced Settings** section.



4. Select functions from the **Use prefilter** drop-down list.

> **Note** A prefilter is a function that is used to process request parameters of APIs. You can create a function and use it as a prefilter.

5. Click **Preview Response** to view the processing results of the prefilters.

2.1.15.5.4.2. Use post filters

A post filter is a function that is used to process the results returned by APIs. You can specify one or more post filters to process the results returned by APIs. This topic describes the limits of post filters, the built-in function template provided by the system, and how to create functions and use them as post filters.

Context

Post filters have the following limits:

- Only Python 3.0 functions can be used as post filters.
- Post filters support importing only the following modules: json, time, random, pickle, re, and math.
- The function name of a post filter must be `def handler(event,context):` .

Function template

The system provides the following built-in function template:

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
# do not modify function name
import json
def handler(event,context):
# load str to json object
obj = json.loads(event) # Convert the string specified by the event parameter to a JSON object.
# add your code here
# end add
return obj
```

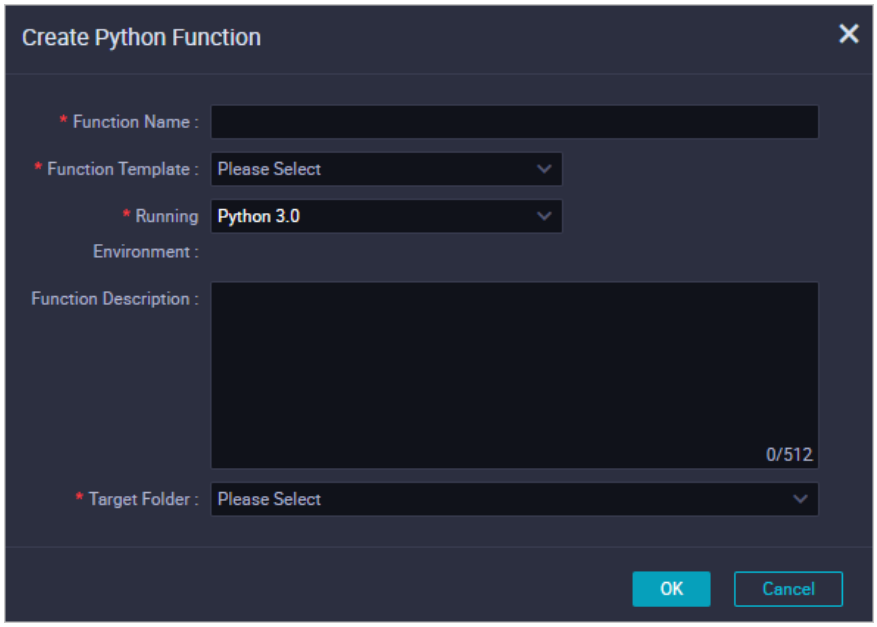
You can modify the function template to write your own function. You can modify the names of the input parameters as needed.

```
Parameter 1 [context]: the context of calling APIs. The value is of the STRING type. This parameter
is not in use and is left empty.
Parameter 2 [event]: the result data returned by APIs or the preceding filter. The value is of the S
TRING type.
```

Create a Python function

1. Log on to the DataWorks console.
2. Click ☰ in the upper-left corner and choose **All Products > Data Service**.
3. On the **Service Development** tab, move the pointer over ➕ and choose **Function > Create Python Function**.

   You can also click a workflow, right-click **Function**, and then choose **New > Create Python Function**.
4. In the **Create Python Function** dialog box, set the parameters as required.



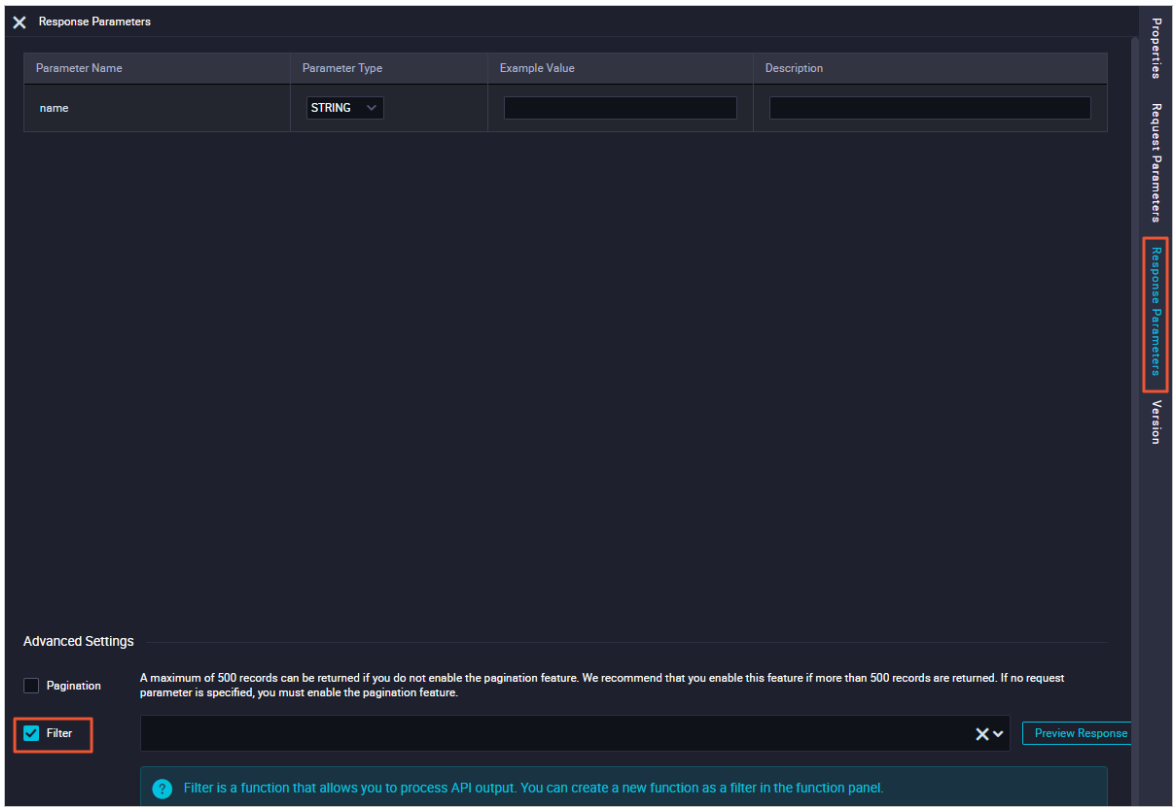
Parameter	Description

Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function.
Target Folder	The directory for storing the function.

5. Click **OK**.

Use post filters

1. On the **Service Development** tab, double-click the target API.
2. On the configuration tab that appears, click **Response Parameters** in the right-side navigation pane.
3. In the **Response Parameters** pane, select **Filter** in the **Advanced Settings** section.



4. Select functions from the **Filter** drop-down list.

> **Note** A post filter is a function that is used to process the results returned by APIs. You can create a function and use it as a post filter.

5. Click **Preview Response** to view the processing results of the post filters.

2.1.15.6. Register APIs

This topic describes how to register APIs and manage and publish them to API Gateway together with APIs created based on data tables.

Currently, DataService Studio allows you to register only RESTful APIs. Supported request methods include GET, POST, PUT, and DELETE. Supported data types include forms, JSON data, and XML data.

Create a group

1. Log on to the DataWorks console.
2. Click the DataWorks icon in the upper-left corner and choose **All Products > DataService Studio**.
3. Go to the **Service Development** page, right-click **Service List**, and then select **New API Group**.
4. In the **Create API Group** dialog box that appears, enter values for **Group Name** and **Description**.
5. Click **OK**.

Configure basic API information

1. Right-click the new group and select **Register API**.
2. In the **Create API** dialog box that appears, set each parameter.

Configuration item	Description
API Name	The name must be 4 to 50 characters in length. It must start with a letter and can contain letters, digits, and underscores (_).
API Group	An API group is a collection of APIs for a specific feature or scenario. It is also the minimum API management unit of API Gateway. To create an API group, move the pointer over the **Create** icon and select **New API Group**.
API Path	API Path is the alias of Backend Service Path. APIs with different API paths can share the same backend service path and backend service host. Parameters defined in Backend Service Path must also be defined in brackets in API Path.
Protocol	Currently, HTTP and HTTPS are supported.
Request Method	You can select GET, POST, PUT, or DELETE as the request method. The parameters to be configured vary with the request method.
Return Type	Currently, JSON and XML return types are supported.
Description	The description of the API.

3. After configuring the basic API information, click **OK** to go to the API parameter configuration page.

Configure API parameters

On the API parameter configuration page, you need to define the backend service, request parameters, response content, and error codes.

Configuration item	Description
Define the back-end Service	• **Backend Service Host**: Enter the host of the API. The host must start with http:// or https://, and cannot contain the path. • **Backend Service Path**: Enter the path of the API. Place parameter names in brackets, for example, /user/[userid]. In the next step, parameters defined in Backend Service Path are automatically added to the request parameter list. • **Backend timeout**: Set the backend timeout period.
Define Request Parameters	• **Parameter Type**: The available request parameter locations (Path, Header, Query, or Body) vary with the request method. • **Constant Parameters**: A constant parameter is fixed and is invisible to the caller. You do not have to specify the constant parameters when calling an API. Instead, the constant parameters and their values are automatically sent to the backend service. This is useful when you want to set a parameter to a fixed value and hide the parameter value from the caller. • **Request Body Definition**: This configuration item is available only when the request method is POST or PUT. You can enter the body description in Request Body Definition. It is equivalent to an example of the request body so that API callers can refer to the format of the request body. The content type of the request body can be JSON or XML. **Note** If a parameter has been defined in both the request body and the request parameter list, the parameter value in the request body takes priority.
Define Response Content	You can enter a successful response example or an error response example for API callers to refer to when writing the return parse code.
Error Codes	Enter the common errors and solutions in API calling. This enables API callers to troubleshoot and solve these errors. **Note** To ensure that the API is easily used by the callers, provide complete API parameter information if possible, especially the parameter sample values, default values, and sample responses.

Test the API

After you have configured and saved the API parameters, click **Test** in the upper-right corner to go to the API test page.

Set the parameters and click **Test** to send an API request. The request and response details are displayed on the right. If the test fails, check carefully the error message, make modifications accordingly, and test the API again.

Pay attention to the settings of the successful response example in the configuration process. When testing an API, the system automatically generates error response examples and error codes. However, successful response examples are not automatically generated. To enable the system to save the test result as the successful response example, you need to select **Save as Successful Response Example** before performing the test. If the response contains sensitive data that must be masked, you can manually edit the response.

> **Note**
>
> - The successful response example is an important reference for API callers, and therefore must be configured.
> - The Call Latency value is the latency of the current API request, which is used to evaluate the API performance. If the latency is long, consider optimizing the database.

After the API test is passed, return to the **Service Development** page, and click **Publish** to generate an API.

2.1.15.7. Test APIs

This topic describes how to test APIs.

When creating and registering an API, you can test the API. The system also provides an independent API test feature, which allows you to test APIs online.

1. Go to the **DataService Studio** page and click **Service Management** in the upper-right corner.
2. Click **Test API** in the left-side navigation pane.
3. Select the API to be tested, set the parameters, and then click **Test**.

> **Note**
>
> - The API Test page provides only online API testing. You cannot update or save the successful response example for an API on this page. To update the successful response example for an API, click the API name in the API list to enter the API edit mode. Then, update the successful response example for the API in the API testing step.
> - You must test an API before publishing it.

2.1.15.8. Publish APIs

API Gateway provides API lifecycle management services, including API publishing, management, maintenance, and monetization. It helps you easily and quickly aggregate microservices, separate the frontend from the backend, and integrate systems at low costs and low risks, making features and data available to partners and developers.

API Gateway provides permission management, traffic control, access control, and metering services. The services make it easy for you to create, monitor, and secure APIs. Therefore, we recommend that you publish the APIs that have been created and registered in DataService Studio to API Gateway. DataService Studio and API Gateway are interconnected, which allows you to publish APIs to API Gateway easily.

Publish APIs to API Gateway

Before publishing an API, you must activate API Gateway and register and test the API.

After the API passes the test, click **Publish** in the upper-right corner to publish the API to API Gateway.

The system automatically registers the API with API Gateway during the publish process. The system also creates a group in API Gateway with the same name as the API group to which the API belongs in DataService Studio and publishes the API in this group. After the API is published, you can access the API Gateway console to view API details or configure bandwidth throttling, access control, and other features.

If you generate an API to be called by your own application, you need to create an application in API Gateway, authorize the application to use the API, and enable the application to call the API by using AppKey and AppSecret. For more information, see *API Gateway documentation*. API Gateway also provides SDKs for mainstream programming languages to help you quickly integrate the API into your own application.

2.1.15.9. Call an API

This topic describes how to call an API after the API is published to API Gateway.

Prerequisites

An API is published to API Gateway. For more information, see Publish APIs.

The following conditions are met:

- The parameter definition of the API is obtained.
- The app that you use to call the API has a key pair that uniquely identifies you. The key pair consists of the AppKey and AppSecret.
- The app is authorized to call the API.

Context

API Gateway allows you to use SDKs to authorize apps to call APIs. You can authorize your own account, a user in your enterprise, or a third party to call APIs.

Procedure

1. Obtain the API documentation.

   The method of obtaining the API documentation varies based on how you obtain an API. You can use one of the following methods to obtain an API:

   - Purchase the API in Alibaba Cloud Marketplace.
   - Obtain the API authorization from the API provider.

2. Create an app in API Gateway.

   In API Gateway, apps define the identities that you use to call APIs. Each app has a key pair that consists of AppKey and AppSecret, which are equivalent to an account and its password.

3. Obtain the permissions to call the API.

   Authorization is to grant an app the permissions to call an API. Your app must be authorized before it can be used to call an API. The authorization method varies based on how you obtain an API.

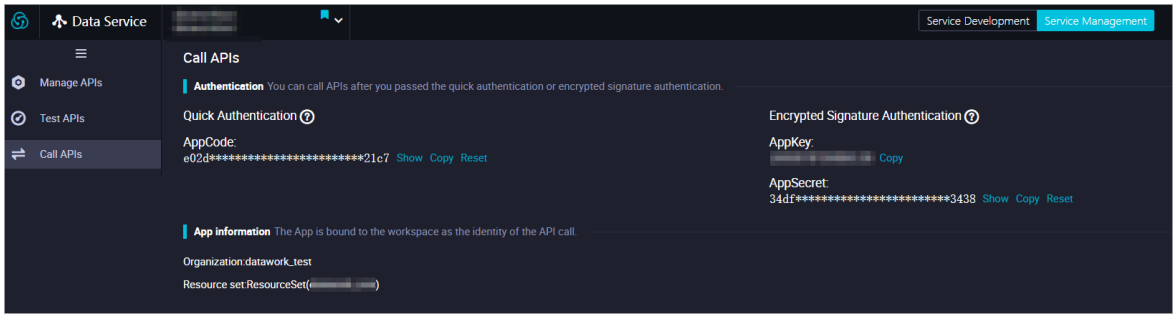
4. Call the API.

   You can send an HTTP or HTTPS request to call the API. Before you call the API, you can test the call by using the API calling examples provided in the API Gateway console. The examples are provided in multiple programming languages.

View the authentication information for calling APIs

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data Development > Data Service**.
3. On the **Service Development** page, click **Service Management** in the upper-right corner.
4. In the left-side navigation pane, click **Call APIs**.

   On the **Call APIs** page, you can view or copy the authentication information that is required to call APIs. You can also view the information about the apps that are bound to the current workspace. This helps you find the apps in the API Gateway console.



2.1.15.10. Use workflows

The workflow feature, also called service orchestration, provides a composite API service. This topic describes the benefits of workflows and how to use workflows.

In DataService Studio, a workflow is represented as a directed acyclic graph (DAG). By dragging and dropping nodes to a DAG, you can arrange APIs and functions in a serial, parallel, or branch structure based on the business logic.

When you run a workflow to call APIs, DataWorks runs the nodes in the workflow in sequence, passes parameters among the nodes, and automatically changes the status of each node. The workflow feature simplifies the process of calling multiple APIs or functions and reduces the cost of development and maintenance. This allows you to focus on business development.

Benefits

- Reduced cost of combining multiple APIs

  By dragging and dropping nodes to a DAG, you can arrange APIs and functions in a serial, parallel, or branch structure without writing code. This reduces the cost of developing APIs.

- Higher performance in calling APIs and functions

  A workflow allows you to call multiple APIs and functions in a container. Compared with writing code to call APIs and functions, the workflow feature reduces the latency of calling APIs and functions.

- Serverless architecture

  The workflow feature adopts a serverless architecture. A serverless architecture supports automatic resource scaling based on business needs. You can focus on the business logic, without worrying about the runtime environment.

Obtain values of request and response parameters

DataService Studio uses JSONPath to obtain parameter values. JSONPath is a query language that allows you to extract data from JSON files.

For example, three nodes are run in the following order: A, B, and then C. Node C needs to use the response parameters of nodes A and B.

- Response parameter of node A: {"namea":"valuea"}

  Expression for obtaining the value of the response parameter of node A: ${A.namea}

- Response parameter of node B: {"nameb":"valueb"}

  Expression for obtaining the value of the response parameter of node B: $.nameb or ${B.nameb}

The built-in start node provides request parameters for the whole workflow. Assume that a request parameter of a workflow is {"namewf":"valuewf"}. All nodes of the workflow can obtain the value of the request parameter by using the ${START.namewf} expression.

Set parameters

Request parameters:

- If you do not specify a value for a request parameter of a node, DataService Studio obtains the value of the same parameter in the first layer of the JSON string returned by the parent node, and assigns the value to the request parameter. If no value is specified for a request parameter of the first node, DataService Studio obtains the value of the same parameter in the request parameters of the workflow.
- If you specify a value for a request parameter, DataService Studio uses the value that you set.
- If you need to use the value of the specified parameter returned by a specified ancestor node, obtain the value by using a JSONPath expression.

Common JSONPath expressions for obtaining parameter values:

- $.: obtains response parameters of the parent node.
- $.param: obtains the value of the param parameter returned by the parent node. To allow you to obtain response parameters of any ancestor nodes, DataService Studio enhances JSONPath expressions.
- ${NODEID1}: obtains response parameters of the node whose ID is NODEID1.
- ${START}: obtains request parameters of the workflow, which are response parameters of the start node.
- ${NODEID1.param}: obtains the value of the param parameter returned by the node whose ID is NODEID1.

JSONPath expressions for setting response parameters of a node:

- $.: sets response parameters of the current node.
- $.param: sets the param parameter to be returned by the current node.
- ${NODEID1.param}: sets the param parameter returned by the node whose ID is NODEID1.

Example

Add a connection before you create and use a workflow. In this example, a MySQL connection is used.

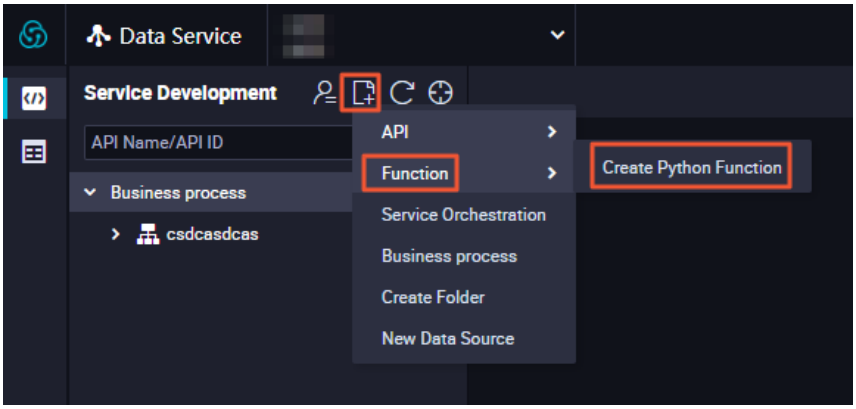
1. Register an API.

   In this example, create an API by using the registration method. For more information, see Register an API.

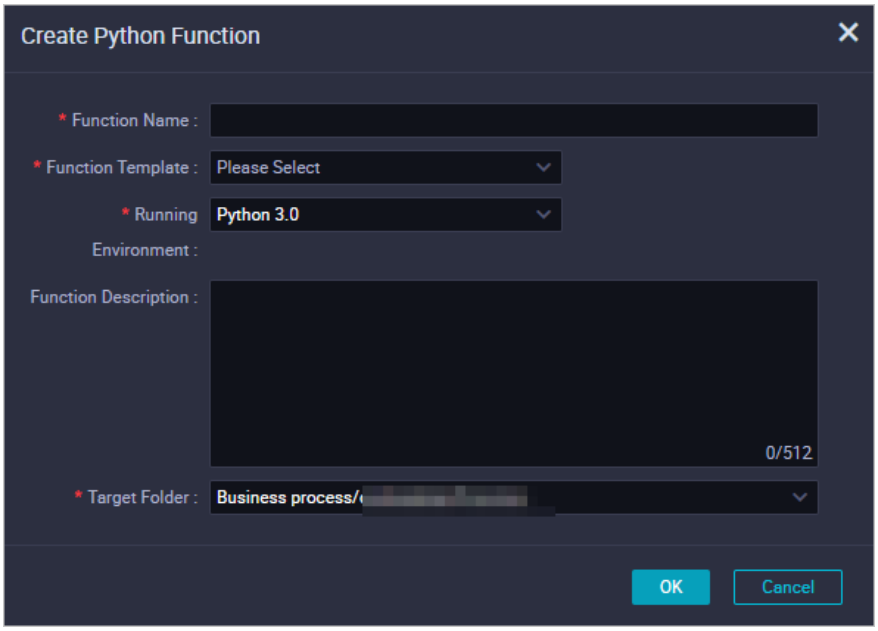
2. Register a function. For more information, see Create a function.

   In this example, create a Python function as a branch node to process the result data of the parent node.

   i. Go to the **Service Development** tab, move the pointer over and choose **Function > Create Python Function**.



ii. In the **Create Python Function** dialog box, set the parameters as required.



Parameter	Description
Function Name	The name of the function to create, which can be up to 256 characters in length.
Function Template	The template used to create the function. Set the value to Python3 Standard v1.
Running Environment	The runtime environment of the function. Set the value to Python 3.0.
Function Description	The description of the function. The description can be up to 512 characters in length.
Target Folder	The directory for storing the function.

iii. Click **OK**.

iv. On the configuration tab of the function, configure the function.

a. In the **Edit Code** section, enter the function code.

```
# -*- coding: utf-8 -*-
# event (str) : in filter it is the API result, in other cases, it is your param
# context : some environment information, temporarily useless
# import module limit: json,time,random,pickle,re,math
import json
def handler(event,context):
    # load str to json object
    obj = json.loads(event)
    # add your code here
    # end add
    return obj
```

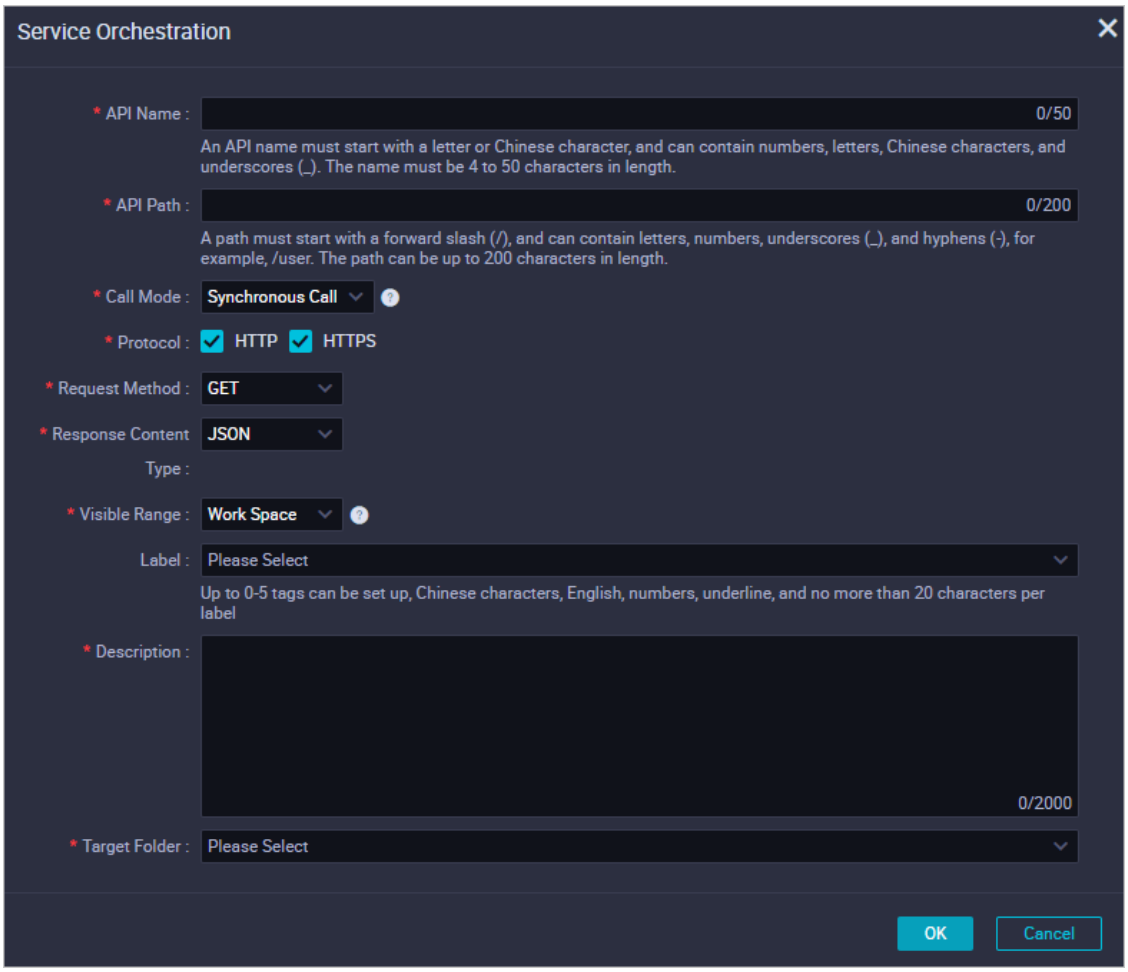
b. In the **Environment Configuration** section, set the **Memory** and **Function Timeout** parameters.

v. Click Save icon in the toolbar.

3. Create a workflow.

i. On the **Service Development** tab, move the pointer over and select **Service Orchestration**.

ii. In the **Service Orchestration** dialog box, set the parameters as required.



Parameter	Description
API Name	The name of the workflow. The name must be 4 to 50 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.
API Path	The path for storing the workflow, for example, */user*.
Call Mode	The mode for calling the API to be arranged in the workflow. Valid values: **Synchronous Call** and **Asynchronous Call**. ■ If you set this parameter to **Synchronous Mode**, the API returns results immediately after it is called. The synchronous mode is most commonly used. ■ If you set this parameter to **Asynchronous Mode**, the API returns the RequestID parameter immediately after it is called. The API caller can then obtain the call result from a message queue based on the request ID.
Protocol	The protocol used by the API. Valid values: **HTTP** and **HTTPS**.
Request Method	The request method used by the API. Valid values: **GET** and **POST**.
Response Content Type	The return type of the API. Set the value to **JSON**.

Parameter	Description
Visible Range	The visibility of the workflow. Valid values: ■ **Work Space**: The workflow is visible to all members in the current workspace. ■ **Private**: The workflow is visible only to its owner and permissions on the workflow cannot be granted to other users. **Note** If you set the Visible Range parameter to Private, the workflow is visible only to you in the directory tree. It is hidden to other members of the workspace.
Label	The tag of the workflow. Select one or more tags from the drop-down list. For more information, see Manage tags. **Note** You can set at most five tags for a workflow.
Description	The description of the workflow, which can be up to 2,000 characters in length.
Target Folder	The directory for storing the workflow.

iii. Click **OK**.

4. Configure the workflow.

i. On the configuration tab of the workflow, drag and drop nodes and connect them as required.

ii. Double-click the **API1** node to edit the node. Select the API that you registered earlier as the API to be called in the node.

Select **set output results** and enter `{"user_id":"$.data[0].id"}`.

Use JSONPath expressions to set response parameters. The syntax for obtaining the value of a parameter is ${NodeA.namea}, which is the same as that for setting request parameters. `{" user_id":"$.data[0].id"}` assigns the value of the id parameter of the first element in the data array to the user_id parameter. Then, the API1 node returns {"user_id":"value"} in JSON format.

iii. Double-click the **PYTHON1** node to edit the node. Select the function that you created earlier as the function to be called in the node.

iv. Double-click the **SWITCH2** node to edit the node. In the right-side pane that appears, click **Set branch conditions**. In the Set branch conditions dialog box, enter conditional expressions based on the response parameter of the parent node. For example, you can enter expressions in the `${Node ID. Parameter}>1` or `$. Parameter>1` format. Conditional expressions support the following operators: ==, ! =, >=, >, <=, <, &&, !, (), +, -, *, /, and %.

In this example, the user_id parameter is the response parameter of the API1 node and is used as the request parameter of the SWITCH2 node.

```
Branch node 1: $.user_id != 1, indicating that the branch node 1 is run if the value of the user_id parameter is not 1.
Branch node 2: $.user_id == 1, indicating that the branch node 2 is run if the value of the user_id parameter is 1.
```

v. Double-click the end node and then click the **Response Parameters** tab on the right side to set response parameters.

5. Click **Test** in the upper-right corner.

6. In the **Test APIs** dialog box, set the parameters as required and click **OK**.

   You can view the test result after the workflow is tested.

2.1.15.11. Manage versions

This topic describes how to manage versions of APIs, workflows, and functions in Data Service.

You can view and compare historical versions of APIs, workflows, and functions. Data Service generates a version record each time an API, a workflow, or a function is published.

View historical versions

1. Log on to the DataWorks console. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > DataService Studio**.
2. On the **Service Development** page that appears, double-click the name of the target API in the API list.

   > **Note** You can also click Function or Table in the left-side navigation pane and double-click the name of a workflow or function to manage its versions.

3. In the right-side navigation pane, click **Version**. In the **Version** dialog box that appears, view historical versions of the API.

Parameter	Description
API ID	The ID of the API. Each API ID is unique.
Version	The version of the API. A version is generated each time the API is published. V1 indicates version 1 and V2 indicates version 2. The version number is incremented by 1 each time.
The Author	The user who published the version.
Submitted Date	The time when the version was published. The time is accurate to second.
Status	The status of the version. Value values: ○ **Release**: indicates that the version of the API is the latest version. ○ **Off-Line**: indicates that the version of the API is a historical version.
Actions	The operations that you can perform on the version. The **Actions** column is only available for API and workflow versions. You can click **API Details** of a version to go to the details page of the version. The **Actions** column is unavailable for function versions.

Compare historical versions

In the **Version** dialog box, select two versions to compare, and click **Contrast**. In the **History Version Contrast** dialog box that appears, compare the code and parameters of the two versions.

2.1.15.12. FAQ

This topic provides answers to commonly asked questions about DataService Studio.

- Q: Do I need to activate the API Gateway service?

  A: API Gateway provides you with high-performance and highly available API hosting services. If you need to make your APIs available to others, activate the API Gateway service first.

- Q: Where can I add and change connections?

  A: After you log on to the DataWorks console, click the DataWorks icon in the upper-left corner and choose **All Products > Data Integration** to go to the **Data Integration** page. In the left-side navigation pane, choose **Sync Resources > Connections**. On the page that appears, perform the relevant configuration. DataService Studio automatically reads data from the connections that you have configured.

- Q: What is the role of an API group in DataService Studio? What is the relationship between an API group in DataService Studio and an API group in API Gateway?

  A: An API group is a set of APIs specific to a feature or scenario. It is the smallest organization unit in DataService Studio, which is similar to an API group in API Gateway. An API group in DataService Studio is equivalent to an API group in API Gateway. After you publish an API from DataService Studio to API Gateway, API Gateway automatically creates an API group with the same name.

- Q: How can I configure an API group appropriately?

  A: Typically, an API group includes APIs that provide similar features or resolve a specific issue. For example, a weather API group can include APIs that are used to check the weather by city and by longitude and latitude.

- Q: How many API groups can I create?

  A: An Alibaba Cloud account can create up to 100 API groups.

- Q: When do I need to enable the pagination feature for an API call so that its return results can be displayed on multiple pages?

  A: By default, an API call returns a maximum of 2,000 records. If an API call may return more than 2,000 records, enable the pagination feature. If you do not specify any request parameters, the API call usually returns a large number of records and the pagination feature is automatically enabled.

- Q: Do APIs created by DataService Studio support POST requests?

  A: APIs created by DataService Studio support GET and POST requests.

- Q: Do APIs created by DataService Studio support the HTTPS protocol?

  A: APIs created by DataService Studio support both HTTP and HTTPS protocols.

2.1.15.13. Appendix: DataService Studio error codes

After DataService Studio receives an API request, it returns a response that contains an error code. You can locate and troubleshoot issues based on the error code. This topic describes common error codes that are returned by DataService Studio.

Error code	Error message	Description
0	success	The error message returned because the data query has succeeded.
1108110583	query timeout	The error message returned because the query has timed out. The timeout occurs because the total runtime of the API in DataService Studio and the database exceeds the timeout period that is configured for the API.
1108110519	param miss	The error message returned because specific required request parameters are not specified.

Error code	Error message	Description
1108110584	api context failed	The error message returned because the system has failed to obtain context information based on the third party. The information includes the connection information of the data source, AccessKey information of the data source, and tenant information.
1108110622	datasource query error	The error message returned because the system has failed to query the data source. The failure may occur because the SQL syntax is invalid, the data source does not respond within the configured timeout period (10s), or the number of connections to the data source exceeds the upper limit.
1108110703	database connection error	The error message returned because the data source has failed to be connected.
Other error codes	Other error messages	If the response contains an error code other than the preceding error codes, you can consult technical support personnel.

2.1.16. Stream Studio

2.1.16.1. Overview

Stream Studio is a one-stop platform provided by DataWorks for developing real-time computing nodes. This topic describes the features and development process of Stream Studio.

Built on Alibaba Cloud Realtime Compute, which is based on Apache Flink, Stream Studio allows you to develop real-time computing nodes in directed acyclic graph (DAG) mode or SQL mode. You can switch between the two modes when you develop nodes.

Stream Studio has the following features:

- Allows you to develop nodes in DAG mode. You can drag components to configure real-time computing nodes.
- Allows you to develop nodes in SQL mode. You can edit Flink SQL code to configure real-time computing nodes.
- Allows you to switch between the DAG mode and the SQL mode. You can check SQL operators with ease.
- Allows you use Function Studio to create and deploy user-defined functions (UDFs) online in exclusive mode.
- Supports smart diagnosis for real-time computing nodes to facilitate online troubleshooting.

Development and maintenance of real-time computing nodes

To develop and manage a real-time computing node, perform the following steps:

1. Bind a Realtime Compute project

   Before you can properly use Stream Studio, you must activate Realtime Compute, create a project, and then bind the project to a DataWorks workspace.

2. Collect data

   Data must be collected before it can be processed in DataWorks. Realtime Compute is integrated with various streaming storage systems that can store source tables. This frees you from manual data collection.

3. Create a real-time computing node

   After data is collected, you can create a real-time computing node.

4. Develop the real-time computing node

   After you create a real-time computing node, you can develop the node for data analytics in Stream Studio.

5. Manage the real-time computing node

   After you develop and deploy the real-time computing node, you can click **OAM** on the **Stream Studio** page to manage the node. The node O&M feature of Stream Studio is provided by Realtime Compute.

2.1.16.2. Bind a Realtime Compute project

This topic describes how to bind a Realtime Compute project to a DataWorks workspace on the Project Management page.

1. Log on to the DataWorks console.
2. On the DataStudio page, click in the upper-right corner.
3. On the **Project Management** page, click the **Real-time computing** tab in the **Computing Engine information** section.
4. Click **Add engine service**.
5. In the **New Blink engine** dialog box, set the **Enter the Realtime Compute project name to add** parameter.
6. Click **Binding**.

2.1.16.3. Create a real-time computing node

This topic describes how to create a real-time computing node and develop data in Stream Studio.

Prerequisites

A workflow is created. You can create real-time computing nodes and develop data under an existing workflow.

Procedure

1. Right-click the workflow that you have created and select **Create task**.
2. In the **Create Node** dialog box that appears, set the parameters and click **Submit**.
3. Develop data in directed acyclic graph (DAG) mode on the **Components** page.

   The Components page consists of the following four sections:

   - Component list section: In this section, you can view the list of available components. You can click **Components** in the left-side navigation pane to go to the Components page and view the list.
   - DAG section: In this section, you can drag and drop components to the DAG and connect them. To configure the dependency between two components, click and hold the highlighted dot at the bottom of a component and move the pointer to link this component with a descendant component. A DAG corresponds to a real-time computing node.
   - Parameter configuration section: Double-click a component in the DAG. Then, you can set the related parameters in this section.
   - Toolbar section: In this section, you can click the icons to perform the save, submit, steal lock, pre-compile, test, stop, reload, and format operations respectively.

   When you configure the DAG, you can right-click a component and select an operation from the menu that appears to perform the operation on the selected component. Available operations include **Rename**, **View schema**, **Delete node**, **View error message**, **New component group**, and **Copy**.

2.1.16.4. Get started with Stream Studio

This topic uses an example to describe how to use Stream Studio to develop and manage a real-time computing node. Stream Studio allows you to create, configure, publish, run, stop, and unpublish a real-time computing node.

Prerequisites

A Realtime Compute project is bound to the current DataWorks workspace.

Context

- Data store: a Datahub table with a created topic, which contains the `m_name, id, m_type, and tag` fields.

  > **Note** The Datahub topic must be created in advance.

- Data processing: splits the tag field by using the `semicolon (;)` as the delimiter to the color, mode, and weight fields.
- Output data: writes the `id, m_type, and weight` fields to a Log Service table.

  > **Note** The Log Service project and Logstore must be created in advance.

Procedure

1. Log on to the DataWorks console. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Stream Studio**.
2. Create a workflow.
   i. On the Stream Studio homepage, click **New business process**.

   You can also move the pointer over the **Create** icon and click **Business process**.

   ii. In the **Create business process** dialog box that appears, set the **Business Name** and **Description** parameters.
   iii. Click **New**.
3. Create a real-time computing node.
   i. Right-click the workflow that you have created and select **Create task**.
   ii. In the **Create node** dialog box that appears, set the relevant parameters.
   iii. Click **Submit**. The **Components** page appears.
   iv. On the left-side navigation submenu, click **Resource Reference** and select **PUBLIC_COMMON**.

   > **Note** If this option is not selected, the message shown when you use the **FixedFieldsSplit** component.
   >
   > You can also go to the Resource Reference page to configure the reference resources after this message appears.

4. Configure the created real-time computing node.

   On the left-side navigation submenu, click **Components**. The **Components** page appears.
   i. Configure the data store of the node on the **Components** page.
      a. Drag and drop the Datahub component in the Data Source section to the directed acyclic graph (DAG).

b. Click the Datahub component and set the parameters as needed on the **Parameter configuration** tab that appears.

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name. If this parameter is not specified, the real table name is used.
table schema	The custom fields and attribute fields to be returned. Click **Custom**. In the **Select field** dialog box that appears, click **+ Add** and enter the name and type of the output field. Then, click **OK**.
endPoint	The endpoint used to access Datahub. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to read data from Datahub. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to read data from Datahub. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Datahub project from which data is to be read. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Datahub topic from which data is to be read. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
startTime	The beginning of the time range when data is read. It corresponds to the startTime parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for reading data from Datahub. It corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement. Default value: *20*.
retryIntervalMs	The retry interval at which data is read. It corresponds to the retryIntervalMs parameter in the WITH clause of the CREATE TABLE statement. Unit: milliseconds. Default value: *1,000*.
batchReadSize	The number of data records that are read at a time. It corresponds to the batchReadSize parameter in the WITH clause of the CREATE TABLE statement. Default value: *10*.
lengthCheck	The rule for checking the number of fields parsed from a row of data. It corresponds to the lengthCheck parameter in the WITH clause of the CREATE TABLE statement. Default value: *NONE*.
columnErrorDebug	Specifies whether to enable debugging. It corresponds to the columnErrorDebug parameter in the WITH clause of the CREATE TABLE statement. If you turn on this switch, logs about parsing errors are returned. You can view the node details Operation Center.

ii. Configure the data operator.

a. Drag and drop the **FixedFieldsSplit** component to the DAG to split the tag field.

b. Click and hold the highlighted dot at the bottom of the **Datahub** component and move the pointer to link this component with the **FixedFieldsSplit** component.

c. Click the **FixedFieldsSplit** component and set the field to tag and the column separator to semicolon (;) on the Parameter configuration tab that appears.

d. Click **Custom** for the Add column parameter. In the **Select field** dialog box that appears, click **+** Add and enter the name and type of the output field. Then, click **OK**.

e. Drag and drop the **Select** component to the DAG. Click and hold the highlighted dot at the bottom of the **FixedFieldsSplit** component and move the pointer to link this component with the **Select** component.

f. Click the **Select** component and click **0 Field has been selected** on the **Parameter configuration** tab that appears.

g. In the dialog box that appears, select the fields to be returned and click **OK**.

iii. Configure the result table.

This example uses the LogService component as the destination.

a. Drag and drop the **LogService** component to the DAG. Click and hold the highlighted dot at the bottom of the **Select** component and move the pointer to link this component with the **LogService** component.

b. Click the **LogService** component and set the parameters as needed on the **Parameter configuration** tab that appears.

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name. If this parameter is not specified, the real table name is used.
Output Field	The fields to be returned. Click **0 Field has been selected** for the Output Field parameter. In the dialog box that appears, select the fields to be returned and click **OK**.
endPoint	The endpoint used to access Log Service. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Log Service project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Log Service topic to which data is to be written. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
source	The name of the Log Service table to which data is to be written. It corresponds to the source parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Log Service. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access Log Service. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
mode	The mode of data writing. It corresponds to the mode parameter in the WITH clause of the CREATE TABLE statement. Default value: *random*.
logStore	The name of the Logstore in the Log Service project to which the data is to be written. It corresponds to the logStore parameter in the WITH clause of the CREATE TABLE statement.

iv. Switch between the DAG mode and SQL mode.

Stream Studio allows you to configure a real-time computing node in both DAG mode and SQL mode. You can switch between these two modes.

By default, you configure a node in DAG mode. You can click **Switch to SQL mode** in the upper-right corner to switch to the SQL mode.

In SQL mode, you can click **Switch to DAG mode** in the upper-right corner to switch back to the DAG mode.

v. Configure the execution plan.

a. Click **Execution Plan** on the right-side navigation submenu to generate an execution plan.

b. Click **Save execution plan**.

5. Publish the real-time computing node.

You can publish the real-time computing node that you have configured. Click **Save** and then click **Submit** to publish the node.

i. Click **Save** and then click **Submit**. If you have not saved the node, a message appears, indicating that you must save it.

ii. In the **Submit New version** dialog box that appears, enter the remarks for the node and click **OK**.

iii. After you publish the node, you can go to the **OAM** page to view the node status and manage the node.

6. Perform O&M on the real-time computing node.

Click **OAM** in the upper-right corner to perform O&M on the real-time computing node.

i. Start the real-time computing node.

Find the real-time computing node that you have created in the node list and click **Start** to start the node.

You can set a custom start time for the real-time computing node based on your business requirement.

After starting the real-time computing node, you can click the node name to view its running status. If the real-time computing node is started properly, it enters the **Run** state.

ii. Stop and unpublish the real-time computing node.

a. Click **Stop** to stop the real-time computing node.

b. After the real-time computing node is stopped, click **Offline** to unpublish it.

Result

Now you have created, configured, published, run, stopped, and unpublished a real-time streaming node.

2.1.16.5. Configure components

2.1.16.5.1. Source tables

2.1.16.5.1.1. Datahub

Datahub is a real-time data distribution platform that is designed to process streaming data. It provides a channel for the Apsara Stack DTplus platform to process big data.

Realtime Compute typically uses Datahub to store source and result tables for streaming data processing. Data Transmission Services (DTS) and the Internet of Things (IoT) also use Datahub to access big data platforms. Datahub stores streaming data that can be used as input data for Realtime Compute.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
table schema	The custom fields and attribute fields to be read from Datahub.	None

Parameter	Description	Remarks
endPoint	The consumer endpoint.	None
accessId	The AccessKey ID used to read data from Datahub.	None
accessKey	The AccessKey secret used to read data from Datahub.	None
project	The name of the Datahub project from which data is to be read.	None
topic	The name of the Datahub topic from which data is to be read.	None
startTime	The beginning of the time range when data is read.	The format is `yyyy-MM-dd hh:mm:ss`.
maxRetryTimes	The maximum number of retries for reading data from Datahub.	None
retryIntervalMs	The retry interval at which data is read. Unit: milliseconds.	None
batchReadSize	The number of data records that are read at a time.	None
lengthCheck	The rule for checking the number of fields parsed from a row of data.	Valid values: *SKIP*, *EXCEPTION*, and *PAD*. Default value: SKIP. • *SKIP*: skips a data record when the number of fields in the data record is not the specified one. • *EXCEPTION*: throws an exception when the number of fields in the data record is not the specified one. • *PAD*: pads fields in sequence. Pad a field with null when the field does not exist.
columnErrorDebug	Specifies whether to enable debugging. If you turn on this switch, logs about parsing errors are returned.	None
BLOB	Specifies whether the type of data read from Datahub is BLOB.	None
Data Quality	Specifies whether to open the Data Quality page to view related monitoring nodes.	None

Field type mapping

The following table lists the mapping between Datahub and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Datahub data type	Realtime Compute data type
BIGINT	BIGINT
DOUBLE	DOUBLE
TIMESTAMP	BIGINT
BOOLEAN	BOOLEAN
DECIMAL	DECIMAL

Attribute fields

You can obtain the attribute field indicating the system time at which each data record is written to Datahub.

Field	Description
System Time	The system time at which each data record is written to Datahub.

2.1.16.5.1.2. Log Service

As an all-in-one real-time data logging service, Log Service allows you to quickly finish tasks such as data ingestion, consumption, delivery, query, and analysis without any extra development work. This can help you improve O&M and operational efficiency, and build up the capability to process large amounts of logs in the data technology era.

Log Service stores streaming data that can be used as input data for Realtime Compute.

The data format of Log Service is consistent with JSON. Example:

```
{
    "a": 1000,
    "b": 1234,
    "c": "li"
}
```

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
table schema	The custom fields and attribute fields to be read from Log Service.	None
endPoint	The consumer endpoint.	Log Service endpoints
accessId	The AccessKey ID used to read data from Log Service.	None
accessKey	The AccessKey secret used to read data from Log Service.	None

Parameter	Description	Remarks
project	The name of the Log Service project from which data is to be read.	None
logStore	The name of the Logstore under the Log Service project.	None
consumerGroup	The name of the consumer group.	You can specify a custom consumer group name. The format of the name is not fixed.
startTime	The beginning of the time range when the log data is consumed.	None
heartBeatIntervalMills	Optional. The heartbeat interval at which the client sends heartbeat messages. Unit: milliseconds.	None
maxRetryTimes	The maximum number of retries for reading data from Log Service.	None
columnErrorDebug	Specifies whether to enable debugging. If you turn on this switch, logs about parsing errors are returned.	None

Field type mapping

The following table lists the mapping between Log Service and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Log Service data type	Realtime Compute data type
STRING	VARCHAR

Attribute fields

Currently, Log Service supports the following three attribute fields by default. You can also specify other custom fields.

Field	Description
`__source__`	Specifies a log source.
`__topic__`	Specifies a log topic.
`__timestamp__`	Specifies the time when a logged event occurs.

Note

- Currently, Log Service does not support the MAP type.
- We recommend that you define the fields in the same order as the fields in the preceding table. Unordered fields are also supported.
- If the input data is in JSON format, define the delimiter and use the built-in function JSON_VALUE to parse the JSON value. Otherwise, the parsing fails and the following error is returned:

```
2017-12-25 15:24:43,467 WARN [Topology-0 (1/1)] com.alibaba.blink.streaming.connectors.common.source.parse.DefaultSourceCollector - Field missing error, table column number: 3, data column number: 3, data field number: 1, data: [{"lg_order_code":"LP00000005","activity_code":"TEST_CODE1","occur_time":"2017-12-10 00:00:01"}]
```

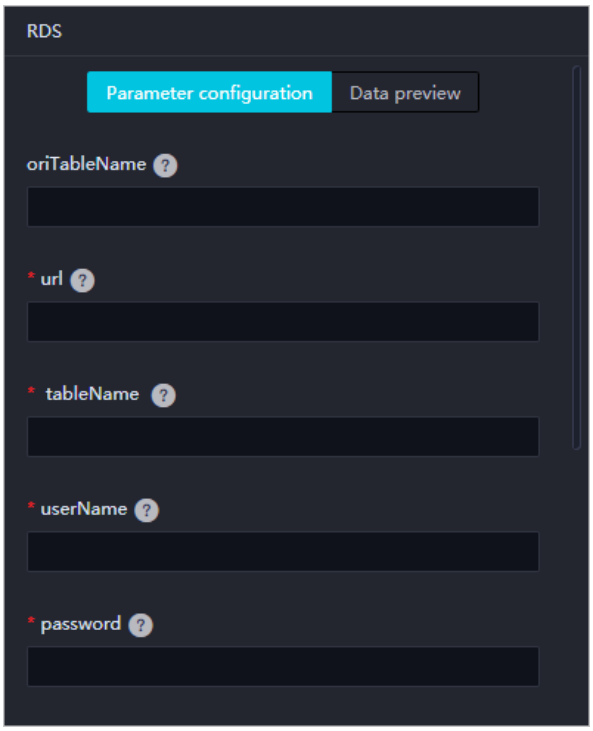
- The batchGetSize value must not exceed 1,000. Otherwise, an error occurs.
- The batchGetSize parameter specifies the number of log items read at a time in a log group. If both the size of a single log item and the batchGetSize value are too large, frequent garbage collection (GC) may be triggered. To avoid this, you must set batchGetSize parameter to a smaller value.

2.1.16.5.2. Dimension tables

2.1.16.5.2.1. ApsaraDB RDS

ApsaraDB RDS is a stable, reliable, and scalable cloud database service.

Parameter configuration



Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None

Parameter	Description	Remarks
url	The URL of your ApsaraDB RDS instance.	None
tableName	The name of the table in your database.	None
userName	The username that is used to connect to the database.	None
password	The password that is used to connect to the database.	None
Output Field	The fields that you want to return to the descendant component.	None
maxRetryTimes	The maximum number of retries for reading data from the table.	None
Cache Policy	The policy that is used to cache data.	Valid values: *None*, *LRU*, and *ALL*.
primaryKey	The primary key field in the output fields.	• You must specify a primary key when you declare a dimension table. • When you join a dimension table with another table, the ON clause must contain the equivalent (=) conditions for all the primary key fields. • The primary key in ApsaraDB RDS or PolarDB-X is the primary key or unique index column of an ApsaraDB RDS or PolarDB-X dimension table.

Additional information

- ApsaraDB RDS and PolarDB-X provide the following cache policies:
  - **None**: indicates that data is not cached.
  - **LRU**: indicates that only the recently used data is cached.

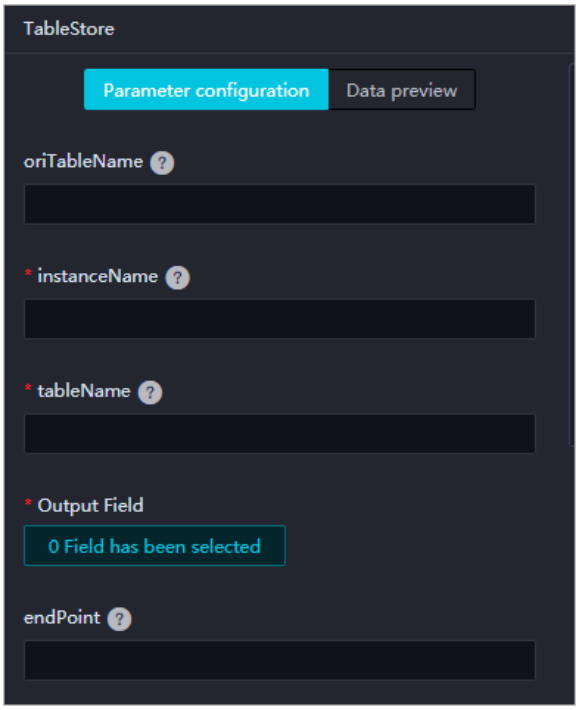
    If this cache policy is selected, you must specify the cacheSize and cacheTTLMs parameters.
  - **ALL**: indicates that all data is cached.

  Before the system runs a node, it loads all the data in the remote table to the memory. Then, the system searches the cache for data in all dimension table queries. If a cache miss occurs, all data is cached again after the cache times out. The ALL cache policy applies to scenarios where the remote table is small but a large number of missing keys exist. If this cache policy is selected, you must specify the cacheTTLMs and cacheReloadTimeBlackList parameters.
- If the ALL cache policy is used, the system reloads data asynchronously. Therefore, you must increase the memory of the JOIN operator. The size of the increased memory is twice the data size of the remote table.
- If the ALL cache policy is used, pay special attention to the memory of the JOIN operator to prevent out of memory (OOM) errors.

2.1.16.5.2.2. Tablestore

Tablestore is a distributed NoSQL database service that is developed based on the Apsara distributed operating system. It features high availability and data reliability.

Parameter configuration



Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
instanceName	The name of the instance.
tableName	The name of the table.
Output Field	The fields that you want to return to the descendant component.
endPoint	The endpoint of the instance. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID of the account that you use to read data from the table.
accessKey	The AccessKey secret of the account that you use to read data from the table.
Cache Policy	The policy used to cache data. Valid values: **None** and **LRU**.
primaryKey	The primary key field in the output fields.

2.1.16.5.2.3. MaxCompute

This topic describes the parameter configuration, field type mapping, and metrics of a MaxCompute dimension table.

Parameter configuration

Parameter	Description	Remarks
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.	None
endPoint	The endpoint used to access MaxCompute. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.	None
tunnelEndpoint	The endpoint of the Tunnel service. It corresponds to the tunnelEndPoint parameter in the WITH clause of the CREATE TABLE statement.	This parameter is required for a MaxCompute dimension table deployed in a Virtual Private Cloud (VPC).
project	The name of the MaxCompute project to which the dimension table belongs.	None
accessId	The AccessKey ID used to read data from MaxCompute.	None
accessKey	The AccessKey secret used to read data from MaxCompute.	None
Output Field	The fields to be returned to the descendant component.	None
partition	The partition name of the MaxCompute dimension table.	None
maxRowCount	The maximum number of data records that can be read from the MaxCompute dimension table	None
Cache Policy	The policy for caching data.	Default value: **ALL**.
cacheSize	The maximum number of data records that can be cached.	This parameter is required if you set the Cache Policy parameter to `LRU`. Default value: 100,000.
cacheTTLMs	The time interval at which the cache is refreshed. It corresponds to the cacheTTLMs parameter in the WITH clause of the CREATE TABLE statement. Units: milliseconds.	This parameter specifies the cache refresh interval when the Cache Policy parameter is set to `ALL`. The cache is not refreshed by default.

Parameter	Description	Remarks
cacheReloadTimeBlackList	Optional. The time period during which the cache is not refreshed. This parameter is valid when the Cache Policy parameter is set to `ALL`. During the time period specified by this parameter, for example, the Double 11 Shopping Festival, the cache is not refreshed.	This parameter is left empty by default. If you want to set this parameter, specify the time period in the format shown in the following example: `2017-10-24 14:00 -> 2017-10-24 15:00, 2017-11-10 23:30 -> 2017-11-11 08:00` Separate multiple time periods with commas (,). Separate the start and end time for a time period with the string "->".
primaryKey	The primary key field of the output fields.	None

Field type mapping

MaxCompute data type	Realtime Compute data type
TINYINT	TINYINT
SMALLINT	SMALLINT
INT	INT
BIGINT	BIGINT
FLOAT	FLOAT
DOUBLE	DOUBLE
BOOLEAN	BOOLEAN
DATETIME	TIMESTAMP
TIMESTAMP	TIMESTAMP
VARCHAR	VARCHAR
STRING	STRING
DECIMAL	DECIMAL
BINARY	VARBINARY

Metrics

When you join the dimension table to another table, you can view metrics such as the correlation degree and cache hit ratio. You can use K-Monitor to view the metrics.

Query statement	Description
fetch qps	Queries the total number of queries per second (QPS) against the dimension table, including hits and misses. The metric name is `blink.projectName.jobName.dimJoin.fetchQPS`.
fetchHitQPS	Queries the number of hits (in QPS) against the dimension table, including cache hits and hits against the physical dimension table. The metric name is `blink.projectName.jobName.dimJoin.fetchHitQPS`.
cacheHitQPS	Queries the number of cache hits (in QPS) against the dimension table. The metric name is `blink.projectName.jobName.dimJoin.cacheHitQPS`.
dimJoin.fetchHit	Queries the correlation degree of the dimension table and the table to which the dimension table is joined. The metric name is `blink.projectName.jobName.dimJoin.fetchHit`.
dimJoin.cacheHit	Queries the cache hit ratio of the dimension table. The metric name is `blink.projectName.jobName.dimJoin.cacheHit`.

Note

- We recommend that you use Realtime Compute V2.1.1 and later.
- To use a MaxCompute dimension table, you must grant the read permission to the account for accessing MaxCompute.
- When you declare a dimension table, you must specify the primary key. When you join a dimension table with another table, the ON condition must contain an equivalent condition that includes the primary key of either table.
- The primary key value for each row of a MaxCompute dimension table must be unique. Otherwise, the duplicate records are removed.
- If the dimension table is a partitioned table, Realtime Compute does not currently support writing the partition key column to the schema.
- When the cache policy is set to ALL, Realtime Compute reloads data asynchronously. Therefore, you must increase the memory of the JOIN operator. The size of the increased memory is twice the data size of the remote table.
- The following failover message may appear when you run a node:

  ```
  RejectedExecutionException: Task
  java.util.concurrent.ScheduledThreadPoolExecutor$ScheduledFutureTas,
  ```

  Generally, this message appears because dimension table joining in Realtime Compute V1.x has certain issues. We recommend that you upgrade Realtime Compute to V2.1.1 or later. If you want to continue using the existing version, we recommend that you pause the node and resume it after troubleshooting. To troubleshoot the failover, check the specific error information that was generated for the first failover record in the failover history.

2.1.16.5.3. Data operators

2.1.16.5.3.1. Filter

The Filter component allows you to configure filter conditions. It corresponds to the WHERE clause in SQL statements.

Parameter configuration

Enter the filter expression to configure this component. The filter expression supports functions and operators (=, <>, >, >=, <, and <=), for example, `city = 'Beijing'`.

2.1.16.5.3.2. GroupBy

The GroupBy component corresponds to the GROUP BY clause in SQL statements.

Parameter configuration

Parameter	Description
Select grouping field	The fields based on which data is grouped. You can specify multiple fields.
Output Field	The fields to be returned, that is, the fields to be selected. You can specify the fields in the same way that you configure the Select component.

2.1.16.5.3.3. Join

The Join component corresponds to the JOIN clause in SQL statements.

Parameter configuration

Parameter	Description
JoinMode	The JOIN mode to be used. Valid values: INNER JOIN, LEFT OUTER JOIN, RIGHT OUTER JOIN, and FULL OUTER JOIN.
expression	The JOIN expression. An equijoin is supported, for example, leftId = rightId AND limit = 0, whereas a non-equijoin is not supported.
Select Field	The fields to be returned, that is, the fields to be selected.

2.1.16.5.3.4. Select

The Select component allows you to configure the fields to be returned and supports field expressions. It corresponds to SELECT statements.

Parameter configuration

Select or configure the output fields in the Select field dialog box.

You can select fields to be returned in the **Field list** section and set an alias for a field in the **Field alias** column. To set a field expression, click the Edit icon next to the target field name. In the Edit dialog box that appears, enter the required SQL statement.

2.1.16.5.3.5. UDTF

The UDTF component allows you to configure custom functions. It corresponds to the UDTF clause in SQL statements.

Parameter configuration

Parameter	Description
JoinMode	The JOIN mode for the custom function. Only *INNER JOIN* and *LEFT OUTER JOIN* are supported. • *INNER JOIN*: returns an empty result set when the UDTF clause returns no result. • *LEFT OUTER JOIN*: returns the NULL string when the UDTF clause returns no result.
Select function	The name of the function that the current node references. To reference a function for the current node, upload the related resources on the Resource Reference page and select the target resource.
parameter expression	The input parameters and output parameters of the referenced function.
Output Field	The fields to be returned. You can configure the name, alias, and expression of each field.

2.1.16.5.3.6. UnionAll

The UnionAll component corresponds to the UNION ALL clause in SQL statements.

Parameter configuration

No parameter configuration is required.

2.1.16.5.3.7. Dynamic column splitting

Dynamic column splitting allows you to split data records with a dynamic number of columns.

Example

Input data:

```
k1=v1,k2=v2,k3=v3,k4=v4
```

In the preceding example, the data is stored in key-value pairs in the format of key=value. Different data records may have different numbers of key-value pairs, that is, they may have different numbers of columns. In this case, you can use the first-level delimiter, which is comma (,) in the preceding example, to split the data to different key-value pairs. Then, you can use the secondary-level delimiter, which is equal sign (=) in the preceding example, to split each key-value pair to the key and value.

Parameter configuration

Parameter	Description
Select Field	The name of the field to split.
first level column delimiter	The delimiter used to split the field at the first level. Default value: \u0001.
secondary level column delimiter	The delimiter used to split the field at the secondary level. Default value: \u0002.
Add column	The fields that store the split data. Specify a key for each field. An alias is allowed.

2.1.16.5.3.8. Static column splitting

Static column splitting allows you to split data records with fixed columns that are separated by a fixed delimiter.

Example

You can use commas (,) as the delimiter to split the following data to four new columns, that is, 1111, 2222, 3333, and 4444.

```
1111,2222,3333,4444
```

The static column splitting method is applicable to data records with fixed columns that are separated by a fixed delimiter.

Parameter configuration

Parameter	Description
Select Field	The name of the field to split.
column separator	The delimiter used to split the field. You can use full-width characters or half-width characters as needed.
Add column	The fields that store the split data. Specify a key and a sequence number for each field. An alias is allowed.

2.1.16.5.3.9. Row splitting

Row splitting allows you split a row to multiple rows based on a field by using the specified delimiter.

Example

The following table lists the input data.

id	num
1	1,2

Split the row to multiple rows based on the num field by using the comma (,) as the delimiter, and place the split data in the new field new_num. The following table lists the output data.

id	num	new_num
1	1,2	1
1	1,2	2

Parameter configuration

Parameter	Description	Remarks
Select Field	The name of the field to split.	This parameter is set to num in the preceding example.

Parameter	Description	Remarks
Field separator	The delimiter used to split the field. Default value: (\n).	This parameter is set to comma (,) in the preceding example.
Define new column name	The name of the new field that stores the split data.	This parameter is set to new_num in the preceding example.

2.1.16.5.4. Result tables

2.1.16.5.4.1. Datahub

Datahub is a real-time data distribution platform that is designed to process streaming data. It provides a channel for the Apsara Stack DTplus platform to process big data. Datahub works with multiple Apsara Stack services to provide an end-to-end data processing solution. Realtime Compute typically uses Datahub to store source and result tables for streaming data processing.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be returned.
endPoint	The endpoint used to access DataHub. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Datahub project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
topic	The name of the Datahub topic to which data is to be written. It corresponds to the topic parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access Datahub. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access Datahub. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to DataHub. It corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.
batchSize	The number of data records that are written at a time. It corresponds to the batchSize parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
batchWriteTimeoutMs	The interval at which the cache is cleared. It corresponds to the batchWriteTimeoutMs parameter in the WITH clause of the CREATE TABLE statement.
maxBlockMessages	The maximum number of data blocks that are written at a time. It corresponds to the maxBlockMessages parameter in the WITH clause of the CREATE TABLE statement.

Field type mapping

The following table lists the mapping between Datahub and Realtime Compute data types. We recommend that you declare the type mapping in the DDL statement.

Datahub data type	Realtime Compute data type
BIGINT	BIGINT
DOUBLE	DOUBLE
TIMESTAMP	BIGINT
BOOLEAN	BOOLEAN
DECIMAL	DECIMAL

2.1.16.5.4.2. Log Service

As an all-in-one real-time data logging service, Log Service allows you to quickly finish tasks such as data ingestion, consumption, delivery, query, and analysis without any extra development work. This can help you improve O&M and operational efficiency, and build up the capability to process large amounts of logs in the data technology era.

Parameter configuration

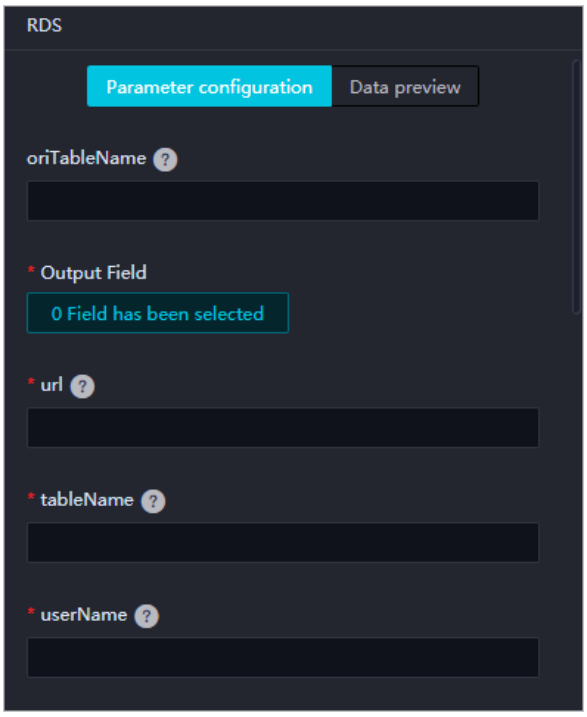
Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields to be returned.
endPoint	The endpoint used to access Log Service. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the Log Service project to which the data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field of the output fields.
source	The name of the log source. It corresponds to the source parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
accessId	The AccessKey ID used to access Log Service.
accessKey	The AccessKey secret used to access Log Service.
mode	The mode of data writing. It corresponds to the mode parameter in the WITH clause of the CREATE TABLE statement. Default value: `random`. If you set this parameter to `partition`, data is written by partition.
logStore	The name of the Logstore in the Log Service project to which the data is to be written.

2.1.16.5.4.3. ApsaraDB RDS

ApsaraDB RDS is a stable, reliable, and scalable cloud database service.

Parameter configuration



Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields that you want to write to the table in your ApsaraDB RDS database.
url	The URL used to access your ApsaraDB RDS instance. This parameter corresponds to the url parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
tableName	The name of the table to which you want to write data. This parameter corresponds to the tableName parameter in the WITH clause of the CREATE TABLE statement.
userName	The username that is used to access your ApsaraDB RDS database. This parameter corresponds to the userName parameter in the WITH clause of the CREATE TABLE statement.
password	The password that is used to access your ApsaraDB RDS database. This parameter corresponds to the password parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to the table. This parameter corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.
batchSize	The number of data records that can be written at a time. This parameter corresponds to the batchSize parameter in the WITH clause of the CREATE TABLE statement.
bufferSize	The maximum number of data records that can be stored in the buffer before deduplication is triggered. This parameter corresponds to the bufferSize parameter in the WITH clause of the CREATE TABLE statement. You can use this parameter only after the primaryKey parameter is specified.
flushIntervalMs	The time interval at which the buffer is cleared. Unit: milliseconds. This parameter corresponds to the flushIntervalMs parameter in the WITH clause of the CREATE TABLE statement.
excludeUpdateColumns	The fields that are not updated when Realtime Compute updates data records with the same primary key value. This parameter corresponds to the excludeUpdateColumns parameter in the WITH clause of the CREATE TABLE statement.
ignoreDelete	Specifies whether to skip delete operations. This parameter corresponds to the ignoreDelete parameter in the WITH clause of the CREATE TABLE statement.
partitionBy	Specifies the partitioning rule for the result table. Before Realtime Compute writes data to the sink node, Realtime Compute performs hash partitioning based on the value of this parameter. The data then flows to the relevant hash node. This parameter corresponds to the partitionBy parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field in the output fields.

Data type mapping

ApsaraDB RDS data type	Realtime Compute data type
TEXT	VARCHAR
BYTE	VARCHAR
INTEGER	INT
LONG	BIGINT
DOUBLE	DOUBLE
DATE	VARCHAR
DATETIME	VARCHAR
TIMESTAMP	VARCHAR
TIME	VARCHAR
YEAR	VARCHAR
FLOAT	FLOAT
DECIMAL	DECIMAL
CHAR	VARCHAR

JDBC parameters

Parameter	Description	Default value	Required JDBC version
useUnicode	Specifies whether to use the Unicode character set. This parameter must be set to true if you set the characterEncoding parameter to gb2312 or gbk.	*false*	1.1g
characterEncoding	The character encoding format. This parameter must be set if the useUnicode parameter is set to true. You can set this parameter to gb2312 or gbk.	*false*	1.1g
autoReconnect	Specifies whether to automatically re-establish a connection if the connection to the database is unexpectedly interrupted.	*false*	1.1
autoReconnectForPools	Specifies whether to apply the reconnection policy to a database connection pool.	*false*	3.1.3

Parameter	Description	Default value	Required JDBC version
failOverReadOnly	Specifies whether to set the connection to read-only after the database is automatically reconnected.	*true*	3.0.12
maxReconnects	The maximum number of reconnection attempts allowed. This parameter must be set if the autoReconnect parameter is set to true.	*3*	1.1
initialTimeout	The interval between two reconnection attempts. Unit: seconds. This parameter must be set if the autoReconnect parameter is set to true.	*2*	1.1
connectTimeout	The timeout period when you use a socket connection to access the database server. Unit: milliseconds. Default value: 0. This value indicates that the connection never times out. This parameter applies to JDK 1.4 and later.	*0*	3.0.1
socketTimeout	The timeout period for read and write operations on a socket connection. Unit: milliseconds. Default value: 0. This value indicates that read or write operations never time out.	*0*	3.0.1

FAQ

- Q: When the output data of Realtime Compute is written to an ApsaraDB RDS table, is the result table updated based on the primary key or is a new data record generated in the table?

  A: The processing method depends on whether the primary key is defined in the DDL statement.

  - If a primary key is defined in the DDL statement, the result table is updated by using `insert into on duplicate key update`. For a data record, if the primary key does not exist, the record is inserted into the table as a new row. If the value of the primary key field exists, the original row in the table is updated.
  - If no primary key is defined in the DDL statement, new data records are inserted into the table by using `insert into`.

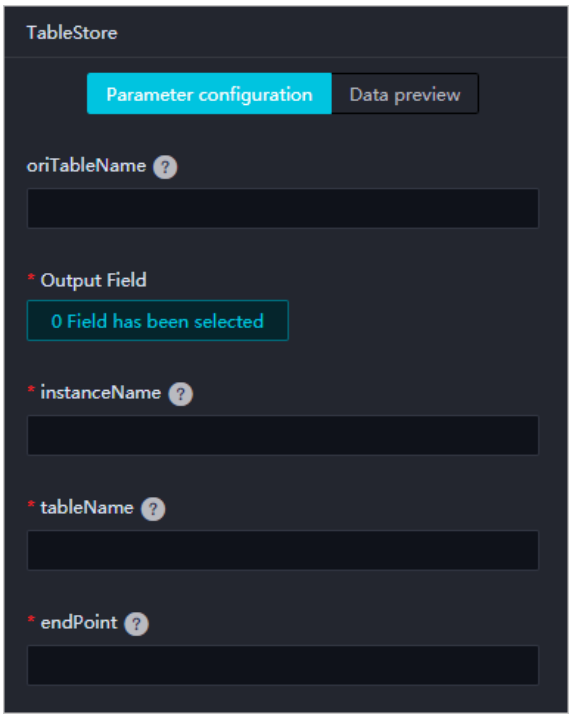
- Q: What do I need to pay attention to when I perform GROUP BY operations based on the unique index of an ApsaraDB RDS table?

A: An ApsaraDB RDS table has only one auto-increment primary key. Therefore, this auto-increment primary key cannot be declared as the primary key in a Realtime Compute job. If you want to perform GROUP BY operations based on the unique index of the table, declare the unique index as the primary key in the job.

2.1.16.5.4.4. TableStore

Tablestore is a NoSQL database service that is built on the Apsara distributed operating system. Tablestore adopts data sharding and load balancing technologies to scale out and handle concurrent transactions. You can use Tablestore to store and access large volumes of structured data in real time.

Parameter configuration



Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
Output Field	The fields that you want to write to the Tablestore table.
instanceName	The name of the Tablestore instance. This parameter corresponds to the instanceName parameter in the WITH clause of the CREATE TABLE statement.
tableName	The name of the table to which you want to write data. This parameter corresponds to the tableName parameter in the WITH clause of the CREATE TABLE statement.
endPoint	The endpoint of the Tablestore instance. This parameter corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.

Parameter	Description
accessId	The AccessKey ID of the account that is used to access the Tablestore instance. This parameter corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret of the account that is used to access the Tablestore instance. This parameter corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
valueColumns	The names of the fields that you want to insert into the result table. Separate multiple names with commas (,).
bufferSize	The maximum number of data records that can be stored in the buffer before deduplication is triggered. This parameter corresponds to the bufferSize parameter in the WITH clause of the CREATE TABLE statement.
batchWriteTimeoutMs	The write timeout period. This parameter corresponds to the batchWriteTimeoutMs parameter in the WITH clause of the CREATE TABLE statement.
maxRetryTimes	The maximum number of retries for writing data to the table. This parameter corresponds to the maxRetryTimes parameter in the WITH clause of the CREATE TABLE statement.
retryIntervalMs	The retry interval. This parameter corresponds to the retryIntervalMs parameter in the WITH clause of the CREATE TABLE statement.
ignoreDelete	Specifies whether to skip delete operations. This parameter corresponds to the ignoreDelete parameter in the WITH clause of the CREATE TABLE statement.
primaryKey	The primary key field in the output fields.

Data type mapping

Tablestore data type	Realtime Compute for Apache Flink data type
integer	bigint
string	varchar
boolean	boolean
double	double

2.1.16.5.4.5. MaxCompute

Realtime Compute supports creating a MaxCompute table as the result table.

Parameter configuration

Parameter	Description
oriTableName	The table name used in the CREATE TABLE statement. It must be a globally unique name.
tableName	The name of the MaxCompute table to which data is to be written.
Output Field	The fields to be written to the MaxCompute table.
endPoint	The endpoint used to access MaxCompute. It corresponds to the endPoint parameter in the WITH clause of the CREATE TABLE statement.
tunnelEndPoint	The endpoint of the Tunnel service, which is required for a MaxCompute project deployed in a Virtual Private Cloud (VPC). It corresponds to the tunnelEndPoint parameter in the WITH clause of the CREATE TABLE statement.
project	The name of the MaxCompute project to which data is to be written. It corresponds to the project parameter in the WITH clause of the CREATE TABLE statement.
accessId	The AccessKey ID used to access MaxCompute. It corresponds to the accessId parameter in the WITH clause of the CREATE TABLE statement.
accessKey	The AccessKey secret used to access MaxCompute. It corresponds to the accessKey parameter in the WITH clause of the CREATE TABLE statement.
partition	The partitions to which the data is to be written. It corresponds to the partition parameter in the WITH clause of the CREATE TABLE statement. This parameter must be specified for a partitioned table. For example, if the partition name of a table is `ds=20180905`, you can specify the parameter as `` `partition` = 'ds=20180905' ``. Separate multiple levels of partitions with commas (,), for example, `` `partition` = 'ds=20180912,dt=xxxyyy' ``.

Note Realtime Compute writes cached data to a MaxCompute table every time when a checkpoint is reached.

Field type mapping

MaxCompute data type	Realtime Compute data type
TINYINT	TINYINT
SMALLINT	SMALLINT
INT	INT
BIGINT	BIGINT

MaxCompute data type	Realtime Compute data type
FLOAT	FLOAT
DOUBLE	DOUBLE
BOOLEAN	BOOLEAN
DATETIME	TIMESTAMP
TIMESTAMP	TIMESTAMP
VARCHAR	VARCHAR
STRING	STRING
DECIMAL	DECIMAL
BINARY	VARBINARY

FAQ

Q: Does a real-time computing node clear the result table before it writes data to the MaxCompute sink that is in Stream mode when `isOverwrite` is set to `true`?

A: The `isOverwrite` parameter is set to `true` by default. That is, a real-time computing node clears the result table and result data before it writes data to the sink. Every time a real-time computing node starts or resumes after being paused, it clears data of the existing result table or the result partition before it writes data. Certain data may be lost when data is cleared after a paused real-time computing node is resumed.

2.1.16.5.5. FAQ

This topic describes the frequently asked questions (FAQs) about Stream Studio.

Q: What computing engine do I need to activate before using Stream Studio?

A: You must first activate Realtime Compute because Stream Studio is a development platform based on Realtime Compute.

Q: Where can I create a Realtime Compute project? How do I bind the project to Stream Studio?

A: You can create a Realtime Compute project in the Realtime Compute console. After a project is created, you can bind it to an existing DataWorks workspace in the DataWorks console or directly create a workspace and bind the project to it. After the Realtime Compute project is bound to your workspace, you can develop real-time computing nodes in Stream Studio.

Q: What are the advantages of the directed acyclic graph (DAG) mode in Stream Studio? What are the similarities and differences between the DAG mode and SQL mode?

A: Stream Studio supports both the DAG mode and the SQL mode to develop real-time computing nodes. In DAG mode, you can perform drag-and-drop operations on components to configure real-time computing nodes without writing code. In this mode, what you see is what you get. You can also switch to the SQL mode to configure nodes by writing SQL statements.

Q: What types of SQL does Stream Studio support?

A: Realtime Compute is based on Apache Flink. Therefore, Stream Studio supports Flink SQL.

2.1.17. Data Protection

2.1.17.1. Overview

Data Protection is a data security management platform. It can be used to detect data assets, detect sensitive data, classify data, de-identify data, monitor data access behavior, report alerts, and audit risks.

Data Protection provides security management services for MaxCompute.

Access Data Protection

1. Log on to the DataWorks console.
2. On the DataWorks page that appears, click the icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the Data Protection page.

Features

Data Protection provides the following features:

- Intelligent sensitive data detection

  Data Protection automatically detects an enterprise's sensitive data based on self-training models and algorithms, and clearly displays statistics on data types, volume, and visitors. It also recognizes custom data types.

- Accurate data classification: Data Protection allows you to classify data and create custom levels for better data management.
- Flexible data de-identification

  Data Protection provides diverse and configurable methods for dynamic data de-identification.

- Risky behavior monitoring and auditing

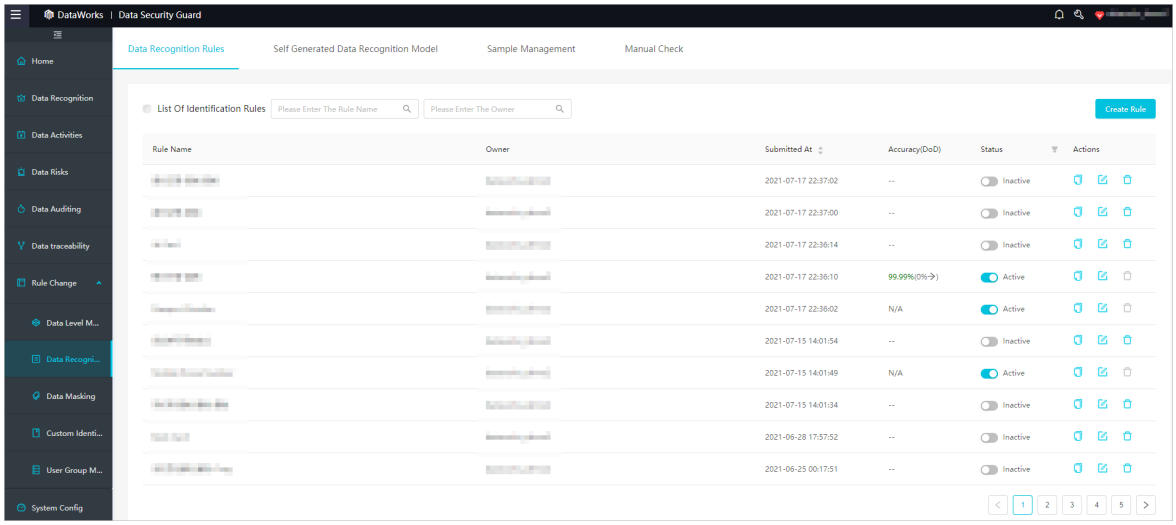
  Data Protection uses various correlation analysis algorithms to detect risky behavior. It also provides alerts and supports visualized auditing for detected risks.

2.1.17.2. Configure rules for defining sensitive data

This topic describes how to configure rules for defining sensitive data.

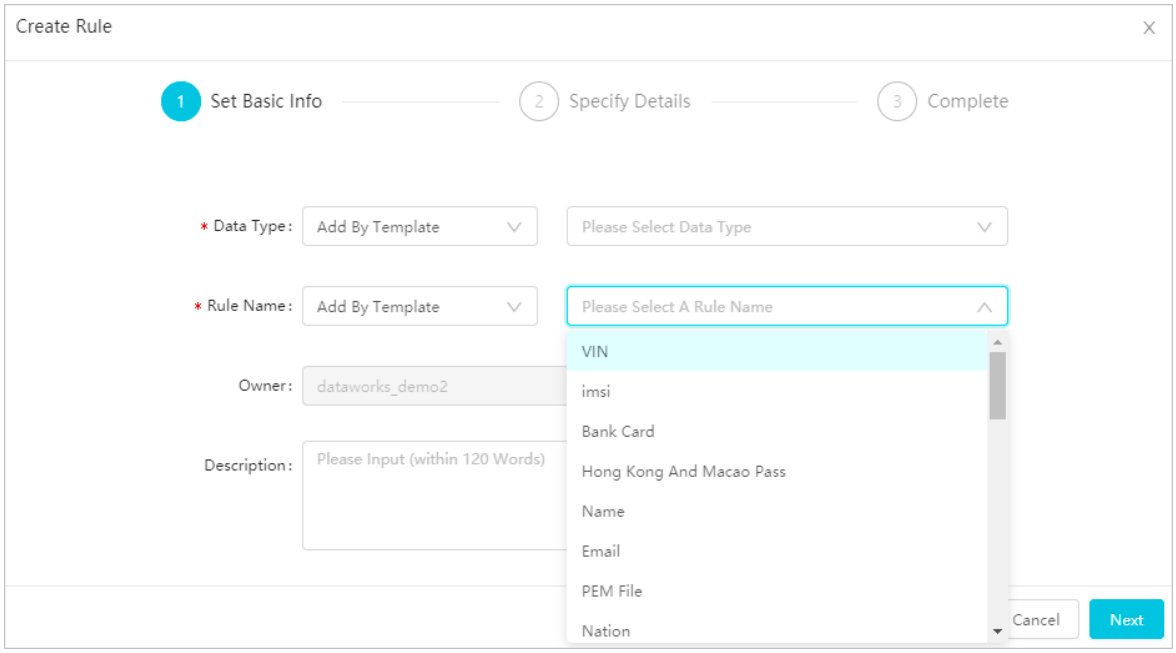
Procedure

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Rule Change > Data Recognition Rules**. On the Data Recognition Rules tab, click **Create Rule**.



5. In the Create Rule dialog box, configure the parameters in the **Set Basic Info** step.

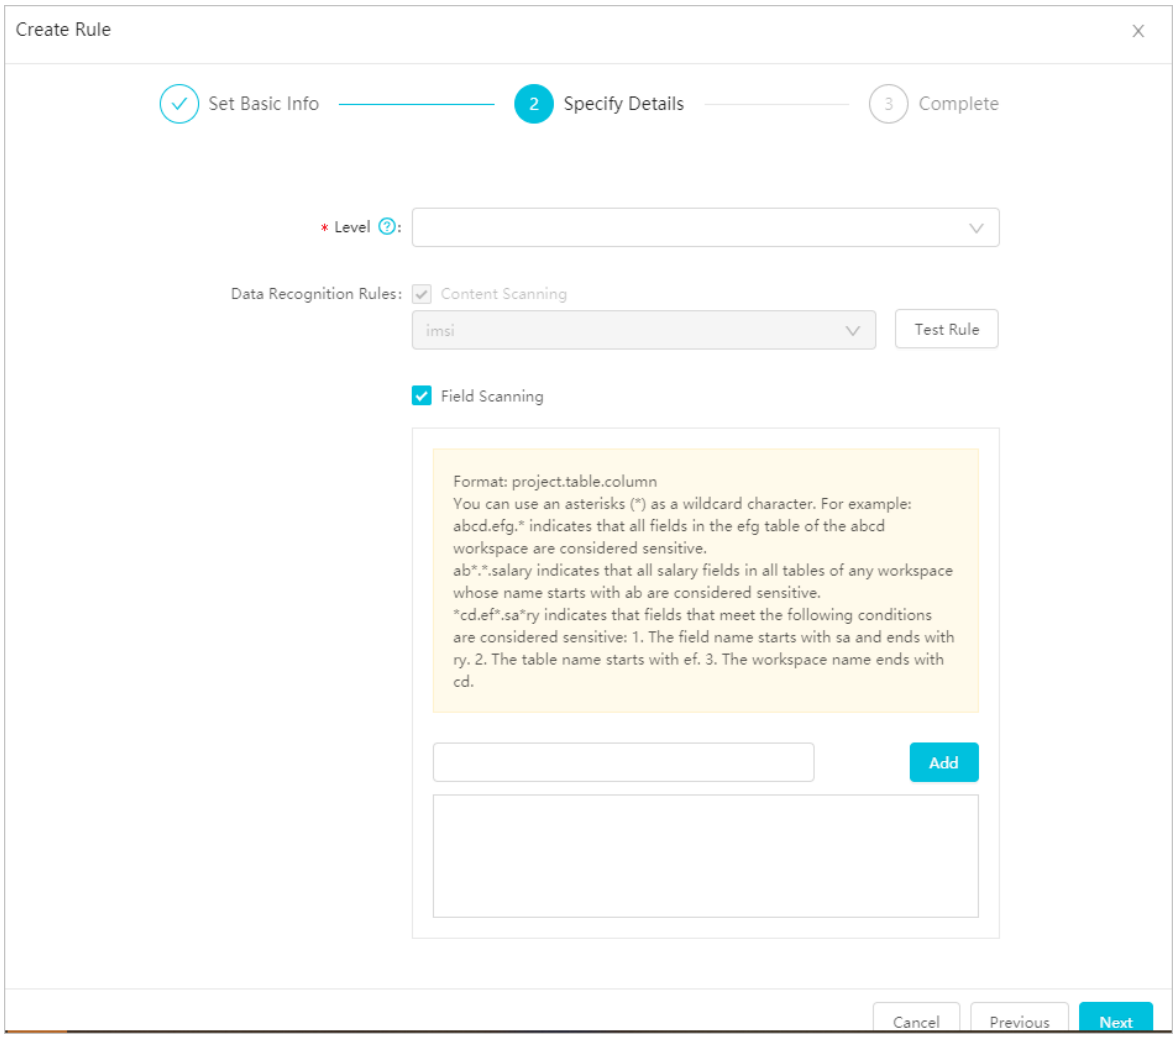
   You can create a template-based rule or a custom rule.



Parameter	Description
Data Type	The category of the rule. You can select Add By Template or Custom from the Data Type drop-down list. ○ If you select **Add By Template**, you can further select **Personal Information**, **Merchant Information**, or **Company Information** from the drop-down list on the right. ○ If you select **Custom**, you can enter a rule category.

Parameter	Description
Rule Name	◦ If you select **Add By Template** from the Rule Name drop-down list, you can select a built-in identification rule template from the drop-down list on the right, such as **Email**, **Seat Number**, **Mobile Phone Number**, **IP**, **Mac Address**, **Car No**, **Post Code**, **Id Card**, or **Bank Card**. ◦ If you select **Custom** from the Rule Name drop-down list, you can enter a rule name.
Owner	The owner of the rule.
Description	The description of the rule.

6. Click **Next**. In the Specify Details step, set the Level and Data Recognition Rules parameters.



Parameter	Description
Level	The security level of the sensitive data to which the rule is applied. If the existing security levels cannot meet your business requirements, choose Rule Change > Data Level Management in the left-side navigation pane to add levels.

Parameter	Description
Content Scanning	Specifies whether to enable content scanning. This option is selected by default for all the built-in sensitive data identification rule templates. ○ If you set Rule Name to Add By Template, you cannot modify the Data Recognition Rules parameter, but you can click Test Rule to verify the accuracy of the identification rule. ○ If you select Regex Express, you can customize the identification rule.
Field Scanning	Specifies whether to enable field scanning. You can use exact match or fuzzy match to specify one or more field names to be identified by the rule. The rule is applied if data matches one of the specified field names.

7. Click **Next**. In the Complete step, confirm the configurations, and click **Save**.

> **Note** When you create a rule to define sensitive data, note the following points:
> ○ The rule name must be unique.
> ○ The content scanning and field scanning configurations must be unique.
> ○ You can only view the sensitive data that is detected based on the data identification rule one day after the rule takes effect.

2.1.17.3. View the distribution of sensitive data

On the next day after you configure and activate sensitive data identification rules as a data security administrator, you can access Data Recognition to view the distribution of sensitive data.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. In the left-side navigation pane, click **Data Recognition**. On the Data Recognition page that appears, you can view the overall data distribution and field details.

2.1.17.4. View the information about data activities

On the next day after you configure and activate sensitive data identification rules as a data security administrator, you can access Data Activities to view related activity statistics, trend, and details.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. In the left-side navigation pane, click **Data Activities** to go to the **Data Activities** page.

   The Data Activities page allows you to view the information of each activity that involves sensitive data. On the Manipulations and Queries tab, you can view the statistics, trend, user, and details of data access activities. On the Export tab, you can view the statistics and details of data export.

2.1.17.5. View the data audited as risky

Data activities are audited manually or based on the risk identification rules and AI-based identification rules. The Data Risks page displays data activities that are audited as risky. You can comment audit results as required.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All**

Products > Data Protection.

3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, click **Data Risks** to filter and view the data audited as risky as needed.

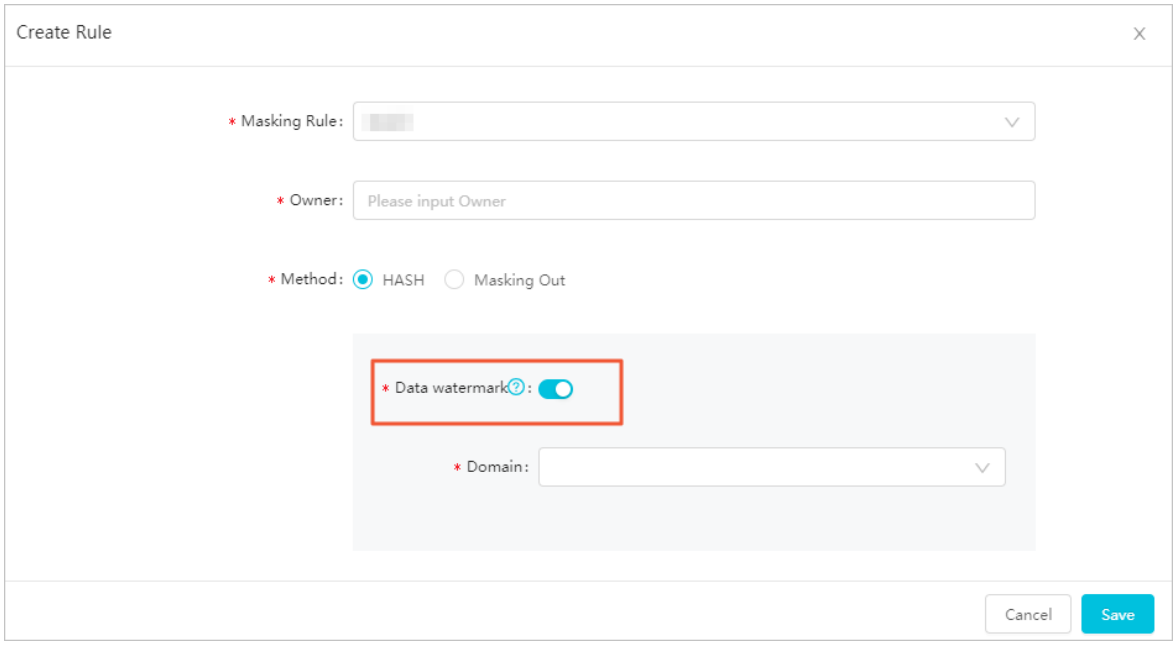
2.1.17.6. Track data

You can create a data tracking task to track the source of leaked data. You can also download a data tracking file and delete a data tracking task.

Configure a data watermark

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. On the page that appears, click **Try now**.
4. On the Data Protection page, choose **Rule Change > Data Masking** in the left-side navigation pane.
5. On the Data Masking page, click Create Rule to create a data masking rule. For more information, see Customize de-identification rules.

   When you configure a data masking rule, you can turn on **Data watermark**. This way, a data watermark can be embedded into data when data masking is performed on the data, which facilitates the tracking of the leaked data.



> **Note** A data watermark cannot be added to Chinese data.

Create a data tracking task

1. In the left-side navigation pane, click **Data traceability**.
2. On the **Data traceability** page, click **New data tracing task**.
3. Drag the file in which data is leaked to the middle part of the **Traceability tasks** dialog box or click **Upload** to upload the file.

> **Note** You can upload a CSV file whose size is no more than 200 MB.

4. Click **Start tracing** to track the source of the leaked data.

> **Note** After the tracking computing starts, you can close the dialog box, and the computing is not affected.

5. After the computing is complete, click the icon that corresponds to your data tracking task and view the tracking result.

   You can also enter a file name in the search box of the Data traceability page to view the historical data tracking task.

> **Note** Tracking results are for reference only. A data tracking task may not generate results or generate one or more results.

Download a data tracking file

On the **Data traceability** page, find a data tracking file that you want to download in the Traceability file column and click the icon to download the file.

Delete a data tracking task

1. On the **Data traceability** page, find a data tracking task that you want to delete and click the icon.
2. In the message that appears, click **Confirm**.

2.1.17.7. Manage a self-generated data recognition model

This topic describes how to train a model that can be used to summarize the data characteristics of specific columns in a table based on these columns. It also describes how to use the trained model to identify sensitive data.

Go to the Self Generated Data Recognition Model tab

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. On the page that appears, click **Try now**.
4. On the Data Protection page, choose **Rule Change > Data Recognition Rules** in the left-side navigation pane.
5. Then, click **Self Generated Data Recognition Model**.

Create a self-generated data recognition model

1. On the **Self Generated Data Recognition Model** tab, click **Add Model**.
2. In the **Add Model** dialog box, configure the parameters.

Parameter	Description
Model Name	The name of the model that you want to create. The name can contain letters, digits, and underscores (_).

Parameter	Description
Owner	The name of the owner for the model. The name of the model can contain letters, digits, spaces, and underscores (_).
Selected Samples	You can select one or more columns from an existing MaxCompute table.

3. Click **Next** to go to the **Model Training** step.
4. Select **I accept data umbrella sampling for model training** and click **Start Training**.

   > **Note** The column that you select must contain more than 10 rows. Otherwise, the system cannot start to train the model.

   After the training starts, you can close the dialog box and view the training progress in the recognition model list.
5. View the status of the model in the recognition model list. After the training is complete, the status of the model becomes **Training Completed**. Click the icon in the Actions column. Then, the Assess step of the Edit Model dialog box appears.
6. View the recognition results in the Assess step. In this step, a maximum of 10 results are displayed. You can also adjust the results based on your business requirements. If the accuracy of the recognition can meet your requirements, click **Create**. Then, the model is created. If excessive mismatches exist, you can click **Retrain** to retrain the model after you adjust the recognition results.

   > **Note** In most cases, you must perform two to three training to optimize the model.

Retrain the self-generated data recognition model

1. Click **Retrain** to retrain the model if the recognition effect presented by the recognition results in the Assess step is not satisfactory.
2. Navigate to the Select Samples step. The system automatically places the recognition results in the Assess step into the Sample Field and Exclude Field sections based on the recognition results. Click **Next** to continue the training.
3. View the recognition results after the training process is complete.
4. Click **Create** if the recognition results are satisfactory to finish creating the model. If the recognition results are still not satisfactory, click **Retrain** to continue retraining the model.

Use the self-generated data recognition model

1. After the model is created, click **Go To Data Recognition Rules Online Page**.
2. In the **Create Rule** dialog box, Configure the parameters.

Parameter	Description
Data Type	You can set this parameter to **Custom** or **Add By Template**.
Rule Name	The value cannot be changed.
Owner	The value cannot be changed.

Parameter	Description
Description	The description of the data recognition rule. The description can be a maximum of 120 characters in length and cannot contain special characters.

3. In the **Specify Details** step, specify **Level** and select **Field Scanning**. Select a trained model from the **Data Recognition Rules** drop-down list and click **Next**.
4. In the Complete step, click **Save**.

Stop training a self-generated data recognition model

1. Find a model that is being trained and click the icon in the Actions column to stop training the model.
2. Find the model whose training is stopped and click the icon to continue the training.

Delete a self-generated data recognition model

Find a model that is not being trained and click the **Delete** icon in the Actions column to delete the model.

> **Note**
> - A model that is being trained cannot be deleted. If you want to delete such a model, you can stop training the model and delete it.
> - A model that is in use cannot be deleted. If you want to delete such a model, you can delete the data recognition rules configured for the model and delete the model.

2.1.17.8. Manage the data security levels

When creating a rule, you can specify a security level for the data to which the rule applies. On the Levels page, you can create and delete security levels. You can also modify the priority of each security level and manage rules by security level.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Levels**.

   On the **Levels** page, you can create and delete security levels. You can also modify the priority of each security level and manage rules by security level.

Operation	Description
Create a security level	Click **Create Level**. Specify the security level name and operator.
Manage rules by security level	Find the target security level and click the icon in the Actions column. In the Manage Rules by Level dialog box that appears, you can select a rule and adjust its security level.
Delete a security level	Find the target security level and click the icon in the Actions column. In the dialog box that appears, click **Delete**.

Operation	Description
Modify the priority of a security level	Find the target security level. Drag and drop the  icon in the Actions column.

2.1.17.9. Manage data that is incorrectly detected

On the Manual Check page, you can manually correct the sensitive data that is incorrectly detected by rules. For example, you can delete incorrectly detected data, change the type of the detected data, and delete or recover data in batches.

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, choose **Management > Manual Check**.

   On the Manual Check page, you can delete incorrectly detected data, change the type of the detected data, and delete or recover data in batches.

   - To delete a data record that is incorrectly detected, turn off the switch in the Status column of the data record.

     > **Note** You can recover data records that you have deleted.

   - To change the type of a data record, click the edit icon next to the name of the target rule and select a rule.

     > **Note** You can only select a rule that has been configured in DataWorks.

   - To delete or recover multiple data records at the same time, you can select the data records and click **Remove** or **Recover**.

2.1.17.10. Customize de-identification rules

This topic describes how to customize de-identification rules in Data Security Guard so that DataWorks can dynamically de-identify the results of ad hoc queries.

Prerequisites

Sensitive data detection rules are created and data security levels are specified. For more information, see Configure rules for defining sensitive data and Manage the data security levels.

Go to the Data Masking page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now**.
4. In the left-side navigation pane, choose **Management > Data Masking**.

   The **Data Masking** page has two tabs: **Data Masking** and **Whitelist**.

Customize de-identification rules in Data Security Guard

1. Set the **Masking Scene** parameter to **Global Config (_default_scene_code)** and click **Create Rule** in the upper-right corner.
2. In the **Create Rule** dialog box, set the **Rule**, **Owner**, and **Method** parameters.

   > **Note** Data Security Guard provides three methods for de-identifying ID card numbers and email addresses, including **Pseudonymisation**, **Hashing**, and **Masking Out**. For other types of data, Data Security Guard only provides the **Hashing** and **Masking Out** methods.

   - **Pseudonymisation**

     This method replaces the text of a data record with an artificial pseudonym of the same data type. If you select this method, specify a security domain. Rules with different security domains generate different pseudonyms for the same data record.

   - **Hashing**

     If you select this method, specify a security domain. Rules with different security domains generate different hash values for the same data record.

   - **Masking Out**

     This method uses asterisks (*) to mask specified parts of a data record. It is commonly used.

Parameter	Description
Recommended	You can select recommended policies to mask data of common types such as ID card numbers and bank card numbers.
Custom	You can flexibly specify whether to mask the specified number of characters at the first, middle, or last part of a data record.

3. Click **OK**.
4. On the **Data Masking** tab of the **Data Masking** page, set the status of the de-identification rule to **Active** or **Inactive**.

   You can click the **Test** icon in the Actions column of the rule to test whether it works.

5. Click the **Whitelist** tab. On the Whitelist tab, click **Add Account**.
6. In the **Add Account** dialog box, set the **Rule**, **Account**, **Effective From**, and To parameters. For more information about user groups, see Manage user groups.

   > **Note** If you query data beyond the time range specified for the whitelist, the query results will be de-identified.

7. Click **Save**.

Verify the de-identification effect in DataWorks

After you create and configure de-identification rules, DataWorks dynamically de-identifies the results of queries in your workspace based on the rules.

> **Note** You must first turn on Mask Data in Page Query Results for your workspace in the DataWorks console.

2.1.17.11. Manage user groups

You can create a user group on the GroupManagement page and reference it in a de-identification whitelist. You can also copy, edit, and delete user groups on the GroupManagement page.

Go to the GroupManagement page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the DataWorks icon in the upper-left corner and choose **All Products > Data Protection**.
3. Click **Try now**.
4. In the left-side navigation pane, choose **Management > GroupManagement**. The GroupManagement page appears.

Create a user group

1. On the **GroupManagement** page, click **Create Group** in the upper-right corner.
2. In the **Create Group** dialog box that appears, set the parameters described in the following table.

Parameter	Description
Name	Enter the name of the user group. **Note** The name of the user group must be unique.
Owner	Enter the owner of the user group.
Source Type	Specify the source of accounts in the user group. Valid values: ○ **Text**: If you select this option, click **Upload File** next to **Source File**, select a local file to upload, and then click **Open**. ○ **Select Existing Accounts**: If you select this option, select the accounts to add next to **Add Members** and click **>**.

3. Click **Save**.

Copy a user group

On the **GroupManagement** page, find the target user group and click in the Actions column. An identical user group is generated.

Note

- The name of the generated user group contains the -copy suffix. You can click to change the name.
- You can only copy the content but not the dependencies of a user group.

Edit a user group

To edit an existing user group, follow these steps:

1. On the **GroupManagement** page, find the target user group and click in the Actions column.
2. In the **Edit Group** dialog box that appears, modify parameters such as **Name**, **Owner**, and **Source Type**.
3. Verify the settings and click **Save**.

Delete a user group

To delete a user group, find the user group on the GroupManagement page and click **Delete** in the Actions column. In the dialog box that appears, click **Delete**.

> **Note** You cannot delete a user group that is referenced in a de-identification whitelist.
>
> If you still want to delete the user group, delete the user group from the corresponding de-identification whitelist first.

2.1.17.12. Automatically mark security levels for sensitive data

After you turn on Open Marking in DataWorks, DataWorks can identify sensitive data, automatically mark the security level of the sensitive data, and then display the security level as a label for the sensitive data that belongs to a MaxCompute project. The security level of the sensitive data is displayed in Data Map of DataWorks.

Precautions

If you turn on Open Marking in DataWorks, Data Protection automatically configures security levels for the columns that contain sensitive data. This configuration affects your access permissions on sensitive data. Fully evaluate the impact before you turn on Open Marking in DataWorks.

Turn on Open Marking in DataWorks

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.
4. In the left-side navigation pane, click **System Config**.
5. On the System Config page, turn on **Open Marking**. **MarkingOpen** is displayed on the right of the switch.

2.1.17.13. Mask the underlying data of a MaxCompute project

This topic describes how to mask the underlying data of a MaxCompute project on the Data Masking page. After the data is masked, the data queried from each of the MaxCompute query entries is masked.

Prerequisites

- The data masking function base_meta.masking_v2 is available. If the function is unavailable, contact O&M personnel to publish the function.
- A network whitelist is enabled and SQL properties are configured for the MaxCompute projects whose underlying data needs to be masked. If no network whitelist is enabled, contact the O&M personnel.
- The rules for identifying sensitive data are created.

Go to the Data Masking page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Data governance > Data Protection**.
3. Click **Try now** to go to the **Data Security Guard** page.

4. In the left-side navigation pane, choose **Rule Change > Data Masking**.

Configure the rules for masking the underlying data of a MaxCompute project

1. On the **Data Masking** page, set **Masking Scene** to **MaxCompute Config(maxcompute_desense_code)**.
2. Select a MaxCompute project whose underlying data needs to be masked.
   i. Click **Select Desensitization Project**.
   ii. In the **Authorize The Desensitization Of Account** dialog box, select the name of the MaxCompute project whose underlying data needs to be masked in the **Not Desensitized Project** section, and click the icon to add it to the **Desensitized project** section.
   iii. Select **I agree to authorize data protection umbrella to desensitize the maxcompute underlying layer of the above projects.**
   iv. Click **OK**.
3. In the left-side navigation pane, choose Rule Change > Custom Identification Rules. On the **Rule Settings** tab of the page that appears, you can create, edit, or delete a data masking rule.

> **Note** The data masking rules that are configured for MaxCompute projects take effect only in underlying data masking scenarios, and can be edited or deleted only in such scenarios.

What's next

You can go to the MaxCompute project for which underlying data masking is enabled to check whether the data is masked.

2.1.18. App Studio

2.1.18.1. Overview

App Studio is a tool designed to help you develop data products. It comes with a rich set of front-end components that you can drag and drop to simply and quickly build front-end apps.

With App Studio, you do not need to download and install a local integrated development environment (IDE) or configure and maintain environment variables. Instead, you can use a browser to write, run, and debug apps and enjoy the same programming experience as that in a local IDE. App Studio also allows you to publish apps online.

Advantages

App Studio has the following core advantages:

- Data development anytime, anywhere

  You do not need to download and install a local IDE or configure and maintain environment variables. Instead, you can use a browser to develop data in your office, at home, or anywhere that you can connect to the network.

- Editor with complete features

  App Studio provides a browser-based editor that allows you to easily write, run, and debug projects. When you enter the code, App Studio provides code hinting, code completion, and repair suggestions. You can also find all references and the definition of a method to automatically generate code.

- Online debugging

  App Studio comes with all breakpoint types and operations of a local IDE. It supports thread switching and filtering, variable checking and watching, remote debugging, and hot code replacement.

- Multi-feature terminal

You can directly access the runtime environment, which is currently built based on CentOS as the base image. The multi-feature terminal supports all bash commands, including vim and other interactive commands.

- Collaborative coding

  You and your team members can use App Studio to share the development environment for collaborative coding. Currently, App Studio allows a maximum of eight users to edit the same file of a project online concurrently, improving work efficiency. In the future, the collaborative coding component will support chatting, bullet screen messages, code annotations, videos, and other features to make teamwork efficient and pleasant.

- Plug-in system

  App Studio supports business plug-ins, tool plug-ins, and language plug-ins.

  - App Studio allows you to customize any required menu or add any service portal based on your business needs.
  - You can customize project management processes, project types, and templates dedicated to your business.
  - You can develop common tools, such as enhanced Git features, code rule scanning, keyboard shortcuts, enhanced editing features, and code snippets, and integrate them into App Studio.
  - You can use language plug-ins to enrich the languages supported by App Studio, enabling App Studio to serve users with more languages while addressing your own business needs.

- Visual building

  App Studio provides a WYSIWYG designer that has rich components and deeply integrates DataService Studio and DataStudio. Among all components of DataWorks, you can call DataWorks API operations only in App Studio. In addition to calling the API operations, you can quickly build front-end apps by dragging and dropping components and configuring them in the WYSIWYG designer based on the santa file system, developing web apps without code.

- Rich templates and flexible project management

  App Studio provides rich project templates, allowing you to develop your project accordingly with fewer steps and higher efficiency. You can also save your project as a template for future development and use, or share it with other users.

2.1.18.2. Get started with App Studio

To build a data portal, engineers need to develop data, build backend services, and develop front-end pages. This topic describes the basic features of App Studio and how to use App Studio.

Originally, DataWorks is mainly used by data engineers to implement offline or streaming data development. As DataWorks becomes increasingly easy to use, many roles such as algorithm engineers, BI analysts, operators, and product managers who are familiar with SQL can use DataWorks to develop data.

App Studio helps different types of users quickly build webpages for data viewing and apps for data query.

Go to the App Studio page

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > App Studio**. The **Projects** page appears.

Create a front-end project

App Studio provides complete front-end development capabilities that allow you to develop front-end projects in the same way as in a local integrated development environment (IDE). Without the need to master or understand any new concepts, you can create front-end projects in App Studio and develop HTML, CSS, JavaScript, and React files in a way that you are familiar with.

1. Create a project based on the sample project.
   i. Go to the **App Studio** page and click **Projects** in the left-side navigation pane. On the Projects page, click **Create Project from Code**.
   ii. On the **Create Project** page, set the **Name** and **Description** parameters, and set the runtime environment to **react-demo**.

   > Note
   > - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
   > - The description of the project can be 2 to 500 characters in length.

   iii. After the configuration is completed, click **Submit**.
2. Set running parameters.

   In the upper-right corner, choose **Edit Config** > Edit Configurations. In the **Run/Debug Configurations** dialog box that appears, set the required parameter. Select the instance type and specify the port number as required. You can use the default configuration unless otherwise required. Then, click **OK**.

Parameter	Description
Install Cmd	The command used to install the dependency, for example, **npm install**.
Start Cmd	The command used to start the app, for example, **npm start**.
Environment Variables	The environment variables.
Initialize Script	The path of the script used to initialize a container in the code library.
PORT	The port of the Elastic Compute Service (ECS) instance. Default value: 3000.
ECS Instance	The instance type. Valid values: **1vCPU 2GMemory**, **2vCPU 3GMemory**, **4vCPU 8GMemory**, and **8vCPU 16GMemory**.

3. Run the project.

   Click the Run icon in the upper-right corner to run the project. Currently, you can run the `tnpm start` command to start front-end projects. You can seamlessly run projects with *webpack-dev-server* configured.

   During project running, you can view the dependency installation and app startup logs. After the project running is completed, the Preview tab appears in the right-side navigation pane. You can edit and save the code in real time. The edited code takes effect immediately.
4. Access the project.

   Click the **Preview** tab in the right-side navigation pane, and click the arrow next to the access link to open the project.

   In App Studio, you can edit and develop front-end projects in the same way as in a local IDE. App Studio supports code completion, method signature, refactoring, and redirection for HTML, CSS, LESS, SCSS, JavaScript, TypeScript, JSX, and TSX files. In addition, you can develop front-end projects based on templates without the need to build any environment or download any dependency.

Create a backend project

1. Create a project based on the sample project.
   i. Go to the **App Studio** page and click **Projects** in the left-side navigation pane. On the Projects page, click **Create Project from Code**.
   ii. On the **Create Project** page, set the **Name** and **Description** parameters, and set the runtime environment to **springboot**.
   - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
   - The description of the project can be 2 to 500 characters in length.

   iii. After the configuration is completed, click **Submit**.
2. Set running parameters.

   In the upper-right corner, choose **Edit Config** > Edit Configurations. In the **Run/Debug Configurations** dialog box that appears, set the required parameter and then click **OK**.

Parameter	Description
Main class	Select the main method. If no main method is available, check whether your project has a main method.
VM options	The virtual machine (VM) options.
Program arguments	The app parameters.
Environment Variables	The environment variables.
JRE	The Java runtime environment (JRE). By default, this parameter cannot be modified.
PORT	The port of the ECS instance. Default value: *7001*.
ECS Instance	The instance type. Valid values: **1vCPU 2GMemory**, **2vCPU 3GMemory**, **4vCPU 8GMemory**, and **8vCPU 16GMemory**.
Pre-Launch Option	The commands to be run before the project is run. You can specify up to three commands.
Enable Hot Code	Specifies whether to enable hot code replacement.

   You can click **Add** on the left of the Run/Debug Configurations dialog box to add multiple configurations for running.
3. Run the project.

   Click the Run icon in the upper-right corner to run the project.

   The first time that the project is run takes a longer time because App Studio needs to allocate the ECS instance and initialize the language service. After the running is completed, the Runtime tab appears, showing the access link.
4. Access the project.

Click **Open Link** to access the project.

Append /testapi to the link and refresh the page.

Understand App Studio

The following operations are supported for created projects:

- Top navigation bar
  - **Project**

    From the Project menu, you can configure the project or view detailed information by selecting **Character Set** or **Project Information**. Provided information about the current project includes the ID specified by **Project ID**, name specified by **Project Name**, type specified by **Project Type**, creation time specified by **Created At**, and **UUID**.

  - **File**

    From the File menu, you can create a file or open a recently created file by selecting **Create File** or **Re-Open Most Recent Files**.

  - **Edit**

    From the Edit menu, you can perform common editing operations. To search all the code in the project and open the related file, select Find in Path.

- **Version**

  From the Version menu, you can select **Switch Branch**, **View Changes**, **Submit**, **View Log**, **Connect to Remote Repo**, and **Merge Abort**.

  - **Switch Branch**

    In the Check Out Branch dialog box, you can click **+Create Branch** to create a local branch and push it to the remote repo. You can click a local branch and select **checkout** from the shortcut menu on the right to switch to the branch. You can also select **merge** to merge the selected branch to the current branch.

    You can click a remote branch and select **check out as a new local branch** from the shortcut menu on the right to check out the remote branch locally. Then rename the branch. You can also select **merge** to merge the selected branch to the current branch.

  - **View Changes**

    Click **View Changes** to view the list of edited files on a local branch in the right-side navigation pane.

  - **Submit**

    Click Submit to commit edits on a local branch for staging. You must enter the commit information.

  - **View Log**

    On the Log page, you can view all commit records of branches and filter them.

  - **Connect to Remote Repo**

    You can associate a new project with a remote repo for version control.

- **View**

  You can click **Toggle Full Screen** or press **Esc** on the keyboard to enter or exit the full screen mode of the page. You can also click **Hide Sidebar** or **Hide Status Bar** to hide the right-side navigation pane or the status bar. If they are hidden, you can click Show Sidebar or Show Status Bar to show them respectively.

- **Debug**
  - If you create a front-end project, you can set running parameters and add custom images.
  - App Studio supports Java-based debugging. In addition to setting running parameters and adding custom images, you can perform many other operations for debugging backend projects. You can also perform full or incremental builds and compile the Main.java file.

- **Settings**

  From the Settings menu, you can set the Git configuration to import the Git code to create a project. You can also configure your preference and shortcut keys.

- **Deploy**

  You can choose **Deploy > Download Source Code** to download the source code.

- **Template**

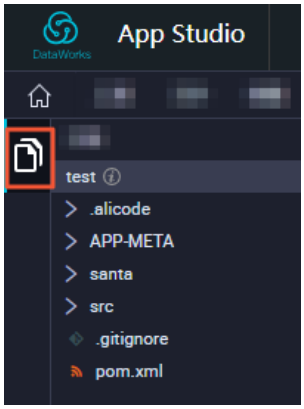
  You can choose **Template > Manage Templates** to go to the **My Templates** page to manage templates.

- Left-side navigation pane
  - Entry

    Click the icon framed in red. The project section appears.

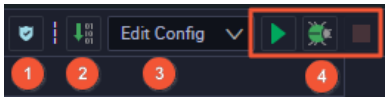
- Edit section

Double-click a file that you want to edit. In the Edit section that appears, right-click the code section to perform the following operations.



Action	Description
Go to Definition	Navigates to the definition page.
Peek Definition	Previews the definition.
Find All References	Searches for all references.
Workspace Symbol	Searches for a symbol in the project.
Go to Symbol...	Navigates to the symbol in the project.
Generate...	Generates the code.
Rename Symbol	Renames the symbol.
Change All Occurrences	Changes the name of all occurrences of a symbol throughout the file.
Format Document	Formats the file.
Cut	Cuts the file.
Copy	Copies the file.
Command Palette	Goes to the command palette.

- Icons in the upper-right corner



No.	Feature
1	Alibaba Coding Guidelines
2	Build Program. You can perform this operation only when the project is running or being debugged.
3	Run/Debug Configurations. You can set parameters for running or debugging the project.

No.	Feature
4	Operations on the project, including running, debugging, or stopping the project.

- Bottom bar

  - OUT tab

    You can click the OUT tab to view the output.

  - RUN or DEBUG tab

    If you click the Run or Debug icon for a project, this tab appears, showing the progress and information of the project.

  - PROBLEM tab

    If you click the Run or Debug icon for a project that has a problem, this tab appears.

  - Terminal tab

    When running or debugging a project, you can click the Terminal tab and run bash or vim commands on the ECS instance.

  - Version Control tab

    You can click the Version Control tab to view the logs and history of the project.

2.1.18.3. Navigation pane

2.1.18.3.1. View and manage projects

You can create and manage projects on the Projects page.

Go to the App Studio page and click Projects in the left-side navigation pane. On the page that appears, you can view projects that you have created. For more information about how to create template-based and code-based projects, see Project management.

Click a project to go to the project editing page. You can also click **Create Template** of a project to create a template based on the project.

Create a template

1. Click **Create Template** of a project.
2. In the **Create Template** dialog box that appears, set each parameter.

Parameter	Description
Name	The name of the template.
Description	The description of the template.
Class	The class of the template.

3. After the configuration is completed, click **OK**.

2.1.18.3.2. View and manage templates

You can view all templates created based on projects on the Templates page.

Click a template to go to the template details page. Then, click **Code Editor** to view the project code that this template is based on.

You can also click **Create Project** of a template to create a project based on this template.

2.1.18.4. Manage projects

This topic describes how to create and manage projects.

You can create a template-based or code-based project.

Create a template-based project

1. Go to the App Studio page and click Projects in the left-side navigation pane. On the **Projects** page, click **Create Project from Template**.
2. On the **Create Project** page, set the **Name** and **Description** parameters, and select a template.

   > Note
   > - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
   > - The description of the project can be 2 to 500 characters in length.
   > - You can select a custom template or a template provided by the system.
   > - All projects created by using templates support WYSIWYG development.

3. After the configuration is completed, click **Submit**.

Create a code-based project

You can create a project by running code. App Studio provides code templates for three types of runtime environments. Select a code template as required.

1. Go to the App Studio page and click Projects in the left-side navigation pane. On the **Projects** page, click **Create Project from Code**.
2. On the **Create Project** page, set the **Name** and **Description** parameters, and select a runtime environment.

   > **Note**
   > - The name of the project must start with a letter and can contain digits, letters, underscores (_), and hyphens (-).
   > - The description of the project can be 2 to 500 characters in length.

3. After the configuration is completed, click **Submit**.

View and manage projects

You can view the created projects on the **Projects** page.

You can click a project name to go to the project editing page. You can also click **Create Template** for a project to create a template based on the project.

> **Note** You can view projects shared by others but cannot create templates based on those projects.

2.1.18.5. Code editing

2.1.18.5.1. Overview

Code editing supports common IDE features, such as automatic completion, code hinting, syntax diagnosis, and global content search.

The following tables list the basic and advanced features that App Studio supports in different languages.

Basic feature	Java	Python	JavaScript and TypeScript
Completion	Supported	Supported	Supported
Hover	Supported	Supported	Supported
Diagnostics	Supported	Supported	Supported
SignatureHelp	Supported	Supported	Supported
Definition	Supported	Supported	Supported
References	Supported	Supported	Supported
Implementation	Supported (coming soon)	Not supported	Not supported
DocumentHighlight	Supported	Supported	Supported
DocumentSymbol	Supported	Supported	Supported
WorkspaceSymbol	Supported	Supported	Supported

Basic feature	Java	Python	JavaScript and TypeScript
CodeAction	Supported (Alibaba Java Guidelines coming soon)	Supported	Supported
CodeLens	References implementation	Not supported	Not supported
Formatting	Supported	Supported	Not supported
RangeFormatting	Supported	Not supported	Not supported
FindInPath	Supported	Supported	Supported

Advanced feature	Java	Python	JavaScript and TypeScript
Rename	Supported	Supported	Supported
WorkspaceEdit	Supported	Not supported	Not supported

MainClassQuickStart	Not supported	Not supported	Not supported
ListModules	Supported	Not supported	Not supported
Generate	Constructor Override Getter and Setter Implement	Not supported	Not supported

2.1.18.5.2. Generate code snippets

Currently, App Studio supports the Java class constructor, getter and setter methods, override methods of the parent class that a child class inherits, and API methods to be implemented.

Entry

Perform either of the following operations to generate the Java code:

- Right-click the code section and select **Generate**.
- Press Command+M on the keyboard. The Java code is automatically generated.

Constructor

On the Generate menu, click **Constructor**.

Select the fields to be included in the constructor and click **OK**.

The constructor that contains the initialization statement of the fields is generated.

Getter and setter methods

Generate the getter and setter methods in a way similar to the constructor.

> **Note** If a Java class does not have any field or the Java class is overwritten by the @data annotation of lombok, the getter or setter method is not required for the Java class. In this case, the Getter, Setter, and Getter And Setter options do not appear on the Generate menu.

Override methods

Click Override Methods on the Generate menu. All methods that can be overridden are listed in the Generate Code dialog box.

Select a method. The corresponding method is generated.

2.1.18.5.3. Run UT

App Studio currently supports unit testing (UT), including automatically generating UT code, detecting the entry for UT, running UT code, and displaying the UT result.

Automatically generate UT code

Open the target file, right-click the code editing section, select **Generate** and then click **Create Test**. The UT class file and UT code are automatically generated in the test directory.

Detect the entry for UT

> **Note**
>
> - UT class files must be stored in the *src/test/java* directory. A Java UT class file that is not stored in this directory cannot be identified as the Java UT class.
> - For a method annotated with @Test annotation, Run Test appears, indicating the entry for UT.

After the Java UT class file is created, add the **@Test** annotation of `org.junit.Test` to the corresponding sample UT method.

Run UT code

Click the Run icon in the upper-right corner. The sample UT starts.

2.1.18.5.4. Find in Path

App Studio provides the Find in Path feature to support global content search.

Move the pointer over **Edit** in the top navigation bar and select **Find in Path**.

You can select **Match Case**, **Words**, **Regex**, and **File Mask** as required. If you select File Mask, you must also select a file name extension from the right drop-down list to search in files of the specified type.

You can also search for content in the specified project, module, or directory.

After selecting a file, you can locate the searched content in the file and open the file in the editor.

2.1.18.6. Debugging

2.1.18.6.1. Configuration and startup

You can configure the entry method, start debugging, and set breakpoints to debug an app.

Configure the entry method

Parameter	Description
Main class	The entry method (which is the main method) you want to start. You can select a value from the drop-down list.
VM options	The parameters for starting a Java Virtual Machine (JVM), for example, -D, -Xms, and -Xmx.
Program arguments	The startup parameter, which is obtained by the args parameter in the main method.
Environment Variables	The environment variables.
JRE	The Java runtime environment. Default value: *1.8 - SDK*.
PORT	The port you want to expose in the app, for example, classic port 7001 or port 8080 for Spring Boot-based projects.
ECS Instance	The type of the ECS instance used for debugging.
Enable Hot Code	This configuration takes effect only in Run mode. By default, the HotCode2 plug-in that Alibaba Cloud provides is used.

Start debugging

Move the pointer over **Debug** in the top navigation bar and click **Start Debugging**.

The first startup is slower, because the system needs to prepare the runtime environment and download Maven dependencies for you. When you restart debugging, App Studio skips this process and provides user experience similar to that in a local IDE.

2.1.18.6.2. Online debugging

App Studio supports the online debugging of Java apps and Spring Boot-based web projects.

Before online debugging, you must configure the entry method and start debugging. For more information, see Configuration and startup.

Exposed services

After your app is started, two basic services are provided. You can click the link next to Backend to debug the backend Java code.

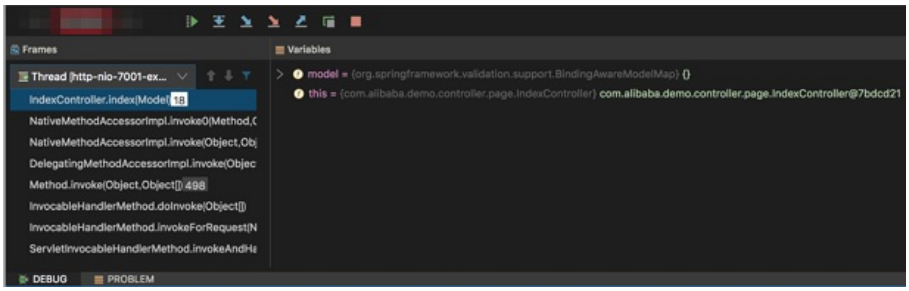
Panel introduction

- Output

  The Output panel displays the standard output, excluding System.in, of all apps. It supports the ANSI color and guarantees consistent experience as a local terminal.

- Call Stack

The Call Stack panel displays the thread list of your app, stack information, variables of the current stack, and observed variables at the current breakpoint. You can double-click a variable in the list and modify the value of the variable to debug your app.

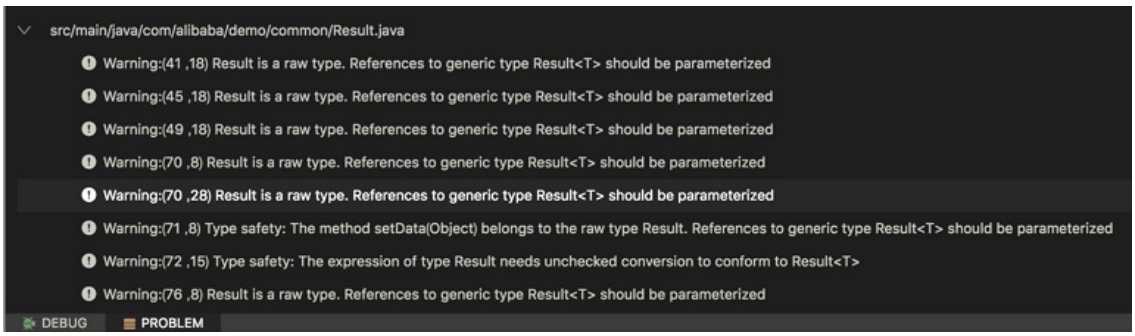


- Breakpoint

  The Breakpoint panel displays the breakpoints that are currently set. For more information about the breakpoint types and usage, see Breakpoint types.

- PROBLEM

  The **PROBLEM** panel displays compilation problems of apps. You can click a record to go to the corresponding line in the file.



2.1.18.6.3. Breakpoint types

App Studio supports normal line breakpoints, method breakpoints, and exception breakpoints.

Normal line breakpoint

You can click the blank section next to a line in the current file to generate a breakpoint for that line. The breakpoint also appears on the Breakpoint panel.

Method breakpoint

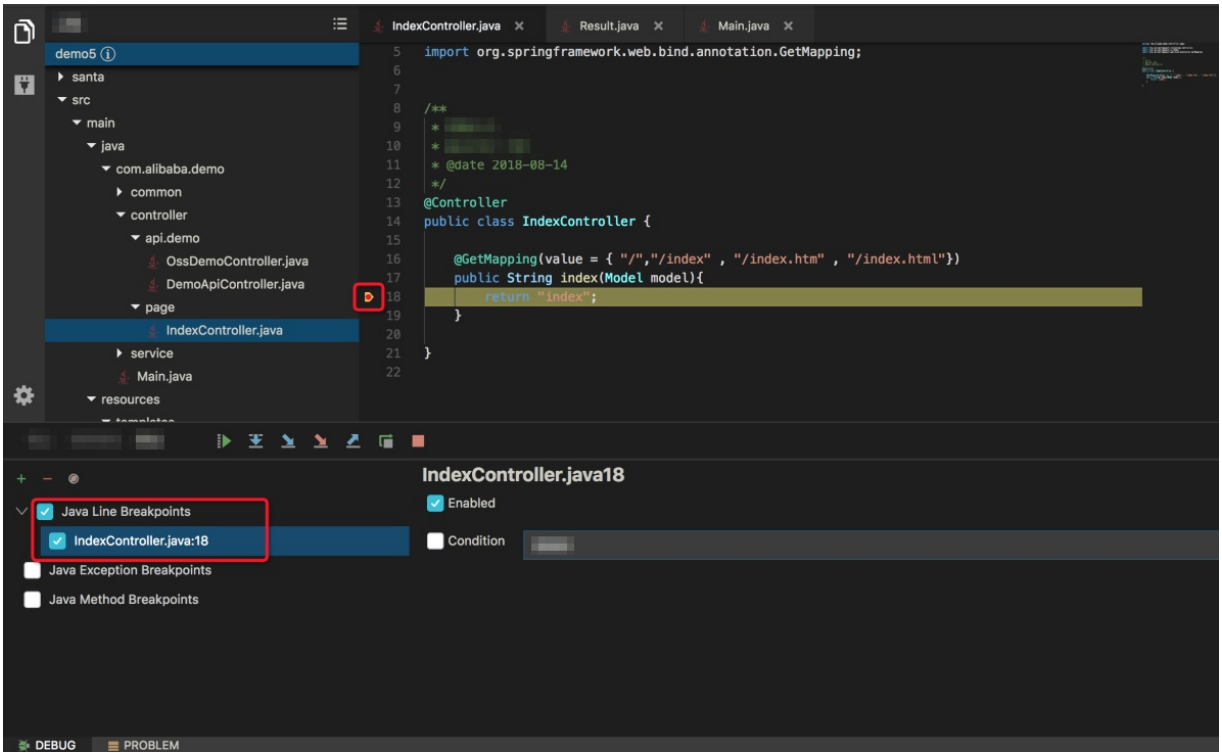
Different from a line breakpoint or an exception breakpoint, a method breakpoint triggers two events, namely, entry and exit. You can manually add a method breakpoint, or set a breakpoint at the place where the method is defined.

If the method breakpoint is triggered, the program stops when stepping into or out of the method.

Exception breakpoint

If an exception breakpoint is set, the program stops when encountering the exception.

As shown in the following figure, after index is triggered, the program stops in line 23 because **NullPointerException** appears.



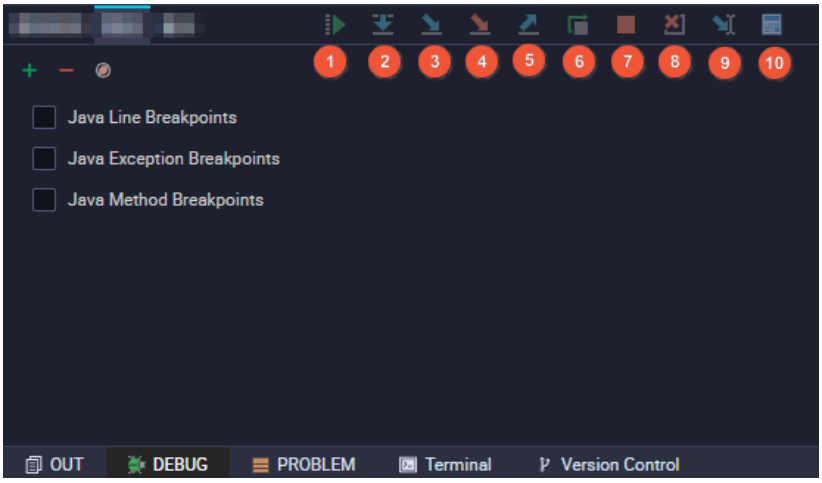
2.1.18.6.4. Breakpoint operations

The Breakpoint panel displays the breakpoints that are currently set. This topic describes how to operate breakpoints.

Breakpoints can be classified into normal line breakpoints, method breakpoints, and exception breakpoints. For more information, see Breakpoint types.

Debugging buttons

You can perform the debugging operations by clicking the following buttons listed in the table:



No.	Feature	Description

No.	Feature	Description
1	**Continue**	Resumes the current breakpoint to continue the current thread.
2	**Step Over**	Runs to the next line.
3	**Step Into**	Steps into a method.
4	**Force Step Into**	Forcibly steps into a method of a class not to be stepped into. Different from **Step Into**, **Force Step Into** enables you to step into a method from a built-in Java library.
5	**Step Out**	Steps out of the current method.
6	**Restart**	Currently, the **Restart** button is not perfect enough and may not be able to clean up the program. This button is being optimized.
7	**Stop**	Stops debugging.
8	**Drop Frame**	Deletes the current stack and returns to the previous method.
9	**Run to Cursor**	Runs to the current line of code. You can set a temporary breakpoint in a line.
10	**Evaluate Expression**	Calculates an expression.

2.1.18.6.5. Terminal

You can start multiple terminals in App Studio.

The **Terminal** tab appears in the lower part of the page.

App Studio supports common shell commands such as **ls** and **cat** and interactive commands such as **vi** and **top**.

2.1.18.6.6. Hot code replacement

Using the hot code replacement feature, you can edit the running code of an app and make the edits effective without restarting the app.

For example, after you edit the code while debugging a Spring Boot-based app, you do not need to restart the app. The edited code takes effect once it is saved. App Studio supports this feature by default.

App Studio also supports hot code replacement while an app is running. To trigger hot code replacement, you only need to save the file without installing any plug-in or manually compiling the file.

If you are editing the code in Debug mode, App Studio automatically deletes the current running stack and returns to the method entry.

Configure hot code replacement in Run mode

Enable hot code replacement on the Run/Debug Configurations page.

After you click Run or Debug, the output information of the HotCode2 plug-in appears on the OUT tab.

Save the file after editing it.

Configure hot code replacement in Debug mode

You can use the native Java Debug Interface (JDI) to enable hot code replacement in Debug mode. However, due to Java Virtual Machine (JVM) restrictions, hot code replacement is unavailable when a method is added to or deleted from a class. You can save the file to trigger hot code replacement.

> **Note** The native JVM supports hot code replacement for operations such as adding or deleting a class. However, hot code replacement is unavailable when you change the class structure.

2.1.18.7. WYSIWYG designer

2.1.18.7.1. Get started with the WYSIWYG designer

This topic describes basic operations in the WYSIWYG designer, including creating a project and building a visual page.

Create a project

1. Log on to the DataWorks console.
2. On the DataStudio page that appears, click the DataWorks icon in the upper-left corner and choose **All Products > App Studio**. The **Projects** page appears.
3. Click **Projects** in the left-side navigation pane. On the page that appears, click **Create Project from Code**.
4. On the **Create Project** page, set the **Name** and **Description** parameters, and set **Select the runtime environment** to **appstudio**.
5. After the configuration is completed, click **Submit**.

Build a visual page

Open a project created by using the WYSIWYG designer. Go to the *santa/pages* directory in your project.

Double-click a .santa file to go to the WYSIWYG designer. For example, you can double-click the file named *home.santa*.

You can also right-click **pages** and choose **Create > Template** to develop the page based on a template.

The WYSIWYG designer consists of the component menu and operation panel.

- Component menu

  The component menu lists all components that the WYSIWYG designer presets, including **layout components**, **basic components**, **form components**, **chart components**, and **advanced components**.

  Select a component from the component menu and drag and drop it to the visual operation section. Click the component. The **Component Settings** panel appears on the right.

  On the **Component Settings** panel, you can configure the component on the **Properties**, **Style**, and **Advance** tabs.

- Operation panel

  You can click the corresponding icon on this panel to **undo an operation**, **redo an operation**, **preview the rendering result**, **enable the code mode**, **use the global style**, **configure the navigation**, **configure a global data flow**, **deploy as a template**, and **save edits**.

  Click the **Configure Navigation** icon in the upper-right corner to go to the navigation configuration page. For more information, see Navigation configuration.

Configure a global data flow

For more information about how to configure a global data flow, see Global data flow.

On the Component Settings panel, you can configure the component on the **Properties**, **Style**, and **Advance** tabs.

- Configure component properties

  On the Properties tab, you can visually configure component properties.

  Based on the rules for configuring component properties, a visual form is generated on the Properties tab. After you configure component properties in this form, the WYSIWYG designer re-renders the component in the visual operation section based on the new properties. You can view the rendering results of the component with different properties in real time.

- Configure component styles

  On the Style tab, you can configure the styles of a component.

  A visual panel for configuring common styles is provided on the Style tab. On this panel, you can customize the basic styles of a component, including the layout, text, background, border, and effect.

  After you add or modify the component styles on this tab, the WYSIWYG designer collects all the style settings and re-renders the component in the visual operation section based on the new component style. You can view the component configuration effect in real time.

- Configure association between components

  On the Advanced Settings tab, you can configure association between components.

  Select a component in the visual operation section and click the **Advance** tab. The properties of the selected component are listed on the left of the tab. Click the Magnifier icon on the right and select the component to be associated to your selected component.

  The properties of the associated component appear on the right of the tab.

  Select a property, for example, searchParams, in the left property list and connect it to a property, for example, requestParams, in the right property list.

  In this way, any change of the searchParams parameter of the left component is transferred to the requestParams parameter of the right component in real time. This achieves property-based association between the two components.

Configure the code mode

By using the code mode, you can implement complex interactions in a more advanced way. For more information, see Code mode.

Save, preview, run, and hot code replacement

For more information, see Save, preview, run, and hot code replacement.

2.1.18.7.2. Code mode

By using the code mode, you can implement complex interactions in a more advanced way.

Click the **Code Mode** icon in the upper-right corner of the operation panel to enable the code mode.

The WYSIWYG designer uses domain-specific language (DSL) at the intermediate layer to switch between the visualization mode and code mode. DSL can be considered as a simplified version of React. The DSL syntax is basically the same as the React syntax.

As shown in the code section in the preceding figure, DSL uses a tag to describe a component. The tag properties are the component properties. The property value can be of a simple data type such as a string or a number. The property value can also be an expression. You can enter `state.xxx` to obtain data from the global data flow.

The code mode has the following features:

- If you drag and drop a component or configure the component properties in the visualization section, the edits are updated in the code in real time.
- If you edit the code in the code section, the edits are updated in the visualization section in real time.
- The drag-and-drop operation and component property configuration in the visualization section and code edits in the code section can be converted between each other.

2.1.18.7.3. DSL syntax

Domain-specific language (DSL) is a component-based language developed based on the features of React JSX and Vue templates and is more suitable for UI layout design.

JSX

The DSL syntax is similar to the JSX syntax in the React.render method. The following section provides a brief description of JSX:

- You can use `{ }` to switch an HTML scope to a JavaScript scope. In a JavaScript scope, you can write any valid JavaScript expression. The return value appears on the page, for example, `<div>{'Hello' + ' Relim'}</div>`.

  Note You can write any JavaScript expressions such as computing statements or literals in `{ }`.

- An HTML tag is used to switch a JavaScript scope to an HTML scope, for example, `{<div>Hello Relim</div>}`.
- The HTML scope and JavaScript scope can be nested, for example, `{<div>{'Hello' + ' Relim'}</div>}`.

Valid JavaScript expressions

```
// Computing statements
{aaa} // √ Variable aaa must be defined.
{aaa * 111} // √
{1 == 1 ? 1 : 0} // √
{/^123/.test(aa)} // √
{[1,2,3].join('')} // √
{(()=>{return 1})()} // The self-executing function. √
// Literals
{1}
{true}
{[11,22,33]} // √
{{aa:"11",bb:"22"}} // √
{()=>1} // Describe a function, which is valid but meaningless. √
```

Note If certain complex logic must be implemented by multiple computing statements rather than only one statement, you can wrap the logic in a self-executing function, which must be a valid expression. The following statements provide an example:

```
{(function(){
    // Sum the even digits of a number array.
    var input = [1,2,3,4,5,6,7,8,9,10];
    var temp = input.filter(i => i % 2 == 0)
    return temp.reduce((buf, cur) => buf + cur, 0)
})()}
```

Invalid JavaScript expressions

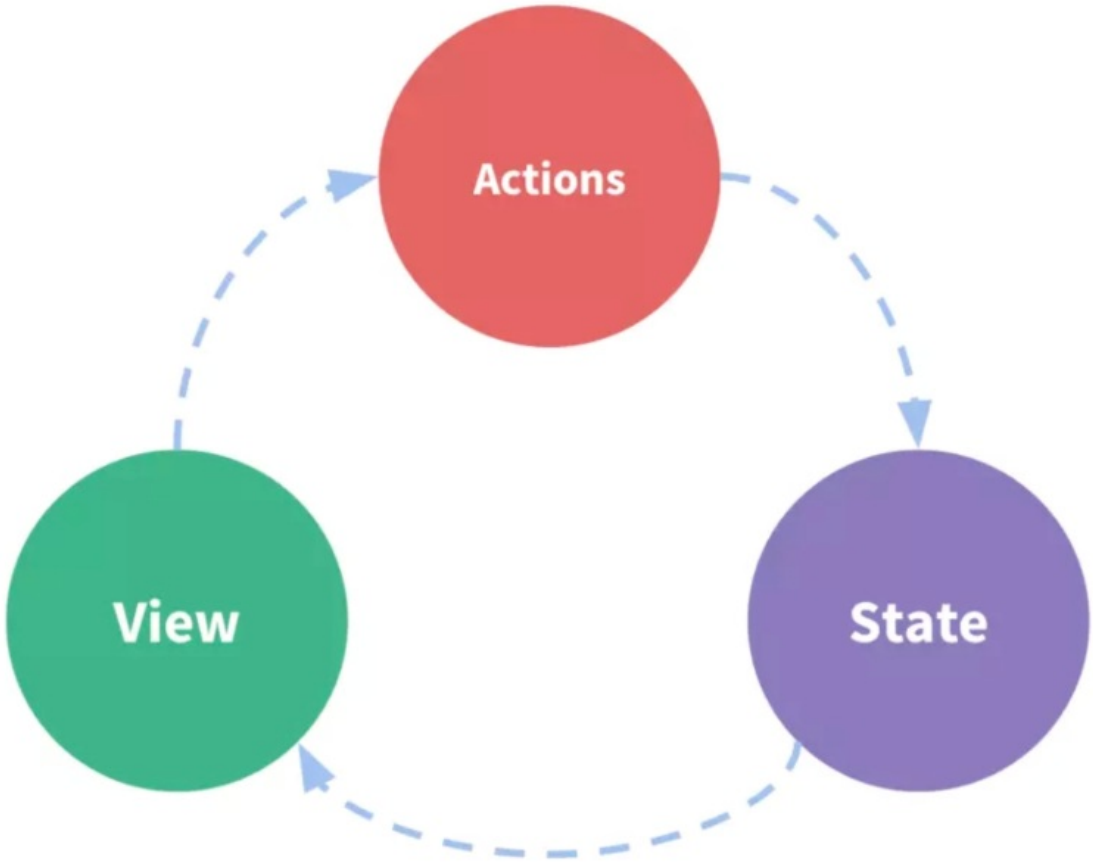
```
{ var a = 1 } // The value assignment statement.
{ aaa * 111; 2} // Multiple statements separated with semicolons (;).
```

2.1.18.7.4. Global data flow

A global data flow is used for front-end data management. For multiple components that need to share a state, it is difficult to transfer the state among them. To resolve this issue, you can extract the shared state and use a global data flow to transfer it to all related components.

Principles

In a global data flow, global data is transferred in a globally unique way. Once the data declared in global data changes, the data flow shown in the following figure is executed.



1. A component triggers an action when, for example, a user clicks the component.
2. The action triggers global data changes.
3. Upon the global data changes, components that reference the global state are automatically re-rendered.

Scenarios

A global data flow is applicable to the association of two or more components on a page. You can refine public data into global data for unified management, and then use a global data flow to associate two or more components.

Configure a global data flow

1. Click the **Global Data Flow Settings** icon in the upper-right corner of the operation panel.
2. In the **Global Data Flow Settings** dialog box that appears, set **Variable Name** and **Value**.
   - The variable value can be a number, character string, or JSON string.
   - If the variable value is declared as an API endpoint, data obtained from the API is automatically used as the value of the variable name.
3. Click **Save**.

Use a global data flow

- Obtain global data

  Use `state.name` in the component to obtain global data.

  ```
  <Input value={state.name} />
  ```

- Modify global data

  Use the $setState() method in the component to modify global data.

  ```
  <Input onChange={value => $setState({ name: value })} />
  ```

  Note You must use the $setState() method to modify global data. If you use `state.name = 'new value'`, re-rendering cannot be triggered.

2.1.18.7.5. Save, preview, run, and hot code replacement

In the WYSIWYG designer, you can perform operations such as saving edits, previewing the rendering result, running an app, or making edits in hot code replacement mode.

Save edits

The WYSIWYG designer periodically saves your edits. You can also click the **Save** icon in the upper-right corner of the operation panel to save edits.

Preview the rendering results

In the WYSIWYG designer, code in the operation section is in the editable status. However, special processing is added for the editable status of some components. For these components, you can run the rendering logic only when the app is running. To preview the rendering result, click the Preview icon in the upper-right corner of the operation panel.

Run an app

In the WYSIWYG designer, you can open and edit only one santa file at a time. To view the effect of the entire app,

click the Run Program icon on the Debug panel of App Studio to run the app.

Make edits in hot code replacement mode

If you are not satisfied with any page after running the app, you can edit the code in the WYSIWYG designer and save the edits.

The edited code takes effect on the running page in hot code replacement mode.

2.1.18.7.6. Navigation configuration

This topic describes how to configure the site navigation in the WYSIWYG designer.

The WYSIWYG designer provides each app with a public page header, a public bottom bar, and public sidebars, where you can configure various menus and themes. You can also specify whether to display the public header, bottom bar, and sidebars as required.

Click the **Navigation Settings** icon in the upper-right corner of the operation panel to go to the page for configuring the navigation of an app.

Configure the public header

You can configure the public header based on your business requirements.

Parameter	Description
Enabled	Specifies whether to display the public header.
Theme	The theme of the public header. You can select a dark or light theme.
Logo Image	The logo image of the site. You can enter an image URL or upload a local image.
Title	The title of the site.
Fix to Page Top	Specifies whether to fix the public header to the top of the page. If you turn on this switch, the public header stays at the top of the page when the page scrolls.
Menu Items	The menu items such as the link name and link URL that are displayed in the public header.

Configure the sidebars

You can configure the sidebars based on your business requirements.

Parameter	Description
Enabled	Specifies whether to display the sidebars.
Theme	The theme of the sidebars. You can select a dark or light theme.
Enable Folding	Specifies whether the sidebar menus can be hidden.

2.1.19. Migration Assistant

2.1.19.1. Overview

The Migration Assistant service of DataWorks allows you to migrate data objects across different DataWorks versions, Alibaba Cloud accounts, regions, and workspaces.

Migration Assistant allows you to export data objects in your workspace, including auto triggered nodes, manually triggered nodes, resources, functions, data sources, table metadata, ad hoc queries, and components. You can create full export tasks, incremental export tasks, or custom export tasks to export your data objects in DataWorks based on your business requirements.

> **Notice** To create export or import tasks, you must use an Alibaba Cloud account or be the workspace administrator. If you use a Resource Access Management (RAM) user that is not assigned the administrator role, you can only view export and import tasks.

Scenarios

- Back up node code

  You can use Migration Assistant to periodically back up your node code to prevent data from being deleted by mistake. In this case, we recommend that you create a full export task.

- Export a common workflow for replication

  You can use Migration Assistant to export a common workflow that can be replicated in other workspaces. In this case, we recommend that you create a custom export task.

- Build a test environment

  You can use Migration Assistant to copy all the node code and replace the production data with test data to build a test environment. In this case, we recommend that you create a full export task or a custom export task.

- Develop data in a hybrid cloud environment

  You can use Migration Assistant to migrate node code from Alibaba Cloud public cloud to Alibaba Cloud Apsara Stack to develop data in a hybrid cloud environment. We recommend that you create a custom export task. If the difference between Alibaba Cloud public cloud and Alibaba Cloud Apsara Stack is large, a compatibility problem may occur when data objects are migrated.

- Migrate data objects between the development environment and production environment

  If a workspace consists of the production environment and development environment that are completely isolated, you can use Migration Assistant to export nodes from the development environment and import them to the production environment for deployment.

2.1.19.2. Cloud tasks

2.1.19.2.1. Export tasks from open source engines

DataWorks allows you to migrate tasks from open source scheduling engines such as Oozie and Azkaban to DataWorks. This topic describes the requirements for the files to be exported.

Context

Before you import a task of an open source scheduling engine to DataWorks, you must export the task to your on-premises machine or Object Storage Service (OSS). For more information about the import procedure, see Import tasks of open source engines.

Export a task from Oozie

Requirements and structure of the package to be exported:

- Requirements

  The package must contain XML-formatted definition files and configuration files of a flow task. The package is exported in the ZIP format.

- Structure

Oozie task descriptions are saved in a Hadoop Distributed File System (HDFS) directory. For example, each subdirectory under the apps directory in the Examples package at the Apache Oozie official website is a flow task of Oozie. Each subdirectory contains XML-formatted definition files and configuration files of a flow task.

```
$tree
.
├── aggregator
│   ├── coordinator-with-offset.xml
│   ├── coordinator.xml
│   ├── job.properties
│   ├── job-with-offset.properties
│   ├── lib

│   └── workflow.xml
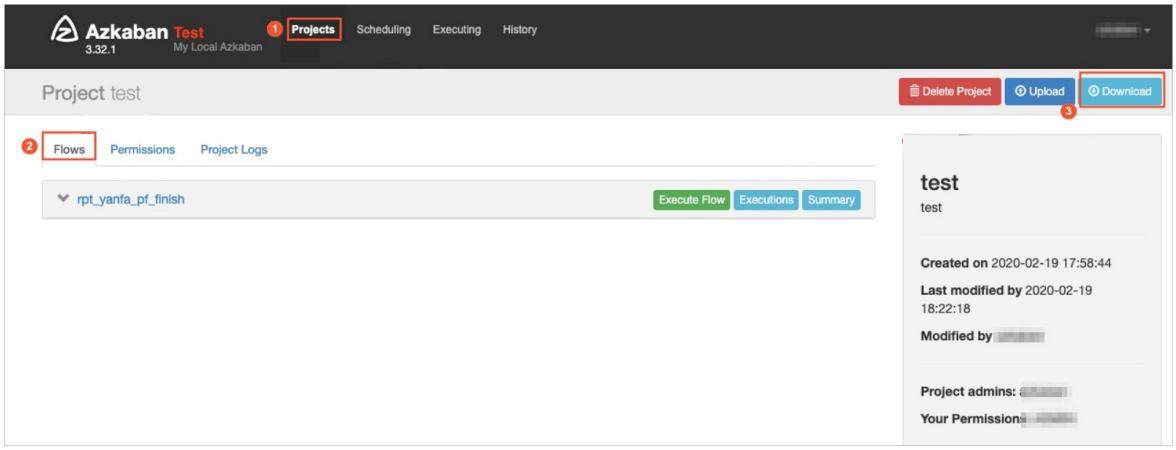
├── cron-schedule
│   ├── coordinator.xml
│   ├── job.properties
│   └── workflow.xml
```

Export a task from Azkaban

You can download a specific flow task in the Azkaban console.

1. Log on to the Azkaban console and go to the **Projects** page.
2. Select a project whose package you want to download. On the page for the project, click **Flows** to show all flow tasks under the project.
3. Click **Download** in the upper-right corner of the page to download the package of the project.



Native Azkaban packages can be exported. No limit is imposed on the packages of Azkaban. The exported package in the ZIP format contains information about all tasks and relationships under a specific project of Azkaban.

Export tasks from other open source engines

DataWorks provides a standard template for you to export the tasks of open source engines except for Oozie and Azkaban. Before you run an export task, you must download the standard template and modify the content to be exported based on the file structure in the template. You can go to the **Open Source engine export** page to download the standard template and view the file structure.

1. Log on to the DataWorks console.
2. On the DataStudio page, click the ☰ icon in the upper-left corner and choose **All Products > Other > Migration Assistant**.
3. In the left-side navigation pane, choose **Cloud tasks > Open Source engine export** to go to the **Open Source engine export scheme selection** page.
4. Click the **Standard Template** tab.
5. On the **Standard Template** tab, click **standard format Template** to download the template.
6. Modify the content to be exported based on the template and generate a package to be exported.

2.1.19.2.2. Import tasks of open source engines

This topic describes how to import tasks that are exported from open source engines into DataWorks.

Procedure

1. Go to the **Open Source engine import** page.
   i. Log on to the DataWorks console.
   ii. On the DataStudio page, click the ☰ icon in the upper-left corner and choose **All Products > Other > Migration Assistant**.
   iii. In the left-side navigation pane, choose **Cloud tasks > Open Source engine import**.

2. Create an import task.
   i. On the **Import Tasks** page, click **Create Import Task** in the upper-right corner.
   ii. In the **Create Import Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the import task. The name can contain only letters, digits, underscores (_), and periods (.).
Engine type	The engine type. Valid values: **Azkaban**, **Oozie**, and **Standard format**.
Upload From	The source of the package that you want to import. Valid values: **Local** and **OSS**. ■ If you select **Local** for this parameter, perform the following steps to upload a package on your machine: a. Click **Upload File**. b. Select the package that you want to upload and click **Open**. c. Click **Check**. d. After the message **The resource package has passed the check** appears, verify that the file format and content are correct. **Note** The size of the package that you want to upload cannot exceed 30 MB. If the size of the package exceeds 30 MB, select OSS for this parameter. ■ If you select **OSS** for this parameter, enter the endpoint of an Object Storage Service (OSS) object in the **OSS Endpoint** field. Then, click **Check** and **Preview** in sequence to check and preview the package that you want to upload.
Remarks	The description of the import task.

   iii. Click **OK**. The **Edit import task** page appears.
3. Edit the import task.
   i. On the **Edit import task** page, specify **Import objects**.

      Periodic tasks is selected for **Import objects** by default. If you want to import data objects of another type, select the required value from the **Import objects** drop-down list.
   ii. (Optional)Click **Advanced Settings**. In the **Advanced Settings** dialog box, configure the mappings between the compute engine instances and the node types and click OK.

      If multiple compute engine instances are bound to the destination workspace, you must complete the settings in the **Advanced Settings** dialog box. You can configure the mappings between compute engine instances and nodes of the Shell, Hive, and Sqoop types.
   iii. On the Edit import task page, click **start import** in the upper-right corner.
4. View the import report.
   i. In the **Import progress** dialog box, confirm the import task progress.
   ii. After the import task is completed, click **Return to import task list**.
   iii. Find the task on the **Import Tasks** page and click **View Import Report** in the Actions column. On the page that appears, view the task information in the **Basic Information**, **Import Settings**, **Import results**, and **Details** sections.

2.1.19.3. Migrate data objects in DataWorks

2.1.19.3.1. Create and view export tasks

Migration Assistant allows you to export data objects in your workspace, including auto triggered nodes, manually triggered nodes, resources, functions, table metadata, data sources, components, and ad hoc queries. This topic describes how to create and view export tasks.

Prerequisites

To create export or import tasks, you must use an Alibaba Cloud account or be the workspace administrator. If you use a Resource Access Management (RAM) user that is not assigned the administrator role, you can only view export and import tasks.

Context

Migration Assistant allows you to export data objects in different modes. These modes include full export, incremental export, and custom export. You can choose an export mode that best suits your business scenario.

- Full export tasks are used to export all the data objects in a workspace. For example, you can run a full export task to back up node code or clone the workspace to a test environment. When you run a full export task, data objects of the latest version are exported.

  Only saved data objects can be exported. If a node is saved in both the development environment and production environment, the node saved in the development environment is exported.

- Incremental export tasks are used to export data objects that were modified after the specified date.

  > **Note** You cannot configure a blacklist for incremental export tasks.

- Custom export tasks are used to export data objects that you specify. For example, you can run a custom export task to extract a common workflow and clone it to other workspaces. If a workspace runs in both a production environment and a development environment that are completely isolated from each other, you can run a custom export task to export nodes from the development environment and import them to the production environment for deployment.

Go to the Migration Assistant page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the icon in the upper-left corner and choose **All Products > Other > Migration Assistant**. The **DataWorks export** page under **DataWorks migration** appears.

Create a full export task

1. On the **Export Tasks** page, click **Create Export Task** in the upper-right corner.
2. In the **Create Export Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the export task. The name can contain only letters, digits, underscores (_), and periods (.).
Type	The type of the export task. Select **Full export** for this parameter. A full export task is used to export all the auto triggered nodes, manually triggered nodes, table metadata, and data sources that have been saved or committed in the current workspace.
Blacklist	Specifies whether to enable the blacklist feature for full export based on your business needs. If you select the **Add to Blacklist** check box, you can add the nodes and resources that do not need to be exported to a blacklist.

Parameter	Description
Export Version	Valid values: **Standard**, **Private Cloud(>=V3.12)**, and **Private Cloud(V3.6.1-V3.1.1)**. The DataWorks version determines the format in which data objects are exported. Check the DataWorks version of the destination workspace before you create an export task.
Remarks	The description of the export task.

3. (Optional)Click Add to Blacklist and run the export task.

   If you select **Add to Blacklist**, perform the following steps to configure the blacklist:

   i. In the **Create Export Task** dialog box, click **Add to Blacklist**.
   ii. On the **Set Blacklist** page, select the data objects that you do not want to export.
   iii. Click **Add Selected to Blacklist**.
   iv. Click **Export** in the upper-right corner.
   v. In the **Export confirmation** message, click **Confirm**.
4. (Optional)If you do not select **Add to Blacklist**, click **Export** in the Create Export Task dialog box.
5. In the **Export Progress** dialog box, view the progress of the export task. After the task succeeds, click **Back to Export Tasks**.

Create an incremental export task

1. On the **Export Tasks** page, click **Create Export Task** in the upper-right corner.
2. In the **Create Export Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the export task. The name can contain only letters, digits, underscores (_), and periods (.).
Type	The type of the export task. Select **Incremental** for this parameter. An incremental export task is used to export data objects that were modified after the specified date. Supported data objects include auto triggered nodes, manually triggered nodes, table metadata, and data sources that have been saved or committed in the current workspace.
Start Date	The date on which data is modified. The data generated after this date is incremental data.
Export Version	Valid values: **Standard**, **Private Cloud(>=V3.12)**, and **Private Cloud(V3.6.1-V3.1.1)**.
Remarks	The description of the export task.

3. Click **Export**.

Create a custom export task

1. On the **Export Tasks** page, click **Create Export Task** in the upper-right corner.
2. In the **Create Export Task** dialog box, configure the parameters as required.

Parameter	Description

Parameter	Description
Name	The name of the export task. The name can contain only letters, digits, underscores (_), and periods (.).
Type	The type of the export task. Select **Custom** for this parameter. A custom export task is used to export data objects that you specify. Supported data objects include auto triggered nodes, manually triggered nodes, table metadata, and data sources that have been saved or committed in the current workspace.
Export Version	Valid values: **Standard**, **Private Cloud(>=V3.12)**, and **Private Cloud(V3.6.1-V3.1.1)**.
Remarks	The description of the export task.

3. Click **Select Export Objects**.
4. On the **Export Objects** page, select a type of data object that you want to export from the **Export Object** drop-down list.

   Valid values of **Export Object**: **Table**, **Periodic tasks**, **Resources**, **Manual tasks**, **Function**, **DATA_SERVICE**, **Data source**, **Components**, and **Temporary query**.
5. Select the data objects that you want to export and click **Add Selected to Export Package**.

   You can also configure filter conditions such as **Export Object**, **Object Type**, and **Export Environment** to search for data objects. Then, click **Add All to Export Package** to add all the data objects that have been found to the package that you want to export.
6. Click **Export** in the upper-right corner.

View and manage export tasks

On the **Export Tasks** page, you can view the name, type, creator, status, update time, and description of created export tasks. The operations that you can perform on export tasks vary based on their status.

- If an export task is in the **Successful** state, you can perform the following operations on the task:
  - Click **View Export Report** in the Actions column. On the page that appears, view the task information in the **Basic Information**, **Overview**, and **Details** sections.
  - Click **Download** in the upper-right corner to download the package of the export task to a local directory.
  - Clone the export task.
    - Full export task for which the blacklist feature is not enabled: Click **Clone** in the **Actions** column. In the **Clone** dialog box, specify **Name** and click **Export**.
    - Full export task for which the blacklist feature is enabled: Click **Clone** in the **Actions** column. In the **Clone** dialog box, specify **Name** and click **Add to Blacklist**.

      On the **Set Blacklist** page, select the data objects that you do not want to export, click **Add Selected to Blacklist**, and then click **Export** in the upper-right corner.
    - Custom export task: Click **Clone** in the **Actions** column. In the **Clone** dialog box, specify **Name** and click **Select Export Objects**.

      On the **Export Objects** page, select the data objects that you want to export, click **Add Selected to Export Package**, and then click **Export** in the upper-right corner.
- If an export task is in the **Export failed** state, you can click **View Export Package**, **Download Export Package**, or **Re-export** in the Actions column as required. To retry the export task, click **Re-export**.
- If an export task is a custom export task that is in the **Editing** state, you can perform the following operations on the task:
  - Click **Edit** in the Actions column. On the Export Objects page, modify the data objects that you want to export.

- Click **View Export Package** in the Actions column. On the **Export Package Details** page, view the task information in the **Basic Information**, **Overview**, and **Details** sections.
- Click **Delete** in the Actions column. In the **Delete** message, click **Ok** to delete the task.

- If an export task is a full export task that is in the **Editing** state, you can click **Edit**, **Delete**, or **View Blacklist** in the Actions column as required. If you click View Blacklist in the Actions column, you can check the blacklist and click **Export** to run the export task or click **Close** in the dialog box that appears.

2.1.19.3.2. Create and view import tasks

After you run an export task to export data objects from a workspace, you can create an import task to import these data objects to a specified workspace.

Prerequisites

To create export or import tasks, you must use an Alibaba Cloud account or be the workspace administrator. If you use a Resource Access Management (RAM) user that is not assigned the administrator role, you can only view export and import tasks.

Go to the Migration Assistant page

1. Log on to the DataWorks console.
2. On the DataStudio page, click the ≡ icon in the upper-left corner and choose **All Products > Other > Migration Assistant**. The **DataWorks export** page under **DataWorks migration** appears.

Create an import task

1. In the left-side navigation pane of Migration Assistant, choose **DataWorks migration > DataWorks import**.
2. On the **Import Tasks** page, click **Create Import Task** in the upper-right corner.
3. In the **Create Import Task** dialog box, configure the parameters as required.

Parameter	Description
Name	The name of the import task. The name can contain only letters, digits, underscores (_), and periods (.).
Upload From	The source of the package that you want to import. Valid values: **Local** and **OSS**. ○ If you select **Local** for this parameter, perform the following steps to upload a package on your machine: a. Click **Upload File**. b. Select the package that you want to upload and click **Open**. c. Click **Check**. d. After the message **The resource package has passed the check** appears, click **Preview**. On the page that appears, check the package that you want to import. **Note** The size of the package that you want to upload cannot exceed 30 MB. ○ If you select **OSS** for this parameter, enter the endpoint of an Object Storage Service (OSS) object in the **OSS Endpoint** field. Then, click **Check** and **Preview** in sequence to check and preview the package that you want to upload.

Parameter	Description
Remarks	The description of the import task.

4. Click **OK**. The **Import Task Settings** page appears.

   Make sure that you have checked the format and content of the package before you click **OK**.

5. Configure the import task.

   When you configure the import task, you must complete the settings in the **Engine Instance Mapping** section. The settings in other sections are optional and can be configured as required.

   (Optional)

   i. In the **Engine Instance Mapping** section, select a compute engine of the destination workspace for each compute engine that is bound to the source workspace.

   If multiple compute engines are bound to the source workspace and only one compute engine is bound to the destination workspace, the import task fails. This is because some types of nodes cannot be created in the destination workspace due to the absence of the required compute engines.

   ii. (Optional)In the **Resource Group Mapping** section, configure resource group mapping between the source and destination workspaces. This ensures that resource groups are available for running imported nodes.

   iii. (Optional)In the **Dependency Mapping** section, configure workspace mapping for relevant nodes.

   Some nodes use the name of the source workspace in their code. In this case, you must configure workspace mapping for the nodes to run properly after they are imported. Set the **New Workspace** parameter to the name of the destination workspace. The system uses this workspace name to replace the original workspace name in the node code and the names of the ancestor and descendant nodes of the current node. After the import task is complete, the original workspace name is replaced with the new workspace name.

   iv. (Optional)In the **Dry-run** section, find the destination node that you want to set as a dry-run node and click **Set up empty run** in the Actions column.

   You can also select multiple nodes and click **Batch Configure** to set these nodes as dry-run nodes.

   This configuration is used to configure the scheduling mode of auto triggered nodes. The auto triggered node that is set as a dry-run node returns a success response without running and does not generate data.

   v. (Optional)In the **Commission Rules** section, configure the commission rules for **Resources**, **Tables**, and **Functions**, and specify whether to enable **Change Owner** as required.

   > Note
   >
   > - If a data object with the same name as the data object you want to import exists in the destination workspace, the imported data object cannot be committed.
   > - If you select No for the Change Owner parameter and no owner is specified for the node you want to import, you are automatically configured as the owner of the node after it is imported.

6. Click **Import** in the upper-right corner.
7. In the **Confirm** message, click **OK**.

View and manage import tasks

On the **Import Tasks** page, the operations that you can perform on import tasks vary based on their status.

- After an import task is complete, you can view the details of the task. To view the task details, find the task on the **Import Tasks** page and click **View Import Report** in the Actions column. On the page that appears, view

the task information in the **Basic Information**, **Import Settings**, **Import results**, and **Details** sections.

- If an import task is in the **Editing** state, you can perform the following operations on the task:
  - Click **Edit** in the Actions column. On the **Import Task Settings** page, modify the task configurations.
  - Click **Preview** in the Actions column. On the page that appears, view the task information in the **Basic Information**, **Overview**, and **Details** sections.
  - Click **Delete** in the Actions column. In the message that appears, click **Ok** to delete the task.
- If an import task is in the **Import failed** state, you can click **Re-import** in the Actions column of the task. In the **Import progress** dialog box, click **Return to import task list** after the import task is complete.

2.1.20. Workspace management

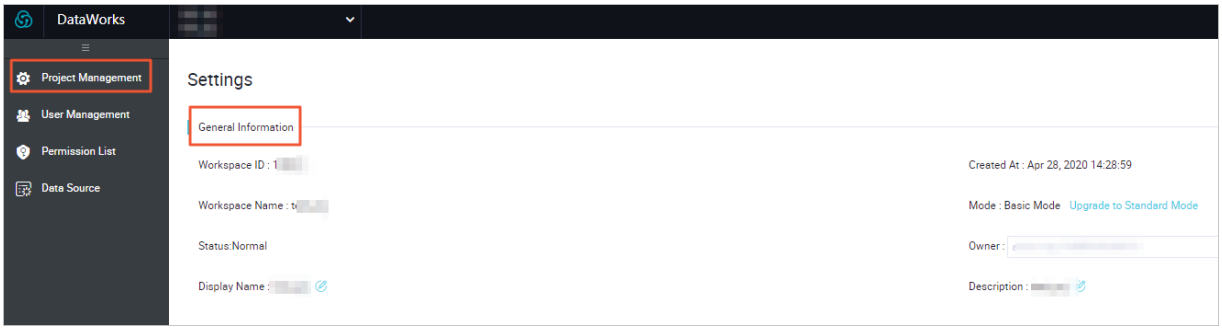
2.1.20.1. Configure a workspace

On the Workspace Management page of a workspace, you can manage and configure the workspace. DataWorks supports a variety of compute engines, such as MaxCompute, E-MapReduce (EMR), Realtime Compute for Apache Flink, Hologres, Graph Compute, AnalyticDB for PostgreSQL, and AnalyticDB for MySQL.

Go to the Workspace Management page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click the icon in the upper-right corner.
3. On the **Project Management** page, set the parameters in the **Basic properties**, **Scheduling Properties**, **Security Settings**, and **Compute Engine Information** sections for the workspace based on your business requirements.

Configure basic properties

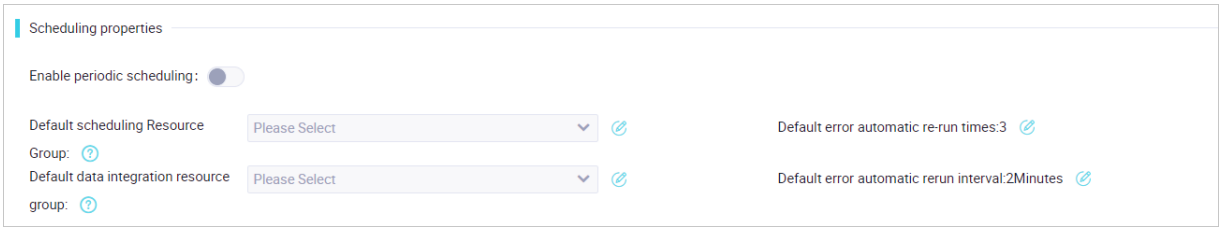


Parameter	Description
Workspace ID	The ID of the workspace, which cannot be changed.
Workspace Name	The name of the workspace. The name must start with a letter and can contain only letters and digits. It is not case-sensitive. The name uniquely identifies the workspace and cannot be changed after the workspace is created.
Status	The status of the workspace.
Display Name	The display name that is used to identify the workspace. The display name can contain only letters and digits. You can change it based on your requirements.
Creation Time	The time when the workspace was created. The value cannot be changed.

Parameter	Description
Mode	The mode of the workspace, which cannot be changed. Valid values: **Simple Mode** and **Standard**.
Owner	The owner of the workspace, which cannot be changed.
Description	The description of the workspace. You can modify the description based on your requirements. The description can be a maximum of 128 characters in length and can contain letters, special characters, and digits.

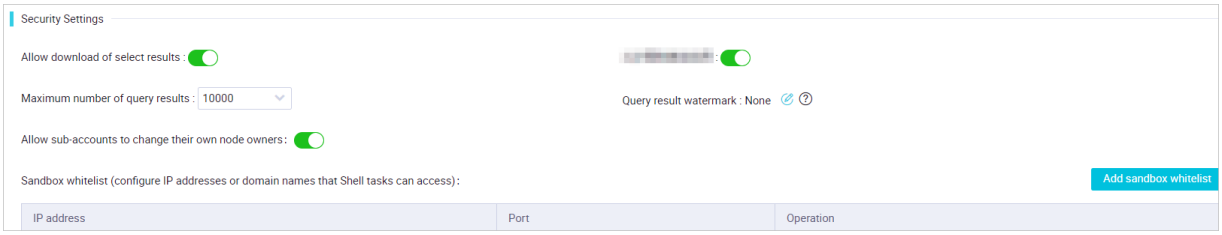
Configure scheduling properties

In the **Scheduling Properties** section, you can enable periodic scheduling for the workspace. You can also set the **Default Scheduling Resource Group**, **Default Data Integration Resource Group**, **Default Automatic Rerun Times Upon Error**, and **Default Automatic Rerun Interval Upon Error** parameters for the workspace.



Nodes can be periodically run in a workspace only after you turn on **Periodic Scheduling** for the workspace.

Configure security settings



Parameter	Description
Allow download of select results	Specifies whether the query results that are returned by SELECT statements in DataStudio can be downloaded. If you turn off this switch, the query results cannot be downloaded.
Copy Query Result	Specifies whether the query results that are returned in DataStudio can be copied.
Maximum Number of Query Results	The maximum number of data records that can be returned for each query. Valid values: **10**, **100**, **500**, **1000**, **5000**, and **10000**. Default value: **10000**. For example, you set the **Maximum Number of Query Results** parameter to **1000**. Go to the **DataStudio** page 5 minutes later. In the left-side navigation pane, click **Ad-Hoc Query**. Create an SQL node and execute a query statement on the node to query data in a table that has more than 1,000 data records. The number of returned records is 1,000.
Watermark for Query Results	Specifies whether watermarks for the query results are displayed.
Change Node Owner by RAM User	Specifies whether to allow RAM users to change the owners of their nodes.

Parameter	Description
Sandbox Whitelist (contains IP addresses and domain names that can be accessed by Shell nodes)	The IP addresses or domain names that can be accessed by a Shell node that runs on the default resource group.

To add an IP address or domain name to the whitelist, perform the following steps:

1. In the **Security Settings** section, click **Add**.
2. In the **Add** dialog box, enter an IP address or a domain name in the **Address** field and a port number in the **Port** field.
3. Click **Confirm**.

Associate a MaxCompute project with a workspace

In the **Computing Engine Information** section, click the **MaxCompute** tab. On this tab, you can view the settings of the **MaxCompute Project Name** and **MaxCompute Visitor Identity** parameters for an associated MaxCompute compute engine instance.

Associate an EMR cluster with a workspace

Note If Kerberos authentication is enabled for an E-MapReduce (EMR) cluster., you cannot create tables, resources, and functions in a visualized manner for this cluster.

1. In the **Compute Engine Information** section, click the **E-MapReduce** tab. On this tab, you can view the information about all the available EMR clusters in the workspace.
2. Click **Add instance**.
3. In the **New EMR cluster** dialog box, set the parameters as required.

Parameter	Description
Instance Display Name	The display name of the EMR cluster to be associated.
Region	The region of the current workspace.
Cluster ID	The ID of the user who created the EMR cluster.
Project ID	The ID of the project in the EMR cluster.
YARN resource queue	The name of the resource queue in the EMR cluster. Unless otherwise specified, set this parameter to *default*.
Endpoint	The endpoint of the EMR cluster. You can obtain the endpoint in the EMR console.

4. Click **Confirm**.

Associate a Realtime Compute for Apache Flink project with a workspace

1. In the **Compute Engine Information** section, click the **Real-time Computing** tab. On this tab, you can view the information about all the available Realtime Compute for Apache Flink compute engine instances in the workspace.
2. Click **Add Instance**.
3. In the **Add a real-time computing instance** dialog box, set the parameters as required.

Parameter	Description
Instance Display Name	The display name of the Realtime Compute for Apache Flink compute engine instance.
Select Project	The Realtime Compute for Apache Flink project that you want to associate with the workspace. Select a project from the drop-down list. If you need to create a project, click **Real-time calculation control platform**.

4. Click **Confirm**.

Associate a Graph Compute compute engine instance with a workspace

1. In the **Compute Engine Information** section, click the **GraphCompute** tab.
2. Click **Bind Graph Compute Instance**.

> **Notice** A Graph Compute instance can be associated with only one DataWorks workspace. After a Graph Compute instance is associated with a DataWorks workspace, the instance cannot be used in other DataWorks workspaces.

3. In the **Bind Graph Compute Instance** dialog box, configure the parameters as required.

Parameter	Description
Instance Display Name	The display name of the Graph Compute instance.
Graph Compute Instance Name	The name of the Graph Compute instance that you want to associate with the workspace.

4. Click **Bind**.

Associate a Hologres compute engine instance with a workspace

1. In the **Compute Engine Information** section, click the **Hologres** tab. On this tab, you can view the information about all the available Hologres compute engine instances in the workspace.
2. Click **Bind Hologres Database**.
3. In the **Bind Hologres Database** dialog box, configure the parameters.

Parameter	Description
Instance Display Name	The display name of the Hologres compute engine instance.
Access identity	The identity that is used to run the code of committed Hologres nodes. Valid values: **Alibaba Cloud primary account** and **Alibaba Cloud sub-account**.
Hologres instance name	The name of the Hologres instance that you want to associate with the workspace.
Database name	The name of the database that was created in **SQL Console**, such as testdb.
Server	The endpoint of the purchased Hologres instance. This value is automatically generated after you select the Hologres instance.
Port	The port of the purchased Hologres instance. This value is automatically generated after you select the Hologres instance.

4. Click **Test Connectivity**.

5. After the connectivity test is passed, click **Confirm**.

Associate an AnalyticDB for PostgreSQL instance with a workspace

1. In the **Computing Engine information** section, click the **AnalyticDB for PostgreSQL** tab.
2. Click **Add Instance**.
3. In the **Add AnalyticDB for PostgreSQL Instance** dialog box, configure the parameters as required.

Parameter	Description
Instance Display Name	The display name of the AnalyticDB for PostgreSQL instance. The display name must be unique.
InstanceName	The name of the AnalyticDB for PostgreSQL instance that you want to associate with the workspace.
DatabaseName	The name of the AnalyticDB for PostgreSQL database that you want to associate with the workspace.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Connectivity Test	AnalyticDB for PostgreSQL nodes must be run on exclusive resource groups. Therefore, you must specify an exclusive resource group. Click **Test connectivity** to test the connectivity between the specified exclusive resource group and AnalyticDB for PostgreSQL instance.

4. After the connectivity test is passed, click **Confirm**.

Associate an AnalyticDB for MySQL instance with a workspace

1. In the **Compute Engine Information** section, click the **AnalyticDB for MySQL** tab.
2. Click **Add Instance**.
3. In the **Add an AnalyticDB for MySQL instance** dialog box, configure the parameters.

Parameter	Description
Instance Display Name	The display name of the AnalyticDB for MySQL cluster. The display name must be unique.
InstanceName	The name of the AnalyticDB for MySQL cluster that you want to associate with the workspace.
DatabaseName	The name of the AnalyticDB for MySQL database that you want to associate with the workspace.
Username	The username that you can use to connect to the database.
Password	The password that you can use to connect to the database.
Connectivity Test	AnalyticDB for MySQL nodes must be run on exclusive resource groups. Therefore, you must specify an exclusive resource group. Click **Test connectivity** to test the connectivity between the specified exclusive resource group and the AnalyticDB for MySQL cluster.

4. After the connectivity test is passed, click **Confirm**.

Associate a CDH cluster with a workspace

1. In the **Compute Engine Information** section, click the **CDH** tab.
2. Click **Add Instance**.

   For a workspace in standard mode, the development environment is isolated from the production environment. If you are using a workspace in standard mode, you must add instances to both the development and production environments.
3. In the **Add CDH Compute Engine** dialog box, configure the parameters.

   You can set Access Mode to **Shortcut mode** or **Security mode**. If **Security mode** is selected, the permissions on the data of the node that is run by different Apsara Stack tenant accounts or RAM users can be isolated.

   Configure the following parameters:

Parameter	Description
Instance Display Name	The display name of the compute engine instance. The display name must be unique.
Access Mode	◦ If **Shortcut mode** is used, multiple Apsara Stack tenant accounts or RAM users map to the same CDH cluster account. These Apsara Stack tenant accounts or RAM users can access data in the same CDH cluster account. In this case, data permissions are not isolated. ◦ If **Security mode** is used, you can configure the mappings between the Apsara Stack tenant accounts or RAM users and CDH cluster accounts to isolate the permissions on the data of the node that is run by the Apsara Stack tenant accounts or RAM users.
Select Cluster	◦ If **Shortcut mode** is selected for **Access Mode**, you must select a CDH cluster whose Authentication Type is set to Kerberos Account Authentication. If you do not have a CDH cluster, create one. ◦ If **Security mode** is selected for **Access Mode**, you must select a CDH cluster whose Authentication Type is set to Kerberos Account Authentication. You can check whether Kerberos Account Authentication is enabled for the CDH cluster in the DataWorks console. On the **Workspace Management** page, click **Hadoop Config** in the left navigation pane and find the cluster of which you want to view the configuration. Then, click **Modify** to view the **Authentication Type** parameter in the **Mapping Configuration** section. If you do not have a CDH cluster, create one.

Parameter	Description
Access identity	◦ If **Shortcut mode** is selected for Access Mode, the Authentication Type parameter is set to No Authentication by default. You can use only the specified accounts, such as admin and hadoop. These accounts are used only to commit nodes. ◦ **Security mode** ▪ You can set **Account for Scheduling Nodes** based on your business requirements. This account is used to automatically schedule and run the node after the node is committed to the scheduling system. You need to configure the mappings between the Apsara Stack tenant accounts or RAM users and CDH cluster accounts. Valid values: **Task owner**, **Alibaba Cloud primary account**, and **Alibaba Cloud sub-account**. **Note** ▪ This parameter is available only for the production environment. ▪ On the DataStudio page, the identity used to run nodes is the CDH cluster account that is mapped to the logon Apsara Stack tenant account or RAM user. Therefore, you must configure the identity mappings not only for scheduling access identities, but also for the workspace developers in a project to prevent node running failures. ▪ For a CDH cluster in the development environment, the default value of this parameter is **Task Owner**.
Resource Group	Select an exclusive resource group for scheduling that connects to the DataWorks workspace. If no exclusive resource group for scheduling is available, create one. After you select an exclusive resource group for scheduling, click **Test Connectivity** to test the connection between the exclusive resource group for scheduling and the CDH cluster.

4. After the connectivity test is passed, click **Confirm**.

2.1.20.2. Manage members and roles

DataWorks provides roles that have different permissions for you to implement finer-grained permission management. You can add the required users to your workspace and assign the required roles to the users. You can also create custom roles and grant permissions to the roles based on your business requirements.

Background information

Multiple users can be added to the same DataWorks workspace. In this case, if the users have excessive permissions on the workspace, the data security of the workspace may be affected by inappropriate permission use. However, if the users have insufficient permissions on the workspace, they may be unable to use the required features. To resolve this issue, DataWorks provides identities such as members and roles. You can assign different roles to users based on their requirements on the use of workspaces.

If the default roles that are provided by DataWorks cannot meet your requirements, you can create custom roles and grant the required permissions to the roles.

DataWorks provides the following identities:

- **Member**: the Apsara Stack tenant accounts or RAM users that are added to a DataWorks workspace.
- **Cloud account**: Apsara Stack tenant accounts or RAM users.
- **Role**: the carriers that have permissions in a workspace and can be assumed by the members of the workspace. DataWorks provides the following roles:
  - **Project Manager**: the administrators that have all the permissions on the features in a workspace. For example, the workspace administrator role can be used to assign the required role to a RAM user and remove a member that is not the workspace owner from a workspace.
  - **Deploy**: the engineers that have the permissions to deploy nodes.
  - **Development**: the developers that have the permissions to develop and commit nodes.
  - **Model Developer**: the designers that have the permissions to use the data modeling feature.
  - **Visitor**: the visitors that have the read-only permissions on a DataWorks workspace.
  - **Project owner**: the owner that has the highest level of permissions on a workspace.
  - **O&M**: the engineers that have the permissions to allocate resources and deploy nodes.
  - **Security Manager**: the administrators that have the permissions to use Data Security Guard.

  For more information about the permissions of different roles, see Permission list.

Limits

- Only the **Project Manager** and the **Project owner** roles can add users, change the roles of users, and remove **users** and the added **custom roles**.
- You can use only an Apsara Stack tenant account or the RAM user whose role is an administrator or a super administrator of a MaxCompute project to map a custom DataWorks role to a role of the MaxCompute project.

Go to the User Management page

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click the icon in the upper-right corner.
3. In the left-side navigation pane, click **User Management** to go to the **User Management** page.

   You can manage members and roles on the **User Management** page.

Manages members

On the **Manage Members** tab, you can perform the following operations:

- View member information.

  You can view the accounts of members and the roles that are assigned to the members in the current workspace. You can also specify the name of the member, account, or role to search for a specific member. Then, you can view the member information and the number of members to which the role has been assigned. This allows you to realize centralized management of members and roles assigned to the members.
- Add a user.
  i. Click **Add Member** in the upper-right corner of the **Manage Members** tab to add a user to the current workspace.
  ii. In the **Add Member** dialog box, select one or more RAM users from the **Available Accounts** list.
    - **Member**: the Apsara Stack tenant accounts or RAM users that are added to a DataWorks workspace.
    - **Cloud account**: Apsara Stack tenant accounts or RAM users.

- **Role**: the carriers that have permissions in a workspace and can be assumed by the members of the workspace. DataWorks provides the following roles:
  - **Project Manager**: the administrators that have all the permissions on the features in a workspace. For example, the workspace administrator role can be used to assign the required role to a RAM user and remove a member that is not the workspace owner from a workspace.
  - **Deploy**: the engineers that have the permissions to deploy nodes.
  - **Development**: the developers that have the permissions to develop and commit nodes.
  - **Model Developer**: the designers that have the permissions to use the data modeling feature.
  - **Visitor**: the visitors that have the read-only permissions on a DataWorks workspace.
  - **Project owner**: the owner that has the highest level of permissions on a workspace.
  - **O&M**: the engineers that have the permissions to allocate resources and deploy nodes.
  - **Security Manager**: the administrators that have the permissions to use Data Security Guard.

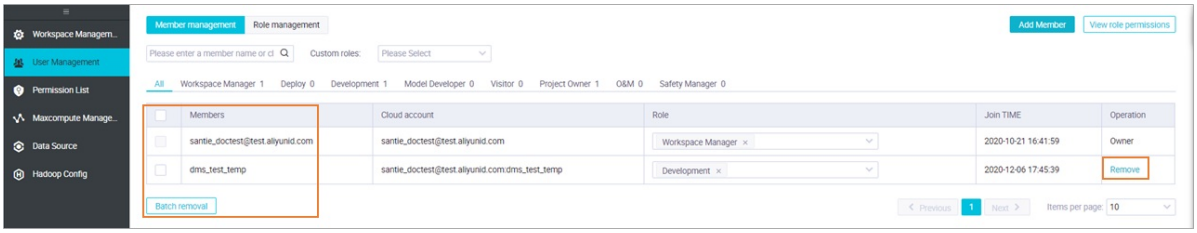
iii. Click the > icon to move the selected RAM users to the **Added Accounts** list.

iv. Select one or more roles that you want to assign to the selected RAM users.

v. Click **Confirm**.

- Remove a member.

  On the **Manage Members** tab, find the member that you want to remove from the workspace and click **Remove** in the **Actions** column to remove the member from the workspace. If you want to remove multiple members from the workspace, you can select them and click Batch removal to remove them at a time.



Manage roles

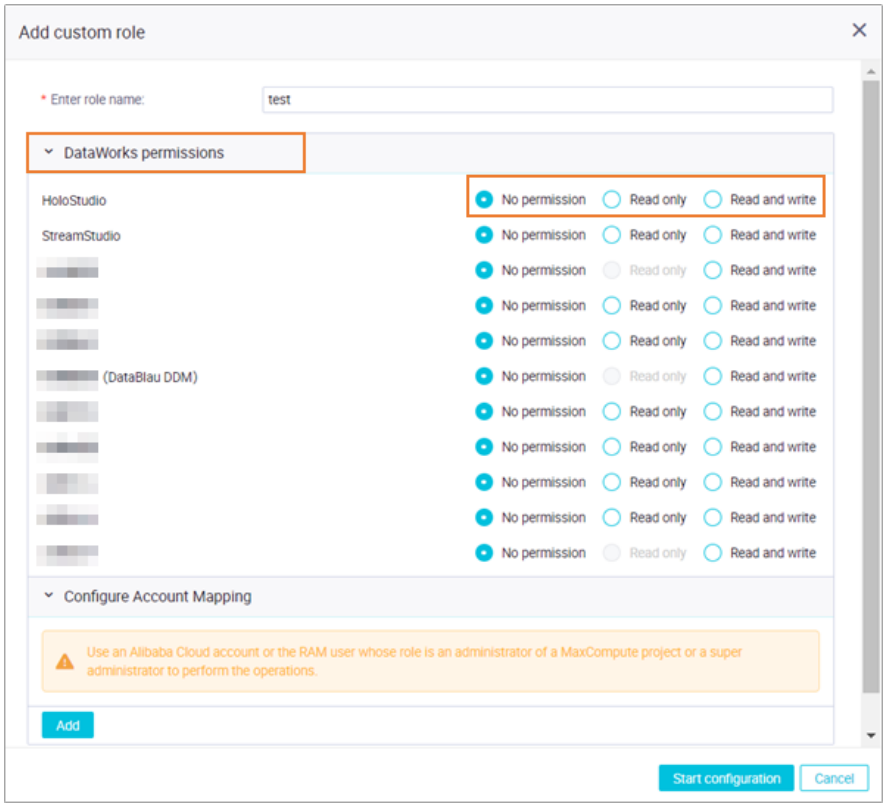
On the **Roles** tab, you can perform the following operations:

- Create a custom role.

  i. Click **Add Custom Role** in the upper-right corner of the **Roles** tab.

  ii. In the **Add Custom Role** dialog box, enter a name for your custom role, such as test.

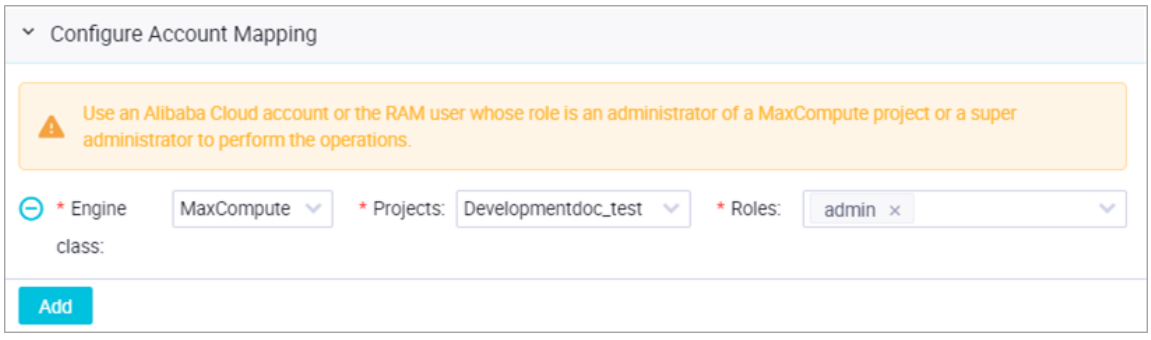
  iii. Grant permissions on the required DataWorks modules to the role.
  - **Unauthorized**: indicates that the role has no permissions on the related module.
  - **Read-only**: indicates that the role can only view the data in the related module.
  - **Read and Write**: indicates that the role can modify the data in the related module.



iv. **Map a custom role to a role of a compute engine.**

You can map a custom role to a role of a compute engine. For example, you can map the custom role test to the **Admin** role of a MaxCompute project. In this case, the Admin role is assumed by the custom role when the custom role accesses the MaxCompute project.

> **Note** You can use only an Apsara Stack tenant account or the RAM user whose role is an administrator or a super administrator of a MaxCompute project to map a custom DataWorks role to a role of the MaxCompute project.



v. Click **Configure**.

- View or edit roles.

  You can view the **preset roles** and **custom roles** that have been configured for the workspace on the **Roles** tab. You can also edit or delete **custom roles**. For more information about the permissions of **preset roles**, see Permission list.

2.1.20.3. Permission list

DataWorks provides seven roles: workspace owner, workspace administrator, developer, administration expert, deployment expert, visitor, and security expert. You cannot grant the role of the workspace owner to other workspace members. This topic describes the permissions of these roles. In the following tables, Yes indicates that a role has the corresponding permission, and No indicates that a role does not have the corresponding permission.

Data management

Permission	Workspace owner	Workspace administrator	Developer	Administration expert	Deployment expert	Visitor	Security expert
Delete self-created tables	Yes	Yes	Yes	No	No	No	No
Specify categories for self-created tables	Yes	Yes	Yes	No	No	No	No
View favorite tables	Yes	Yes	Yes	No	No	No	No
Create tables	Yes	Yes	Yes	No	No	No	No
Unhide self-created tables	Yes	Yes	Yes	No	No	No	No
Modify the schemas of self-created tables	Yes	Yes	Yes	No	No	No	No
View self-created tables	Yes	Yes	Yes	No	No	No	No
View the content of self-submitted permission requests	Yes	Yes	Yes	No	No	No	No
Hide self-created tables	Yes	Yes	Yes	No	No	No	No
Specify the time-to-live (TTL) for self-created tables	Yes	Yes	Yes	No	No	No	No
Request permissions on tables created by others	Yes	Yes	Yes	No	No	No	No
Delete tables	No	Yes	Yes	No	No	No	No

2.1.20.4. Manage connections

Connections are used to configure readers and writers during data integration. On the Data Source page of a workspace, you can view and add connections.

Procedure

1. Log on to the DataWorks console.
2. On the **DataStudio** page, click  in the upper-right corner.
3. In the left-side navigation pane, click **Data Source**.

   On the **Data Source** page, you can filter connections by conditions such as **Connect To** and **Connection Name**.

Click **Add Connection** in the upper-right corner to add a connection. For more information, see Data sources.

3.Realtime Compute

3.1. User Guide

3.1.1. What is Realtime Compute?

Realtime Compute is a big data processing platform that analyzes streaming data in real time based on Apsara Stack. You can create streaming data analysis and computing jobs by using Alibaba Cloud Flink SQL. When you use Flink SQL, you do not need to develop the underlying logic for streaming data processing.

As the demands for high data timeliness and operability increase, software systems need to process more data in less time. In traditional models for big data processing, online transaction processing (OLTP) and offline data analysis are separately performed at different times.

Realtime Compute is designed to respond to the increasing demand for the timeliness of data processing. The business value of data decreases as time passes by. Therefore, data must be computed and processed as soon as possible after it is generated. Traditional models for big data processing follow the scheduled processing mode, which accumulates and processes data in a computing cycle that can last hours or even days. These models cannot satisfy the growing demand for real-time big data processing. Batch processing cannot meet the business requirements in scenarios in which an extremely low processing delay is required. These scenarios include real-time big data analysis, early warning and risk control, real-time forecasting, and financial transactions. Realtime Compute enables real-time processing over data streams. Realtime Compute shortens the data processing delay, implements real-time computational logic, and greatly reduces computing costs. This helps you meet business requirements for real-time processing of big data.

Streaming data

Big data can be viewed as a series of discrete events. These discrete events form event streams or data streams along a timeline. Streaming data is continuously generated from thousands of data sources and is typically sent in data records. Streaming data has a smaller scale than offline data. Each type of data is produced as a stream of events. Streaming data includes a wide variety of data, such as the log files generated by your mobile or web applications, online purchases, in-game player activities, information from social networks, financial trade centers, geospatial services, and telemetry data from connected devices in data centers.

Realtime Compute has the following advantages:

- Real-time and unbounded data streams

  Realtime Compute processes data streams in real time. Streaming data is continuously generated from data sources and is subscribed and consumed in chronological order. Data streams continuously flow into the Realtime Compute system. For example, when Realtime Compute processes data streams from website visit logs, the log data streams continuously enter the Realtime Compute system if the website is online. In Realtime Compute, unbounded data streams are processed in real time.

- Continuous and efficient computing

  Realtime Compute is an event-driven system in which unbounded event or data streams continuously trigger real-time computations. Each streaming data record triggers a computational task. Realtime Compute performs continuous and real-time computations over data streams.

- Real-time integration of streaming data

  Realtime Compute writes the computing result of each streaming data record into the target data store in real time. For example, the system directly writes the data of a computed report to an ApsaraDB RDS instance for report display. Realtime Compute continuously writes the results into the target data store in real time. Therefore, Realtime Compute can be viewed as a data source that generates data streams for the target data store.

3.1.2. Quick start

3.1.2.1. Log on to the Realtime Compute console

This topic describes how to log on to the Realtime Compute console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, move the pointer over Products and click **Realtime Compute**.
5. Specify **Organization** and **Region**.
6. Click **Blink**.

3.1.2.2. Frequently used words

3.1.2.2.1. Overview

Statistical analysis of frequently used words is widely applied in diverse fields, including the analysis of frequently used words in search engines, forums, and tags. For example, you can easily view the latest and most frequently searched words in microblogging websites through real-time statistics. Statistical analysis of frequently used words is, at its core, a simple word count job. In word count jobs for streaming data, real-time processing logic is used to analyze and display frequently used words in real time.

If you are new to working with big data computing, a word count job is for you to easily get started. The word count job in big data computing is similar to a `Hello, World!` program that is often the first program that a developer learns to write. The following topics take a word count job in Realtime Compute as an example to describe how to create a word count job based on real-time processing logic. This example helps you quickly get familiar with basic Flink SQL syntax and basic operations of Realtime Compute jobs, such as creating an SQL file for a job and publishing the job.

3.1.2.2.2. Code development

This topic uses a word count job as an example to describe how to create a Realtime Compute job.

Prerequisites

Before you create a word count job, a source table named stream_source and a result table named stream_result are created in external data stores. The stream_source table includes only one column. The column is named word and its data type is STRING. The stream_result table includes two columns. One column is named word and its data type is STRING. The other column is named cnt and its data type is BIGINT. The two tables are registered in Realtime Compute.

1. Log on to the Realtime Compute console to go to the homepage of Realtime Compute.
2. In the top navigation bar, click **Development**.
3. Right-click the folder that you created.
4. Click the **Create File** icon.
5. In the Create File dialog box, configure the following parameters:
   - File Name: Enter `wordcount`.
   - File Type: Select FLINK_STREAM / SQL.
   - Storage Path: Keep the default setting.
6. Enter the following code in the code editor.

> **Note** In the SQL statements for the word count job, the STRING data type for the referenced table must be declared as the VARCHAR data type.

```
  create table stream_source (word varchar);
create table stream_result (word varchar, cnt bigint);
insert into
    stream_result
select
    t.word,
    count (1)
from
    stream_source t
group by
    t.word;
```

The following section explains the SQL code.

Line 1 creates a reference to the stream_source source table.

> **Note** Streaming data continuously enters Realtime Compute and triggers stream processing procedures. Each streaming data record or each batch of data from the stream_source table triggers a stream processing procedure.

Line 2 creates a reference to the stream_result result table. The stream_result table stores the computing results of the word count job.

> **Note** Realtime Compute does not have built-in components for data storage, and the result data is stored in external data stores, such as ApsaraDB RDS and Tablestore. This line of code creates a reference to a result table that contains the result data.

Lines 5 through 11 implement the computing logic: Realtime Compute reads data from the stream_source table and counts how often words occur based on inbound data records.

> **Note** Flink SQL supports most standard SQL statements. This allows you to easily and cost-effectively adopt Realtime Compute for stream processing.

The method of performing a word count job for stream processing is similar to that for batch processing. The word count job for stream processing continuously processes unbounded data streams until the job is terminated.

3.1.2.2.3. Code debugging

Realtime Compute provides a powerful debugging feature to verify SQL statements. You can debug Realtime Compute jobs by simulating data stores where streaming data, static data, and result data are stored.

> **Note**
> - To avoid negative impacts on online data stores, Realtime Compute is not allowed to read data from these data stores during the debugging process. Before debugging, you must prepare test data for input tables.
> - The outputs of INSERT operations are exported only to local screens. This does not affect online systems.

Debugging method

1. On the top of the **Development** page, click **Debug**.
2. On the page that appears, click **Download Template** and edit the template based on your debugging rules.

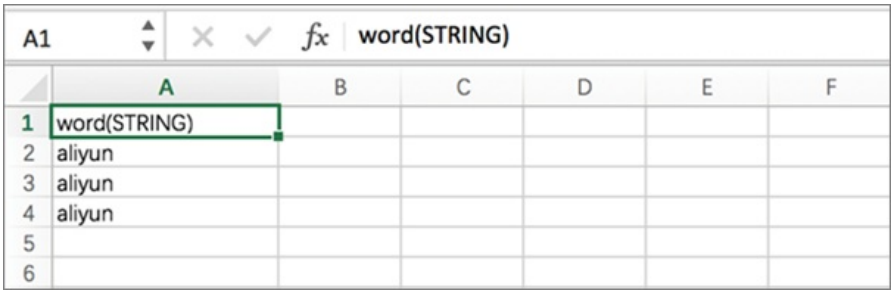
   > **Note** The file that is uploaded for debugging must meet the following requirements:
   > - The file size cannot exceed 1 MB, and the file contains maximum of 1,000 records.
   > - The file must use UTF-8 encoding.
   > - Commas (,) cannot be used in test data, because the file uses the comma-separated values (CSV) format.
   > - Numeric values can be displayed only in the general format, and cannot be displayed in the scientific notation format.

3. Click **Upload** to upload the file.
4. Click **OK**.
5. View the debugging result in the output window.

Sample file for debugging the word count job

> **Note** The file for debugging is in the CSV format. We recommend that you use the following software applications to open and modify the template:
> - Excel for Windows users.
> - Vim or Sublime Text for MacOS users. We do not recommend that you use Number because it adds unnecessary fields when you modify CSV files.

Sample file for debugging the word count job



Test data

You can download test data and upload the data on the **Debug File** page.

> **Note** The *test data for statistical analysis of frequently used words* is unavailable for download in a PDF file. You can contact system administrators to download the test data.

View the debugging result

Real-time computing is triggered by data streams. Each data record from the stream_source table triggers a stream processing procedure. After each procedure is complete, a computing result is exported. The test file contains three data records. After each data record reaches Realtime Compute, a stream processing procedure is triggered. Therefore, a total of three data records are displayed on the screen. Realtime Compute uses the following computing logic:

- The first data record (aliyun) reaches Realtime Compute. This is the first time that the system has detected the word "aliyun." Therefore, the computing result is `<aliyun, 1>`, which is displayed on the screen.
- The second data record (aliyun) reaches Realtime Compute. The system detects an existing record of `<aliyun, 1>` and increases the value by one. Therefore, the computing result is `<aliyun, 2>`, which is displayed on the screen.
- The third data record (aliyun) reaches Realtime Compute. The system detects an existing record of `<aliyun, 2>` and increases the value by one. Therefore, the computing result is `<aliyun, 3>`, which is displayed on the screen.

The third computing result `<aliyun, 3>` is considered as the final output of the debugging. Another sample of test data is provided for you to test the debugging feature. You can use different samples of test data and view the debugging outputs.

3.1.2.2.4. Administration

After the SQL file has been verified, you can publish the SQL file for the job on the **Administration** page of Realtime Compute. Then, you can start the job. The job runs on a Realtime Compute cluster.

Procedure

1. On the **Development** page, click **Publish**. The **Publish New Version** dialog box appears.
2. In the **Resource Configuration** step, click **Next**.
3. In the **Check** step, click **Next**.
4. In the **Publish File** step, click **Publish**.
5. On the **Administration** page, view the published word count job.
6. Click **Start** in the **Actions** column of the word count job. The **Start** dialog box appears.
7. Specify **Start Time of Reading Data** and click **OK**. Then, the job runs on a Realtime Compute cluster.

Result

After the job is started, click the job name. The **Overview** page appears.

FAQ

Q: Why does the word count job have no input or output while it is running on the distributed compute clusters of Realtime Compute?

A: When you created the `my_source` and `my_result` tables, you did not specify the data storage type of the referenced data source. In this scenario, the source table is considered to be a random table of strings or digits, and the result table is considered to be discarded data.

3.1.2.3. Big screen service for the Tmall Double Eleven Global Shopping Festival

3.1.2.3.1. Overview

During Double 11, a big screen shows the total sales volume of Alibaba Group in real time. The big screen service is a highlight for the shopping festival.

Stream processing for the big screen service was previously based on Apache Storm that is an open source distributed real-time computation system. The Apache Storm-based development process took around one month. The application of Flink SQL reduces the period for the development of the big screen service to three days. The underlying layer of Realtime Compute removes the Apache Storm modules that are designed for execution optimization and troubleshooting. This achieves a higher processing efficiency for Realtime Compute jobs.

3.1.2.3.2. Scenario description

The streaming data input for the Tmall big screen service is the transaction data from the Tmall platform. The incoming transaction data is organized based on a two-dimensional table: `tmall_trade_detail`.

Field	Type	Description
tid	BIGINT	The order ID.
buyer_uid	BIGINT	The buyer ID.
seller_uid	BIGINT	The seller ID.
gmtdate	TIMESTAMP	The time when the order is completed.
payment	DOUBLE	The order amount.

Realtime Compute calculates two metrics based on the preceding table: the total number of orders and the total order amount up to the current time. The two metrics are written to an online RDS system and displayed on a big screen in real time. The online RDS system is used to store the result table: `tmall_trade_state`.

Field	Type	Description
gmtdate	VARCHAR(16)	The date when the order is completed.
trade_count	BIGINT	The total number of orders.
trade_sum	DOUBLE	The total order amount.

The following topics describe how to build an end-to-end solution for the Tmall big screen service in around 10 minutes.

3.1.2.3.3. Preparations

Before editing Flink SQL statements for a Realtime Compute job, you must register data stores for source tables and result tables in Realtime Compute. This topic uses DataHub as an example to describe how to register a data store in Realtime Compute.

Create a DataHub topic

1. Log on to the DataHub console. For more information, see the "Log on to the DataHub console" section in *DataHub User Guide*.
2. If one or more projects have been created, click **View** in the **Actions** column for the target project. If no projects have been created, click **Create Project** to create a project and click **View** in the **Actions** column.
3. On the page that appears, click **Create Topic**.
4. Configure the topic based on the schema of the tmall_trade_state RDS table in the "Scenario description" section.

After performing these steps, you can edit Flink SQL statements for the Realtime Compute job.

Upload data to DataHub

You can upload data to the DataHub topic that you have created. To do this, follow these steps. Log on to the **DataHub** console. You can upload data to the DataHub topic that you have created. To do this, follow these steps:

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Data Acquisition**.
3. Click **Upload File**.
4. On the page that appears, double-click the target project and click the target DataHub topic.
5. Click **Select File** to select a file.
6. Click **Upload**.

To simplify the test procedure, you can use thetest data about the Double 11. You can download the data and then upload it to the DataHub topic for data collection.

3.1.2.3.4. Register a data store

The data store registration feature of Realtime Compute allows you to easily register DataHub topics, create tables, and reference data stores. To register a data store, perform the following steps:

Procedure

1. Log on to the Realtime Compute console to go to the homepage of Realtime Compute.
2. In the top navigation bar, click Development.
3. In the left-side navigation pane, click the **Storage** tab.
4. Click the **DataHub Data Storage** folder.
5. On the top of the page, click **+Registration and Connection**.
6. Register a DataHub project in Realtime Compute. For more information about parameter settings, see Register a DataHub project.

   If you use ApsaraDB RDS for MySQL to store the result data for data visualization, you must register an ApsaraDB RDS data store in Realtime Compute. For more information, see Register an RDS instance.

3.1.2.3.5. Development

After the data has been collected to Realtime Compute, you can continue to edit Flink SQL statements.

1. Create a reference to the source.

   To create references to the DataHub source table and RDS result table, click Data Storage in the left-side navigation pane of the **Development** page in the Realtime Compute console, and perform the following operations:

   - Find the target DataHub topic, and click **Reference as Source Table**. Realtime Compute automatically parses the schema of the topic and adds the corresponding SQL statements to the **Development** page.
   - Find the target RDS table, and click **Reference as Result Table**. Realtime Compute automatically parses the schema of the table and adds the corresponding SQL statements to the **Development** page.

2. Edit Flink SQL statements.

   If you have created the DataHub topic and RDS table as described in the previous topics, the Flink SQL code for the tmall_d11 job can be executed directly. Otherwise, change the names of the DataHub topic and RDS table based on the topic and table that you have created. The sample code is as follows:

   ```
   replace into tmall_trade_state
       select
           from_unixtime(FLOOR(tmall_trade_detail.gmtdate/1000), 'yyyy-MM-dd') as gmt_date,
           count(tid) as trade_count,
           sum(payment) as trade_sum
       from
           tmall_trade_detail
       group by
           from_unixtime(FLOOR(tmall_trade_detail.gmtdate/1000), 'yyyy-MM-dd');
   ```

   > **Note** You can modify the information about tables and fields as required.

3. Debug the Flink SQL code.

   The data during the Double 11 Shopping Festival is available for testing. To debug the code, download the test data and upload the data on the **Development** page for debugging.

4. Publish the SQL file for the tmall_d11 job.

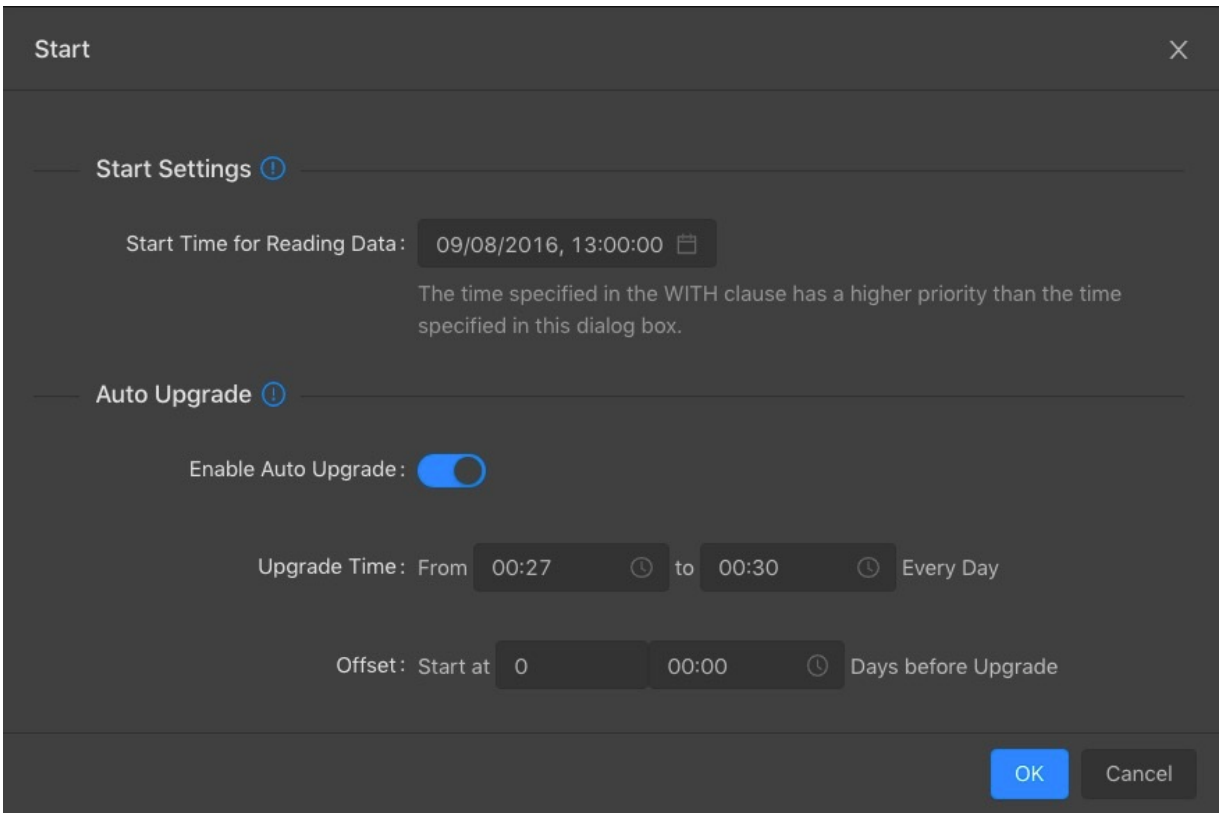
   After the computational logic has been verified in the debugging phase, click **Publish** on the **Development** page to publish the SQL file for the tmall_d11 job. Then, you can view the tmall_d11 job on the **Administration** page of the Realtime Compute console, and manage the job in the production environment, such as starting the job.

3.1.2.3.6. Operations and maintenance (O&M)

On the Administration page, you can click Start in the Actions column and specify the parameters on the page that appears to start a stream processing job, for example, the tmall_d11 job.

> **Note** After you click Start, a dialog box is displayed. In the dialog box, you can specify the start time for reading data from the source data store.

The specified start time must be earlier than the file upload time. For example, the start time can be one hour earlier than the file upload time. In the Double 11 use case, the current time is 14:10, and 10 minutes have elapsed since the source data is uploaded. Therefore, the start time is set to 13:00.



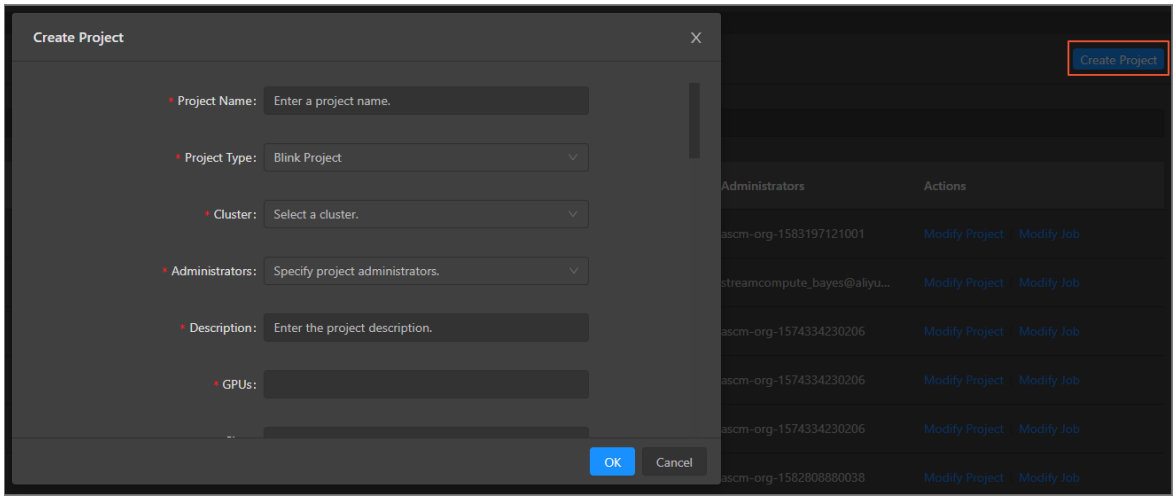
You can check the result data in the ApsaraDB RDS data store after the job runs as expected. In the result table, five transactions and a turnover of CNY 500 are displayed. This is consistent with the source data for testing. In this way, an end-to-end verification is performed to check the SQL code.

3.1.3. Project management

This topic describes how to create and search for a project.

Create a project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, move the pointer over your profile picture and click **Project Management**.
3. In the upper-right corner of the **Projects** page, click **Create Project**.
4. Configure the project information.



Parameter description

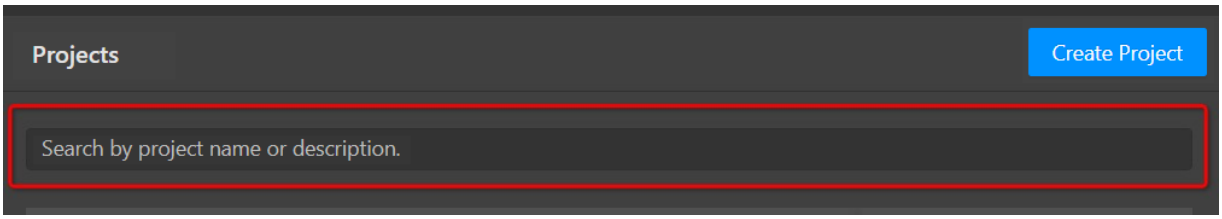
Parameter	Description
Project Name	The name of the project.
Project Type	The type of the project. **Blink Project** is selected by default.
Cluster	The cluster on which the jobs in the project run.
Administrators	The Administrators of the project.
Description	The description of the project.
GPUs	The number of GPUs that are used by the project.
Slots	The number of compute units (CUs) that are used by the project. One CU is assigned with one CPU core and 4 GB memory.
Alert Methods	The methods in which alerts are sent when errors occur during job running. You can receive alerts by using text messages or TradeManager messages.
File Types	The supported file types. You can keep the default setting.
Storage Types	The supported data store types. You can keep the default setting.
Max Data Stores	The maximum number of data stores that can be registered in Realtime Compute. You can keep the default setting.
Max File Versions	The maximum number of code versions for an SQL file. You can keep the default setting.
Max Folders	The maximum number of folders that can be created in the project. You can keep the default setting.
Max Folder Levels	The maximum number of folder levels in the project. You can keep the default setting.
Max Files	The maximum number of job SQL files that can be created in the project. You can keep the default setting.
Max Resources	The maximum number of JAR files and DICTIONARY resources that can be uploaded. You can keep the default setting.

Parameter	Description
Max Referenced Resources	The maximum number of JAR files and DICTIONARY resources that can be referenced. You can keep the default setting.
Monitoring and Alerting	Specifies whether to enable the monitoring and alerting feature. You can keep the default setting.
Data Collection	Specifies whether to collect data while a job is running. You can keep the default setting.
Data Display	Specifies whether to display data. You can keep the default setting.
Metastore	Specifies whether to display metadata. You can keep the default setting.
Data Storage	Specifies whether to enable data store registration. This feature is enabled by default. You can keep the default setting.
Engine	Specifies whether to display the engine. You can keep the default setting.
Online Logs	Specifies whether to record the job running logs. This feature is enabled by default. You can keep the default setting.
Resource Management	Specifies whether resources such as JAR files can be uploaded. This feature is enabled by default. You can keep the default setting.
Switch Version	Specifies whether to enable the job version switch feature. This feature is enabled by default. You can keep the default setting.
Project Protection	Specifies whether to enable the project lock feature. You can keep the default setting.

5. Click **OK**.

Search for a project

On the **Projects** page, enter a keyword or full name of a project in the search box to find the project.



3.1.4. Data storage

3.1.4.1. Overview

This chapter describes data storage systems supported by Realtime Compute.

3.1.4.2. Authorize Realtime Compute to access a VPC

Before you use Realtime Compute to access storage resources in a virtual private cloud (VPC), you must authorize Realtime Compute to access the VPC. This topic describes how to authorize Realtime Compute to access a VPC.

Procedure

1. Log on to the Realtime Compute console.
2. Move the pointer over the username in the upper-right corner.
3. In the list that appears, click **Project Management**.
4. In the left-side navigation pane, click **VPC Access Authorization**.
5. In the upper-right corner of the **VPC Access Authorization** page, click **Add Authorization**.
6. In the **Authorize StreamCompute VPC Access** dialog box, configure the parameters as required. The following table describes the parameters.

Parameter	Description
Name	The name of the VPC.
Region	The region where the storage resource resides.
VPC ID	The ID of the VPC. To view the VPC ID of an ApsaraDB RDS instance, perform the following steps: i. Log on to the ApsaraDB RDS console. ii. In the top navigation bar, select the region where the ApsaraDB RDS instance resides. iii. On the Instances page, find the ApsaraDB RDS instance and click the instance ID in the Instance ID/Name column. iv. In the left-side navigation pane, click **Database Connection**. v. On the **Instance Connection** tab, view the VPC ID next to the value of **Network Type** in the **Database Connection** section. For example, the VPC ID is `vpc-bp1lysht98wrvl9n3****`.
Instance ID	The instance ID of the storage resource in the VPC. To view the ID of an ApsaraDB RDS instance, perform the following steps: i. Log on to the ApsaraDB RDS console. ii. In the top navigation bar, select the region where the ApsaraDB RDS instance resides. iii. On the Instances page, find the ApsaraDB RDS instance and click the instance ID in the Instance ID/Name column to go to the **Basic Information** page. iv. View **Instance ID** in the **Basic Information** section.
Instance Port	The port of the storage resource in the VPC.

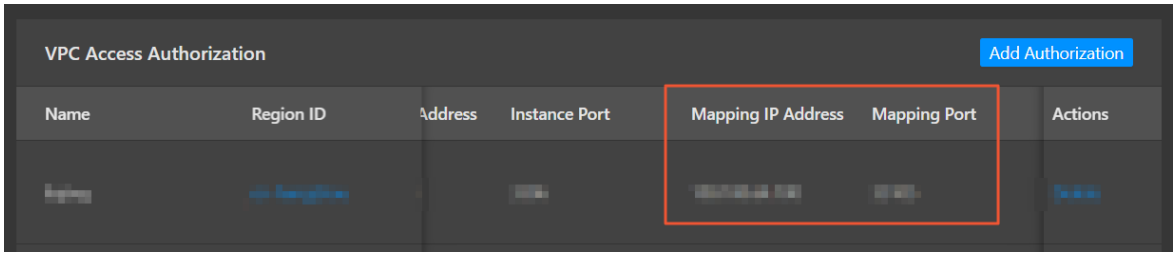
FAQ

Q: How do I set the url parameter when I use data definition language (DDL) statements to reference a storage resource in a VPC?

A: When you use DDL statements to reference storage resources in a VPC, you can set the url parameter in the WITH clause based on the **Mapping IP Address** and **Mapping Port** parameters on the **VPC Access Authorization** page. For example, you can set url='jdbc:mysql://<mappingIP>:<mappingPort>/<databaseName>'. To obtain the values of the **Mapping IP Address** and **Mapping Port** parameters, perform the following steps:

1. Log on to the Realtime Compute console.
2. Move the pointer over the username in the upper-right corner.
3. In the list that appears, click **Project Management**.
4. In the left-side navigation pane, click **VPC Access Authorization**.

5. On the **VPC Access Authorization** page, view the values of the **Mapping IP Address** and **Mapping Port** parameters.



3.1.4.3. Overview

3.1.4.3.1. Overview

To facilitate data storage management, you can register data storage resources on the Realtime Compute development platform. This enables you to use the advantages of the one-stop Realtime Compute service. In Realtime Compute, you can manage multiple data storage systems, such ApsaraDB RDS, AnalyticDB for MySQL, and Tablestore. This one-stop management service allows you use manage data stores in the cloud on the Realtime Compute development platform without the need to navigate across multiple management consoles of different storage systems.

3.1.4.3.2. Types

Realtime Compute supports both streaming data storage and static data storage.

Streaming data storage

Streaming data storage systems provide inputs and outputs for downstream Realtime Compute jobs.

Streaming data storage

Storage system	Input	Output
DataHub	Supported	Supported
Log Service	Supported	Supported
MQ	Supported	Supported

Static data storage

Static data storage systems provide outputs for downstream Realtime Compute jobs and allow you to perform association queries.

Static data storage

Support	Dimension table	Output
ApsaraDB RDS	Supported	Supported
Tablestore	Supported	Supported

3.1.4.3.3. Registration and usage

This topic describes how to register and use external data stores in Realtime Compute.

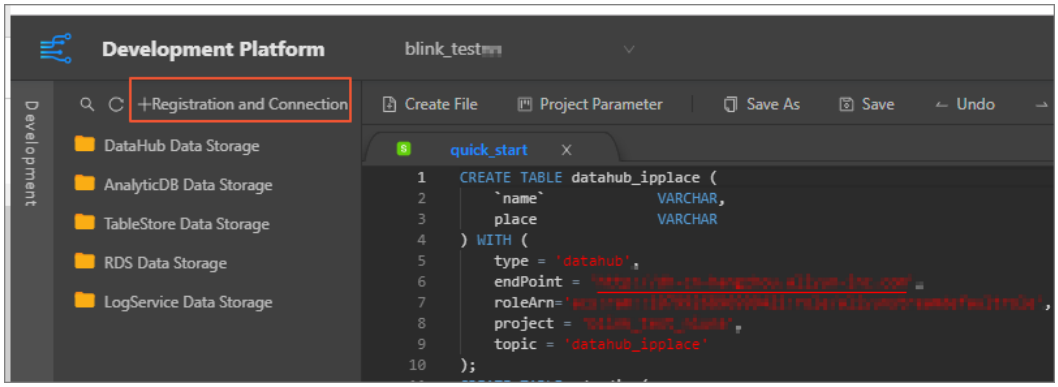
> **Note** If a job requires the use of the data stores owned by another Apsara Stack tenant account, you can write DDL statements to reference the data stores. In the DDL statements, you must specify the AccessKey ID and AccessKey secret of the account. In this scenario, you cannot use the codeless UI to manage the data stores.

Register a data store

To register a data store, follow these steps:

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane of the page that appears, click the **Storage** tab. Select the folder for the data store that you want to register. Then, click **+Registration and Connection**.

   Register a data store



4. In the dialog box that appears, configure the required parameters and click **OK**.

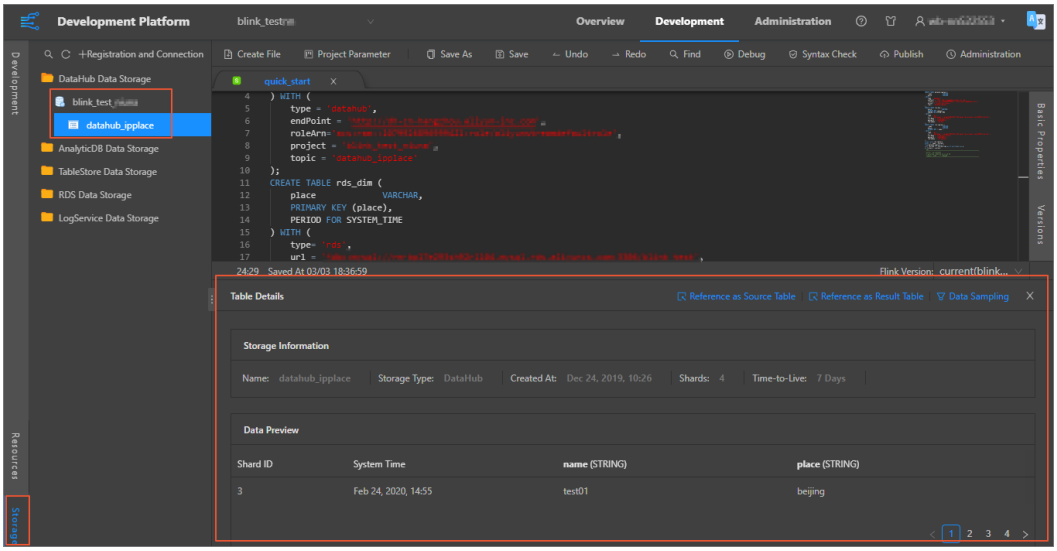
> **Note** After you enable the data store registration feature, you can only register data stores that are owned by your organization.

Preview data from a data store

Realtime Compute provides the data preview feature for each registered data store. To preview data, click the **Storage** tab and double-click the folder of the target data store in the left-side navigation pane. The following example shows how to preview data from a DataHub data store.

1. Log on to the Realtime Compute console. In the top-navigation bar, click Development. On the page that appears, click the **Storage** tab and double-click the **DataHub Data Storage** folder.
2. Double-click the target project and then the target topic to view the details.

   Table details



Use the auto DDL generation feature

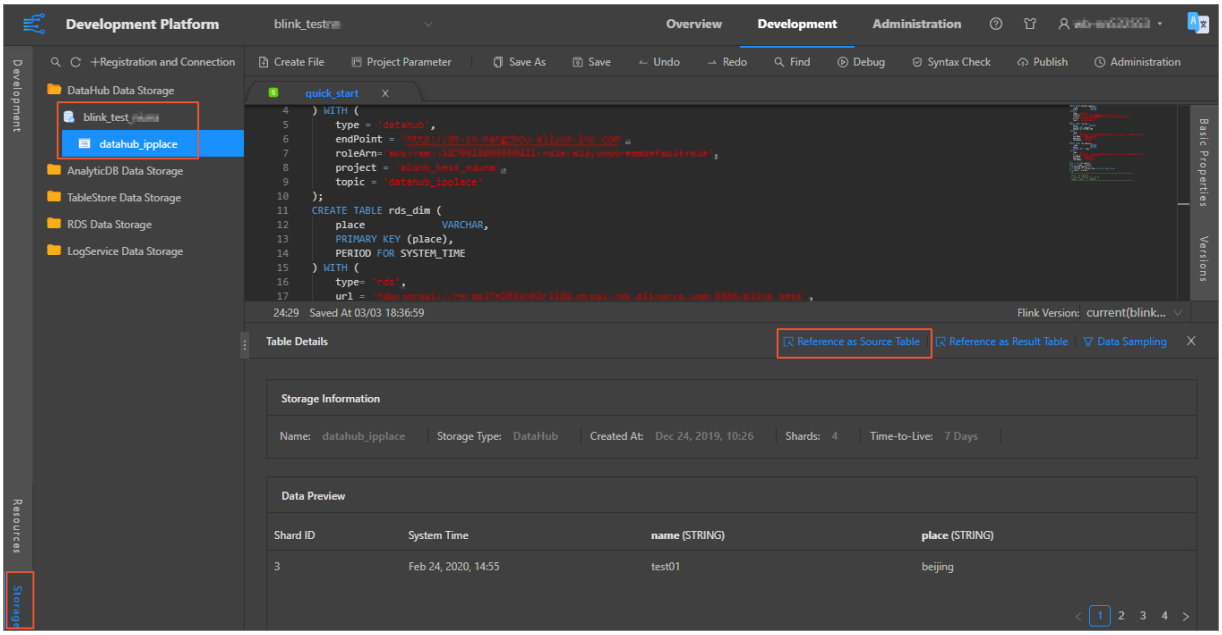
You must declare tables from external data stores before you can reference these tables. The following example shows how to reference a source table that contains streaming data:

```
CREATE TABLE in_stream( a varchar, b varchar, c timeStamp) with ( type='datahub', endPoint='http://dh-cn-hangzhou.aliyuncs.com', project='blink_test', topic='ip_count02', accessId='LTAIYtaf******', accessKey='gUqyVwfkK2vfJI7jF90******');
```

The field names in the table that is referenced on the Development page must be the same as those in the DataHub topic. You must declare the field data types in the code based on the field type mapping between DataHub and Realtime Compute to ensure that Realtime Compute can identify the data. Realtime Compute offers the auto DDL generation feature. The following section describes how to use this feature.

1. In the left-side navigation pane of the **Development** page, click the **Storage** tab.
2. On the **Storage** tab, navigate through cascaded folders and nodes to find the target table. Then, double-click the name of the target table.
3. In the **Table Details** pane that appears, click **Reference as Source Table**, **Reference as Result Table**, or **Reference as Dimension Table** as required. Then, you can obtain the DDL statements that are automatically generated to reference the target table.

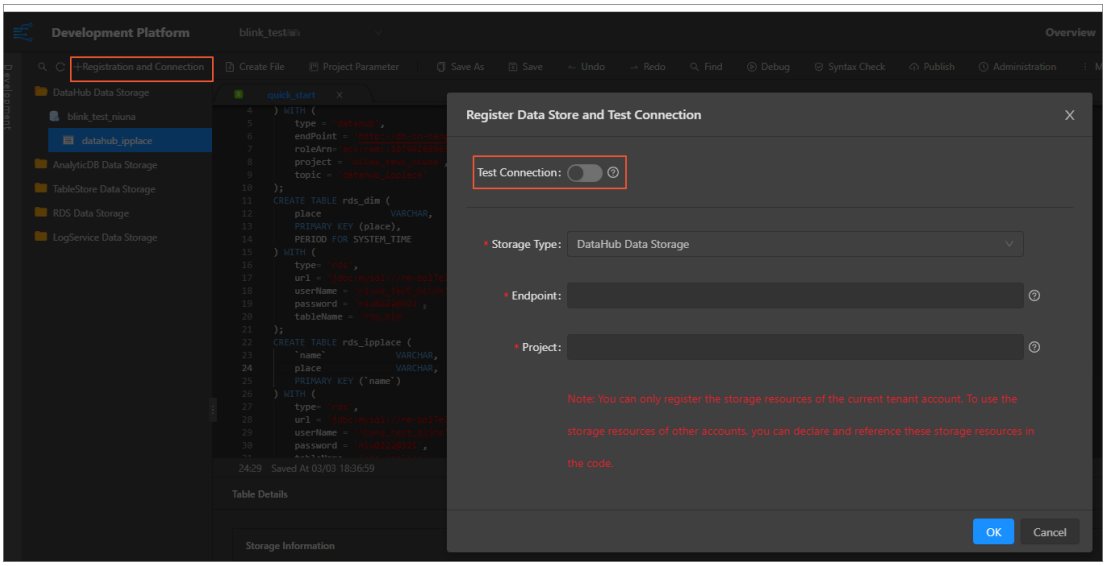
To reference a source table, log on to the Realtime Compute console and open the target SQL file on the Development page. Click the Storage tab, select the table for reference, and then click **Reference as Source Table**. The required DDL statements are displayed on the current page.



Test network connection

Realtime Compute offers the network connection test feature for data stores. This feature allows you to test the connection between Realtime Compute and a target data store. To enable the network connection test feature, follow these steps:

1. In the left-side navigation pane of the **Development** page, click the **Storage** tab.
2. In the upper-right corner of the **Storage** tab, click **+Registration and Connection**.
3. In the **Register Data Store and Test Connection** dialog box, turn on **Test Connection**.



Example: Reference data stores owned by another level-1 organization

You can only register and use data stores that are owned by your level-1 organization. To use data stores that are owned by another level-1 organization, write DDL statements to create a reference to these data stores. For example, if a user from Organization A wants to use the data stores owned by Organization B, the user can enter the following DDL statements:

```
CREATE TABLE in_stream( a varchar, b varchar, c timeStamp) with ( type='datahub', endPoint='http://dh-cn-hangzhou.aliyuncs.com', project='blink_test', topic='ip_count02', accessId='AccessKey ID authorized by Organization B users', accessKey='AccessKey secret authorized by Organization B users');
```

3.1.4.4. Register a DataHub data store

DataHub, an Alibaba Cloud streaming data service, is a real-time data distribution platform designed to process streaming data. You can publish and subscribe to applications for streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data. Realtime Compute often uses DataHub to store source and result tables that contain streaming data.

Register a DataHub project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click the **DataHub Data Storage** folder and select **Register Data Store** to register a DataHub project in Realtime Compute. Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. DataHub Data Storage is selected by default.
Endpoint	The endpoint of DataHub. The endpoint of DataHub varies with regions. For more information about endpoints, contact your administrator. **Note** To specify this parameter for Apsara Stack, contact your Apsara Stack administrator to obtain the endpoint of DataHub.
Project	The name of the DataHub project. **Note** You can only register DataHub projects that are owned by your level-1 organization. For example, if DataHub Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the DataHub project.

Scenarios

DataHub is a streaming data storage system that can be used to store source and result tables. However, it cannot be used to store dimension tables for Realtime Compute.

FAQ

Q: Why am I unable to register a DataHub project in Realtime Compute?

A: Realtime Compute uses a storage software development kit (SDK) to access different data stores. The Storage tab in the Realtime Compute console only helps you manage data from different data stores. You can perform the following operations to troubleshoot registration errors:

- Check whether you have created a DataHub project and have the permissions to access the project. You can log on to the DataHub console and check whether you can access the project.
- Check whether you are the project owner. You can only register DataHub projects that are owned by your level-1 organization. For example, if DataHub Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.
- Check whether you have specified the correct DataHub endpoint and project name.
- Check whether you have specified a classic network endpoint for the Endpoint parameter. If you specify a VPC endpoint, the DataHub project will fail to be registered.
- Check whether you have registered the DataHub project. Realtime Compute provides a registration check mechanism to prevent duplicate registration.

Q: Why does Realtime Compute only support time-based sampling?

A: DataHub stores streaming data, and you can only specify time parameters in the API. Therefore, Realtime Compute supports only time-based sampling.

3.1.4.5. Register a Log Service data store

Log Service (previously known as SLS) provides an end-to-end solution for log management. You can use Log Service to easily collect, subscribe to, dump, and query large amounts of log data. Realtime Compute can integrate with Log Service to process logs. This eliminates the need of data migration.

Register a Log Service project

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click the **LogService Data Storage** folder and select **Register Data Store** to register a Log Service project in Realtime Compute. Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the Test Connection switch.
Storage Type	The type of the data store. LogService Data Storage is selected by default.
Endpoint	The endpoint of Log Service. The endpoint of Log Service varies with regions. **Note** For more information about the endpoint of Log Service, contact the Apsara Stack system administrator.

Parameter	Description
Project	The name of the Log Service project. **Note** You can only register Log Service projects that are owned by your level-1 organization. For example, if Log Service Project A is owned by Organization A, users from Organization B cannot register Project A in Realtime Compute.
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the Log Service project.

Scenarios

Log Service is a streaming data storage system that can be used to store source tables and result tables. However, it cannot be used to store dimension tables for Realtime Compute.

FAQ

- Q: Why am I unable to register a Log Service project in Realtime Compute?

  A: Realtime Compute uses a storage software development kit (SDK) to access different data stores. The Storage tab in the Realtime Compute console only helps you manage data from different data stores. You can perform the following operations to troubleshoot registration errors:

  - Check whether you have created a Log Service project and have the permissions to access the project. You can log on to the Log Service console and check whether you can access the project.
  - Check whether you are the project owner. You can only register Log Service projects that are owned by your level-1 organization. For example, if Log Service Project A is owned by Organization A, a user from Organization B cannot register Project A in Realtime Compute.
  - Check whether you have specified the correct Log Service endpoint and project name.

    Note The endpoint must start with http and cannot end with a forward slash (/). For example, *http://cn-hangzhou.log.aliyuncs.com* is correct, and *http://cn-hangzhou.log.aliyuncs.com/* is incorrect.

  - Check whether you have registered the Log Service project. Realtime Compute provides a registration check mechanism that prevents duplicate registration.

- Q: Why does Realtime Compute support only time-based sampling?

  A: Log Service stores streaming data, and you can only specify time parameters in the API. Therefore, Realtime Compute supports only time-based sampling.

  Note To use the search feature of Log Service, log on to the Log Service console.

3.1.4.6. Register a Tablestore data store

Tablestore is a NoSQL database service that is based on the Apsara distributed system. Tablestore allows you to store and access large amounts of structured data in real time. Tablestore features massive data storage and low access delays, which makes it suitable to store dimension tables and result tables for Realtime Compute.

Register a Tablestore instance

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click **TableStore Data Storage** and select **Register Data Store**. In the dialog box that appears, register a Tablestore instance in Realtime Compute. Parameters

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on the **Test Connection** switch.
Storage Type	The type of the data store. **TableStore Data Storage** is selected by default.
Endpoint	The endpoint of the Tablestore instance. You must enter the internal endpoint of the Tablestore instance. You can log on to the Tablestore console to view the internal endpoint of the instance.
Instance Name	The name of the Tablestore instance.
AccessKey ID	The AccessKey ID of the current account.
AccessKey Secret	The AccessKey secret of the current account. The AccessKey secret enables Realtime Compute to access the Tablestore instance.

3.1.4.7. Register an ApsaraDB RDS data store

This topic describes how to register and use an ApsaraDB RDS data store in Realtime Compute.

Introduction to ApsaraDB RDS

ApsaraDB RDS offers a stable, reliable, and scalable online database service. Based on the Apsara distributed operating system and high performance SSD storage, ApsaraDB RDS supports a wide range of engines, such as MySQL, PostgreSQL, and Postgres Plus Advanced Server (PPAS, highly compatible with Oracle). Realtime Compute supports the following ApsaraDB RDS engines: MySQL and PostgreSQL.

The performance of Tablestore in high concurrency scenarios where large amounts of data need to be processed is higher than that of ApsaraDB RDS. The performance of ApsaraDB RDS is restricted by the limits of relational models. Therefore, ApsaraDB RDS is often used to store result tables for Realtime Compute. In low concurrency scenarios where a small number of data needs to be processed, ApsaraDB RDS can be used to store dimension tables.

> **Note** Realtime Compute uses relational databases, such as ApsaraDB RDS for MySQL, to store result data. Distributed Relational Database Service (DRDS) and ApsaraDB RDS connectors are used. If Realtime Compute frequently writes data to a DRDS table or an ApsaraDB RDS table, deadlocks may occur. In scenarios that require high queries per second (QPS), high transactions per second (TPS), or highly concurrent write operations, we recommend that you do not use DRDS or ApsaraDB RDS to store the result tables of Blink jobs. To prevent deadlocks, we recommend that you use Tablestore to store result tables.

Register an ApsaraDB RDS instance

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Development**.

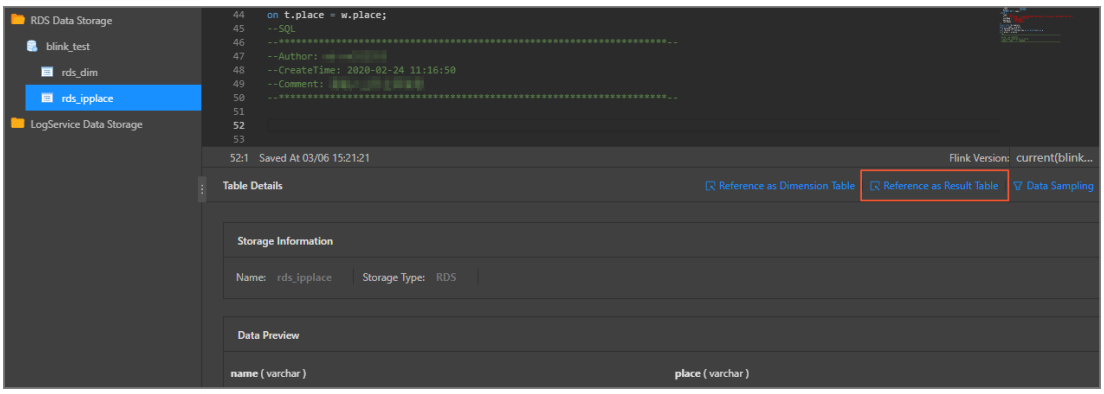
3. In the left-side navigation pane, click the **Storage** tab.
4. Right-click **RDS Data Storage**, and select **Register Data Store**. In the dialog box that appears, register an ApsaraDB RDS instance in Realtime Compute. Parameter description

Parameter	Description
Test Connection	Specifies whether to enable the network connection test feature. Network connection tests are automatically performed on data stores that can be registered in Realtime Compute. To test the connection between Realtime Compute and data stores that cannot be registered, turn on Test Connection.
Storage Type	The type of the data store. RDS Data Storage is selected by default.
URL	The URL that is used to access the ApsaraDB RDS database.
DBName	The name of the ApsaraDB RDS database to be accessed by Realtime Compute. **Note** This parameter specifies the ApsaraDB RDS database name instead of the ApsaraDB RDS instance name. ApsaraDB RDS uses whitelists for access control to ensure system security. The IP addresses of the Realtime Compute console and worker nodes must be added to the whitelists of ApsaraDB RDS. Otherwise, Realtime Compute may fail to connect to ApsaraDB RDS. For more information, see Specify whitelist settings.
User Name	The username that is used to log on to the ApsaraDB RDS database.
Password	The password that is used to log on to the ApsaraDB RDS database.
Engine	The type of the ApsaraDB RDS database. Valid values: ○ **mysql** ○ **postgresql** ○ **sqlserver**

Reference an ApsaraDB RDS table as a result table

After you register an ApsaraDB RDS data store, double-click the ApsaraDB RDS database, double-click the ApsaraDB RDS table that you want to reference as a result table, and then click **Reference as Result Table**.

Reference an ApsaraDB RDS table as a result table



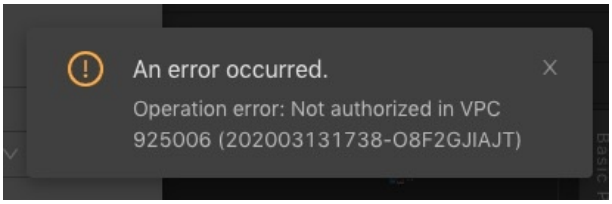
After you click Reference as Result Table, Realtime Compute automatically generates the related DDL statements on the current page.

Result

```
31      place             VARCHAR,
32      PRIMARY KEY (`name`)
33  ) WITH (
34      type= 'rds',
35      url = '[redacted]',
36      userName = [redacted],
37      password = [redacted]
38      tableName = [redacted]
39  );
```

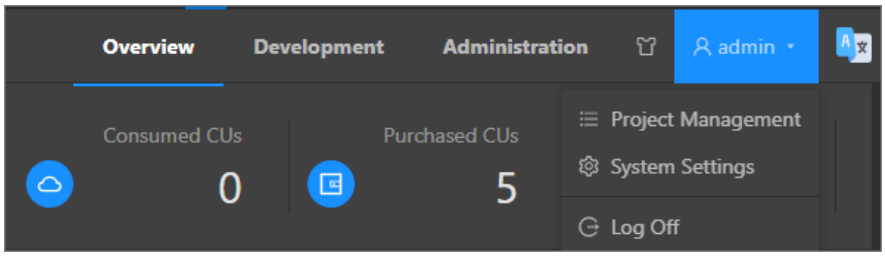
If the following error message appears, troubleshoot and rectify the fault in the following way.

Error message



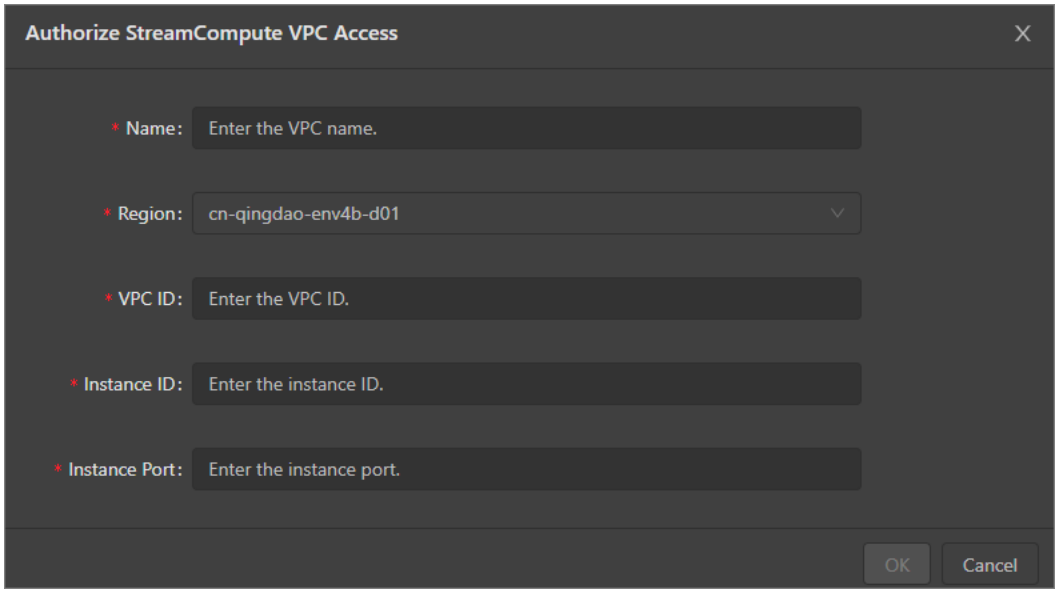
The error occurs because a VPC instead of a classic network was selected when you created the ApsaraDB RDS instance. You can perform the following steps to rectify this fault:

1. Move the pointer over the administrator icon, as shown in the following figure.



2. Click **System Settings**.
3. In the left-side navigation pane, click **VPC Access Authorization**.
4. Click **Add Authorization**. The **Authorize StreamCompute VPC Access** page appears.

Authorization



Parameter description

Parameter	Description
Name	The name of the VPC.
Region	The region where the ApsaraDB RDS instance resides.
VPC ID	The ID of the VPC.
Instance ID	The ID of the ApsaraDB RDS instance. You can log on to the ApsaraDB RDS console and view the instance ID. Instance information Instance Port	The port that is used to access the ApsaraDB RDS instance. To view the internal port number, log on to the ApsaraDB RDS console, click the ID or name of the instance that you want to access in the Instance ID/Name column. On the page that appears, view the internal port number in the Basic Information section.

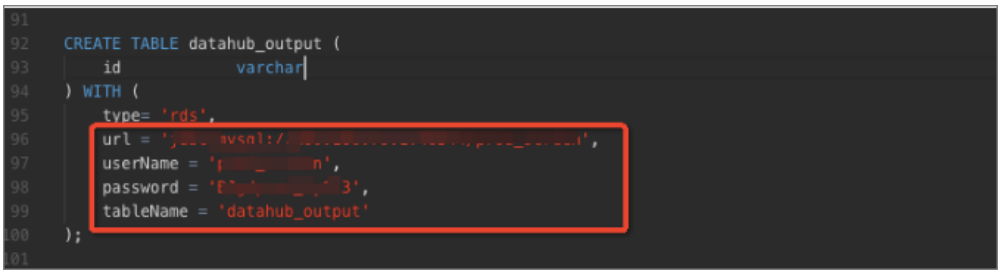
5. Register the ApsaraDB RDS instance. You must specify the required parameters during the registration.

You can register only data storage resources that are owned by your level-1 organization. For example, if ApsaraDB RDS Instance A is owned by Organization A, a user from Organization B cannot register ApsaraDB RDS Instance A in the Realtime Compute console. To use Instance A in a stream processing job, the user from Organization B must use SQL code to create a reference to Instance A.

> **Note** If you want to use the ApsaraDB RDS storage resources owned by your level-1 organization, we recommend that you do not use SQL code to create a reference to these resources.

The user from Organization B must also specify the following parameters in the WITH clause based on the information of Instance A: url, userName, password, and tableName.

Configuration category



To use ApsaraDB RDS storage resources by writing SQL code, the user from Organization B must specify whitelist settings.

Specify whitelist settings

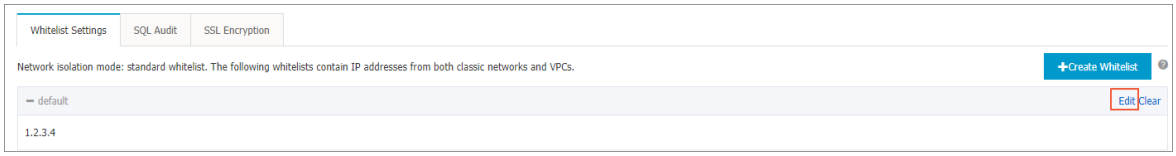
Some data stores use whitelists for access control to ensure high-level security. These data stores allow access only from the IP addresses that are added to the whitelists. This prevents unauthorized Apsara Stack services from accessing data in these data stores. For example, a newly created ApsaraDB RDS database denies all access. You must add IP addresses to a whitelist of the ApsaraDB RDS database to allow access to the database.

ApsaraDB RDS can be accessed from both external and internal networks. To enable Realtime Compute to access ApsaraDB RDS, you must add the CIDR blocks of Realtime Compute to a whitelist of the ApsaraDB RDS database.

Procedure:

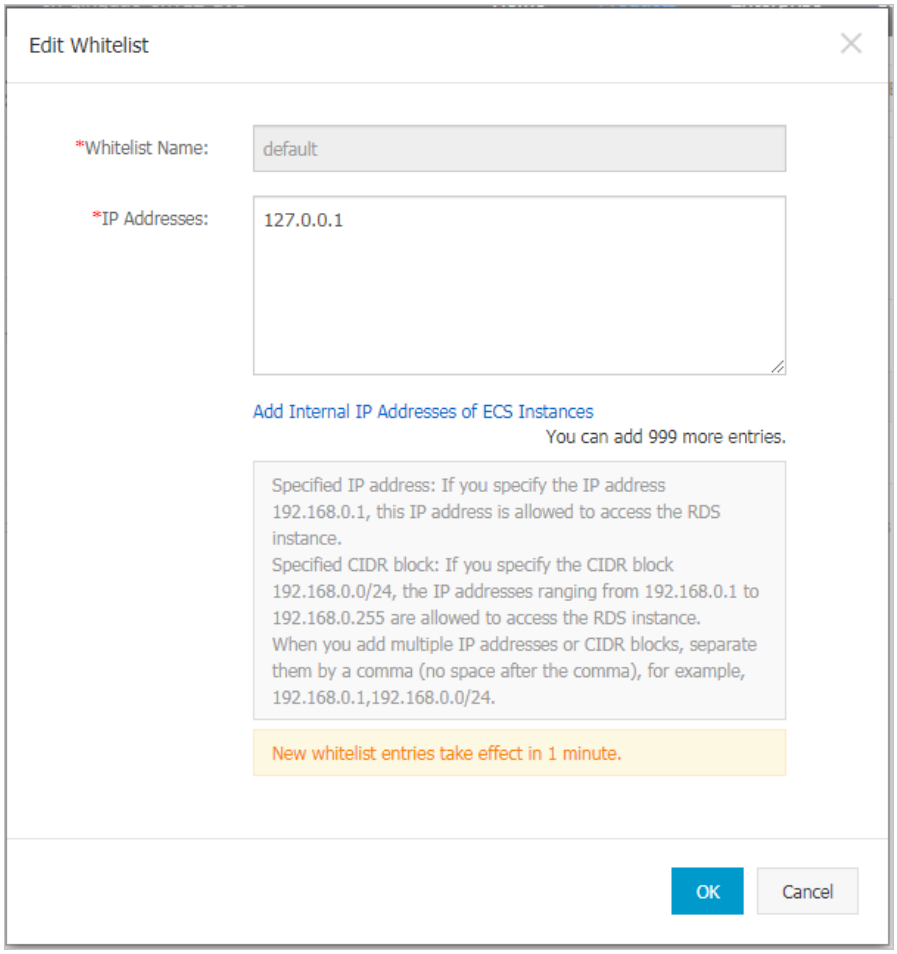
1. Log on to the ApsaraDB RDS console.

2. On the **Instances** page, click the ID of an instance in the **Instance ID/Name** column.
3. In the left-side navigation pane, click **Data Security**.
4. On the **Whitelist Settings** tab, click **Edit** that corresponds to the **default** whitelist.



> **Note**
>
> - If you want to connect an ECS instance to an ApsaraDB RDS instance by using an internal endpoint, you must make sure that the two instances are in the same region and have the same network type. Otherwise, the connection fails.
> - You can also click **Create Whitelist** to create a whitelist.

5. In the **Edit Whitelist** dialog box, specify the IP addresses or CIDR blocks that are used to access the instance, and then click **OK**.



- If you specify the 10.10.10.0/24 CIDR block, IP addresses in the 10.10.10.X format are allowed to access the ApsaraDB RDS instance.
- If you want to add multiple IP addresses or CIDR blocks, separate entries with commas (without spaces), such as 192.168.0.1,172.16.213.9.
- After you click **Add Internal IP Addresses of ECS Instances**, the IP addresses of all the ECS instances under your Apsara Stack account are displayed. You can select the required IP addresses to add to the

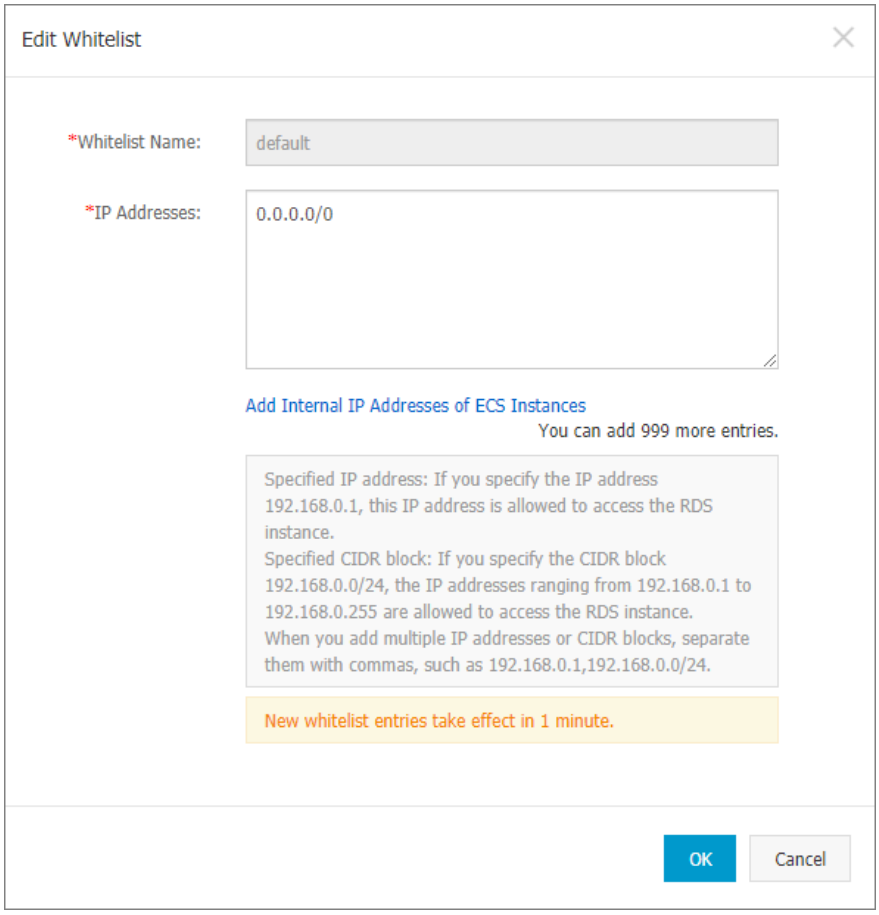
whitelist.

> **Note** If you add a new IP address or CIDR block to the **default** whitelist, the default address 127.0.0.1 is automatically deleted.

FAQ

- Fault description

  A stack exception occurs while the system is running, as shown in the following figure.



- Solution

  Add the IP address of your region to an RDS whitelist. For more information, see Specify whitelist settings.

3.1.5. Data development

3.1.5.1. Create a job

This topic describes how to create a Realtime Compute job.

Procedure

1. Log on to the Realtime Compute console.
2. Click **Development Platform**.
3. Click **Development** in the top navigation bar.
4. Click **Create File** in the toolbar.

5. In the **Create File** dialog box, specify the required fields.

Field	Description
File Name	The name of the file. The specified name must be 3 to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter.
File Type	The type of the file. Valid values: FLINK_STREAM/SQL and FLINK_STREAM/DATASTREAM.
Storage Path	The folder of the file. You can click the icon on the right side of an existing folder and create a subfolder.

6. Click **OK**.

3.1.5.2. Development

3.1.5.2.1. SQL code assistance

The development platform of Realtime Compute offers a complete set of SQL tools in the integrated development environment (IDE). These tools provide the following features to help you with Flink SQL-based development:

- Syntax check

  On the **Development** page of Realtime Compute, the revised script is automatically saved. When the script is saved, an SQL syntax check is automatically performed. If a syntax error is detected, the **Development** page shows the row and column where the error is located, and the cause of the error.

- Intelligent code completion

  When you enter SQL statements on the **Development** page of Realtime Compute, auto completion popups about keywords, built-in functions, tables, or fields are automatically displayed.

- Syntax highlighting

  Flink SQL keywords are highlighted in different colors to differentiate data structures.

3.1.5.2.2. SQL code version management

Realtime Compute provides key features that help you complete development tasks, such as coding assistance and code version management. A new code version is generated each time you publish a job SQL file. The code version management feature allows you to track code changes and roll back to an earlier version if required.

- Manage code versions

  On the **Development** page, you can manage Flink SQL code versions. A new code version is generated each time you publish a job SQL file. You can use the code version management feature to track versions, modify the code, and roll the code back to an earlier version.

  On the **Versions** tab on the right side of the **Development** page, click **More** in the **Actions** column to manage code versions.

  - **Compare**: Check the differences between the current version and an earlier version.
  - **Rollback**: Roll back to an earlier version.
  - **Delete**: Delete an earlier version.
  - **Locked**: Lock the current version.

    > **Note** You cannot submit a new version before you unlock the SQL file.

- Delete code versions

  A snapshot of a code version is created each time you submit an SQL file for publishing a job. This allows you to track code changes. The maximum number of code versions has been specified. If you use Apsara Stack, a maximum of 20 code versions can be published. To find out the maximum number of code versions in other environments, contact the system administrator. If the number of code versions reaches the upper limit, an error message is displayed to alert you to delete one or more earlier versions.

  In this scenario, you must delete one or more earlier versions before you publish new versions. To do this, click the **Versions** tab on the right side of the **Development** page, click **More** in the **Actions** column, and select **Delete** to delete expired versions that are no longer needed.

3.1.5.2.3. Data store management

The Development page of the Realtime Compute console provides an easy and effective method to manage data stores. For example, you can register external data stores to reference the data stores.

- Data preview

  The **Development** page of Realtime Compute allows you to preview data from a wide range of data stores. Data preview allows you to analyze the characteristics of upstream and downstream data, identify key business logic, and complete development tasks with high efficiency.

- Auto DDL generation

  Realtime Compute provides the auto DDL generation feature. The system can automatically generate DDL statements to reference data stores that can be registered in Realtime Compute. This feature provides a simple method to edit SQL statements for stream processing jobs. This improves overall efficiency and reduces errors when you manually enter SQL statements.

3.1.5.3. Debug job code

The Realtime Compute development platform provides a simulated running environment where you can customize uploaded data, simulate operations, and check outputs.

After you write SQL code that implements the computing logic, perform the following steps to debug the code:

1. Log on to the Realtime Compute console to go to the homepage of Alibaba Cloud Realtime Compute.
2. In the top navigation bar, click Development.
3. In the left-side navigation pane, click **Development**.
4. On the **Development** tab, double-click the folder and file name to open the job file.
5. In the top menu bar, click **Syntax Check**.

   > **Note** You can use the syntax check feature to check whether the SQL file includes syntax errors. Error messages are displayed for syntax errors.

6. In the top menu bar, click **Debug**. On the **Debug File** page, debug your SQL code.

   The test data for debugging can be acquired by using either of the following two methods:

   - Upload local data.
     a. Click **Download Template**.
     b. Prepare test data based on the template.
     c. Click **Upload**. After the file is uploaded, you can view the uploaded data in the data preview section.
   - Sample online data.
     a. Click **Random Online Data Sampling** or **Sequential Online Data Sampling**.
     b. View the sampled data in the data preview section.

7. Click **OK**.
8. In the output window, view the debugging result.

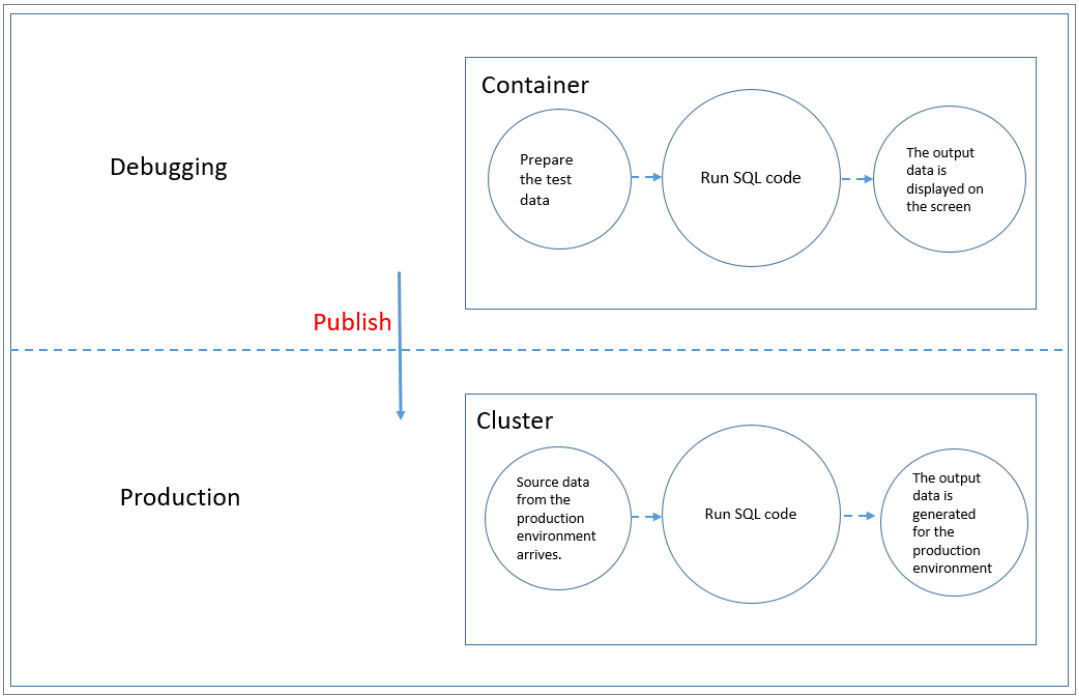
The debugging feature of Realtime Compute provides the following functions:

- Enables isolation between debugging and production environments.

  In the debugging environment, the Flink SQL code runs in a separate container, and computing result data is only displayed on the screen of the Development page. In this way, the debugging does not affect the running jobs and data stores in the production environment.

  In the debugging phase, result data is not written to external data stores. In the production environment, failures may occur due to format errors when result data is written to the target data stores. Such failures cannot be identified or prevented in the debugging phase, and can be detected only while jobs are running. For example, failures may occur in the production environment if your result data is too long. This occurs when the result data is written to a result table in ApsaraDB RDS and the length of character strings reaches the upper limit for an ApsaraDB RDS table. The Realtime Compute team is working on support for writing result data to external data stores in the production environment. This allows you to effectively simulate the production environment and resolve more issues in the debugging phase.

  Isolation between debugging and production environments



- Supports the customization of test data.

  In the debugging environment, Realtime Compute does not read data from source data stores, such as DataHub topics that store source tables and ApsaraDB RDS instances that store dimension tables. You must create a set of test data and upload the test data on the Development page.

  To make the debugging feature easy to use, Realtime Compute provides a template of test data for each type of job. You can download the template and enter your test data.

  > **Note** We recommend that you use the templates to prevent errors.

- Specifies a separator.

  A comma (,) is used as the separator in files for debugging by default. The following example shows a file for debugging:

```
id,name,age
1,alicloud,13
2,stream,1
```

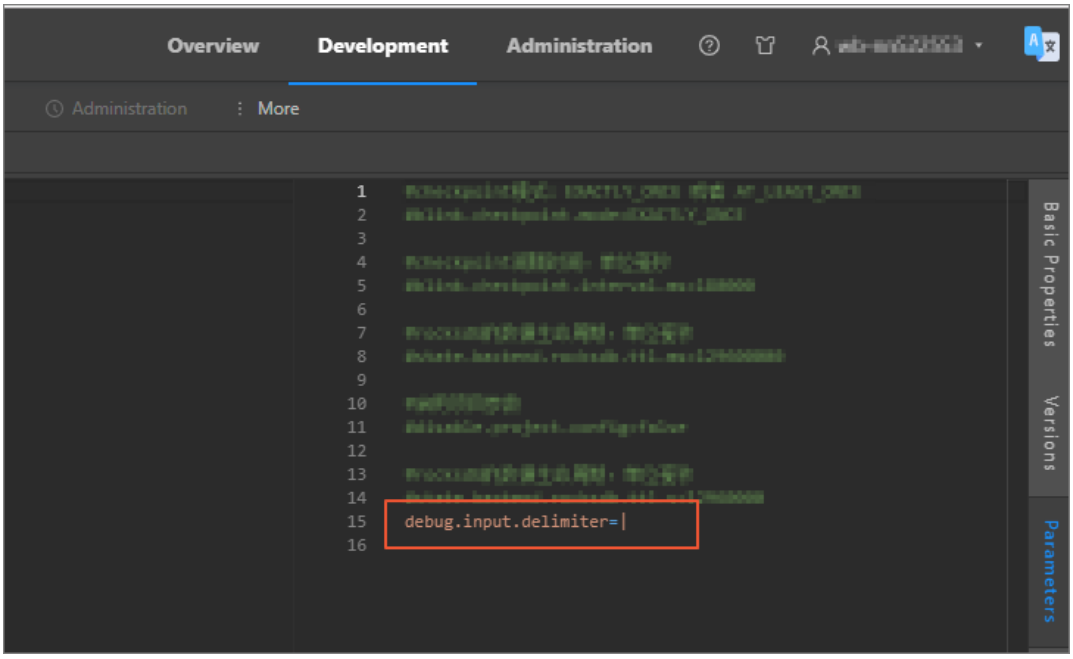
If the separator is not specified, a comma (,) is used to separate fields. If you need to use a JSON string as the field data and the string contains commas (,), you must specify another character as the separator.

> **Note** Realtime Compute allows you to specify a character as the separator, but not a multi-character string, such as aaa.

```
id|name|age
1|alicloud|13
2|stream|1
```

In this example, set `debug.input.delimiter=|`.

Specify a separator



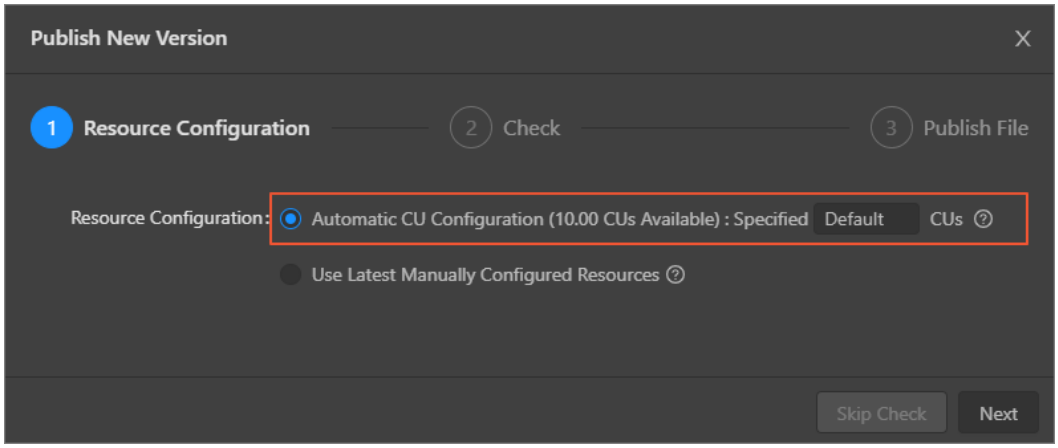
3.1.5.4. Publish a job SQL file

After you have created and debugged a job Flink SQL file, you can publish the SQL file and manage the job in the production environment.

Procedure

1. Log on to the Realtime Compute console.
2. In the top navigation bar, Click **Development**.
3. In the top menu bar, click **Publish**.
4. In the dialog box that appears, select **Automatic CU Configuration**. If you are performing automatic configuration for the first time, we recommend that you use the default number of CUs. Click **Next**.

   Configure resources



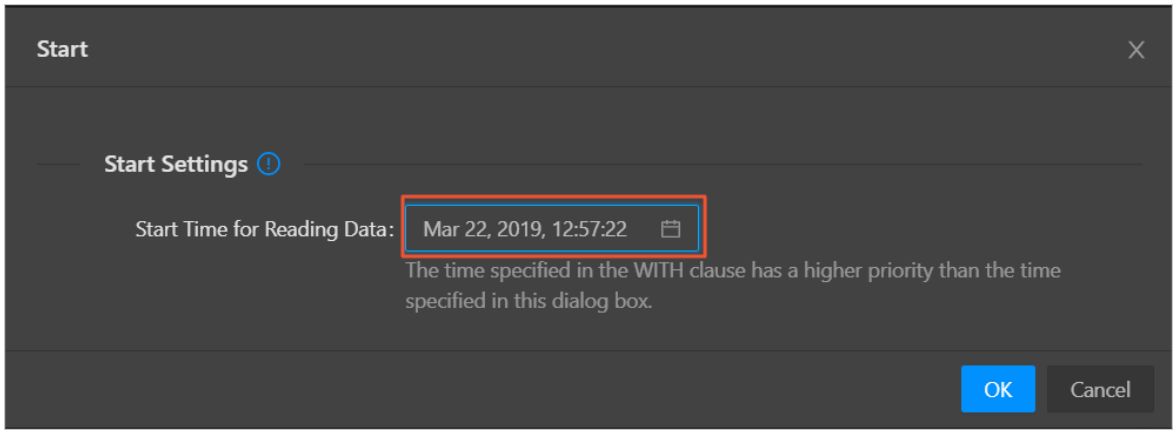
5. Check the data. After the check is completed, click **Next**.
6. Click **Publish**.
7. Go to the **Administration** page to start the job.
   i. In the top navigation bar, click **Administration**.
   ii. On the **Administration** page, find the target job, and click **Start** in the **Actions** column.

3.1.5.5. Start a job

After you develop and publish a job, you can start the job on the Administration page.

Procedure

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Administration**.
3. Find the job that you want to start, and click **Start** in the **Actions** column.
4. In the **Start** dialog box, set the **Start Time for Reading Data** parameter.



5. Click **OK**. The job is started.

   Start Time for Reading Data indicates the time at which the system starts to read data from the source table.

   - If you select the current time, Realtime Compute reads the data generated after the current time.
   - If you select a previous time, Realtime Compute reads the data generated after the specified time. This is used to track historical data.

3.1.5.6. Suspend a job

After you modify the resource configuration of a job, you must suspend and resume the job to make the changes take effect. This topic describes how to suspend a job.

Context

Notice

- You can only **suspend** a job that is in the **Running** state.
- If you **suspend** a job, its task status is not cleared. For example, if the job you **suspend** is running a COUNT operation, the COUNT operation continues from the last successful checkpoint after you **resume** the job.
- The Suspend (checkpoint) operation is supported in Realtime Compute V3.5.0 and later. If your Realtime Compute is earlier than V3.5.0, the following error message appears when you try to perform this operation: **An error occurred. System error: The Blink version is abnormal. Error reason: blink version >= blink-3.5 is required, instance blink-3.4.4.**

Procedure

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Administration**.
3. On the **Administration** page, find the job that you want to suspend, and click **Suspend** in the **Actions** column.

Note The **Suspend (checkpoint)** operation in **More** suspends the job and triggers a checkpoint event. Therefore, the time consumed to suspend a job by performing the **Suspend (checkpoint)** operation is longer than that by performing the **Suspend** operation.

3.1.5.7. Terminate a job

After you modify the SQL logic, change the job version, add parameters to the WITH clause, or add job parameters for a job, you must terminate and then start the job to make the changes take effect. This topic describes how to terminate a job.

Notice

- You can only **terminate** a job that is in the **Running** or **Starting** state.
- If you **terminate** a job, its task status is cleared. For example, if the job you **terminate** is running a COUNT operation, the COUNT operation starts from 0 after you **start** the job.
- The **Terminate (checkpoint)** operation is supported in Realtime Compute V3.5.0 and later. If your Realtime Compute version is earlier than V3.5.0, the following error message appears when you try to perform this operation: **An error occurred. System error: The Blink version is abnormal. Error reason: blink version >= blink-3.5 is required, instance blink-3.4.4.**

To terminate a job, perform the following steps:

1. Log on to the Realtime Compute console.
2. In the top navigation bar, click **Administration**.
3. On the **Administration** page, find the job that you want to terminate, and click **Terminate** in the **Actions** column.

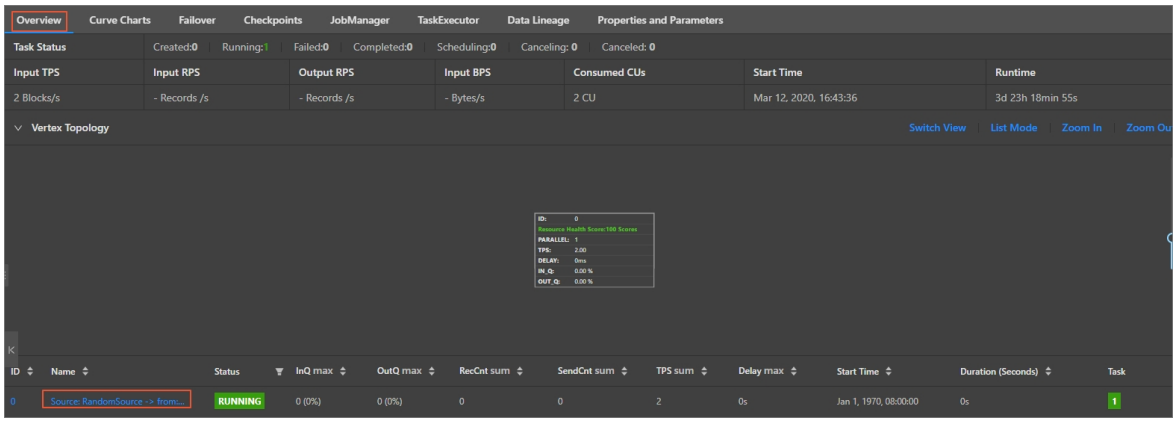
> **Note** The **Terminate (checkpoint)** operation under **More** is different from the **Terminate** operation. The system triggers a checkpoint when you perform the **Terminate (checkpoint)** operation to terminate a job. Therefore, the time consumed to terminate a job by performing the **Terminate (checkpoint)** operation is longer than that by performing the **Terminate** operation. The job status is cleared after the job is terminated. The Terminate (checkpoint) operation has other functions in some scenarios. For example, if the upstream storage system is Message Queue for Apache Kafka, the system submits an offset each time it triggers a checkpoint. This ensures that the number of offsets submitted to the Kafka server is consistent with the amount of data consumed.

3.1.5.8. View logs

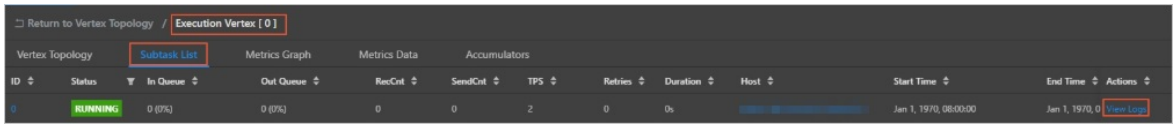
You can view the operational logs of a job to learn the job operation information. This topic describes how to view job logs.

Procedure

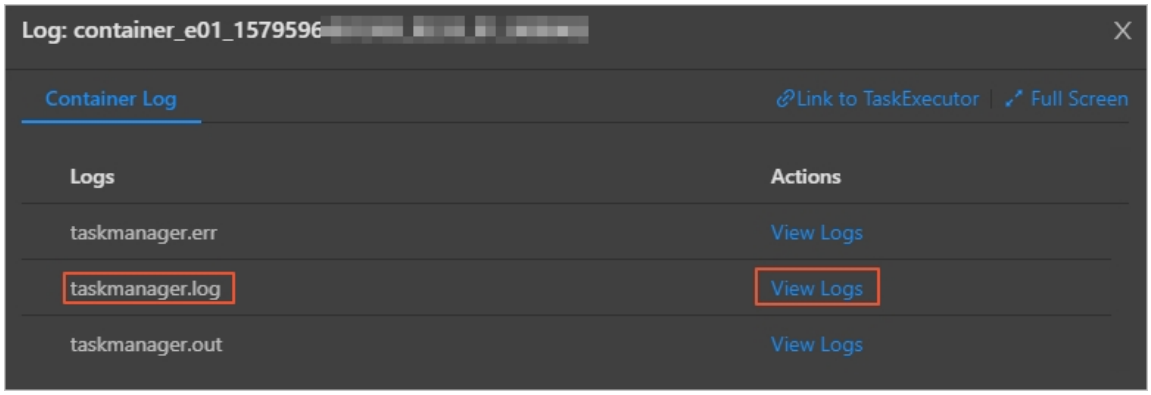
1. Go to the **Administration** page in Realtime Compute.
   i. Log on to the Realtime Compute console.
   ii. In the top navigation bar, click **Administration**.
   iii. On the **Jobs** page, click the name of the job whose logs you want to view in the **Job Name** column.
2. At the bottom of the **Overview** tab, click the name of the desired vertex.



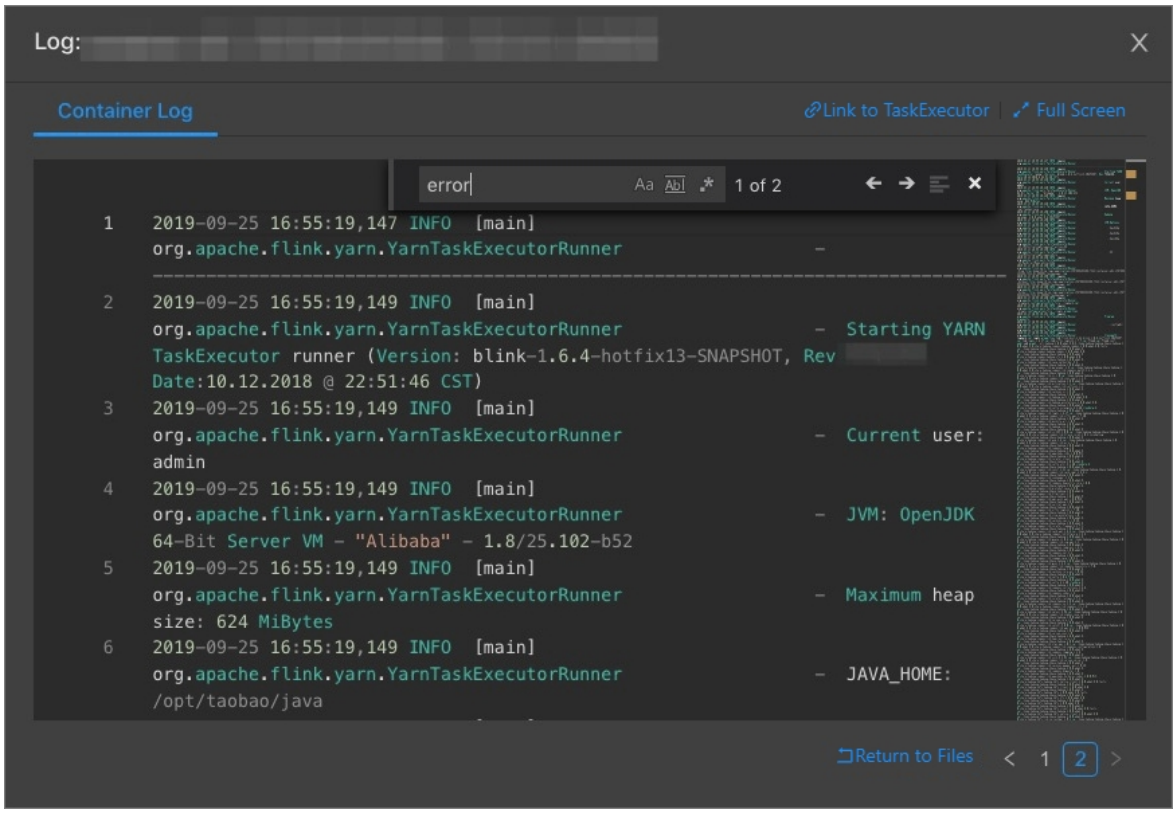
3. On the **Execution Vertex** page, click the **Subtask List** tab. Then, find the desired subtask and click **View Logs** in the **Actions** column.



4. In the **Log** dialog box, click **View Logs** for **taskmanager.log** in the **Actions** column.



5. On the **Container Log** tab, view the log entries.



> **Note** You can press **Ctrl+F** for Windows or **cmd+F** for MacOS to search for specified log entries. We recommend that you view the log entries from the last page. The first error recorded in the log describes the Root cause of the job error.

4.Machine Learning Platform for AI

4.1. User Guide

4.1.1. What is machine learning?

Machine learning is a process of using statistical algorithms to learn large amounts of historical data and generate an empirical model to provide business strategies.

Apsara Stack Machine Learning Platform for AI is a set of data mining, modeling, and prediction tools. It is developed based on MaxCompute (also known as ODPS). Machine Learning Platform for AI supports the following functions:

- Provides an all-in-one algorithm service covering algorithm development, sharing, model training, deployment, and monitoring.
- Allows you to complete the entire procedure of an experiment either through the GUI or by running PAI commands. This function is typically intended for data mining personnel, analysts, algorithm developers, and data explorers.
- In Apsara Stack, Machine Learning Platform for AI runs on MaxCompute. Machine Learning Platform for AI allows you to call algorithms to decouple the applications and compute engines after you have deployed algorithm packages in MaxCompute clusters.
- Provides various algorithms and reliable technical support, providing more options to resolve service issues. In the Data Technology (DT) era, you can use Machine Learning Platform for AI to implement data-driven services.

Machine Learning Platform for AI can be applied in the following scenarios:

- Marketing: commodity recommendations, user profiling, and precise advertising.
- Finance: loan delivery prediction, financial risk control, stock trend prediction, and gold price prediction.
- Social network sites (SNSs): microblog leader analysis and social relationship chain analysis.
- Text: news classification, keyword extraction, text summarization, and text analysis.
- Unstructured data processing: image classification and image text extraction through OCR.
- Other prediction cases: rainfall forecast and football match result prediction.

Machine learning can be divided into three types:

- Supervised learning: Each sample has an expected value. You can create a model and map input feature vectors to target values. Typical examples of this learning mode include regression and classification.
- Unsupervised learning: No samples have a target value. This learning mode is used to discover potential regular patterns from data. Typical examples of this learning mode include simple clustering.
- Reinforcement learning: This learning mode is complex. A system constantly interacts with the external environment to obtain external feedback and determines its own behavior to achieve a long-term optimization of targets. Typical examples of this learning mode include AlphaGo and driverless vehicles.

4.1.2. Features supported by Hygon servers and Intel servers

This topic describes the features that are supported by Hygon servers and Intel servers.

Feature	Hygon server	Intel server
Data labeling	Not supported	Supported

Feature		Hygon server	Intel server
Machine Learning Studio	General algorithm components	Supported	Supported
	Deep learning components	Not supported	Supported
	Video intelligent platforms	Not supported	Supported
	AutoML	Not supported	Supported
	Algorithm market	Not supported	Supported
Data Science Workshop (DSW)		Supported	Supported
Elastic Algorithm Service (EAS)		Supported	Supported

4.1.3. Log on to the PAI console

This topic describes how to log on to the PAI console.

Prerequisites

- The IP address or domain name of the Apsara Uni-manager Management Console is obtained from deployment engineers before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use Google Chrome.

Procedure

1. Enter the URL of the Apsara Uni-manager Management Console in the address bar and press the Enter key.
2. Enter your username and password.

   Obtain the username and password that are used to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. For higher security, the password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Log On**.
4. If your account has multi-factor authentication (MFA) enabled, perform corresponding operations in the following scenarios:
   - It is the first time that you log on to the console after MFA is forcibly enabled by the administrator.
     a. On the Bind Virtual MFA Device page, bind an MFA device.
     b. Enter the account and password again as in Step 2 and click **Log On**.
     c. Enter a six-digit MFA verification code and click **Authenticate**.
   - You have enabled MFA and bound an MFA device.

Enter a six-digit MFA authentication code and click **Authenticate**.

> **Note** For more information, see the *Bind a virtual MFA device to enable MFA* topic in *Apsara Uni-manager Management Console User Guide*.

5. In the top navigation bar of the Apsara Uni-manager Management Console, choose **Products > Big Data > Machine Learning Platform for AI** to go to the PAI console.
6. On the page that appears, set the Organization and Region parameters and click **Access as Administrator** to go to the PAI console.

> **Note** If this is the first time that you log on to the PAI console, you must perform the following steps:
>
> i. Create an organization
>
> Create an organization to store resource sets and their resources.
>
> ii. Create users
>
> Create users and assign the users different roles to meet different requirements for system access control.
>
> iii. Create a resource set
>
> Create a resource set before you apply for resources.
>
> iv. Add members to the resource set
>
> Add the created users to the resource set.
>
> v. Go to the homepage of the Apsara Uni-manager Management Console. In the top navigation bar, choose **Product > Big Data > MaxCompute**. Then, create a task account and a project in MaxCompute.
>
> a. When you create a task account, set the **Organization** parameter to the organization that you created in Step 1.
>
> b. When you create a MaxCompute project, set the **Organization** parameter to the organization that you created in Step 1. Set the **Resource Set** parameter to the resource set you created in Step 3. Set the **Task Account** parameter to the task account that you created.
>
> vi. Go to the Project Management page of the DataWorks console to create a DataWorks workspace. In the **Advanced Settings** section of the Create a workspace dialog box, set the **MaxCompute Project Name** parameter to the name of the MaxCompute project that you created in the preceding step.

4.1.4. Data labeling

> **Note** The data labeling feature is applicable only to Intel servers, but not to Hygon servers.

4.1.4.1. Register a dataset

PAI allows you to register a dataset by creating a dataset or importing a dataset file. It also allows you to use **manifest** files to manage all registered datasets.

Register a dataset by creating a dataset

If your source data, such as image, text, video, and audio files, is stored in OSS buckets, you can **create a dataset** in the PAI console. The system scans all files of the specified type in the specified OSS folder and generates a manifest file in the specified OSS path.

1. Go to the **Register Dataset** page.
   i. In the left-side navigation pane of the PAI console, choose **Data Preprocessing > Dataset Manager**.
   ii. On the **Dataset Manager** page, click **Register Dataset**.
2. On the **Register Dataset** page, set the parameters.

Parameter	Description
Dataset Name	The name must be 1 to 24 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or a digit.
Method	Set the **Method** parameter to **New Dataset**.
Storage Type	Only **OSS** is supported. You cannot change the value.
Path	Set the **Path** parameter to the OSS folder where your source data is stored.
Data Type	Only **Image** is supported. You cannot change the value.
Tags	You can add a maximum of 10 tags to each dataset. Each tag can contain underscores (_) and hyphens (-). It must start with a letter or a digit.

3. Click **Submit**. Then, a manifest file is generated. The following code provides an example of the manifest file.

```
null
null
null
...
```

After you register a dataset, you can view the dataset on the **Dataset Manager** page.

Register a dataset by importing a dataset file

If you have an on-premises CSV file or manifest file, you can register a dataset by **importing the dataset file**. If you import a CSV file, the system automatically converts it to a **manifest** file.

1. Go to the **Register Dataset** page.
   i. In the left-side navigation pane of the PAI console, choose **Data Preprocessing > Dataset Manager**.
   ii. On the **Dataset Manager** page, click **Register Dataset**.
2. On the **Register Dataset** page, set the parameters.

Parameter	Description
Dataset Name	The name must be 1 to 24 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or a digit.
Method	Set the **Method** parameter to **Import Dataset**.
Storage Type	Only **OSS** is supported. You cannot change the value.
Path	Select an OSS path.

Parameter	Description
Data Type	Drag an on-premises CSV file or **manifest** file to the upload area on the right side of the **Data Type** parameter. **Note** If the imported file is used in a labeling job, the names of the fields in the file must comply with the data structure of the template that is used to create the labeling job. For more information, see Data labeling templates.
Tags	You can add a maximum of 10 tags to each dataset. Each tag must be 1 to 10 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or a digit.

3. Click **Submit**.

   After you register a dataset, you can view the dataset on the **Dataset Manager** page.

4.1.4.2. Data labeling templates

Machine Learning Platform for AI provides the following templates: object detection, semantic segmentation, comprehensive image labeling, Optical Character Recognition (OCR), single-label image classification, and multi-label image classification. When you create a labeling job, you can select a template based on your requirements.

Object detection

Object detection is used to locate a specific object in an image. The rectangle selection tool is commonly used.

- Scenarios

  Object detection applies to scenarios such as vehicle detection, passenger detection, and image search.

- Data structure
  - Input data

    Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/pics/fruit/apple-1.jpg"}}
...
```

- Output data

  Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
    "data": {
        "picUrl": "oss://****/pics/fruit/apple-1.jpg"
    },
    "label-****(Labeling job ID)": {
        "results": [{
            "data": [{
                "id":"Znyumd-*****",
                "type":"image/rectangleLabel",
                "value":{
                    "rotation":0,
                    "x":40.68320610687023,
                    "width":327.52035623409665,
                    "y":5.762467474590647,
                    "height":296.68117192104745
                },
                "labelColor":"#72bf7d",
                "labels":["apple"]
            }],
            "id":"44****",
            "type":"image"
        }]
    }
}
```

Semantic segmentation

Semantic segmentation is used to recognize an object in an image and retrieve the coordinates of the object by scanning all pixels of the object. The commonly used tools are the polygon selection tool, brush tool, and superpixel tool.

- Scenarios

  Semantic segmentation applies to scenarios such as autonomous driving, facial expression recognition, and apparel classification.

- Data structure
  - Input data

    Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/pics/fruit/apple-1.jpg"}}
...
```

- Output data

  Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
    "data": {
        "picUrl": "oss://****/pics/fruit/apple-1.jpg"
    },
    "label-****(Labeling job ID)": {
        "results": [{
            "data": [{
                "id":"Znyumd-*****",
                "type":"image/polygonLabel",
                "value":{
                    "points": [
                        [110, 46],
                        [52, 196],
                        [48, 168],
                        [48, 145],
                        [54, 120],
                        [63, 93],
                        [76, 74]
                    ]
                },
                "labelColor":"#72bf7d",
                "labels":["apple"]
            }],
            "id":"44****",
            "type":"image"
        }]
    }
}
```

Comprehensive image labeling

Comprehensive image labeling is used to match the content of the input images against a set of labels. This template allows you to use all image labeling tools as needed.

- Scenarios

  Comprehensive image labeling applies to scenarios such as autonomous driving, content moderation, and content recognition.

- Data structure
  - Input data

    Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/pics/fruit/apple-10.jpg"}}
```

- Output data

  Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
    "data": {
        "picUrl": "oss://****/pics/fruit/apple-10.jpg"
    },
    "label-****(Labeling job ID)": {
        "results": [{
            "data": [{
                "id":"Znyumd-****",
                "type":"image/rectangleLabel",
                "value":{
                    "rotation":0,
                    "x":40.68320610687023,
                    "width":327.52035623409665,
                    "y":5.762467474590647,
                    "height":296.68117192104745
                },
                "labelColor":"#72bf7d",
                "labels":["Red apple"]
            }],
            "id":"44****",
            "type":"image"
        }]
    }
}
```

OCR

OCR is used to extract text from input images, and then classify the images based on the text.

- Scenarios

  OCR applies to scenarios such as the recognition of identity cards, tickets, license plates, and bank cards.

- Data structure
  - Input data

    Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/img/ocr_card/img0.jpeg"}}
```

- Output data

  Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
    "data": {
        "picUrl": "oss://****/img/ocr_card/img0.jpeg"
    },
    "label-****(Labeling job ID)": {
        "results": [{
            "data": [{
                "direction_of_picture":"downward",
                "type":"ocr/meta"
            },
            {
                "id": "Y4ZFoC-****",
                "direction_of_text": "downward",
                "text": "Alibaba Cloud Intelligence",
                "type": "ocr/polygonLabel",
                "value": {
                    "points": [[325.08789110183716,397.47582054138184]]
                },
                "labelColor": "#67bd3a",
                "labels": "Enterprise"
            }],
            "id":"24****",
            "type":"ocr"
        }]
    }
}
```

Single-label image classification

Single-label image classification is used to find a label from a set of labels to match the content of an input image, and then attach the label to the image.

- Scenarios

  Single-label image classification applies to scenarios such as photo classification, image recognition, and image search.

- Data structure
  - Input data

    Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/img/ocr_card/img0.jpeg"}}
```

- Output data

  Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example of the JSON string in each row:

```
{
    "data": {
        "picUrl": "oss://****/img/ocr_card/img0.jpeg"
    },
    "label-****(Labeling job ID)": {
        "results": [{
            "data": [{
                "data":"red",
                "id":"33****",
                "type":"survey/value"
            }],
            "id":"33****",
            "type":"survey"
        }]
    }
}
```

Multi-label image classification

Multi-label image classification is used to find multiple labels from a set of labels to match the content of an input image, and then attach the labels to the image.

- Scenarios

  Multi-label image classification applies to scenarios such as content recommendation, advertising, and image search.

- Data structure
  - Input data

    Each row in the **manifest** file contains a topic. Each topic must contain the picUrl field.

```
{"data":{"picUrl":"oss://****/img/ocr_card/img0.jpeg"}}
```

  - Each row in the **manifest** file contains a topic and the corresponding labeling result. The following code provides an example on the JSON string in each row:

```
{
    "data": {
        "picUrl": "oss://****/img/ocr_card/img0.jpeg"
    },
    "label-****(Labeling job ID)": {
        "results": [{
            "data": [{
                "data":["red","more","green"],
                "id":"33****",
                "type":"survey/multivalue"
            }],
            "id":"33****",
            "type":"survey"
        }]
    }
}
```

4.1.4.3. Create a labeling job

This topic describes how to create a labeling job.

Prerequisites

A dataset is registered. For more information about how to register a dataset, see Register a dataset.

Procedure

1. Log on to the Machine Learning Platform for AI console
2. In the left-side navigation pane of the PAI console, choose **Data Preprocessing > Smart Labeling**.
3. On the **Smart Labeling** page, click **Create Labeling Job**.
4. In the **Basic Information** step, set the parameters and click **Next**.

Parameter	Description
Task Name	The task name must be 1 to 24 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or digit.
Description	The description must be 1 to 64 characters in length, and can contain underscores (_) and hyphens (-). It must start with a letter or digit.
Input Dataset	You can select one or more datasets to create a labeling job. The datasets must correspond to the topic of the labeling job. If no dataset is available, click **Register Dataset** next to the **Input Dataset** parameter to register a dataset.
Output Dataset Path	Select an Object Storage Service (OSS) path to store the labeling results. When you handle a labeling job, every time you click **Generate Result Dataset**, a result dataset is generated in the specified OSS path. The dataset contains the results of all topics that you have completed.

5. In the **Template** step, set the parameters and click **Next**.

Parameter		Description
Template		The template to be used in the labeling job. The system supports the following templates: ○ **Target detection** ○ **Semantic segmentation** ○ **Image comprehensive labeling** ○ **OCR template** ○ **Single-label image classification** ○ **Multi-label image classification**
Categories		The labels that are used to classify images. This parameter takes effect only if **Single-label image classification** or **Multi-label classification** is selected for the **Template** parameter.
Label Image Orientation	**Label Image Orientation**	Specifies whether to annotate image orientation. This parameter takes effect only if you select **OCR template** for the **Template** parameter.
	Flip Text	Specifies whether to annotate text orientation. If the text in an image is placed in the same direction as the image, you can turn off this switch. This parameter takes effect only if you select **OCR template** for the **Template** parameter.

Parameter	Description
Text Type	The labels that are used to classify the text. This parameter takes effect only if you select **OCR template** for the **Template** parameter.
Add Custom Label	The custom labels that are used to classify the text. This parameter takes effect only if you select **OCR template** for the **Template** parameter.
Labels	The labels that are used to classify images. Labels are displayed in different colors. This parameter takes effect only if you select **Target detection**, **Semantic segmentation**, or **Image comprehensive labeling** for the **Template** parameter.

6. In the **Labeling Policy** step, set the parameters and click **Submit**.

Parameter	Description
Dispatch Policy	The default dispatch policy is **Number of topics collected by a worker each time** and cannot be changed.
Topics per Collection	The number of topics that are collected by each worker each time. **Note** The value of the **Topics per Collection** parameter can be smaller than the total number of topics divided by the total number of workers. This allows workers with high efficiency to collect more topics and improves the overall efficiency of data labeling.
Add Worker	You can specify one or more workers. You can select both Apsara Stack tenant accounts and RAM users.

4.1.4.4. Label images

This topic describes how to label images.

Prerequisites

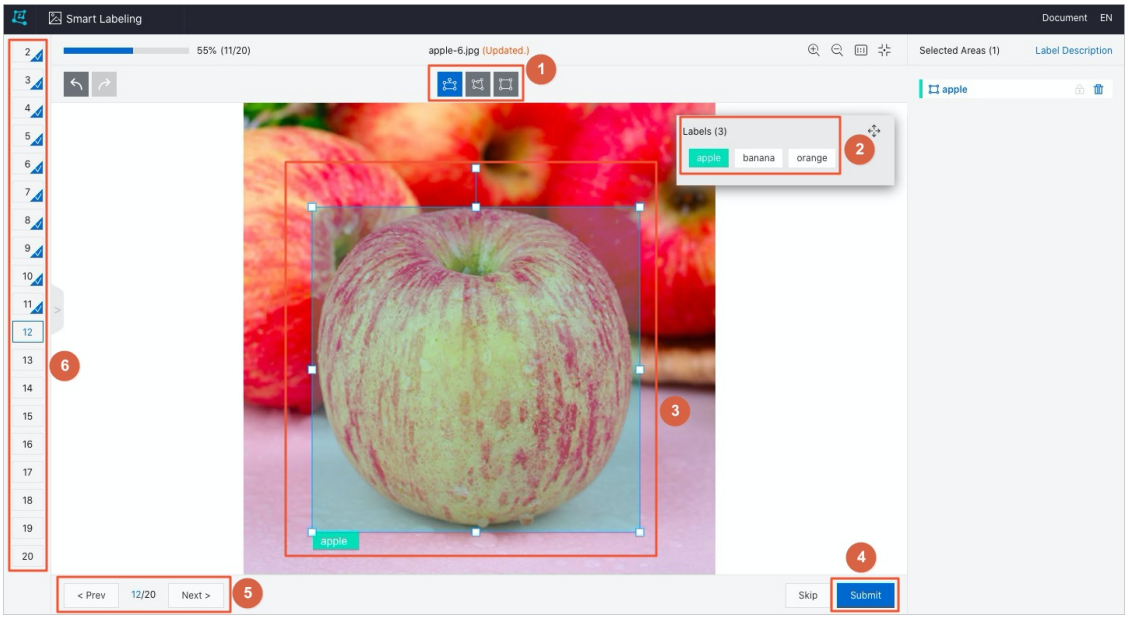
A labeling job is created or assigned to you by the administrator. For more information, see Create a labeling job.

Procedure

1. Go to the Smart Labeling page.
   i. In the left-side navigation pane of the PAI console, choose **Data Preprocessing > Smart Labeling**.
   ii. On the **Smart Labeling** page, click **My Labeling Jobs**.
   iii. In the job list, find your labeling job and click **Start** in the **Actions** column.
2. Label images.
   i. On the labeling page, click the icon.
   ii. In the **Labels** section, select a label.

   Note The system adds the selected label to each image unless you select another label.

iii. Use the selection tool to select an area in the image.



iv. (Optional)If you do not need to label the image, click **Skip**.

v. Click **Submit**.

vi. You can use one of the following methods to browse and complete topics:

- Click **Prev** or **Next** in the lower part of the Smart Labeling page.
- Click the thumbnails of the topics in the left-side navigation pane.

4.1.5. Machine Learning Studio

4.1.5.1. Quick start

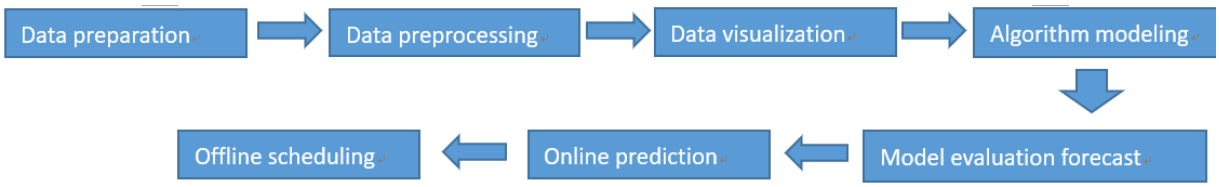
4.1.5.1.1. Overview

This topic describes how to perform data preparation, data preprocessing, data visualization, algorithm modeling, model prediction and evaluation, online prediction, and DataWorks task scheduling to set up a machine learning experiment.

> **Note** This document covers Apsara Stack Machine Learning Platform for AI, online model service, and deep learning framework. The online model service and deep learning framework are not basic functions of Apsara Stack Machine Learning Platform for AI and must be purchased separately.

For more information, see Machine learning experiment creation flowchart.

Machine learning experiment creation flowchart



1. Data preparation

   Import target data into the Apsara Stack Machine Learning Platform for AI console.

2. Data preprocessing

   Perform data processing, including SQL-based conversion, normalization, and standardization, to ensure that all data has the same dimensions.

3. Data visualization

   Display data in charts to view the features of the data and the distribution of the values. This serves as the basis for model algorithm selection.

4. Algorithm modeling

   Use machine learning algorithms to train data and ultimately build a model.

5. Model prediction evaluation

   Make predictions from and evaluate the model, and use the prediction results to create business development strategies.

6. Deploy an online model service

   Use online prediction to deploy the generated model and adjust your business strategy based on the prediction results.

7. DataWorks task scheduling

   Deploy experiments in DataStudio and run them on a regular basis.

4.1.5.1.2. Prepare data

This topic describes how to import data into the PAI console for modelling.

Prerequisites

A MaxCompute project is created and your data is imported to the MaxCompute project. You can download datasets from Machine Learning Repository.

Procedure

1. Log on to Apsara Stack Machine Learning Platform for AI.
2. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
3. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
4. In the left-side navigation pane, click **Experiments**.
5. On the **Experiments** page, right-click **My Experiments** and select **New Experiment** from the shortcut menu. In the New Experiment dialog box, set the **Name** and **Description** parameters and click **OK**. The **Components** pane appears.
6. In the **Components** pane, click **Data Source/Target** and drag the **Read MaxCompute Table** component to the canvas.
7. Click the **Read MaxCompute Table** component and set the parameters for the component. Enter the name of the MaxCompute table in **Table Name** in the right-side pane.
8. In the right-side pane, click the **Fields Information** tab to view the column name, data type, and the first 100 rows of data in the input table. The following figure shows the Fields Information tab.

4.1.5.1.3. Preprocess data

This topic describes how to preprocess data by using methods such as normalization, SQL scripts, and data splitting.

Prerequisites

Data is prepared before data preprocessing. For more information, see Data preparation.

Procedure

1. Log on to Apsara Stack Machine Learning Platform for AI.
2. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
3. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
4. In the left-side navigation pane, click **Components**.
5. In the **Components** pane, click **Tools**. Drag the **SQL Script** component to the canvas. Click **Data Preprocessing**, drag the **Normalization** component to the canvas, and then connect the components.
6. Click the **SQL Script** component. In the **SQL Script** section of the **Parameters Settings** pane, enter the following SQL scripts to convert the features from strings to numeric values.

```
select age,
(case sex when 'male' then 1 else 0 end) as sex,
(case cp when 'angina' then 0  when 'notang' then 1 else 2 end) as cp,
trestbps,
chol,
(case fbs when 'true' then 1 else 0 end) as fbs,
(case restecg when 'norm' then 0  when 'abn' then 1 else 2 end) as restecg,
thalach,
(case exang when 'true' then 1 else 0 end) as exang,
oldpeak,
(case slop when 'up' then 0  when 'flat' then 1 else 2 end) as slop,
ca,
(case thal when 'norm' then 0  when 'fix' then 1 else 2 end) as thal,
(case status  when 'sick' then 1 else 0 end) as ifHealth
from  ${t2};
```

7. Click the **Normalization** component and select all columns to normalize the numeric features to values ranging from 0 to 1.
8. Click **Data Preprocessing**. Drag the **Split** component to the canvas and set the **Split Fraction** parameter to **0.7**.

> **Note** This step splits data into two parts: 70% of the data is used as the model training set, and 30% of the data is used as the model prediction set.

4.1.5.1.4. Visualize data

This topic describes how to view the features and value distribution by using statistical analysis components.

Prerequisites

Data is preprocessed before data visualization. For more information, see Preprocess data.

Procedure

1. Log on to Apsara Stack Machine Learning Platform for AI.
2. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
3. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
4. In the left-side navigation pane, click **Components**.
5. In the **Components** pane, click **Statistics**. Drag the **Whole Table Statistics** component to the canvas.

Connect the components and click **Run** in the upper-left corner of the canvas.

6. After the experiment stops running, right-click the **Whole Table Statistics** component and select **View Data** from the shortcut menu. The analysis report is displayed.

4.1.5.1.5. Generate a model

This topic describes how to perform feature training and generate models by using the machine learning components.

Prerequisites

The following operations are performed before algorithm modeling: Preprocess data and learn the data characteristics and value distribution by Visualize data.

Procedure

1. Log on to Apsara Stack Machine Learning Platform for AI.
2. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
3. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
4. In the left-side navigation pane, click **Components**.
5. In the Components pane, choose **Modeling > Binary Classification**. Drag the **Logistic Regression for Binary Classification** component to the canvas and connect the components on the canvas.
6. Click the component, and select 13 feature columns for the **Training Feature Columns** parameter on the Fields Setting tab of the right-side pane. All parameters use the default settings.
7. Click **Run**.
8. Click **Models** in the left-side navigation pane to view the generated model.

4.1.5.1.6. Use a model for prediction and evaluation

This topic describes how to use a model to make predictions and evaluate its results by using the prediction and evaluation components.

Prerequisites

A machine learning model is generated from an experiment before predication and evaluation. For more information, see Generate a model.

Procedure

1. Log on to Apsara Stack Machine Learning Platform for AI.
2. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
3. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
4. In the left-side navigation pane, click **Components**.
5. In the **Components** pane, click **Modeling**. Drag the **Prediction** component to the canvas and connect the components on the canvas.
6. In the Components pane, choose **Modeling > Evaluation**. Drag the **Binary Classification Evaluation** component to the canvas and connect the components on the canvas.
7. Click **Run** in the upper-left corner of the canvas.

   During experiment execution, select a component and click the **Developer Tool** icon in the lower-right corner of the canvas to view the status of the component.

8. Right-click the **Binary Classification Evaluation** component and select **View Evaluation Report** from the shortcut menu to generate the receiver operating characteristic (ROC) curve of the LR model trained with different parameters.

4.1.5.1.7. Schedule an experiment

After you have run all nodes in an experiment, you can deploy the experiment to DataWorks and schedule DataWorks to periodically run the experiment. This topic uses air quality prediction as an example scenario.

Prerequisites

Before you schedule an experiment, all nodes are run in the experiment and the experiment is deployed to DataWorks.

Procedure

1. Open the **Experiments** pane.
   i. Log on to Apsara Stack Machine Learning Platform for AI.
   ii. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
   iii. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
   iv. In the left-side navigation pane, click **Experiments**.
2. Click **My Experiments** and click the experiment that you want to schedule.

   > **Notice** Make sure that all components are run as expected in the experiment. A green tick means that the component is successful.

3. In the upper-left corner of the canvas, choose **Deploy > DataWorks Offline Schedule** to go to DataStudio.
4. On the DataStudio page, move the pointer over the **Create** icon, choose **Machine Learning > Machine Learning Platform for AI**, and then create a machine learning node.
5. In the **Create Node** dialog box, enter the node name, select the folder where the node resides, and click **Commit**.

   > **Notice** You must select the Algorithm folder of a workflow.

   After the machine learning node is created, perform the steps on the canvas, as shown in the following figure.
6. Select the experiment from the drop-down list.
7. Configure scheduling properties for the machine learning node, including the recurrence, input, and output parameters.
8. Click the **Submit** icon. The node will be run the next day.
9. Click **Operation Center** in the upper-right corner to go to Operation Center. You can view the status of the machine learning node and the system log. You can also perform other operations, such as generating retroactive data and testing the experiment.

4.1.5.2. Components

4.1.5.2.1. Overview

This topic describes how to use and configure machine learning components. When building a machine learning experiment, you can select components based on the features of existing data to generate a model and make accurate predictions for your business.

Each component has one or more input or output ports. You can move the pointer over the ports to view their descriptions and connect the components.

4.1.5.2.2. Data source and target

This topic describes components in the **Data Source/Target** category, such as the Read MaxCompute Table and Write MaxCompute Table components.

Read MaxCompute tables

You can use the Read MaxCompute Table component to read MaxCompute tables. By default, this component reads data of the current project. If you want to read data from tables in another project for which you have access, you can prefix the table name with the project name in the `project name. table name` format. For example, `tianchi_project.weibo_data`. After you specify the input table, the system reads the structural data of the table. You can click the **Column Information** tab to view the data. This component does not support views.

If the selected input table is a partitioned table, the back end automatically selects the Partition checkbox. You can select or configure partition parameters. Only one partition can be selected. If you do not select the Partition checkbox or do not specify the partition parameters, the whole table is selected. If the input table is non-partitioned, the Partition checkbox cannot be selected.

Write MaxCompute tables

You can use the Write MaxCompute Table component to write data to tables in the current project or tables in other projects. This component can write data to partitions. Partitions must be created for the table in the MaxCompute console before this component can write data to the partitions. You can set the table lifecycle measured in days.

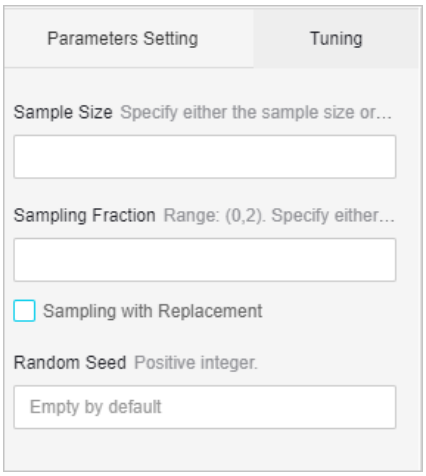
4.1.5.2.3. Data preprocessing

4.1.5.2.3.1. Sampling and filtering

Random sampling

Data is sampled randomly and independently. You can specify a ratio or quantity of samples to be taken and choose whether to enable sampling with replacement.

Parameter settings



PAI command

```
Pai -name sample
-project algo_public
-DinputTableName=wbpc
-DoutputTableName=wpbc_sample
-Dratio=0.3;
```

Algorithm parameters

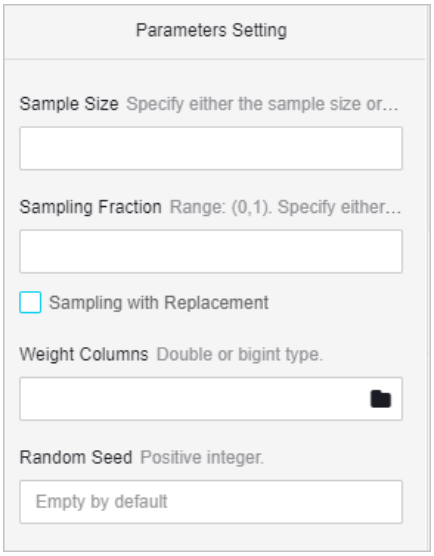
Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
ratio	Required. The sampling fraction.	(0, 1)	-
outputTableName	Required. The name of the output table.	-	-
outputTablePartition	Optional. The partition of the output table.	-	The output table is a non-partitioned table by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.

Weighted sampling

Sample data is collected based on weights. The weight column must be of double or int type. Data is sampled based on the value of its corresponding weight. For example, data with a col value of 1.2 has a higher probability to be sampled than data with a col value of 1.0.

Parameter settings



Parameter settings

Parameter	Description
Sample Size	You can specify the number of samples to be taken, which is 10,000 by default. For sampling without replacement, the number of samples cannot be greater than the number of data entries.
Sampling Fraction	You can use either the Sample Size or Sampling Fraction parameter. You can choose sampling with or without replacement, the latter of which is used by default. Select the checkbox to enable sampling with replacement.
Weight Columns	You can select a weight column from the drop-down list. The weight column can be of the double or bigint type.
Random Seed	The random seed, which is a positive integer. This parameter is empty by default.

- You can choose sampling with or without replacement, the latter of which is used by default. Select the checkbox to enable sampling with replacement.
- You can specify the number of samples to be taken, which is 10,000 by default.

  > **Note** For sampling without replacement, the number of samples cannot be greater than the number of data entries.

- You can select a weight column from the drop-down list. The weight column can be of the double or bigint type.

PAI command

```
PAI -name WeightedSample
-project algo_public
-DprobCol="previous"
-DsampleSize="500"
-DoutputTableName="test2"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
replace	Indicates whether sampled data is replaced. If this parameter is set to true, data is replaced after it is sampled. If this parameter is set to false, data is not replaced after it is sampled.
probCol	The columns to be weighted. Each value indicates the weight of an entry. Normalization is not required.
sampleSize	The number of samples to be taken. For sampling without replacement, the number of samples cannot be greater than the number of data entries.
outputTableNames	The name of the output table. Separate multiple table names with commas (,).
inputPartitions	Optional. The partitions selected from the input table for training. If no partitions are specified, the entire table is selected.
inputTableName	The name of the input table.
replace	Optional. This parameter indicates whether sampled data is replaced. If this parameter is set to true, data is replaced after it is sampled. If this parameter is set to false, data is not replaced after it is sampled.

Filtering and mapping

You can filter data based on filtering expressions and rename columns.

Parameter settings

1. Use the WHERE condition to filter data similar to how it would function in an SQL statement.

   Filtering conditions: Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), less than or equal to (<=) signs, as well as like and rlike.

2. Rename columns.

PAI command

```
PAI -name Filter
-project algo_public
-DoutTableName="test_9"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-Dfilter="age>=40";
```

Parameters

Parameter	Description
name	The name of the component.

Parameter	Description
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outTableName	The name of the output table.
inputPartitions	Optional. The partitions selected from the input table for training. If no partitions are specified, the entire table is selected.
inputTableName	The name of the input table.
filter	The WHERE condition to filter data. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), less than or equal to (<=) signs, as well as like and rlike.

Stratified sampling

Stratified sampling is a statistical computing method. It works by dividing a population into several strata based on specified features, performing random sampling at each stratum, and creating a sample collection.

Parameter settings

Parameter	Description
Column Settings	Stratification Column: Required. Samples are stratified based on this column.
Parameter Settings	Sampling Fraction/Sample Size: Required. A value less than 1 represents the sampling fraction per stratum. A value greater than 1 represents the number of samples at each stratum.
	Other Sampling Configurations: Optional. This parameter allows you to collect different numbers of samples at different strata.
	Random Seed: Optional. Valid values: 1, 2, 3, 4, 5, 6, and 7.

PAI command

```
Pai -name sample
-project algo_public
-DinputTableName=wbpc
-DoutputTableName=wpbc_sample
-DstrataColName="label"
-DsampleSize="A:200,B:300,C:500"
-DrandomSeed=1007
-Dlifecycle=30
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
strataColName	Required. The stratification column.	-	-
outputTableName	Required. The name of the output table.	-	-
sampleSize	Optional. An integer value that specifies the number of samples taken from each stratum. A string value must be in the `strata0:n0,strata1:n1....` format. Each item in the string represents the number of samples to be taken from the corresponding stratum.	-	
sampleRatio	Optional. A decimal value from 0 to 1 that represents the ratio of data for each stratum to be sampled. A string value must be in the `strata0:r0,strata1:r1...` format. Each item in the string represents the sampling fraction for the corresponding stratum.	-	-
randomSeed	Optional. The number of random seeds.	-	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

4.1.5.2.3.2. Data merge

Join

This component merges two tables by associating the information in the tables and outputting the specified columns. This component is similar to the JOIN statement of SQL.

Parameter settings

- Join types: left join, internal join, right join, and full join.
- Only the equation condition is supported.
- You can manually add or delete join conditions.

PAI command

No PAI command is available.

Merge columns

You can merge data of two tables by column. The two tables must have the same number of rows.

Parameter settings

Procedure

1. Select input columns from the left table.
2. Select input columns from the right table.

   When merging columns:

   - The two tables must have the same number of rows.
   - The names of output columns selected from the left and right tables cannot be the same.
   - When selecting an output column, you can change its name.
   - If no output columns are selected from the left or right table, the whole table is selected. In this case, if **Automatically Rename Output Columns** is selected, the duplicate columns are renamed and then output.

PAI command

```
PAI -name AppendColumns
-project algo_public
-DoutputTableColNames="petal_length,petal_width,petal_length2,petal_width2"
-DautoRenameCol="false"
-DoutputTableName="pai_temp_770_6840_1"
-DinputTableNames="iris_twopartition,iris_twopartition"
-DinputPartitionsInfoList="dt=20150125/dp=20150124;dt=20150124/dp=20150123"
-DselectedColNamesList="petal_length,petal_width;sepal_length,sepal_width";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.

Parameter	Description
outputTableColNames	The names of the columns in the new table. The column names must be separated with commas (,). If autoRenameCol is set to true, this parameter is ignored.
autoRenameCol	Optional. This parameter specifies whether to automatically rename the columns in the output table. If the value is true, the columns are renamed. If the value is false, the columns are not renamed. Default value: false.
outputTableName	The name of the output table.
inputTableNames	The name of the input table. Separate multiple table names with commas (,).
inputPartitionsInfoList	Optional. A list of partitions selected from the corresponding input tables. Partitions of the same table must be separated with commas (,) and partitions of different tables must be separated with semicolons (;).
selectedColNamesList	The names of selected columns. The names of columns in the same table must be separated with commas (,) and the names of columns in different tables must be separated with semicolons (;).

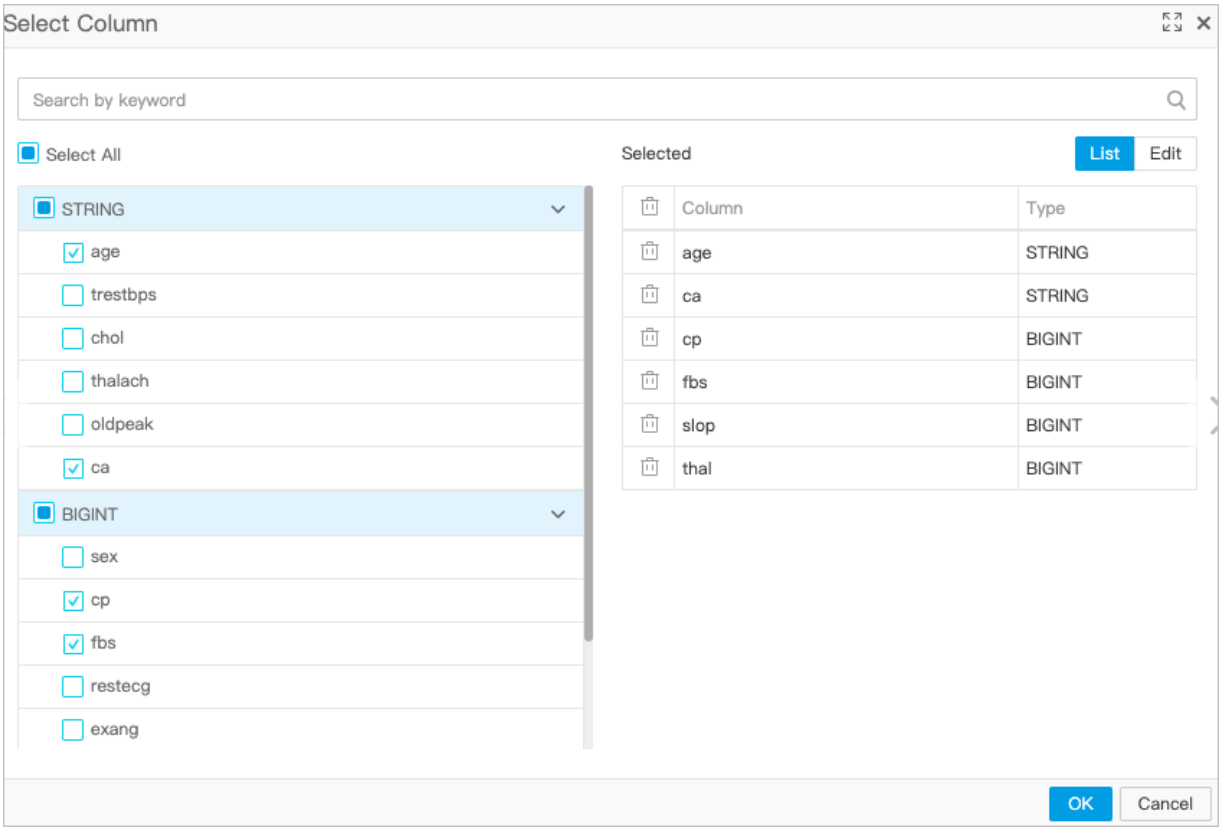
Merge rows (UNION)

To merge the data of two tables by row, the quantity and data type of the output columns selected from the left and right tables must be the same. The function is integrated with the UNION and UNION ALL functions.

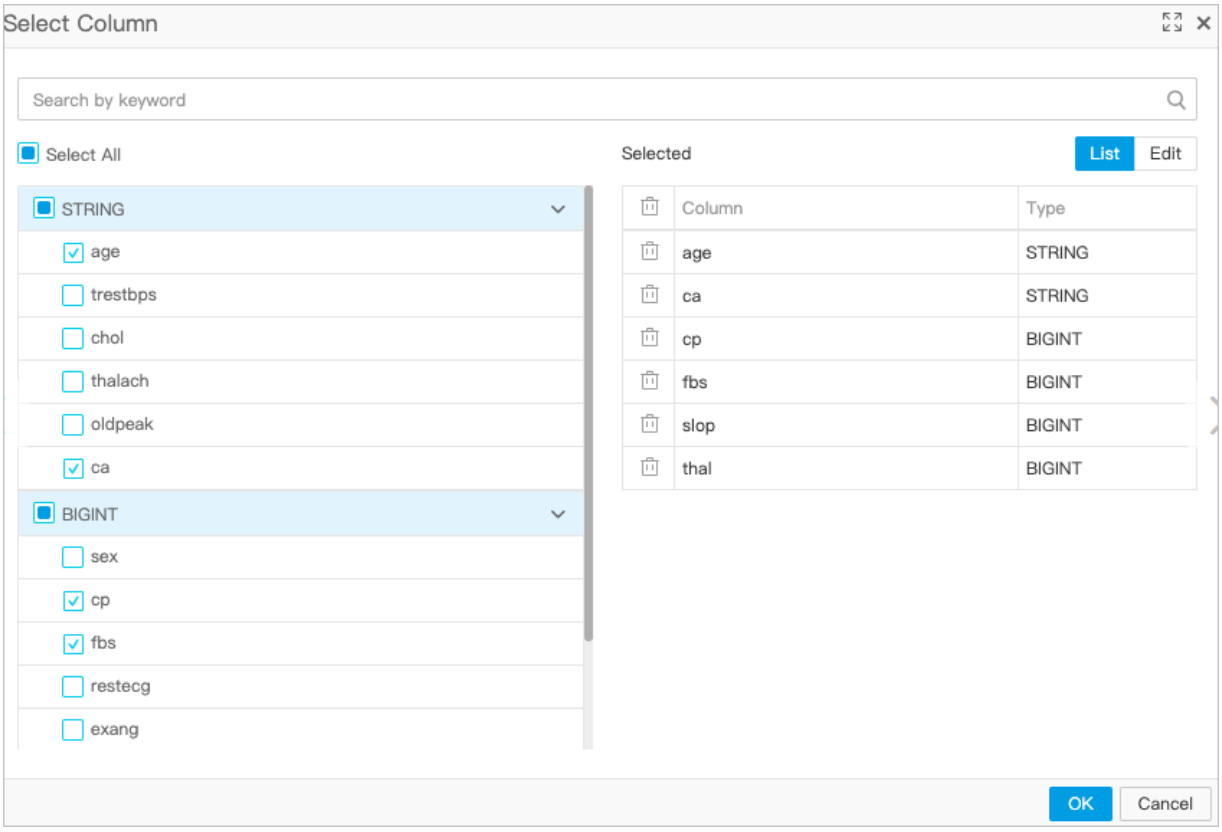
Parameter settings

- During the merge process, the numbers of columns selected from the left and right tables must be the same, and the data types of the corresponding columns must be the same.
- You can enter conditions in the text box by which to filter and select columns. The whole table is selected by default. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.
- **Remove Duplicates** is selected by default. When this option is selected, duplicate rows in the output table are removed.

The following figure shows the union columns selected from the left table.



The following figure shows the union columns selected from the right table.



PAI command

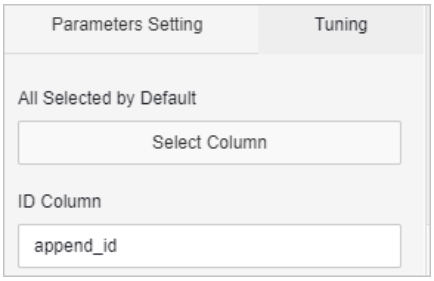
No PAI command is available.

4.1.5.2.3.3. Others

Add ID column

You can append an ID column to a table as the first column and save the table as a new table.

Parameter settings



PAI command

```
PAI -name AppendId
-project algo_public
-DIDColName="append_id"
-DoutputTableName="test_11"
-DinputTableName="bank_data"
-DselectedColNames="age,campaign,cons_conf_idx,cons_price_idx,emp_var_rate,euribor3m,nr_employed,pdays,poutcome,previous,y";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
IDColName	The name of the appended ID column. ID numbers start from 0 and increment by one. Example: 0, 1, 2, 3, ...
outputTableName	The name of the output table.
inputTableName	The name of the input table.
selectedColNames	The names of the columns to be retained. Separate multiple columns with commas (,).

Split

This component is used to split an input table or a partition based on a specified ratio, and output two tables from two output ports.

Algorithm component

Parameter settings

- The Split component has two output ports.
- In Parameter settings, if the splitting fraction is set to 0.7, the left output port outputs 70% of the data and

the right output port outputs 30% of the data.

PAI command

```
pai -name split -project algo_public
      -DinputTableName=wbpc
          -Doutput1TableName=wpbc_split1
      -Doutput2TableName=wpbc_split2
      -Dfraction=0.25;
```

Parameter settings

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
output1TableName	Required. The name of output table 1.	-	-
output1TablePartition	Optional. The partitions in output table 1.	-	Output table 1 is a non-partitioned table by default.
output2TableName	Required. The name of output table 2.	-	-
output2TablePartition	Optional. The partitions in output table 2.	-	Output table 2 is a non-partitioned table by default.
fraction	Required. The portion of data diverted to output table 1.	(0, 1)	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer in the range of [1, 3650]	No lifecycle is set by default.

Missing value imputation

This component replaces a null value or a specified value with the maximum, minimum, average, or custom value. A list of values is defined to impute the missing values in an input table with the specified values.

- This component can replace a numeric null value with the maximum, minimum, average, or custom value.
- This component can also replace a null string, empty string, null and empty string, or specified value with a custom value.

- The missing values to be imputed can be null strings, empty strings, or custom values. If you choose empty strings, the data type of the target column must be string.

The parameters for the two input ports are as follows:

- inputTableName: the name of the input table for which to replace missing data.
- inputParaTableName: the name of the input configuration table that contains parameters generated by the missing value imputation node. Based on this parameter, configuration parameters in one table can be applied to a new table.

Parameters for the two output ports are as follows:

- outputTableName: the name of the imputed output table.
- outputParaTableName: the name of the output configuration table, which can be applied to other datasets.
- Columns to Impute: the names of the columns for which to replace missing values.
- Original Value: the values to be replaced.
- Replaced With: the replacement values.

PAI command

```
PAI -name FillMissingValues
    -project algo_public
    -Dconfigs="poutcome,null-empty,testing" \
    -DoutputTableName="test_3"
    -DinputPartitions="pt=20150501"
    -DinputTableName="bank_data_partition";
```

Algorithm parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
inputTablePartitions	Optional. The partitions selected from the input table for training.	Partition name	The whole table is selected by default.
outputTableName	Required. The name of the output table.	Table name	N/A

Parameter	Description	Valid value	Default value
configs	Required. The configurations for missing value imputation. Example: `col1, null, 3.14; col2, empty, hello; col3, empty-null, world`, where *null* indicates a null value and *empty* indicates an empty string. If you choose to use empty strings to fill the target columns, the data type of the target column must be string. The variables used to specify the replacement value as maximum, minimum, and average are max, min, and mean respectively. If you want to impute a custom value to the target column, use a user-defined variable in the `col4,user-defined,str,str123` format.	N/A	N/A
outputParaTableName	Required. The name of the output configuration table.	Table name	N/A
inputParaTableName	Optional. The name of the input configuration table.	Table name	No input configuration table is set by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Examples

Test data

- SQL statement to generate data:

```
drop table if exists fill_missing_values_test_input;
create table fill_missing_values_test_input(
    col_string string,
    col_bigint bigint,
    col_double double,
    col_boolean boolean,
    col_datetime datetime);
insert overwrite table fill_missing_values_test_input
select
    *
```

```
from
(
    select
        '01' as col_string,
        10 as col_bigint,
        10.1 as col_double,
        True as col_boolean,
        cast('2016-07-01 10:00:00' as datetime) as col_datetime
    from dual
    union all
        select
            cast(null as string) as col_string,
            11 as col_bigint,
            10.2 as col_double,
            False as col_boolean,
            cast('2016-07-02 10:00:00' as datetime) as col_datetime
        from dual
    union all
        select
            '02' as col_string,
            cast(null as bigint) as col_bigint,
            10.3 as col_double,
            True as col_boolean,
            cast('2016-07-03 10:00:00' as datetime) as col_datetime
        from dual
    union all
        select
            '03' as col_string,
            12 as col_bigint,
            cast(null as double) as col_double,
            False as col_boolean,
            cast('2016-07-04 10:00:00' as datetime) as col_datetime
        from dual
    union all
        select
            '04' as col_string,
            13 as col_bigint,
            10.4 as col_double,
            cast(null as boolean) as col_boolean,
            cast('2016-07-05 10:00:00' as datetime) as col_datetime
        from dual
    union all
        select
            '05' as col_string,
            14 as col_bigint,
            10.5 as col_double,
            True as col_boolean,
            cast(null as datetime) as col_datetime
        from dual
) tmp;
```

```

Normalization

You can normalize one or more columns in a table and save the generated data to a new table.

Linear function transformation is supported. The transformation expression is `y=(x-MinValue)/(MaxValue-MinValue)`.

MaxValue and *MinValue* indicate the maximum and minimum values of the sample respectively.

- Click **Columns** to select the columns to be normalized. Double and bigint types are supported.
- You can choose whether to retain the original columns. If you select the corresponding checkbox, the original columns will be retained. Processed columns will be renamed.

PAI command

```
PAI -name normalize_wf
-project algo_public
-DkeepOriginal="true"
-DoutputTableName="test_4"
-DinputPartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-DselectedColNames="emp_var_rate,euribor3m";
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	N/A
selectedColNames	Optional. The names of columns selected from the input table.	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for training.	The whole table is selected by default.
outputTableName	Required. The name of the output table.	N/A
outputParaTableName	Required. The name of the output configuration table.	N/A
inputParaTableName	Optional. The name of the input configuration table.	No input configuration table is set by default.
outputPMMLTableName	Required. The name of the output PMML table.	N/A
keepOriginal	Optional. This parameter specifies whether to retain the original columns. If `keepOriginal` is set to true, processed columns are renamed with the `normalized_` prefix and the original columns are retained and their data overwritten. If `keepOriginal` is set to false, all columns are retained but not renamed.	false
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	Automatically calculated.

Standardization

You can standardize one or more columns in a table and save the generated data to a new table.

- The formula used for standardization is `(X - Mean)/(Standard deviation)`.

- Mean: The mean of samples.
- Standard deviation: The standard deviation of samples. This variable is used when samples are used to calculate the total deviation. To make the calculated value closer to the mean, you must moderately increase the calculated standard deviation by using the formula $\frac{1}{N-1}$.
- The formula for calculating the standard deviation of samples:

$$S = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(X_i - \bar{X})^2}$$

$\bar{X}$ represents the mean of samples X1, X2, ..., Xn.

- You can choose whether to retain the original columns. If you select the corresponding checkbox, the original columns will be retained. Processed columns will be renamed.
- Click **Columns** and select columns to be standardized. Double and bigint types are supported.

PAI command

```
PAI -name Standardize
-project algo_public
-DkeepOriginal="false"
-DoutputTableName="test_5"
-DinputTablePartitions="pt=20150501"
-DinputTableName="bank_data_partition"
-DselectedColNames="euribor3m,pdays"
```

Standardization component

Parameters for the two input ports are as follows:

- inputTableName: the name of the input table to be standardized.
- inputParaTableName: the name of the input configuration table that contains the parameters generated by the standardization node. You can use an input configuration table to apply the configuration parameters of one table to a new table.

Parameters for the two output ports are as follows:

- outputTableName: the name of the standardized output table.
- outputParaTableName: the name of the output parameter table, which can be applied to other datasets.

Standardization parameters

The corresponding algorithm parameter for Reserve Original Columns is `keepOriginal`.

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-

Parameter	Description	Valid values	Default value
selectedColNames	Optional. The names of columns selected from the input table.	-	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
outputParaTableName	Required. The name of the output configuration table.	-	-
outputPartition	Optional. The partitions in the output table.	-	-
inputParaTableName	Optional. The name of the input configuration table.	-	No input configuration table is set by default.
keepOriginal	Optional. This parameter specifies whether to retain the original columns. If this parameter is set to true, the original columns are retained and the column name is suffixed with `_orig`.	true and false	false
lifecycle	Optional. The lifecycle of the output table.	-	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

Examples

```
drop table if exists standardize_test_input;
create table standardize_test_input(
col_string string,
col_bigint bigint,
col_double double,
col_boolean boolean,
col_datetime datetime);
insert overwrite table standardize_test_input  select      * from  (
select         '01' as col_string,
10 as col_bigint,
10.1 as col_double,
True as col_boolean,
cast('2016-07-01 10:00:00' as datetime) as col_datetime     from dual     union all
select             cast(null as string) as col_string,
11 as col_bigint,
10.2 as col_double,
False as col_boolean,
cast('2016-07-02 10:00:00' as datetime) as col_datetime         from dual     union all
select
'02' as col_string,
cast(null as bigint) as col_bigint,
10.3 as col_double,
True as col_boolean,
cast('2016-07-03 10:00:00' as datetime) as col_datetime         from dual     union all
select             '03' as col_string,
12 as col_bigint,
cast(null as double) as col_double,
False as col_boolean,
cast('2016-07-04 10:00:00' as datetime) as col_datetime         from dual     union all
select             '04' as col_string,
13 as col_bigint,
10.4 as col_double,
cast(null as boolean) as col_boolean,
cast('2016-07-05 10:00:00' as datetime) as col_datetime         from dual     union all
select             '05' as col_string,
14 as col_bigint,
10.5 as col_double,
True as col_boolean,
cast(null as datetime) as col_datetime         from dual ) tmp;
```

PAI command

```
drop table if exists standardize_test_input_output;
drop table if exists standardize_test_input_model_output;
PAI -name Standardize
-project algo_public

KV to Table

This component is used to convert KV pairs to a table. The key is converted to a table column, while the value is converted to a column value in the corresponding row.

KV table format definition:

- A key is the index of a column. Key values can be of the bigint or double types.
- A KV table can be input in the sparse format to algorithm components such as logistic and linear regression.
- Keys must be of the string type. You can input a key_map table to the KV to Table component to map keys to columns. This component outputs a key_map table that contains all key-column mappings after conversion, regardless of whether you input a key_map table.

kv
1:10;2:20;3:30

key_map table format definition: a table that contains index-to-column mappings and data type information. The data types of the col_name, col_index, and col_datatype columns must be string. The default data type of the col_datatype column is double if not specified.

col_name	col_index	col_datatype
col1	1	bigint
col2	2	double

PAI command

```
PAI -name KVToTable
    -project algo_public
    -DinputTableName=test
    -DoutputTableName=test_out
    -DoutputKeyMapTableName=test_keymap_out
    -DkvColName=kv;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	The table cannot be empty.
kvColName	Required. The name of the KV column.	Only one column can be selected.	-
outputTableName	Required. The name of the output table.	Table name	-
outputKeyMapTableName	Required. The name of the output index table.	Table name	-
inputKeyMapTableName	Optional. The name of the input index table.	Table name	No input index table is set by default.
appendColName	Optional. The name of the appended column.	Multiple columns can be selected.	No column is appended by default.

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	No partition is specified by default.
kvDelimiter	Optional. The delimiter used to separate keys and values.	Symbol	The default delimiter is a semicolon (;).
itemDelimiter	Optional. The delimiter used to separate key-value pairs.	Symbol	The default delimiter is a comma (,).
top1200	Optional. This parameter specifies whether to output the first 1,200 columns.	true and false	Default value: true. If the value is false, an error is returned when the number of columns reaches the upper limit.
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1.	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer greater than 0.	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

SQL statement to generate data:

```
drop table if exists test;
    create table test as
      select
        *
      from
      (
        select '1:1,2:2,3:-3.3' as kv from dual
        union all
        select '1:10,2:20,3:-33.3' as kv from dual
      ) tmp;
```

PAI command

```
PAI -name KVToTable
    -project algo_public
    -DinputTableName=test
    -DoutputTableName=test_out
    -DoutputKeyMapTableName=test_keymap_out
    -DkvColName=kv;
```

Output

The output table is shown as follows.

```
+------------+------------+------------+
| kv_1       | kv_2       | kv_3       |
+------------+------------+------------+
| 1.0        | 2.0        | -3.3       |
| 10.0       | 20.0       | -33.3      |
+------------+------------+------------+
```

The output mapping table is shown as follows.

```
+------------+------------+------------+
| col_name   | col_index  | col_type   |
+------------+------------+------------+
| kv_1       | 1          | double     |
| kv_2       | 2          | double     |
| kv_3       | 3          | double     |
+------------+------------+------------+
```

Input and output restrictions

Converted columns include appended columns and columns converted from KV pairs. The KV columns are output before the appended columns. MaxCompute supports a maximum of 1,200 columns. When the number of columns exceeds the maximum value, and top1200 is set to true, only the first 1,200 columns are output. If top1200 is set to false, an error is returned. The number of input data entries cannot exceed 100 million.

Restrictions and guidelines

- If a key_map table is input, columns are converted from the keys that exist in both the key_map and key-value tables.
- The converted column type can only be numeric.
- If a key_map table is input, the data type of the converted key column is the same as that of the key_map table. If no key_map table is input, the data type of the converted key column is double.
- If a key_map table is not input, the name of the converted key column is in the format of 'kv column name+""+key'. An error is returned if the key contains any of the following characters: %&()*+-. /;<>=?
- If an appended column is specified and the name of the appended column is the same as that of the converted key column, an error is returned indicating a column name conflict.
- If a row contains multiple keys, the values are added.
- A column name can contain up to 128 characters. If more than 128 characters are entered, only the first 128 characters are kept.

Table to KV

This component is used to convert data tables to KV tables. Null values in the table to be converted are not displayed in the KV table. You can specify columns to be retained in the new table. These columns will remain unchanged.

PAI command

```
PAI -name TableToKV
    -project algo_public
    -DinputTableName=maple_tabletokv_basic_input
    -DoutputTableName=maple_tabletokv_basic_output
    -DselectedColNames=col0,col1,col2
    -DappendColNames=rowid;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
selectedColNames	Optional. The names of selected columns from the input table.	The column type must be bigint or double.	The whole table is selected by default.
appendColNames	Optional. The names of columns to remain unchanged. These columns are written in the output table without any changes.	Multiple columns can be selected.	-
outputTableName	Required. The name of the output KV table.	Table name	-
kvDelimiter	Optional. The delimiter used to separate keys and values.	Symbol	The default delimiter is a colon (:).
itemDelimiter	Optional. The delimiter used to separate key-value pairs.	Symbol	The default delimiter is a comma (,).
convertColToIndexId	Optional. This parameter specifies whether to convert columns into IDs.	0 and 1	0

Parameter	Description	Valid values	Default value
inputKeyMapTableName	Optional. The name of the input index table. This parameter takes effect only in the case of `convertColToIndexId=1`. If this parameter is not specified, IDs are automatically generated.	Table name	No input index table is set by default.
outputKeyMapTableName	The name of the output index table. This parameter is required only in the case of `convertColToIndexId=1`.	Table name	The default value is determined by convertColToIndexId.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Example 1

Data generation

rowid	kv
0	col0:1,col1:1.1,col2:2
1	col0:0,col1:1.2,col2:3
2	col0:1,col1:2.3
3	col0:1,col1:0.0,col2:4

PAI command

```
PAI -name TableToKV
    -project algo_public
    -DinputTableName=maple_tabletokv_basic_input
    -DoutputTableName=maple_tabletokv_basic_output
    -DselectedColNames=col0,col1,col2
    -DappendColNames=rowid;
```

Output

The output table is shown as follows.

maple_tabletokv_basic_output

rowid:bigint	kv:string
0	1:1.1,2:2
1	1:1.2,2:3
2	1:2.3
3	1:0.0,2:4

Example 2

PAI command

```
PAI -name TableToKV
    -project projectxlib4 -DinputTableName=maple_tabletokv_basic_input
    -DoutputTableName=maple_tabletokv_basic_output
    -DselectedColNames=col0,col1,col2 -DappendColNames=rowid
    -DconvertColToIndexId=1
    -DinputKeyMapTableName=maple_test_tabletokv_basic_map_input
    -DoutputKeyMapTableName=maple_test_tabletokv_basic_map_output;
```

Output

The output table is shown as follows.

maple_test_tabletokv_basic_map_output

col_name:string	col_index:string	col_datatype:string
col1	1	bigint
col2	2	double

Restrictions and guidelines

- If a key_map table is input, columns are converted from the keys that exist in both the key_map and key-value tables.
- If a key_map table is input and its type is different from the input table, the output key_map table uses the type specified by the user.
- The type of the columns that need to be converted into KV pairs in the input table must be bigint or double.

4.1.5.2.4. Feature engineering

4.1.5.2.4.1. Feature transformation

Principal Component Analysis

Principal Component Analysis (PCA) is used to reduce dimensions.

- For more information, see Wikipedia.
- PCA supports dense data.

PAI command

```
PAI -name PrinCompAnalysis
-project algo_public
-DinputTableName=bank_data
-DeigOutputTableName=pai_temp_2032_17900_2
-DprincompOutputTableName=pai_temp_2032_17900_1
-DselectedColNames=pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed
-DtransType=Simple
-DcalcuType=CORR
-DcontriRate=0.9;
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The input table for PCA.	-
eigOutputTableName	Required. The output table that contains feature vectors and feature values.	-
princompOutputTableName	Required. The output table that contains the results of PCA dimension reduction and noise reduction.	-
selectedColNames	Required. The feature columns that are involved in PCA.	-
transType	Optional. The method used to transform the original table to the principal component table. Valid values: Simple, Sub-Mean, and Normalization.	Simple
calcuType	Optional. The eigendecomposition mode of the original table. Valid values: CORR, COVAR_SAMP, and COVAR_POP.	CORR
contriRate	Optional. The ratio of information to be retained after dimension reduction.	0.9
remainColumns	Optional. The columns retained from the original table after dimension reduction.	-

4.1.5.2.4.2. Feature importance evaluation

Linear model feature importance

You can evaluate the quality of a linear algorithm model based on the predicted and actual output results such as the indicators and residual histogram. Indicators include SST, SSE, SSR, R2, R, MSE, RMSE, MAE, MAD, MAPE, count, yMean, and predictMean.

PAI command

```
pai -name regression_evaluation
-project algo_public
-DinputTableName=input_table
-DyColName=y_col
-DpredictionColName=prediction_col
-DindexOutputTableName=index_output_table
-DresidualOutputTableName=residual_output_table
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	All partitions in the input table are selected by default.
yColName	Required. The name of the expected dependent variable column in the input table. It must be a numerical value.	-	-
predictionColName	Required. The name of the predicted dependent variable column. It must be a numerical value.	-	-
indexOutputTableName	Required. The name of the regression indicator output table.	-	-
residualOutputTableName	Required. The name of the residual histogram output table.	-	-
intervalNum	Optional. The number of intervals to divide the histogram over.	-	100
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	-	Automatically calculated.

Output

The output table is in JSON format. Field description describes the JSON fields.

Field description

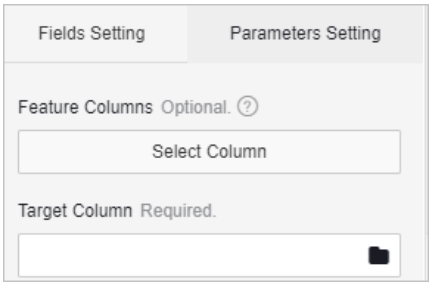
Field	Description
SST	Total sum of squares.
SSE	Sum of squared errors.
SSR	Sum of squares due to regression.
R2	Coefficient of determination.
R	Coefficient of multiple correlation.

Field	Description
MSE	Mean squared error.
RMSE	Root-mean-square error.
MAE	Mean absolute error.
MAD	Mean absolute difference.
MAPE	Mean absolute percentage error.
count	Number of rows.
yMean	Mean of expected dependent variables.
predictionMean	Mean of prediction results.

Random forest feature importance

You can calculate the importance of features in a random forest model.

Column settings



PAI command

```
pai -name feature_importance
-project algo_public
-DinputTableName=input
-DoutputTableName=output
-Dlabel=label
-DmodelName=model
```

Algorithm parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	-
outputTableName	Required. The name of the output table.	-
labelColName	Required. The name of the label column.	-

Parameter	Description	Default value
modelName	Required. The name of the input model.	-
featureColNames	Optional. The names of feature columns selected from the input table.	All columns except the label column are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table.	The whole table is selected by default.
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	Automatically calculated.

4.1.5.2.5. Statistical analysis

4.1.5.2.5.1. Data Pivoting

The Data Pivoting component allows you to view the distributions of feature values, feature columns, and label columns. This facilitates future data analysis. Both the sparse and dense data formats are supported.

PAI command

```
PAI -name fe_meta_runner -project algo_public
-DinputTable="pai_dense_10_10"
-DoutputTable="pai_temp_2263_20384_1"
-DmapTable="pai_temp_2263_20384_2"
-DselectedCols="pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed,age,campaign,poutcome"
-DlabelCol="y"
-DcategoryCols="previous"
-Dlifecycle="28"-DmaxBins="5" ;
```

Algorithm parameters

Parameter	Description	Required	Default value
inputTable	The name of the input table.	Yes	N/A
inputTablePartitions	The partitions that are selected from the input table.	No	N/A
outputTable	The name of the output table.	Yes	N/A

Parameter	Description	Required	Default value
mapTable	The output mapping table. The Data Pivoting component maps data of the STRING type to the INT type to facilitate machine learning and training.	Yes	N/A
selectedCols	The columns that are selected from the input table.	Yes	N/A
categoryCols	The columns of the INT or DOUBLE type that you want to use as enumeration features.	No	Empty
maxBins	The maximum number of intervals for equal-distance division of continuous features.	No	100
isSparse	Specifies whether the features are in the sparse format.	No	false
itemSpliter	The delimiter that is used to separate sparse feature items.	No	","
kvSpliter	The delimiter that is used to separate keys and values of a feature item.	No	":"
lifecycle	The lifecycle of the output table. Unit: day.	No	28

4.1.5.2.5.2. Whole table statistics

This component analyzes a table or selected columns of a table.

Parameter settings

In the Input Columns box, select the columns of the table to be analyzed. By default, all columns are selected. You can enter filtering conditions for the selected columns in the condition text box. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.

PAI command

```
PAI -name SimpleSummary
-project algo_public
-DsummaryColNames="euribor3m,pdays"
-DoutputTableNames="pai_temp_667_6017_1"
-DinputTableName="bank_data"
-Dfilter="age>40";
```

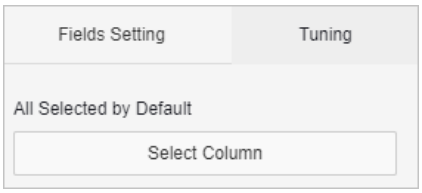
Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
summaryColNames	The columns that require analysis. Separate the columns with commas(,).
outputTableNames	The names of the output tables generated after the system performs the whole table statistics operation.
inputTableName	The name of the input table.
filter	The filtering conditions. Operators available include the equal (=), not equal (!=), greater than (>), less than (<), greater than or equal to (>=), and less than or equal to (<=) signs, as well as like and rlike.

4.1.5.2.5.3. Correlation coefficient matrix

The correlation coefficient is a measure of the correlation between columns in a matrix. The valid range of values for this parameter is [-1, 1]. The count equals the number of non-zero elements in two successive columns.

Column settings



PAI command

```
PAI -name corrcoef
-project algo_public
-DinputTableName=maple_test_corrcoef_basic12x10_input
-DoutputTableName=maple_test_corrcoef_basic12x10_output
-DcoreNum=1
-DmemSizePerCore=110
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-

Parameter	Description	Valid values	Default value
inputTablePartition	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions are selected by default.
outputTableName	Required. A list of output table names.	Table name	-
selectedColNames	Optional. The names of columns selected from the input table.	Column name	All columns are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

Data generation describes the data generation result.

Data generation

col0:double	col1:bigint	col2:double	col3:bigint	col4:double	col5:bigint	col6:double	col7:bigint	col8:double	col9:double

4.1.5.2.5.4. Covariance

In probability theory and statistics, covariance is a measure of the joint variability of two random variables. Variance is a special case of covariance where the two measured variables are the same. If the expected values are E(X) = μ and E(Y) = v, the covariance between real-number random variables X and Y is cov(X, Y) = E((X - μ) (Y - v)).

PAI command

```
PAI -name cov
    -project algo_public
    -DinputTableName=maple_test_cov_basic12x10_input
    -DoutputTableName=maple_test_cov_basic12x10_output
    -DcoreNum=6
    -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
outputTableName	Required. A list of output table names.	Table name	-
selectedColNames	Optional. The names of columns selected from the input table.	Column name	All columns are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

4.1.5.2.5.5. Empirical probability density chart

An empirical distribution is an estimated non-parametric distribution of probability in scenarios where accurate parametric distributions cannot be made.

The algorithm uses kernel distribution to estimate the probability density of sample data. Similar to a histogram, the algorithm generates functions to describe the distribution of sample data. However, kernel distribution is different in that it overlays the contributions of all parts to generate a smooth and continuous distribution curve, while a histogram only generates discrete descriptions. When kernel distribution is used, the probability density of non-sample data points is not 0, but an overlay of weighted probability density of all sampling points in a certain kernel distribution. In this document, the kernel distribution used is Gaussian distribution.

- For more information about kernel distribution, see Wikipedia.
- For more information about empirical distribution, see Wikipedia.

PAI command

```
PAI -name empirical_pdf
-project algo_public
-DinputTableName="test_data"
-DoutputTableName="test_epdf_out"
-DfeatureColNames="col0,col1,col2"
-DinputTablePartitions="ds='20160101'"
-Dlifecycle=1
-DintervalNum=100
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name	-
featureColNames	Required. The names of input columns.	Multiple columns of the double or bigint type can be selected.	-
labelColName	Optional. The name of the input label column.The feature column is stratified based on the label values in the label column.	Only one column of the bigint or string type can be selected. The number of label values cannot exceed 100.	No input label column is set by default.
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	All partitions are selected by default.
intervalNum	The number of calculation intervals. The larger the number, the higher the accuracy.	[1, 1E14)	Default value: -1. This value indicates that the number of intervals is determined based on the range of data values for each column.
lifecycle	The lifecycle of the output table.	A positive integer	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	A positive integer	Default value: -1. This value indicates that the number of instances is determined based on the volume of input data.

Parameter	Description	Valid values	Default value
memSizePerCore	Optional. The memory size of each core.	A positive integer in the range of [1024, 65536]	Default value: -1. This value indicates that the memory size is determined based on the volume of input data.

Examples

SQL statement to generate data:

```
drop table if exists epdf_test;
create table epdf_test as
select
  *
from
(
  select 1.0 as col1 from dual
    union all
  select 2.0 as col1 from dual
    union all
  select 3.0 as col1 from dual
    union all
  select 4.0 as col1 from dual
    union all
  select 5.0 as col1 from dual
) tmp;
```

PAI command

```
PAI -name empirical_pdf
-project algo_public
-DinputTableName=epdf_test
-DoutputTableName=epdf_test_out
-DfeatureColNames=col1;
```

Input description

You can select multiple columns to be calculated. You can select a label column and stratify the columns by label. For example, if the label column contains labels 0 and 1, the columns that need to be calculated are stratified into two groups. One group only contains columns with label 0 and the other group only contains columns with label 1. The probability density for each group is then calculated. If no label column is selected, all feature columns are calculated.

Output description

This component outputs a diagram and a result table. The columns in the result table are as follows. If no label column is selected, NULL is output in the label column.

Column name	Data type
colName	string
label	string
x	double

Column name	Data type
pdf	double

Output table:

```
+------------+------------+------------+------------+
| colname    | label      | x          | pdf        |

```

Input and output restrictions

The maximum number of label columns that can be specified is 100.

4.1.5.2.5.6. Chi-square goodness of fit test

This component is used to determine the differences between the observed frequencies and the expected frequencies for each classification of a single multiclass classification nominal variable. The null hypothesis assumes that the observed frequencies and the expected frequencies are consistent.

PAI command

```
PAI -name chisq_test
    -project algo_public
    -DinputTableName=pai_chisq_test_input
    -DcolName=f0
    -DprobConfig=0:0.3,1:0.7
    -DoutputTableName=pai_chisq_test_output0
    -DoutputDetailTableName=pai_chisq_test_output0_detail
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
colName	Required. The name of the column that requires a chi-square test.	Column name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
outputDetailTableName	Required. The name of the output detail table.	Table name that has not been used	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition list	All partitions are selected by default.
probConfig	Optional. The class probability configuration.	The configuration is stored in a key-value pair format: `class:probability`. The sum of all probabilities is 1.	All classes have the same probability by default.

Examples

Testing data

```
create table pai_chisq_test_input as
select * from
(
  select '1' as f0,'2' as f1 from dual
  union all
  select '1' as f0,'3' as f1 from dual
  union all
  select '1' as f0,'4' as f1 from dual
  union all
  select '0' as f0,'3' as f1 from dual
  union all
  select '0' as f0,'4' as f1 from dual
)tmp;
```

PAI command

```
PAI -name chisq_test
    -project algo_public
    -DinputTableName=pai_chisq_test_input
    -DcolName=f0
    -DprobConfig=0:0.3,1:0.7
    -DoutputTableName=pai_chisq_test_output0
    -DoutputDetailTableName=pai_chisq_test_output0_detail
```

Output description

Output table outputTableName is a JSON array containing only one row and one column.

```
{
    "Chi-Square": {
        "comment": "Pearsons chi-square test",
        "df": 1,
        "p-value": 0.75,
        "value": 0.2380952380952381
    }
}
```

Output table outputDetailTableName includes the following columns: data source class (**f0** or **f1**), observed frequency (**observed**), expected frequency (**expected**), and standard residuals (**residuals** = `(observed - expected)/sqrt (expected)`).

f0	f1	observed	expected	residuals
0	2	0.0	0.4	-0.6324555320336759
0	3	1.0	0.8	0.22360679774997894
0	4	1.0	0.8	0.22360679774997894
1	2	1.0	0.6000000000000001	0.5163977794943221
1	3	1.0	1.2000000000000002	-0.1825741858350555
1	4	1.0	1.2000000000000002	-0.1825741858350555

4.1.5.2.5.7. Chi-square test of independence

This component verifies whether two factors (each having two or more classes) are mutually independent. The null hypothesis is that two factors are independent of each other.

PAI command

```
PAI -name chisq_test
    -project algo_public
    -DinputTableName=pai_chisq_test_input
    -DxColName=f0
    -DyColName=f1
    -DoutputTableName=pai_chisq_test_output2
    -DoutputDetailTableName=pai_chisq_test_output2_detail
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
xColName	Required. The name of the column that requires a chi-square test.	Column name	-
yColName	Required. The name of the column that require a chi-square test.	Column name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
outputDetailTableName	Required. The name of the output detail table.	Table name that has not been used	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition list	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Examples

- Testing data

```
create table pai_chisq_test_input as
select * from
(
select '1' as f0,'2' as f1 from dual
union all
select '1' as f0,'3' as f1 from dual
union all
select '1' as f0,'4' as f1 from dual
union all
select '0' as f0,'3' as f1 from dual
union all
select '0' as f0,'4' as f1 from dual
)tmp;
```

- PAI command

```
PAI -name chisq_test
  -project algo_public
  -DinputTableName=pai_chisq_test_input
  -DxColName=f0
  -DyColName=f1
  -DoutputTableName=pai_chisq_test_output2
  -DoutputDetailTableName=pai_chisq_test_output2_detail
```

- Output description

  Output table outputTableName is a JSON array containing only one row and one column.

```
{
    "Chi-Square": {
        "comment": "Pearsons chi-square test",
        "df": 2,
        "p-value": 0.75,
        "value": 0.8333333333333334
    }
}
```

  Output table outputDetailTableName has the following columns:

Column name	Description
xColName	Class
yColName	Class
observed	Observed frequency
expected	Expected frequency
residuals	Residuals = (observed - expected)/sqrt (expected)

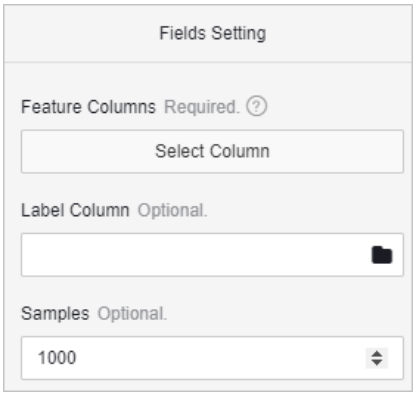
  Data:

f0	f1	observed	expected	residuals
0	2	0.0	0.4	-0.6324555320336759
0	3	1.0	0.8	0.22360679774997894
0	4	1.0	0.8	0.22360679774997894
1	2	1.0	0.6000000000000001	0.5163977794943221
1	3	1.0	1.2000000000000002	-0.1825741858350555
1	4	1.0	1.2000000000000002	-0.1825741858350555

4.1.5.2.5.8. Scatter plot

In regression analysis, this component outputs a scatter plot that shows the distribution of data points in a Cartesian coordinate system.

Column settings



PAI command

```
PAI -name scatter_diagram
-project algo_public
-DselectedCols=emp_var_rate,cons_price_rate,cons_conf_idx,euribor3m
-DsampleSize=1000
-DlabelCol=y
-DmapTable=pai_temp_2447_22859_2
-DinputTable=scatter_diagram
-DoutputTable=pai_temp_2447_22859_1
```

Parameters

Parameter	Description	Default value
inputTable	Required. The name of the input table.	-
inputTablePartitions	Optional. The partitions selected from the input table.	-
outputTable	Required. The name of the output table that stores the samples.	-
mapTable	Required. The name of the output table that stores the maximum value, minimum value, and enumeration values of each feature.	-
selectedCols	Required. The columns selected from the input table from which to draw a scatter plot. A maximum of five features can be selected.	-
labelCol	Optional. An Int or String column to serve as the enumeration label column.	No enumeration label column is set by default.
sampleSize	Optional. The number of samples to collect from the input data.	1000
lifecycle	Optional. The lifecycle of the output table measured in days.	28

Examples

Input data

```
create table scatter_diagram as select emp_var_rate,cons_price_rate, cons_conf_idx,euribor3m,y from pai_bank_data limit 10
```

Parameters

emp_var_rate	cons_price_rate	cons_conf_idx	euribor3m	y
1.4	93.918	-42.7	4.962	0

1.1	93.994	-36.4	4.858	0
1.4	93.444	-36.1	4.963	0

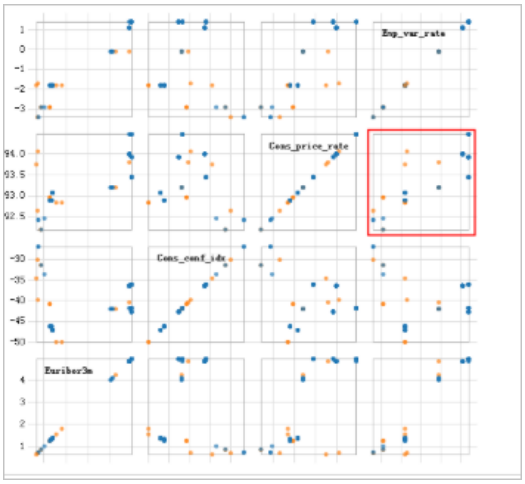
Parameter settings

Scatter plot configuration: select **select emp_var_rate**, **cons_price_rate**, **cons_conf_idx**, and **euribor3m** as the feature columns, and select **y** as the label column.

Output



You can view the distribution of classification tags between every two features in the scatter plot.

4.1.5.2.5.9. Two-sample T-test

A two-sample T-test is composed of an independent sample T-test and a paired sample T-test. Two samples independent of each other are called independent samples. An independent sample T-test checks whether two samples are significantly different from each other. The T-test is based on the premise that two samples are independent of each other and come from two normally distributed populations. A paired sample T-test checks whether the mean values from two paired populations are significantly different from each other.

PAI command

```
PAI -name t_test
    -project algo_public
    -DxTableName=pai_t_test_all_type
    -DxColName=col1_double
    -DxTablePartitions=ds=2010/dt=1
    -DyTableName=pai_t_test_all_type
    -DyColName=col1_double
    -DyTablePartitions=ds=2010/dt=1
    -DoutputTableName=pai_t_test_out
    -Dalternative=less
    -Dmu=47
    -DconfidenceLevel=0.95
    -Dpaired=False
    -DvarEqual=True
```

Parameters

Parameter	Description	Valid values	Default value
xTableName	Required. The name of input table x.	Table name	-
xTablePartitions	Optional. The partitions selected from input table x for testing, in the format of `Partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
xColName	Required. The column selected from table x for testing.	Column name. The type must be double or bigint.	-
yTableName	Required. The name of input table y.	Table name	-
yTablePartitions	Optional. The partitions selected from input table y for testing, in the format of `Partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
yColName	Required. The name of the column selected from table y for testing.	Column name. The type must be double or bigint.	-

Parameter	Description	Valid values	Default value
paired	Optional. A value of True indicates that it is a paired sample T-test. A value of False indicates that it is an independent sample T-test.	True and False	False
alternative	Optional. The alternative hypothesis.	two.sided, less, and greater	two.sided
mu	Optional. The hypothesized mean.	double	0
varEqual	Optional. This parameter indicates whether two population variances are equal.	True and False	False
confidenceLevel	Optional. The confidence level.	0.8, 0.9, 0.95, 0.99, 0. 995, and 0.999	0.95
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each node. Unit: MB.	A positive integer in the range of [1024, 65536].	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Custom resources

Note

- For a regular table, we recommend that you do not set coreNum and memSizePerCore, and instead allow the default values to be used automatically.
- If you do not have sufficient compute resources, use the following code to calculate the amount of compute resources needed:

```
def CalcCoreNumAndMem(row, centerCount, kOneCoreDataSize=1024):
    """Calculates the number of nodes and memory size needed for each node.
       Args:
           row: the number of rows in the input table.
           col: the number of columns in the input table.
           kOneCoreDataSize: the amount of data needed to be calculated per node. Unit: MB. The valu
e must be a positive integer. Default value: 1024.
       Return:
           coreNum, memSizePerCore
       Example:
           coreNum, memSizePerCore = CalcCoreNumAndMem(1000,99, 100, kOneCoreDataSize=2048)
    """
    kMBytes = 1024.0 * 1024.0
    #Number of compute nodes
    coreNum = max(1, int(row * 2 * 8 / kMBytes / kOneCoreDataSize))
    #Memory size per node = Data volume
    memSizePerCore = max(1024,  int(kOneCoreDataSize*2))
    return coreNum,  memSizePerCore
```

Examples

- SQL statement to generate data:

```
create table pai_test_input as
select * from
(
  select 1 as f0,2 as f1 from dual
  union all
  select 1 as f0,3 as f1 from dual
  union all
  select 1 as f0,4 as f1 from dual
  union all
  select 0 as f0,3 as f1 from dual
  union all
  select 0 as f0,4 as f1 from dual
)tmp;
```

- PAI command

```
PAI -name t_test
    -project algo_public
    -DxTableName=pai_test_input
    -DxColName=f0
    -DyTableName=pai_test_input
    -DyColName=f1
    -DyTablePartitions=ds=2010/dt=1
    -DoutputTableName=pai_t_test_out
    -Dalternative=less
    -Dmu=47
    -DconfidenceLevel=0.95
    -Dpaired=False
    -DvarEqual=True
```

- Output description

  The output table is a JSON array containing only one row and one column.

```
{
    "AlternativeHypthesis": "difference in means not equals to 0",
    "ConfidenceInterval": "(-2.5465, -0.4535)",
    "ConfidenceLevel": 0.95,
    "alpha": 0.05000000000000004,
    "df": 19,
    "mean of the differences": -1.5,
    "p": 0.008000000000000007,
    "t": -3
}
```

Input and output restrictions

The input and output are not limited.

4.1.5.2.5.10. One-sample T-test

A one-sample T-test verifies whether the mean of a normally distributed population differs significantly from a target value. A T-test is performed based on the condition that the sample population is normally distributed.

PAI command

```
PAI -name t_test -project algo_public
    -DxTableName=pai_t_test_all_type
    -DxColName=col1_double
    -DoutputTableName=pai_t_test_out
    -DxTablePartitions=ds=2010/dt=1
    -Dalternative=less
    -Dmu=47
    -DconfidenceLevel=0.95
```

Algorithm parameters

Parameter	Description	Valid values	Default value
xTableName	Required. The name of input table x.	Table name	-
xColName	Required. The column selected from table x for testing.	Column name. The type must be double or bigint.	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-
xTablePartitions	Optional. The partitions selected from input table x.	Partition list	All partitions are selected by default.
alternative	Optional. The alternative hypothesis.	two.sided, less, and greater	two.sided
mu	Optional. The hypothesized mean.	double	0
confidenceLevel	Optional. The confidence level.	0.8, 0.9, 0.95, 0.99, 0. 995, and 0.999	0.95

Output description

The output table is a JSON array containing only one row and one column.

```
{
    "AlternativeHypthesis": "mean not equals to 0",
    "ConfidenceInterval": "(44.72234194006504, 46.27765805993496)",
    "ConfidenceLevel": 0.95,
    "alpha": 0.05,
    "df": 99,
    "mean": 45.5,
    "p": 0,
    "stdDeviation": 3.919647479510927,
    "t": 116.081867662439
}
```

4.1.5.2.5.11. Lorenz curve

The Lorenz curve is a graph to illustrate the distribution of wealth across a population. The X axis represents the total population arranged from least wealthy to most wealthy, while the Y axis represents the total wealth. If this graph is a straight line, it indicates perfectly equal distribution of wealth. The Gini coefficient is calculated by taking the area between the equal distribution curve and the actual Lorenz curve for a population as a fraction of the total area beneath the equal distribution curve. As the distribution of wealth becomes less equal, the Gini coefficient will increase, whereas a population with equal distribution of wealth will have a Gini coefficient of 0.

To study the distribution of income among a population, American statistician Max Otto Lorenz proposed the famous Lorenz curve in 1905. In 1921, Italian economist Corrado Gini defined the Gini coefficient as a measure of inequality in a population based on the Lorenz curve.

PAI command

```
PAI -name LorenzCurve
    -project algo_public
    -DinputTableName=maple_test_lorenz_basic10_input
    -DcolName=col0
    -DoutputTableName=maple_test_lorenz_basic10_output -DcoreNum=20
    -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name that has not been used	N/A
colName	Optional. The column name. Separate multiple columns with commas (,).	Column name	The whole table is selected by default.
N	The number of quantiles.	N/A	100

Parameter	Description	Valid value	Default value
inputPartitions	Optional. The partitions selected from the input table for training, in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

4.1.5.2.5.12. Normality test

This component is used to determine whether observed values are normally distributed.

This component consists of three test methods: Anderson-Darling test (see Wikipedia), Kolmogorov-Smirnov test (see Wikipedia), and Q-Q plot (see Wikipedia). You can use one or more methods as needed.

Algorithm description:

- Original hypothesis H0: The observed values are normally distributed. H1: The observed values are not normally distributed.
- The KS p-value calculation method progressively calculates CDF of KS distribution regardless of the sample size. For more information, see Wikipedia.
- If the sample size is greater than 1000, the Q-Q plot method collects samples to calculate and output plots. This means that the data points in plots do not necessarily cover all samples.

PAI command

```
PAI -name normality_test
    -project algo_public
    -DinputTableName=test
    -DoutputTableName=test_out
    -DselectedColNames=col1,col2
    -Dlifecycle=1;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name that has not been used	-

Parameter	Description	Valid values	Default value
selectedColNames	Optional. The names of selected columns.	Multiple double or bigint type columns can be selected.	-
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	All partitions are selected by default.
enableQQplot	Optional. This parameter specifies whether to use the Q-Q plot.	true and false	true
enableADtest	Optional. This parameter specifies whether to perform the Anderson-Darling test.	true and false	true
enableKStest	Optional. This parameter specifies whether to perform the Kolmogorov-Smirnov test.	true and false	true
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer greater than 0	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

- **SQL statement to generate data:**

```
drop table if exists normality_test_input;
    create table normality_test_input as
    select
      *
    from
    (
      select 1 as x from dual
        union all
      select 2 as x from dual
        union all
      select 3 as x from dual
        union all
      select 4 as x from dual
        union all
      select 5 as x from dual
        union all
      select 6 as x from dual
        union all
      select 7 as x from dual
        union all
      select 8 as x from dual
        union all
      select 9 as x from dual
        union all
      select 10 as x from dual
    ) tmp;
```

- **PAI command**

```
PAI -name normality_test
    -project projectxlib4
    -DinputTableName=normality_test_input
    -DoutputTableName=normality_test_output
    -DselectedColNames=x
    -Dlifecycle=1;
```

- **Input description**

  Input format: select the columns that need to be calculated. The columns must be of the double or bigint type.

- **Output description**

  A diagram and a result table are output. The columns in the result table are as follows. The result table has two partitions:

  - `p='test'` shows the result of the AD or KS test. Data is output when *enableADtest* or *enableKStest* is set to true.
  - `p='plot'` shows the Q-Q plot data. When *enableQQplot* is set to true, data is output and the columns that meet the `p='test'` condition are reused. In the case of `p='plot'`, the *testvalue* column records the original observed data (x axis of the Q-Q plot), and the *pvalue* column records the expected data that is normally distributed (y axis of the Q-Q plot).

  Output table:

```
+------------+------------+------------+------------+------------+
| colname    | testname   | testvalue  | pvalue     | p          |
+------------+------------+------------+------------+------------+
| x          | NULL       | 1.0        | 0.8173291742279805 | plot       |
| x          | NULL       | 2.0        | 2.470864450785345 | plot       |
| x          | NULL       | 3.0        | 3.5156067948020056 | plot       |
| x          | NULL       | 4.0        | 4.3632330349313095 | plot       |
| x          | NULL       | 5.0        | 5.128868067945126 | plot       |
| x          | NULL       | 6.0        | 5.871131932054874 | plot       |
| x          | NULL       | 7.0        | 6.6367669650686905 | plot       |

| x          | NULL       | 9.0        | 8.529135549214654 | plot       |
| x          | NULL       | 10.0       | 10.182670825772018 | plot       |
| x          | Anderson_Darling_Test | 0.1411092332197832 | 0.9566579606430077 | test       |
| x          | Kolmogorov_Smirnov_Test | 0.09551932503797644 | 0.9999888659426232 | test       |
+------------+------------+------------+------------+------------+
```

Column name	Data type	Definition
colName	string	Column name
testname	string	Test name
testvalue	double	Test value on the x axis of the Q-Q plot
pvalue	double	Test p value on the y axis of the Q-Q plot
p	double	Partition name

4.1.5.2.5.13. Percentile

This component calculates the percentile of the values in a column.

Parameter settings

Select the column to be analyzed. Only the double and bigint types are supported.

PAI command

```
PAI -name Percentile
-project algo_public
-DoutputTableName="pai_temp_666_6014_1"
-DcolName="euribor3m"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.

Parameter	Description
outputTableName	The name of the output table automatically generated after the system performs the percentile calculation.
colName	The column selected for percentile calculation. Only the numeric type is supported.
inputTableName	The name of the input table.

4.1.5.2.5.14. Pearson coefficient

This component calculates the Pearson correlation coefficient of two numeric columns in an input table or a partition, and saves the result to the output table.

Component description

- The component has only two parameters: input column 1 and input column 2. Enter the names of the two columns for which the Pearson correlation coefficient is calculated.
- After you run the component, right-click the component and choose **View Analytics Report** from the shortcut menu.
- The Pearson correlation coefficient is listed in the row.

PAI command

```
pai -name pearson
-project algo_test
-DinputTableName=wpbc
-Dcol1Name=f1
-Dcol2Name=f2
-DoutputTableName=wpbc_pear;
```

Algorithm prameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	The partitions selected from the input table for calculation.	The parameter value must be in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	All partitions in the input table are selected by default.
col1Name	Required. The name of input column 1.	Column name	-
col2Name	Required. The name of input column 2.	Column name	-
outputTableName	Required. The name of the output table.	Table name	-

4.1.5.2.5.15. Histogram

This component analyzes data in a column and outputs a histogram.

Parameter settings

- Select the columns to be analyzed. Only the double and bigint types are supported.
- View the analysis report.
- You can adjust the step and move the slider to view the entire histogram.

4.1.5.2.6. Machine learning

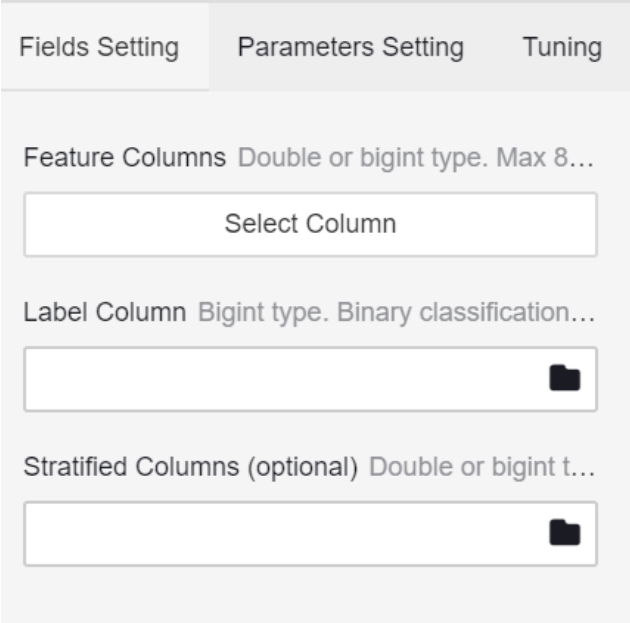
4.1.5.2.6.1. Binary classification

GBDT binary classification

This component is used for binary classification based on GBDT regression and sorting. Values greater than the threshold value are considered positive samples, while values that are less than or equal to the threshold value are considered negative samples.

Procedure

1. Drag and drop the GBDT Binary Classification component onto the canvas for training and set the parameters, as shown in the following figure.



Parameters

Parameter	Description
Feature Columns	The double and bigint types are supported. A maximum of 800 columns can be specified.
Label Column	You can select all columns except the input column. The values must be of the binary type.

Parameter	Description
Stratification Column	Optional. The whole table is selected by default. The double and bigint types are supported.

2. You can change the data type of the input columns.

   The input columns of GBDT binary classification only support the continuous type and are processed in the same way as the discrete type.

3. Set the parameters. Parameters

Parameter	Description
Metric Type	The normalized discounted cumulative gain (NDCG) and discounted cumulative gain (DCG).
Trees	Valid values: [1,10000]. Default value: 500.
Learning Rate	Valid values: (0, 1). Default value: 0.05.
Training Sample Fraction	Valid values: (0, 1). Default value: 0.6.
Training Feature Fraction	Valid values: (0, 1). Default value: 0.6.
Maximum Leaves	The value must be an integer in the range of [2, 1000]. Default value: 32.
Testing Data Fraction	Valid values: [0, 1]. Default value: 0.0.
Maximum Tree Depth	The value must be an integer in the range of [1, 11]. Default value: 11.
Minimum Samples per Leaf Node	The value must be an integer in the range of [100, 1000]. Default value: 500.
Random Seed	The value must be an integer in the range of [0, 10]. Default value: 0.
Maximum Splits per Feature	Valid values: [1, 1000]. Default value: 500.

4. View the output. For more information, see the description of the Random forest component.

> **Note**
>
> - GBDT and GBDT_LR have different default types of loss functions. The default loss function of GBDT is regression loss:mean squared error loss. The default loss function of GBDT_LR is logistic regression loss. The system automatically writes the default loss function for GBDT_LR.
> - For GBDT binary classification, the label column must be of the binary type. String type data is not supported.
> - When connecting the ROC curve component, set the prediction component parameters and select a base value.

PAI command (F/L setup settings are not used)

```
PAI -name GBDT_LR
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DrandSeed="0"
-Dshrinkage="0.5"
-DmaxLeafCount="32"
-DlabelColName="y"
-DinputTableName="bank_data_partition"
-DminLeafSampleCount="500"
-DgroupIDColName="nr_employed"
-DsampleRatio="0.6"
-DmaxDepth="11"
-DmodelName="xlab_m_GBDT_LR_21208"
-DmetricType="2"
-DfeatureRatio="0.6"
-DinputTablePartitions="pt=20150501"
-DtestRatio="0.0"
-DfeatureColNames="age,previous,cons_conf_idx,euribor3m"
-DtreeCount="500";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
featureSplitValueMaxSize	Optional. The maximum number of splits per feature. Valid values: [1, 1000]. Default value: 500.
randSeed	Optional. The number of random seeds. The value must be an integer in the range of [0, 10]. Default value: 0.
shrinkage	Optional. The learning rate. Valid values: (0, 1). Default value: 0.05.
maxLeafCount	Optional. The maximum number of leaves. The value must be an integer in the range of [2, 1000]. Default value: 32.
labelColName	The name of the label column selected from the input table.
inputTableName	The name of the input table for training.
minLeafSampleCount	Optional. The minimum number of samples per leaf node. The value must be an integer in the range of [100, 1000]. Default value: 500.
groupIDColName	Optional. The name of the stratification column. The whole table is considered as a stratum by default.
sampleRatio	Optional. The fraction of samples collected for training. Valid values: (0, 1). Default value: 0.6.
maxDepth	Optional. The maximum depth of a tree. The value must be an integer in the range of [1, 11]. Default value: 11.
modelName	The name of the output model.

Parameter	Description
metricType	Optional. The type of a metric. Valid values: 0 and 1. 0 represents normalized discounted cumulative gain (NDCG) and 1 represents discounted cumulative gain (DCG).
featureRatio	Optional. The fraction of features collected for training. Valid values: (0, 1). Default value: 0.6.
inputTablePartitions	Optional. The partitions selected from the input prediction table. If no partitions are specified, the whole table is selected.
testRatio	Optional. The fraction of testing samples. Valid values: [0, 1]. Default value: 0.0.
featureColNames	The names of feature columns selected from the input table for training.
treeCount	Optional. The number of trees. Valid values: [1, 10000]. Default value: 500.

Linear SVM

Support-vector machines (SVMs) are developed based on the VC dimension theory and the structural risk minimization principle.

This linear SVM version is not implemented using the kernel function. For more information, see Trust Region Method for L2-SVM at http://www.csie.ntu.edu.tw/~cjlin/papers/logistic.pdf. This algorithm only supports binary classification.

Procedure

1. Configure column settings.
   - Feature Columns: You can select a feature column of the bigint or double type.
   - Label Column: The data type of the label column can be bigint, double, or string. This component only supports binary classification.
2. Set parameters. Parameters

Parameter	Description
Positive Sample Label	Optional. The value of the positive sample. If this parameter is not specified, the system randomly selects a value. We recommend that you specify this parameter when the positive and negative samples are significantly different.
Positive Penalty Factor	Optional. The weight of the positive sample. Valid values: (0, +∞). Default value: 1.0.
Negative Penalty Factor	Optional. The weight of the negative sample. Valid values: (0, +∞). Default value: 1.0.
Convergence Coefficient	Optional. The convergence deviation. Valid values: (0, 1). Default value: 0.001. **Note** If no base value is specified, Positive Penalty Factor and Negative Penalty Factor must be set to the same value.

3. View the output. For more information, see the description of the Random Forest component.

PAI command (F/L setup settings are not used)

```
PAI -name LinearSVM
-project algo_public
-DnegativeCost="1.0"
-DmodelName="xlab_m_LinearSVM_6143"
-DpositiveCost="1.0"
-Depsilon="0.001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate,cons_conf_idx"
-DinputTableName="bank_data"
-DpositiveLabel="0";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
negativeCost	Optional. The weight of the negative sample. It is the penalty factor of the negative sample. Valid values: (0, +∞). Default value: 1.0.
modelName	The name of the output model.
positiveCost	Optional. The weight of the positive sample. It is the penalty factor of the positive sample. Valid values: (0, +∞). Default value: 1.0.
epsilon	Optional. The convergence coefficient. Valid values: (0, 1). Default value: 0.001.
labelColName	The name of the label column.
featureColNames	The names of feature columns selected from the input table for training.
inputTableName	The name of the input table for training.
positiveLabel	Optional. The value of the positive sample. If this parameter is not specified, the system randomly selects a value.

Logistic regression for binary classification

Binary classification is a classic logistic regression method. Logistic regression on the algorithm platform supports multiclass classification. The logistic regression component supports two data types: sparse and dense.

Parameter settings

Parameters

Parameter	Description
Regularization Type	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
Maximum Iterations	Optional. The maximum number of L-BFGS iterations. Default value: 100.
Regularization Coefficient	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to *None*, this parameter is ignored.

Parameter	Description
Minimum Convergence Deviance	Optional. The condition to terminate L-BFGS. This is the log-likelihood deviation between two iterations. Default value: *1.0e-06*.

The logistic regression component outputs a model, which is available in the model list.

Model name format: `Experiment Name + "-" + Component Name + "model"` .

PAI command (F/L setup settings are not used)

```
PAI -name LogisticRegression
-project algo_public
-DmodelName="xlab_m_logistic_regression_6096"
-DregularizedLevel="1"
-DmaxIter="100"
-DregularizedType="l1"
-Depsilon="0.000001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate"
-DgoodValue="1"
-DinputTableName="bank_data";
```

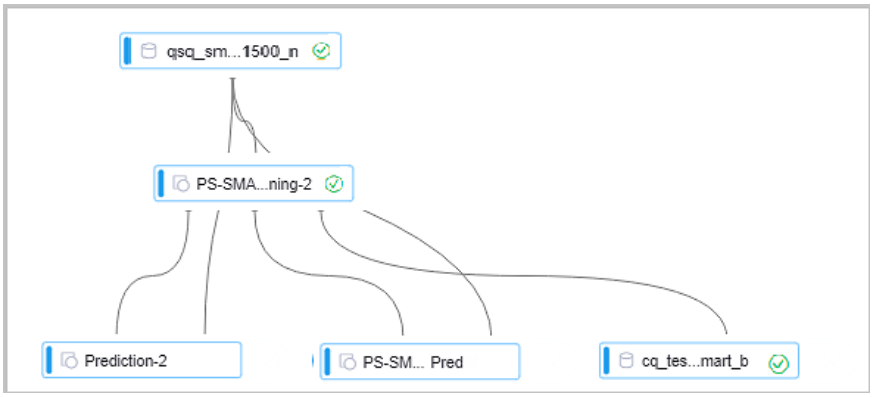
Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
regularizedLevel	Optional. The regularization coefficient. Default value: 1.0. If regularizedType is set to *None*, this parameter is ignored.
maxIter	Optional. The maximum number of L-BFGS iterations. Default value: 100.
regularizedType	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
epsilon	Optional. The convergence deviation. It is the condition to terminate L-BFGS. This is the log-likelihood deviation between two iterations. Default value: *1.0e-06*.
labelColName	The name of the label column selected from the input table.
featureColNames	The names of feature columns selected from the input table for training.
goodValue	Optional. The base value. For binary classification, specify the label value of the training coefficient. If this parameter is not specified, the system randomly selects a value.
inputTableName	The name of the input table for training.

PS-SMART binary classification

A parameter server (PS) is used to train a large number of models online and offline. Scalable Multiple Additive Regression Tree (SMART) is an implementation of Gradient Boosting Decision Tree (GBDT) on PS. PS-SMART can run training tasks containing up to tens of billions of samples and hundreds of thousands of features on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram approximation for training acceleration.

Quick start



As shown in the figure, a PS-SMART binary classification model is learned based on training data. The model has three output ports:

- Output model: offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table supports the output of leaf node numbers, which ensures higher efficiency, less resource consumption, and higher stability.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see Parameters.

PAI command

- Training

```
PAI -name ps_smart
    -project algo_public
    -DinputTableName="smart_binary_input"
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545859_2"
    -DoutputImportanceTableName="pai_temp_24515_545859_3"
    -DlabelColName="label"
    -DfeatureColNames="f0,f1,f2,f3,f4,f5"
    -DenableSparse="false"
    -Dobjective="binary:logistic"
    -Dmetric="error"
    -DfeatureImportanceType="gain"
    -DtreeCount="5";
    -DmaxDepth="5"
    -Dshrinkage="0.3"
    -Dl2="1.0"
    -Dl1="0"
    -Dlifecycle="3"
    -DsketchEps="0.03"
    -DsampleRatio="1.0"
    -DfeatureRatio="1.0"
    -DbaseScore="0.5"
    -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
    -project algo_public
    -DinputTableName="smart_binary_input";
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545860_1"
    -DfeatureColNames="f0,f1,f2,f3,f4,f5"
    -DappendColNames="label,qid,f0,f1,f2,f3,f4,f5"
    -DenableSparse="false"
    -Dlifecycle="28"
```

Parameters

- Data parameters

Command option	Parameter	Description	Valid values	Remarks
featureColNames	Feature Columns	The names of feature columns selected from the input table for training.	If the column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string, and its keys and values must be numeric.	Required

Command option	Parameter	Description	Valid values	Remarks
labelColName	Label Column	The name of the label column selected from the input table.	The column name can be of either string or numeric type, but only numeric data can be stored in the columns. For example, in binary classification, the column value can be 0 or 1.	Required
weightCol	Weight Column	This column specifies the weight of each sample.	The column name can be of the numeric type.	Optional. Default value: null.
enableSparse	Use Sparse Format	This parameter specifies whether the data in the input table is in sparse format, in which key-value pairs are separated by spaces whereas keys and values are separated by colons (:), for example, 1:0.3 3:0.9.	[true, false]	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required
modelName	Output Model Name	N/A	N/A	Required
outputImportanceTableName	Output Feature Importance Table Name	N/A	N/A	Optional. Default value: null.
inputTablePartitions	Input Table Partitions	N/A	N/A	Optional. The parameter value must be in ds=1/pt=1 format.
outputTableName	Output Model Table Name	The output table is a MaxCompute table that uses the binary format and is not readable. The prediction component that comes with SMART can be used to generate leaf node numbers.	String	Optional
lifecycle	Output Table Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Command option	Parameter	Description	Valid values	Remarks
objective	Objective Function Type	The objective function type affects learning and must be selected properly. Select **binary:logistic** for binary classification.	N/A	Required
metric	Evaluation Indicator Type	Evaluation indicators in the training set, which are exported to stdout of the coordinator in a logview.	logloss, error and auc	Optional. Default value: null.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Tree Depth	The maximum depth of a tree. We recommend that you set this value to 5, which means the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0, 1]	Optional. The default value is 1.0, which means feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the less the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.

Command option	Parameter	Description	Valid values	Remarks
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0, 1]	Optional. Default value: 0.3.
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of buckets is O(1.0/sketchEps). The smaller the parameter value, the more buckets are generated. Typically, you do not need to modify this value.	(0, 1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss Change	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional
baseScore	Global Offset	Original predicted values of all samples.	Real number	Optional. Default value: 0.5.

Command option	Parameter	Description	Valid values	Remarks
featureImportanceType	Feature Importance Type	The type of feature importance. **weight** indicates the number of times that a feature splits. **gain** indicates information gain brought by the feature. **cover** indicates the number of samples that the feature covers on the splitting nodes.	**weight**, **gain**, and **cover**	Optional. Default value: **gain**.

- Note
  - Specify different values for the objective parameter in different learning models. On the binary classification Web GUI, the objective function is automatically specified and invisible to users. On the command line, set the objective parameter to `binary:logistic`.
  - Mappings between metrics and objective functions are: **logloss** for **negative loglikelihood for logistic regression**, **error** for **binary classification error**, and **auc** for **Area under curve for classification**.

Execution optimization

Command option	Parameter	Description	Valid values	Remarks
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. Automatically calculated.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core, where 1024 represents 1 GB of memory.	Positive integer	Optional. Automatically calculated.

Example

- Data generation

  The following example uses data in dense format.

```
drop table if exists lm_test_input;
create table smart_binary_input lifecycle 3 as
select
*
from
(
select 0.72 as f0, 0.42 as f1, 0.55 as f2, -0.09 as f3, 1.79 as f4, -1.2 as f5, 0 as label from dual
union all
select 1.23 as f0, -0.33 as f1, -1.55 as f2, 0.92 as f3, -0.04 as f4, -0.1 as f5, 1 as label from dual
union all
select -0.2 as f0, -0.55 as f1, -1.28 as f2, 0.48 as f3, -1.7 as f4, 1.13 as f5, 1 as label from dual
union all
select 1.24 as f0, -0.68 as f1, 1.82 as f2, 1.57 as f3, 1.18 as f4, 0.2 as f5, 0 as label from dual
union all
select -0.85 as f0, 0.19 as f1, -0.06 as f2, -0.55 as f3, 0.31 as f4, 0.08 as f5, 1 as label from dual
union all
select 0.58 as f0, -1.39 as f1, 0.05 as f2, 2.18 as f3, -0.02 as f4, 1.71 as f5, 0 as label from dual
union all
select -0.48 as f0, 0.79 as f1, 2.52 as f2, -1.19 as f3, 0.9 as f4, -1.04 as f5, 1 as label from dual
union all
select 1.02 as f0, -0.88 as f1, 0.82 as f2, 1.82 as f3, 1.55 as f4, 0.53 as f5, 0 as label from dual
union all
select 1.19 as f0, -1.18 as f1, -1.1 as f2, 2.26 as f3, 1.22 as f4, 0.92 as f5, 0 as label from dual
union all
select -2.78 as f0, 2.33 as f1, 1.18 as f2, -4.5 as f3, -1.31 as f4, -1.8 as f5, 1 as label from dual
) tmp;
```

- Training

  Configure the training data and training components, as shown in Quick start. Select the label column as the target column and columns f0, f1, f2, f3, f4, f5 as feature columns.

  - You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate the amount of required resources, specify the actual number of features.
  - To accelerate the training, set the number of cores on the execution optimization page. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the required resources. Therefore, you may need to wait for a longer period of time when the cluster is busy and resources are requested in large volumes.
  - You can view the output values of the metrics in the stdout of the coordinator in a logview (HTTP link starting with http://logview.odps.aliyun-inc.com:8080/logview). A single PS-SMART training job can contain multiple tasks, and therefore multiple logviews are created. Select the logview whose name starts with PS to view the output of the PS job.

- Prediction

- Use the unified prediction component

  The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in Quick start.

  If the dense format is used, you only need to select feature columns. (All columns are selected by default, and extra columns do not affect the prediction.) If the KV format is used, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated by space characters. Therefore, the delimiter must be set to space or \u0020 (escape expression of spaces).

  In the "prediction_detail" column, value 1 indicates a positive sample, and value 0 indicates a negative sample. The values following 0 and 1 indicate the probabilities of the corresponding classes.

- Use the PS-SMART prediction component

  The output model table obtained after training is saved in binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in Quick start. Set the required parameters, including the data format, feature columns, target column, and number of classes. The ID column can only be a string type column other than a feature column or a target column. The loss function must be set to binary:logistic.

  The **prediction_score** column lists probabilities of predicted positive samples. A sample is predicted as a positive sample if its score is greater than 0.5. Otherwise, it is predicted as a negative sample. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N numbers, where N is the number of decision trees. Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

  > **Note**
  > - The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved, and may be replaced by another component in the future.
  > - A string type column must be selected as the label column. You can enter strings in the column but cannot be blank or NULL. A feature column can be converted to the string type by using the data type conversion component.
  > - The loss function must be explicitly set to **binary:logistic**. By default, the function does not work.

- View feature importance

  To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > Output Feature Importance Table** from the shortcut menu.

order	id	value
1	0	0.5690338015556335
2	1	0.21714292466640472
3	4	0.21382322907447815

  In the table, the ID column lists the numbers of input features. In this example, the data is in dense format. The input features are **f0,f1,f2,f3,f4,f5**. Therefore, ID 0 represents f0 and ID 4 represents f4. If the KV format is used, the IDs represent keys in key-value pairs. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only three features because only these three features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can we use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume large amounts of resources and run slowly. Therefore, we recommend that you do not use such a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding to filter out infrequent features before they can be used for training. The continuous numerical features can be used for training with the GBDT algorithm directly. Discretization is not recommended for numerical features.
- Q: Why is the result different every time although the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the data_sample_ratio and fea_sample_ratio items introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Although different merging orders result in different tree structures, this does not introduce too much variation to the output model. Therefore, it is normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

> **Note**
>
> - The target column in a PS-SMART binary classification model supports only numerical values (0 for negative samples and 1 for positive samples). Even if values in the MaxCompute table are strings, they are saved as numerical values. If the classification target is a type string similar to **Good** or **Bad**, convert it to 1 or 0.
> - In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.1.5.2.6.2. Multiclass classification

KNN

The KNN algorithm is used to resolve classification issues. For a row in a prediction table, this component selects K-nearest records from the training table. Then, it adds the row to the class that is most common among the K records.

PAI command

You can run the following PAI command to use the component:

```
PAI -name knn
    -DtrainTableName=pai_knn_test_input
    -DtrainFeatureColNames=f0,f1
    -DtrainLabelColName=class
    -DpredictTableName=pai_knn_test_input
    -DpredictFeatureColNames=f0,f1
    -DoutputTableName=pai_knn_test_output
    -Dk=2;
```

Parameters

The following table describes the parameters in the PAI command.

Parameter	Description	Valid value	Default value
trainTableName	Required. The name of the training table.	Table name	N/A
trainFeatureColNames	Required. The names of feature columns that are selected from the training table.	Column name	N/A
trainLabelColName	Required. The name of the label column that is selected from the training table.	Column name	N/A
trainTablePartitions	Optional. The partitions that are selected from the training table.	Partition name	All partitions
predictTableName	Required. The name of the prediction table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
predictFeatureColNames	Optional. The names of feature columns that are selected from the prediction table.	Column name	N/A
predictTablePartitions	Optional. The partitions that are selected from the prediction table.	Partition name	All partitions
appendColNames	Optional. The names of columns that are appended to the output table from the prediction table.	Column name	N/A
outputTablePartition	Optional. The partitions in the output table.	Partition name	By default, the output table is non-partitioned.
k	Optional. The number of the nearest neighbors.	A positive integer in the range of [1, 1000]	100
enableSparse	Optional. This parameter specifies whether the data in the input table is in the sparse format.	true and false	false
itemDelimiter	Optional. The delimiter that is used to separate key-value pairs when the data in the input table is in the sparse format.	Character	The default delimiter is a space.

Parameter	Description	Valid value	Default value
kvDelimiter	Optional. The delimiter that is used to separate keys and values when the data in the input table is in the sparse format.	Character	The default delimiter is a colon (:).
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 20000].	The default value is determined by the system.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	The default value is determined by the system.
lifecycle	Optional. The lifecycle of the specified output table.	Positive integer	No lifecycle is set by default.

Example

- **Test data**

```
create table pai_knn_test_input as
select * from
(
  select 1 as f0,2 as f1, 'good' as class from dual
  union all
  select 1 as f0,3 as f1, 'good' as class from dual
  union all
  select 1 as f0,4 as f1, 'bad' as class from dual
  union all
  select 0 as f0,3 as f1, 'good' as class from dual
  union all
  select 0 as f0,4 as f1, 'bad' as class from dual
)tmp;
```

- **PAI command**

```
PAI -name knn
    -DtrainTableName=pai_knn_test_input
    -DtrainFeatureColNames=f0,f1
    -DtrainLabelColName=class
    -DpredictTableName=pai_knn_test_input
    -DpredictFeatureColNames=f0,f1
    -DoutputTableName=pai_knn_test_output
    -Dk=2;
```

- **Output**

f0	f1	prediction_result	prediction_score	prediction_detail
1	4	bad	1.0	{"bad": 1}
0	4	bad	1.0	{"bad": 1}
0	3	bad	0.5	{"bad": 0.5, "good": 0.5}
1	3	good	1.0	{"good": 1}
1	2	good	1.0	{"good": 1}

- f0 and f1: the appended columns in the output table.
- prediction_result: the classification result.
- prediction_score: the probabilities for the classification result.
- prediction_detail: the latest K conclusions and their probabilities.

Logistic Regression for Multiclass Classification

The common logistic regression algorithm is used for binary classification. PAI allows you to use the logistic regression algorithm for multiclass classification. The Logistic Regression for Multiclass Classification component supports both the sparse and dense data formats.

Parameters

The following figure how to set the parameters on the Parameter Setting tab for the Logistic Regression for Multiclass Classification component. The following table describes the parameters.

Parameter	Description
Regularization Type	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
Maximum Iterations	Optional. The maximum number of L-BFGS iterations. Default value: 100.
Regularization Coefficient	Optional. The regularization coefficient. Default value: 1.0. If the Regularization Type parameter is set to *None*, this parameter is ignored.
Minimum Convergence Deviance	Optional. The condition to terminate L-BFGS. This is the log-likelihood deviance between two iterations. Default value: *1.0e-06*.

The Logistic Regression for Multiclass Classification component outputs a model, which is available in the model list.

Model naming format: `Experiment Name + "-" + Component Name + "model"` .

PAI command (F/L setup settings are not used)

You can run the following PAI command to use the Logistic Regression for Multiclass Classification component.

```
PAI -name LogisticRegression
-project algo_public
-DmodelName="xlab_m_logistic_regression_6096"
-DregularizedLevel="1"
-DmaxIter="100"
-DregularizedType="l1"
-Depsilon="0.000001"
-DlabelColName="y"
-DfeatureColNames="pdays,emp_var_rate"
-DgoodValue="1"
-DinputTableName="bank_data";
```

The following table describes the parameters in the PAI command.

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.

Parameter	Description
modelName	The name of the output model.
regularizedLevel	Optional. The regularization coefficient. Default value: 1.0. If the regularizedType parameter is set to *None*, this parameter is ignored.
maxIter	Optional. The maximum number of L-BFGS iterations. Default value: 100.
regularizedType	Optional. The type of regularization. Valid values: *L1*, *L2*, and *None*. Default value: *L1*.
epsilon	Optional. The convergence deviation. It is the condition to terminate L-BFGS and is the loglikelihood deviation between two iterations. Default value: *1.0e-06*.
labelColName	The name of the label column that is selected from the input table.
featureColNames	The names of feature columns that are selected from the input table for training.
goodValue	Optional. The base value. For multiclass classification, specify the label value of the training coefficient. If this parameter is not specified, the system randomly selects a value.
inputTableName	The name of the input table for training.

Random Forest

A random forest is a classifier that contains multiple decision trees. The classification result is determined by the mode of output classes of individual trees.

Procedure

1. Go to a Machine Learning Studio project. For more information, see Data preparation.
2. Drag the Random Forest component from the Components pane to the canvas and select columns. The following table describes the parameters.

Parameter	Description
Feature Columns	Optional. By default, all columns except the label and weight columns are selected.
Excluded Columns	Optional. The columns that are excluded from training. This parameter is mutually exclusive with the featureColNames parameter.
Columns Forced to Convert	Optional. Comply with the following rules to parse columns: ◦ Parse the columns of the STRING, BOOLEAN, or DATETIME type to the columns of a discrete type. ◦ Parse the columns of the DOUBLE or BIGINT type to the columns of a continuous type. ◦ To parse the columns of the BIGINT type to the columns of a categorical type, you must use the *forceCategorical* parameter to specify the type.
Weight Columns	Optional. You can select all columns except the input and label columns. Columns of the DOUBLE and BIGINT types are supported.
Label Column	You can select a column rather than the input column. Columns of the STRING, DOUBLE, and BIGINT types are supported.

3. On the **Parameter Settings** tab, set the parameters of the Random Forest component. The following table

describes the parameters.

Parameter	Description
Trees	The number of trees in the forest. Valid values: (0, 1000).
Single-tree Algorithm Type	Optional. The algorithm type of each tree in the forest. The ID3, CART, and C4.5 algorithms are supported. If a forest has N trees and the condition is `algorithmTypes=[a,b]`: `[0, a)` indicates the `ID3` algorithm. `[a,b)` indicates the `CART` algorithm. `[b,n)` indicates the `C4.5` algorithm. For example, if a forest has five trees and [2,4] indicates 0, 1 indicates the ID3 algorithm, 2 and 3 indicate the CART algorithm, and 4 indicates the C4.5 algorithm. If the value is None, the algorithms are evenly allocated across the forest.
Random Features per Tree	The number of features that are randomly selected. Valid values: 1 to N. N indicates the number of features.
Minimum Number of Leaf Nodes	Optional. The minimum number of samples per leaf node. The value must be a positive integer no less than 2.
Minimum Fraction of Leaf Nodes to Parent Node	The minimum fraction of samples on a leaf node to samples on a parent node. A value of -1 indicates that no limit is set. Default value: -1. Valid values: [0, 1].
Maximum Tree Depth	The maximum depth of a tree. -1 indicates a completely grown tree. Valid values: [1, ∞).
Number of Random Data Entries Input per Tree	The number of input random samples for a tree. Valid values: (1000, 1000000].

Note

- After the bagging method is optimized, the Random Forest component builds a forest without correlated trees based on a large dataset. Random forests are similar to the boosting method in many aspects, particularly their training processes.
- The ID3, CART, C4.5 algorithms are supported for the growth of a single tree. The treeNum parameter is used to specify the number of trees in the forest, in the range of [1, 1000]. The structure of a single tree can be controlled based on the edited template. You can use other parameters to specify the minimum number of samples per leaf node, the minimum fraction of samples on a leaf node to samples on a parent node, and the maximum depth of a tree.
- Each row in the weight column corresponds to a sample and indicates the proportion of this sample in training. If the age column is selected as the weight column, the sample in the row with a higher weight value in the age column has a higher proportion during the training.
- The "input table is empty!" error may occur in the following situations:The sampling fraction is too small, which means that the value of maxRecordSize is too small, or the input table is empty.

PAI command (F/L setup settings are not used)

You can run the following PAI command to use the component:

```
PAI -name RandomForests
-project algo_public
-DmodelName="xlab_m_random_forests_6036"
-DrandomColNum="1.0"
-DlabelColName="campaign"
-DmaxTreeDeep="10"
-DmaxRecordSize="100000"
-DfeatureColNames="age,pdays,previous,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed"
-DisFeatureContinuous="1,1,1,1,1,1,1,1"
-DminNumPer="-1"
-DminNumObj="2"
-DinputTableName="bank_data"
-DweightColName="y"
-DtreeNum="10";
```

The following table describes the parameters in the PAI command.

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the output model.
randomColNum	Optional. The number of features that are randomly selected each time a single tree is generated. *-1* indicates `log2N`. Valid values: 1 to N. N indicates the number of features.
labelColName	The name of the label column that is selected from the input table.
maxTreeDeep	Optional. The maximum depth of a tree. *-1* indicates a completely grown tree. Valid values: [1, ∞].
maxRecordSize	Optional. The maximum number of samples per tree. Valid values: (1000, 1000000). *-1* indicates 100,000 samples.
featureColNames	The names of feature columns that are selected from the input table for training.
isFeatureContinuous	Specifies whether the values of the feature columns are continuous or discrete. *1* indicates that the values of the feature columns are continuous. *0* indicates that the values of the feature columns are discrete. *1,0,0* indicates that values are continuous in the first feature column and discrete in the second and third feature columns. The number of values corresponds to the feature length.
minNumPer	Optional. The minimum fraction of samples on a leaf node to samples on a parent node. A value of *-1* indicates that no limit is set. Valid values: [0.0, 1.0].
minNumObj	Optional. The minimum number of samples per leaf node.
inputTableName	The name of the input table for training.
weightColName	Optional. The name of the weight column that is selected from the input table. If the input table does not contain a weight column, set this parameter to *None*. The values of the weight column must be greater than 0.

Parameter	Description
treeNum	The number of trees. Valid values: (0, 1000).

Naive Bayes

Naive Bayes classifier is a simple probabilistic classifier based on applying Bayes theorem with strong independence assumptions between the features. A probabilistic model that can more accurately describe this potential is called an independent feature model.

Overview

The following figure shows how to set the parameters for the Naive Bayes component. For more information, see Random forest.

PAI command

You can run the following PAI command to use the component:

```
PAI -name NaiveBayes
-project algo_public
-DmodelName="xlab_m_NaiveBayes_23772"
-DinputTablePartitions="pt=20150501"
-DlabelColName="poutcome"
-DfeatureColNames="age,previous,cons_conf_idx,euribor3m"
-DisFeatureContinuous="1,1,1,1"
-DinputTableName="bank_data_partition";
```

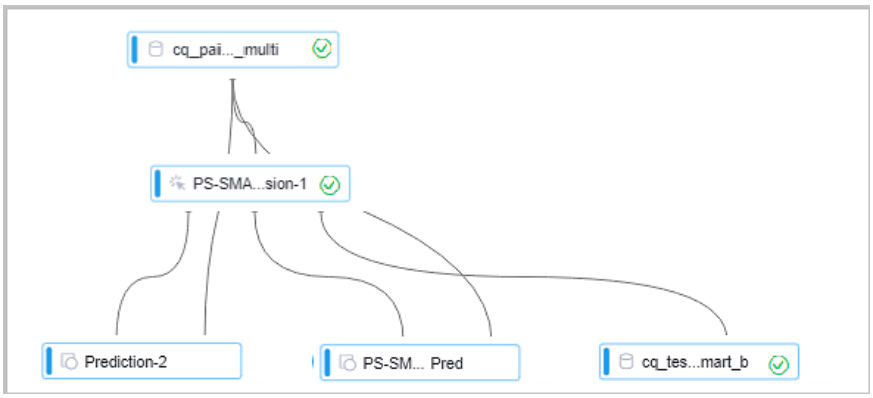
The following table describes the parameters in the PAI command.

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
modelName	The name of the model generated by training.
inputTablePartitions	Optional. The partitions that are selected from the input prediction table. If you want to select the entire table, set the parameter to None.
labelColName	The name of the label column that is selected from the input table.
featureColNames	The names of feature columns that are selected from the input table for training.
isFeatureContinuous	Specifies whether the feature for subsequent columns is continuous or discrete. *1* indicates continuous and *0* indicates discrete. *1,0,0* indicates that values are continuous in the first feature column and discrete in the second and third feature columns. The number of values corresponds to the feature length.
inputTableName	The name of the input table.

PS-SMART Multiclass Classification

A parameter server (PS) is used to process a large number of offline and online training tasks. SMART is short for scalable multiple additive regression tree. PS-SMART is an algorithm that is implemented by using a PS-based gradient boosting decision tree (GBDT). PS-SMART supports training tasks for tens of billions of samples and hundreds of thousands of features. It can run training tasks on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram-based approximation for training acceleration.

Quick start



In the preceding figure, a PS-SMART multiclass classification model is learned based on training data. The PS-SMART Multiclass Classification component has three output ports:

- Output model: an offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation metrics. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved and may be replaced by another component in the future.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see Parameters.

PAI commands

- Training

```
PAI -name ps_smart
    -project algo_public
    -DinputTableName="smart_multiclass_input"
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545859_2"
    -DoutputImportanceTableName="pai_temp_24515_545859_3"
    -DlabelColName="label"
    -DfeatureColNames="features"
    -DenableSparse="true"
    -Dobjective="multi:softprob"
    -Dmetric="mlogloss"
    -DfeatureImportanceType="gain"
    -DtreeCount="5";
    -DmaxDepth="5"
    -Dshrinkage="0.3"
    -Dl2="1.0"
    -Dl1="0"
    -Dlifecycle="3"
    -DsketchEps="0.03"
    -DsampleRatio="1.0"
    -DfeatureRatio="1.0"
    -DbaseScore="0.5"
    -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
    -project algo_public

Parameters

- Data parameters

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
featureColNames	Feature Columns	The names of feature columns that are selected from the input table for training.	If data in the input table is in the dense format, only the columns of the BIGINT and DOUBLE types are supported. If data in the input table is key-value pairs in the sparse format, only columns of the STRING type are supported and the keys and values must be numeric.	Required.
labelColName	Label Column	The name of the label column that is selected from the input table.	The column name can be a string or a numeric value, but only numeric data can be stored in the columns. For multiclass classification, column values range from 0 to n-1. n is the number of classes.	Required.
weightCol	Weight Column	The column that contains the weight of each row of samples.	The columns of numeric data types are supported.	Optional. By default, this parameter is empty.
enableSparse	Use Sparse Format	Specifies whether data in the input table is in the sparse format. If data in the input table is in the sparse format, key-value pairs are separated by spaces whereas keys and values are separated by colons (:). Example: **1:0.3 3:0.9**.	true and false	Optional. Default value: false.
inputTableName	Input Table Name	N/A	N/A	Required.
modelName	Output Model Name	N/A	N/A	Required.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
outputImportanceTableName	Output Feature Importance Table	N/A	N/A	Optional. By default, this parameter is empty.
inputTablePartitions	Partition	N/A	N/A	Optional. The parameter value must be in the ds=1/pt=1 format.
outputTableName	Output Model Table	The output table is a MaxCompute table that uses the binary format and is not readable. The PS-SMART prediction component can be used to generate leaf node numbers.	String	Optional.
lifecycle	Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- Algorithm parameters

Parameter in PAI commands	Parameter	Description	Valid value	Required/Default value
classNum	Classes	The number of classes for multiclass classification. If the number of classes is n, the values of the label column range from 0 to n-1.	A non-negative integer, greater than or equal to 3.	Required.
objective	Objective Function Type	The objective function type affects learning. You must select an appropriate objective function type. Set the parameter to **multi:softprob** for multiclass classification.	N/A	Required.

Parameter in PAI commands	Parameter	Description	Valid value	Required/Default value
metric	Evaluation Indicator Type	The evaluation metric type in the training set, which is contained in stdout of the coordinator in a logview.	**mlogloss** and **merror**	Optional. By default, this parameter is empty.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.
maxDepth	Maximum Tree Depth	The maximum depth of a tree. We recommend that you set the parameter to 5, indicating that the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0,1]	Optional. Default value: 1.0. The default value indicates that data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0,1]	Optional. Default value: 1.0. The default value indicates that feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the less the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.

Parameter in PAI commands	Parameter	Description	Valid value	Required/Default value
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0,1]	Optional. Default value: 0.3.
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of bins is O(1.0/sketchEps). The smaller the parameter value, the more bins are generated. Typically, you do not need to change this value.	(0,1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss Change	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional.
baseScore	Global Offset	The initial predicted values of all samples.	Real number	Optional. Default value: 0.5.

Parameter in PAI commands	Parameter	Description	Valid value	Required/Default value
featureImportanceType	Feature Importance Type	The type of feature importance. **weight** indicates the number of times that a feature splits. **gain** indicates information gain brought by the feature. **cover** indicates the number of samples that the feature covers on the splitting nodes.	**weight**, **gain**, and **cover**	Optional. Default value: **gain**.

- Usage notes
  - Specify different values for the objective parameter in different learning models. In the PAI console, the objective function is automatically specified and invisible to users. On the command line, set the objective parameter to `multi:softprob`.
  - Mappings between metrics and objective functions are: **mlogloss** for **multiclass negative log likelihood**, and **merror** for **multiclass classification error**.
- Tuning parameters

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. By default, the system determines the value.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core. A value of 1024 represents 1 GB of memory.	Positive integer	Optional. By default, the system determines the value.

Example

- Generate input data

  The following sample code is used to generate data in the sparse format that consists of key-value pairs:

```
drop table if exists smart_multiclass_input;
create table smart_multiclass_input lifecycle 3 as
select
*
from
(
select 2 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
    union all
select 1 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
    union all
select 1 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
    union all
select 2 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
    union all
select 1 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
    union all
select 1 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
    union all
select 0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
    union all
select 1 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
    union all
select 0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
    union all
select 1 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

- Configure the component for training

  Configure the training data and training component, as shown in Quick start. Select the label column as the label column and the features column as the feature column.

  - You do not need to set the number of features because this number is calculated automatically by the algorithm. If you have a large number of features and want the algorithm to accurately estimate required resources, specify the actual number of features.
  - To accelerate the training, set the number of cores on the Tuning tab. The greater the number, the faster the algorithm runs. Typically, you do not need to enter the memory size of each core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the resources. Therefore, you may need to wait a longer period of time when the cluster is busy and a large number of resources are requested.

- Configure the components for prediction
  - Use the unified prediction component

    The model generated after training is saved in binary format and can be used for prediction. Configure the input model and test data for the prediction component, as shown in Quick start.

    If the dense format is used, you need only to select feature columns. All columns are selected by default, and extra columns do not affect the prediction. If data consists of key-value pairs, set the data format to sparse format and select the correct delimiter. In the SMART model, key-value pairs are separated by spaces. Therefore, the delimiter must be set to space or **\u0020** (escape expression of a space).

    In the **prediction_detail**column, values 0, 1, and 2 indicate classes, and the values following them indicate probabilities of the corresponding classes. The **predict_result** column lists the selected classes with the highest probability, and the **predict_score** column lists the probability of each selected class.

- Use the PS-SMART prediction component

  The output model table obtained after training is saved in the binary format and can be used by the PS-SMART prediction component for prediction. Configure the input model and test data for the prediction component, as shown in Quick start. Set the required parameters, including the data format, feature columns, objective column, and number of classes. The ID column can only be of a STRING-type column other than a feature column or the label column. The loss function must be explicitly set to **multi:softprob**.

  The **score_class_k** columns list probabilities of class k. The class with the highest probability is the predicted class. The **leaf_index** column lists the predicted leaf node numbers. Each sample has N × M numbers, where N is the number of decision trees, and M is the number of classes. In this example, each sample has 15 numbers (5 × 3 = 15). Each tree is mapped to a number, which indicates the leaf node number of the sample on this tree.

  > **Note**
  > - The output model table is a binary table that is not readable and is used to support the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation indicators. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved and may be replaced by another component in the future.
  > - A column of the STRING type must be selected as the label column. You can enter strings in the column but cannot be empty or NULL. A feature column can be converted to the STRING type by using the Data Type Conversion component.
  > - The loss function must be explicitly set to **multi:softprob**. By default, the loss function does not work.

- View feature importance

  To view feature importance, you can export the third output port to an output table, or right-click **PS-SMART training component** and choose **View Data > View Output Port 3** from the shortcut menu. The following figure shows the output feature importance table.

  In the table, the ID column lists the numbers of input features. In this example, the data is in key-value format, and the IDs represent keys in key-value pairs. If the dense format is used and input features are **f0,f1,f2,f3,f4,f5**, ID 0 represents f0 and ID 4 represents f4. Each value indicates a feature importance type. The default value is **gain**, indicating the sum of information gains brought by a feature in the model. The preceding figure shows only four features because only these four features are used during the tree split process. In this case, the importance of unused features is 0.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can I use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume a large number of resources and run slowly. Therefore, we recommend that you do not use such a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding to filter out infrequent features before they can be used for training. The continuous numerical features can be directly used for training with the GBDT algorithm. Discretization is not recommended for numerical features.
- Q: Why is the result different every time even though the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the data_sample_ratio and fea_sample_ratio parameters introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local

sketches are merged to global sketches in a random order. Different merging orders result in different tree structures, but this does not introduce too much variation to the output model. Therefore, it is a normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

> **Note**
>
> - The label column in a PS-SMART multiclass classification model supports only positive integer IDs . Class numbers range from 0 to n-1 and n is the number of classes. Even if the values in the MaxCompute table are strings, they are saved as numerical values. If the classification target is a type string similar to **Good**, **Medium**, or **Bad**, convert it into a numeric value from 0 to n-1.
> - In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.1.5.2.6.3. K-means clustering

K-means clustering is a widely used algorithm that is used to divide n objects into k clusters while maintaining high similarity within each cluster. Similarity is calculated based on the average value of objects in a cluster. This algorithm is similar to the expectation maximization algorithm for calculating mixed normality distribution, as both algorithms try to find the natural clustering center in data. K-means clustering randomly selects k objects. Each object represents the average value or center of a cluster. Based on its distance from each cluster center, each remaining object is then assigned to the nearest cluster and the average value of each cluster is re-calculated. This process is repeated until the criterion function converges. This algorithm assumes that object properties are from the spatial vector. Its objective is to minimize the sum of the mean square deviance inside each group.

Parameter settings

Parameters

Parameter	Description
Clusters	The number of clusters. Default value: 10.
Distance Measurement Method	Valid values: *euclidean*, *cityblock* (the sum of absolute deviations), and *cosine*. Default value: euclidean.
Initial Centroid Location	Valid values: *sample* (randomly selected), *topk* (first K rows), *uniform* (evenly distributed and randomly generated), *matrix* (an initial centroid table must be specified), and *kmpp* (k-means++ initialization). Default value: sample.
Maximum Iterations	The maximum number of iterations. Default value: 100.
Minimum Iteration Precision	The minimum iteration precision. Default value: 0.0.

Procedure

1. After running the K-means Clustering component, you can view the cluster center table.

   Cluster center table: The number of columns in this table is equal to the total number of columns selected from the input table. The number of rows is equal to the number of clusters, with each row representing a cluster center location.

2. Right-click the target table and choose **View Data** to view the cluster index table (idxTablename).
   - Cluster index table: The number of rows is equal to the total number of rows in the input table. The value

in each row represents the cluster index of the point in the corresponding row of the input table.

- The names of all columns are displayed. A classification marking column is appended to the table.
- 0, 1, 2, 3 are classification IDs.
- You can also use the table name generated by PAI command to view the cluster center table, cluster index table, and cluster count table in IDE.

Note If *matrix* is selected as the initial centroid location, you must define the initial centroid table, with the same columns as the original table. The number of rows is the same as the number of clusters. When you prepare the table, configure k centers and use SQL or MapReduce for sampling, or select another method based on your requirements.

PAI command

```
 PAI -name KMeans
-project algo_public
-DcenterCount="10"
-DidxTableName="bank_data_index"
-DdistanceType="euclidean"
-DappendColsIndex="0,1,2,3,4,5,6,7,8,9,10"
-DcenterTableName="pai_temp_3300_27298_3"
-Dloop="100"
-DclusterCountTableName="pai_temp_3300_27298_2"
-DinitCentersMethod="sample"
-Daccuracy="0.0"
-DinputTableName="bank_data"
-DselectedColNames="cons_conf_idx,emp_var_rate,euribor3m,pdays,previous";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
centerCount	The number of clusters. The value must be an integer. Default value: 10.
idxTableName	The name of the output cluster index table. The number of rows is equal to the total number of rows in the input table. The value in each row represents the cluster index of the point in the corresponding row of the input table.
distanceType	Optional. The method used to measure the distance. Valid values: euclidean, cityblock, and cosine. Default value: euclidean.
appendColsIndex	Optional. The name of the ID column appended to the output table. No ID column is appended to the output table by default.
centerTableName	The name of the output cluster center table. The number of columns in this table is equal to the total number of columns selected from the input table. The number of rows is equal to the number of clusters, with each row representing a cluster center location.
loop	Optional. The maximum number of iterations. The value must be an integer. Default value: 100.

Parameter	Description
clusterCountTableName	The name of the cluster point count table. The number of rows is equal to the number of clusters, which indicates the total number of cluster points in the class in each clustering centroid row.
initCentersMethod	Optional. The method used to determine the initial centroid location. The options include sample (randomly selected), topk (first K rows), uniform (evenly distributed and randomly generated), matrix (an initial centroid table must be specified), and kmpp (k-means++ initialization). Default value: sample.
accuracy	The minimum iteration precision. Default value: 0.0.
inputTableName	The name of the input table.
selectedColNames	The names of columns selected from the input table, which are separated with commas (,). Only double type is supported.
initCenterTableName	Optional. The name of the table that stores the initial center values. This table is not required unless initCentersMethod is set to *matrix*.

4.1.5.2.6.4. Regression

GBDT regression

Gradient boosting decision tree (GBDT) is an iterative decision tree algorithm based on multiple decision trees. The final output is the sum of conclusions of all trees. GBDT can be applied to almost all regression models (linear or nonlinear) and has a wider scope of application than logistic regression that is only applicable to linear regression.

For more information, see A Regression Framework for Learning Ranking Functions Using Relative Relevance Judgments. For more information, see GBDT binary classification.

PAI command

```
PAI -name gbdt
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DlossType="0"
-DrandSeed="0"
-DnewtonStep="0"
-Dshrinkage="0.05"
-DmaxLeafCount="32"
-DlabelColName="campaign"
-DinputTableName="bank_data_partition"
-DminLeafSampleCount="500"
-DsampleRatio="0.6"
-DgroupIDColName="age"
-DmaxDepth="11"
-DmodelName="xlab_m_GBDT_83602"
-DmetricType="2"
-DfeatureRatio="0.6"
-DinputTablePartitions="pt=20150501"
-Dtau="0.6"
-Dp="1"
-DtestRatio="0.0"
-DfeatureColNames="previous,cons_conf_idx,euribor3m"
-DtreeCount="500"
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
featureColNames	Optional. The names of feature columns selected from the input table for training.	Column name	All columns are selected by default.
labelColName	Optional. The name of the label column selected from the input table.	Column name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions are selected by default.
modelName	Required. The name of the output model.	-	-
outputImportanceTableName	Optional. The name of the output feature importance table.	-	-
groupIDColName	Optional. The name of the stratification column.	Column name	The whole table is selected by default.
lossType	Optional. The loss function type. The function types include *0: GBRANK*, *1:LAMBDAMART_DCG*, *2: LAMBDAMART_NDCG*, *3: LEAST_SQUARE*, and *4: LOG_LIKELIHOOD*.	0, 1, 2, 3, and 4	0
metricType	Optional. The type of metrics. *0(NDCG)* indicates the normalized discounted cumulative gain, *1 (DCG)* indicates the discounted cumulative gain, and *2 (AUC)* is applicable only to 0/1 label.	0, 1, and 2	2
treeCount	Optional. The number of trees.	[1, 10000]	500

Parameter	Description	Valid values	Default value
shrinkage	Optional. The learning rate.	(0, 1]	0.05
maxLeafCount	Optional. The maximum number of leaves. This value must be an integer.	[2, 1000]	32
maxDepth	Optional. The maximum depth of a tree. This value must be an integer.	[1, 11]	11
minLeafSampleCount	Optional. The minimum number of samples on a leaf node. This value must be an integer.	[100, 1000]	500
sampleRatio	Optional. The fraction of training samples.	(0, 1]	0.6
featureRatio	Optional. The fraction of training features.	(0, 1]	0.6
tau	Optional. The Tau parameter in gbrank loss.	[0, 1]	0.6
p	Optional. The p parameter in gbrank loss.	[1, 10]	1
randSeed	Optional. The random seed.	[0, 10]	0
newtonStep	Optional. This parameter specifies whether to use the Newton method.	0 and 1	1
featureSplitValueMaxSize	Optional. The maximum number of splits per feature.	[1, 1000]	500
lifecycle	Optional. The lifecycle of the output table.	-	No lifecycle is set by default.

Examples

SQL statement to generate data:

```
drop table if exists gbdt_ls_test_input;
create table gbdt_ls_test_input as select     * from (
select         cast(1 as double) as f0,
cast(0 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label     from dual     union all
select             cast(0 as double) as f0,
cast(1 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label     from dual     union all
select             cast(0 as double) as f0,
cast(0 as double) as f1,
cast(1 as double) as f2,
cast(0 as double) as f3,
cast(1 as bigint) as label     from dual     union all
select             cast(0 as double) as f0,
cast(0 as double) as f1,
cast(0 as double) as f2,
cast(1 as double) as f3,
cast(1 as bigint) as label     from dual     union all
select             cast(1 as double) as f0,
cast(0 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label     from dual     union all
select             cast(0 as double) as f0,
cast(1 as double) as f1,
cast(0 as double) as f2,
cast(0 as double) as f3,
cast(0 as bigint) as label     from dual ) a;
```

PAI command

- Training:

```
drop offlinemodel if exists gbdt_ls_test_model;
PAI -name gbdt
-project algo_public
-DfeatureSplitValueMaxSize="500"
-DlossType="3"
-DrandSeed="0"
-DnewtonStep="1"
-Dshrinkage="0.5"
-DmaxLeafCount="32"
-DlabelColName="label"
-DinputTableName="gbdt_ls_test_input"
-DminLeafSampleCount="1"
-DsampleRatio="1"
-DmaxDepth="10"
-DmetricType="0"
-DmodelName="gbdt_ls_test_model"
-DfeatureRatio="1"
-Dp="1"
-Dtau="0.6"
-DtestRatio="0"
-DfeatureColNames="f0,f1,f2,f3"
-DtreeCount="10"
```

- Prediction:

```
drop table if exists gbdt_ls_test_prediction_result;
PAI -name prediction
-project algo_public
-DdetailColName="prediction_detail"
-DmodelName="gbdt_ls_test_model"
-DitemDelimiter=","
-DresultColName="prediction_result"
-Dlifecycle="28"
-DoutputTableName="gbdt_ls_test_prediction_result"
-DscoreColName="prediction_score"
-DkvDelimiter=":"
-DinputTableName="gbdt_ls_test_input"
-DenableSparse="false"
-DappendColNames="label"
```

Input description

gbdt_ls_test_input

f0	f1	f2	f3	label
1.0	0.0	0.0	0.0	0
0.0	0.0	1.0	0.0	1
0.0	0.0	0.0	1.0	1
0.0	1.0	0.0	0.0	0
1.0	0.0	0.0	0.0	0
0.0	1.0	0.0	0.0	0

Output description

gbdt_ls_test_prediction_result

label	prediction_result	prediction_score	prediction_detail
0	NULL	0.0	{"label": 0}
0	NULL	0.0	{"label": 0}
1	NULL	0.9990234375	{"label": 0.9990234375}
1	NULL	0.9990234375	{"label": 0.9990234375}
0	NULL	0.0	{"label": 0}
0	NULL	0.0	{"label": 0}

Linear regression

This component is used to resolve regression issues and analyze the linear relationship between a dependent variable and multiple independent variables. Certain columns from an input table are selected as feature columns and one column is selected as the label column for linear regression training and linear regression model generation.

PAI command

```
PAI -name linearregression
    -project algo_public
    -DinputTableName=lm_test_input
    -DfeatureColNames=x
    -DlabelColName=y
    -DmodelName=lm_test_input_model_out;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
modelName	Required. The name of the output model.	-	-
outputTableName	Optional. The name of the output model evaluation table.	This parameter must be specified when enableFitGoodness is set to *true*.	-
labelColName	Required. The name of the label column.	The name must be a double or bigint type value. Only one column can be specified.	-

Parameter	Description	Valid values	Default value
featureColNames	Required. The name of the feature column.	The name must be a double or bigint type value in dense format, or a string type value in sparse format. Multiple columns can be specified.	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	No partitions are selected by default.
maxIter	Optional. The maximum number of iterations.	-	100
epsilon	Optional. The minimum likelihood deviance.	-	0.000001
enableSparse	Optional. This parameter specifies whether the data is in sparse format.	true and false	false
enableFitGoodness	Optional. This parameter specifies whether to perform model evaluation. Model evaluation can be performed using a variety of metrics, including R-squared, adjusted R-Squared, Akaike information criterion, degrees of freedom, residual standard deviation, and deviation.	true and false	false
enableCoefficientEstimate	Optional. This parameter specifies whether to estimate the regression coefficient. The metrics of this parameter are value t, value p, and confidence interval [2.5%, 97.5%]. This parameter takes effect only when enableFitGoodness is set to *true*. This parameter is ignored when enableFitGoodness is set to *false*.	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs. This parameter takes effect only when enableSparse is set to *true*.	-	Use spaces on command lines and use commas (,) on webpages.

Parameter	Description	Valid values	Default value
kvDelimiter	Optional. The delimiter used to separate keys and values. This parameter takes effect only when enableSparse is set to *true*.	-	The default delimiter is a colon (:).
lifecycle	Optional. The lifecycle of the output table.	An integer greater than or equal to -1	Default value: -1. This value indicates that no lifecycle is set.
coreNum	Optional. The number of cores.	An integer larger than 0	Default value: -1. This value indicates that the number of instances is determined by the amount of input data.
memSizePerCore	Optional. The memory size of each core.	(100, 65536)	Default value: -1. This value indicates that the memory size is determined by the amount of input data.

Examples

- SQL statement to generate data:

```
drop table if exists lm_test_input;
      create table lm_test_input as
      select
        *
      from
      (
        select 10 as y, 1.84 as x1, 1 as x2, '0:1.84 1:1' as sparsecol1 from dual
          union all
        select 20 as y, 2.13 as x1, 0 as x2, '0:2.13' as sparsecol1 from dual
          union all
        select 30 as y, 3.89 as x1, 0 as x2, '0:3.89' as sparsecol1 from dual
          union all
        select 40 as y, 4.19 as x1, 0 as x2, '0:4.19' as sparsecol1 from dual
          union all
        select 50 as y, 5.76 as x1, 0 as x2, '0:5.76' as sparsecol1 from dual
          union all
        select 60 as y, 6.68 as x1, 2 as x2, '0:6.68 1:2' as sparsecol1 from dual
          union all
        select 70 as y, 7.58 as x1, 0 as x2, '0:7.58' as sparsecol1 from dual
          union all
        select 80 as y, 8.01 as x1, 0 as x2, '0:8.01' as sparsecol1 from dual
          union all
        select 90 as y, 9.02 as x1, 3 as x2, '0:9.02 1:3' as sparsecol1 from dual
          union all
        select 100 as y, 10.56 as x1, 0 as x2, '0:10.56' as sparsecol1 from dual
      ) tmp;
```

- PAI command

```
PAI -name linearregression
    -project algo_public
    -DinputTableName=lm_test_input
    -DlabelColName=y
    -DfeatureColNames=x1,x2
    -DmodelName=lm_test_input_model_out
    -DoutputTableName=lm_test_input_conf_out
    -DenableCoefficientEstimate=true
    -DenableFitGoodness=true
    -Dlifecycle=1;
pai -name prediction
    -project algo_public
    -DmodelName=lm_test_input_model_out
    -DinputTableName=lm_test_input
    -DoutputTableName=lm_test_input_predict_out
    -DappendColNames=y;
```

- Output description:
  - When enableFitGoodness is set to *true*, partitions specified by `p='goodness'` are created in the model evaluation table. The output metrics are *R-squared*, *adjusted R-Squared*, *Akaike information criterion*, *degrees of freedom*, *residual standard deviation*, and *deviation*.
  - When enableCoefficientEstimate is set to *true*, partitions specified by `p='coefficient'` are created in the model evaluation table. The table contains the intercepts and the *name*, *coefficient*, *t-score*, *p-value*, and *confidence interval [2.5%, 97.5%]* of the features.
  - Output model evaluation table: lm_test_input_conf_out.

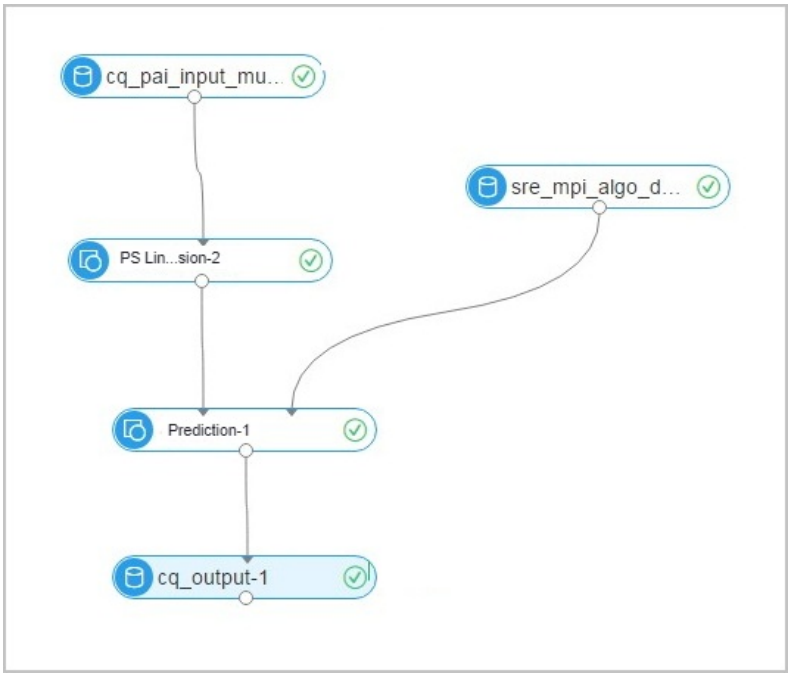
PS linear regression

Linear regression is a classic regression algorithm used to analyze the linear relationship between a dependent variable and multiple independent variables. Parameter servers (PSs) are used to run large amounts of training tasks online and offline. Parameter servers can use hundreds of billions of samples to efficiently train billions of feature models. The PS linear regression model can run training tasks with hundreds of billions of samples and billions of features, and supports L1 and L2 regular expressions.

Quick start



PAI command

- **Training**

```
PAI -name ps_linearregression
    -project algo_public
    -DinputTableName="lm_test_input"
    -DmodelName="linear_regression_model"
    -DlabelColName="label"
    -DfeatureColNames="features"
    -Dl1Weight=1.0
    -Dl2Weight=0.0
    -DmaxIter=100
    -Depsilon=1e-6
    -DenableSparse=true
```

- **Prediction**

```
drop table if exists logistic_regression_predict;
PAI -name prediction
    -DmodelName="linear_regression_model"
    -DoutputTableName="linear_regression_predict"
    -DinputTableName="lm_test_input"
    -DappendColNames="label,features"
    -DfeatureColNames="features"
    -DenableSparse=true
```

Parameters

- **Data parameters**

Command option	Parameter	Description	Valid values	Default value
featureColNames	Feature Columns	Required. The names of feature columns selected from the input table for training.	If a column name is in dense format, it must be of the bigint or double type. If the column name is in sparse KV format, it must be a string.	-
labelColName	Label Column	Required. The name of the label column selected from the input table.	The column name must be of the bigint or double type.	-
enableSparse	Use Sparse Format	Optional. If you choose to use the sparse KV format, do not use feature ID 0. We recommend that the feature IDs start from 1.	true and false	false
itemDelimiter	KV Pair Delimiter	Optional. The delimiter used to separate key-value pairs when data in the input table is in sparse format.	Symbol	The default delimiter is a space.

Command option	Parameter	Description	Valid values	Default value
kvDelimiter	KV Delimiter	Optional. The delimiter used to separate keys and values when data in the input table is in sparse format.	Symbol	The default delimiter is a colon (:).
inputTableName	Input Table Name	Required.	Table name	-
modelName	Output Model Name	Required.	Model name	-
inputTablePartitions	Input Table Partitions	Optional.	Partition name	The parameter value must be in the ds=1/pt=1 format.
enableModelIo	Output to Offline Model	Optional. When this parameter is set to false, the data is output to a MaxCompute table where you can view model weights.	true and false	true

- Algorithm parameters

Command option	Parameter	Description	Valid values	Default value
l1Weight	L1 Weight	Optional. The L1 regularization coefficient. The larger this value is, the fewer non-zero elements a model has. To overfit the model, set this parameter to a larger value.	A non-negative real number	1.0
l2Weight	L2 Weight	Optional. The L2 regularization coefficient. The larger this value is, the smaller the absolute values of the model parameters are. To overfit the model, set this parameter to a larger value.	A non-negative real number	0
maxIter	Maximum Iterations	Optional. The maximum number of LBFGS/OWL-QN iterations. Value 0 indicates that no limit is set.	A non-negative integer	100

Command option	Parameter	Description	Valid values	Default value
epsilon	Minimum Convergence Deviance	Optional. The mean of the relative loss change rates in ten iterations, which is used as a condition to determine whether to terminate the optimization algorithm. The smaller this value is, the stricter the condition is, and the longer the algorithm runs.	A real number between 0 and 1	1.0e-06
modelSize	Largest Feature ID	Optional. The largest feature ID among all feature IDs (feature dimension). It can be larger than the actual largest feature ID. The larger this value is, the higher the memory usage is. If you leave this parameter empty, the system starts an SQL task to calculate the largest feature ID automatically.	A non-negative integer	0

Note Both the maximum iterations and minimum convergence deviance determine when the algorithm stops. If both parameters are set, the algorithm stops when one of the conditions is met.

- **Execution optimization**

Command option	Parameter	Description	Valid values	Default value
coreNum	Cores	Optional. The number of cores. The larger this value is, the faster the computing algorithm runs.	A positive integer	Automatically allocated.

Command option	Parameter	Description	Valid values	Default value
memSizePerCore	Memory Size per Core (MB)	Optional. The memory size of each core, where 1024 represents 1 GB of memory.	A positive integer	Automatically allocated. Typically, you do not need to set this parameter because the algorithm can accurately estimate the memory size required.

Examples

- **Data generation**

  The following example uses data in sparse KV format:

```
drop table if exists lm_test_input;
create table lm_test_input as
select
*
from
(
select 2 as label, '1:0.55 2:-0.15 3:0.82 4:-0.99 5:0.17' as features from dual
    union all
select 1 as label, '1:-1.26 2:1.36 3:-0.13 4:-2.82 5:-0.41' as features from dual
    union all
select 1 as label, '1:-0.77 2:0.91 3:-0.23 4:-4.46 5:0.91' as features from dual
    union all
select 2 as label, '1:0.86 2:-0.22 3:-0.46 4:0.08 5:-0.60' as features from dual
    union all
select 1 as label, '1:-0.76 2:0.89 3:1.02 4:-0.78 5:-0.86' as features from dual
    union all
select 1 as label, '1:2.22 2:-0.46 3:0.49 4:0.31 5:-1.84' as features from dual
    union all
select 0 as label, '1:-1.21 2:0.09 3:0.23 4:2.04 5:0.30' as features from dual
    union all
select 1 as label, '1:2.17 2:-0.45 3:-1.22 4:-0.48 5:-1.41' as features from dual
    union all
select 0 as label, '1:-0.40 2:0.63 3:0.56 4:0.74 5:-1.44' as features from dual
    union all
select 1 as label, '1:0.17 2:0.49 3:-1.50 4:-2.20 5:-0.35' as features from dual
) tmp;
```

  The feature IDs start from 1, and the maximum feature ID is 5.

- **Training**

  Configure the training data and training components based on Quick start. Select the label column as the target column and features column as the feature column. Then, select the sparse data format.

  - You can retain the default value 0 for the largest feature ID. The algorithm can start an SQL task to calculate the largest feature ID automatically. If you do not want to start the SQL task, enter a value greater than 5. This value indicates the number of feature columns in dense format and indicates the largest feature ID in KV format.

- To accelerate the training, you can set the number of cores on the tuning page. The larger the number is, the faster the algorithm runs. Typically, you do not need to enter the memory size per core because the algorithm can accurately calculate the memory size. The PS algorithm starts to run only when all hosts have obtained the resources. Therefore, you may need to wait a longer period of time when the cluster is busy and resources are requested in large volume.

- **Prediction**

  The model generated after training is saved in binary format and can be used for prediction. Configure the input settings (model and testing data) for the prediction component and set parameters based on Quick start.

  Select the KV format for training and set a correct delimiter. When the KV format is used, key-value pairs are separated by spaces. Therefore, the delimiter must be set to space or `\u0020` (the escape expression of space).

Restrictions and guidelines

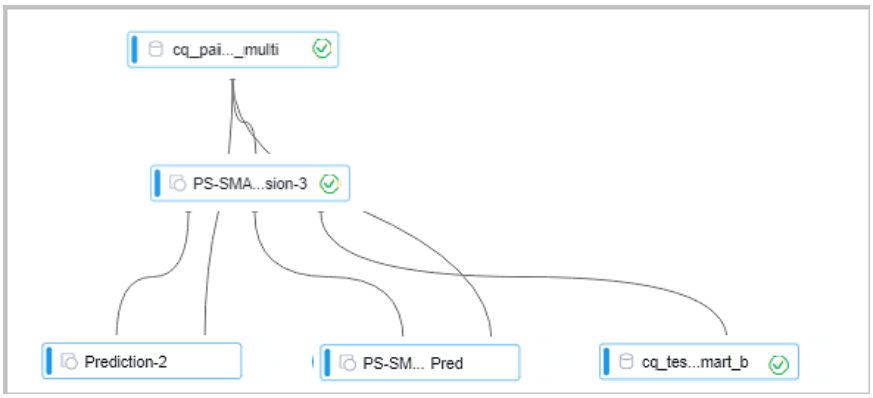
In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

PS-SMART Regression

A parameter server (PS) is used to train a large number of models online and offline. SMART is short for scalable multiple additive regression tree. PS-SMART is an algorithm that is implemented by using a PS-based gradient boosting decision tree (GBDT). PS-SMART supports training tasks for tens of billions of samples and hundreds of thousands of features. It can run training tasks on thousands of nodes. It also supports failover for high stability. PS-SMART supports various data formats, training targets, evaluation targets, output feature importance, and histogram-based approximation for training acceleration.

Quick start

The following figure shows the output details of the PS-SMART Regression component.



The PS-SMART Regression component has three output ports:

- Output model: an offline model, which is connected to the unified prediction component. This model does not support the output of leaf node numbers.
- Output model table: a binary table that is not readable and is used to ensure compatibility with the PS-SMART prediction component. The table provides outputs such as leaf node numbers and evaluation metrics. However, the output table has strict requirements on data formats, which negatively affects user experience. This component is being continually improved and may be replaced by another component in the future.
- Output feature importance table: lists the importance of each feature. Three importance types are supported. For more information, see Parameters.

PAI commands

You can run the following PAI commands to use the PS-SMART Regression component and the prediction component.

- Training

```
PAI -name ps_smart
    -project algo_public
    -DinputTableName="smart_regression_input"
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545859_2"
    -DoutputImportanceTableName="pai_temp_24515_545859_3"
    -DlabelColName="label"
    -DfeatureColNames="features"
    -DenableSparse="true"
    -Dobjective="reg:linear"
    -Dmetric="rmse"
    -DfeatureImportanceType="gain"
    -DtreeCount="5";
    -DmaxDepth="5"
    -Dshrinkage="0.3"
    -Dl2="1.0"
    -Dl1="0"
    -Dlifecycle="3"
    -DsketchEps="0.03"
    -DsampleRatio="1.0"
    -DfeatureRatio="1.0"
    -DbaseScore="0.5"
    -DminSplitLoss="0"
```

- Prediction

```
PAI -name prediction
    -project algo_public
    -DinputTableName="smart_regression_input";
    -DmodelName="xlab_m_pai_ps_smart_bi_545859_v0"
    -DoutputTableName="pai_temp_24515_545860_1"
    -DfeatureColNames="features"
    -DappendColNames="label,features"
    -DenableSparse="true"
    -Dlifecycle="28"
```

Parameters

- The following table describes the data parameters in PAI commands.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
featureColNames	Feature Columns	The names of feature columns that are selected from the input table for training.	If data in the input table is in the dense format, only the columns of the BIGINT and DOUBLE types are supported. If data in the input table is key-value pairs in the sparse format, only columns of the STRING type are supported and the keys and values must be numeric.	Required.
labelColName	Label Column	The name of the label column that is selected from the input table.	The column name can be a string or a numeric value, but only numeric data can be stored in the columns. For example, the column value can be 0 or 1 for regression.	Required.
weightCol	Weight Column	The column that contains the weight of each row of samples.	The columns of numeric data types are supported.	Optional. By default, this parameter is empty.
enableSparse	Use Sparse Format	Specifies whether data in the input table is in the sparse format. If data in the input table is in the sparse format, key-value pairs are separated by spaces whereas keys and values are separated by colons (:). Example: **1:0.3 3:0.9**.	true and false	Optional. Default value: false.
inputTableName	The name of the input table.	N/A	N/A	Required.
modelName	Output Model Name	N/A	N/A	Required.
outputImportanceTableName	Output Feature Importance Table	N/A	N/A	Optional. By default, this parameter is empty.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
inputTablePartitions	Partition	N/A	N/A	Optional. The parameter value must be in the ds=1/pt=1 format.
outputTableName	Output Model Table	The output table is a MaxCompute table that uses the binary format and is not readable. The PS-SMART prediction component can be used to generate leaf node numbers.	String	Optional.
lifecycle	Lifecycle	N/A	Positive integer	Optional. Default value: 3.

- The following table describes the algorithm parameters in PAI commands.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
objective	Objective Function Type	The objective function type affects learning. You must select an appropriate objective function type. Multiple loss functions are available for regression. For more information, see Usage notes.	For more information, see Usage notes.	Required. The default type is linear regression.
metric	Evaluation Indicator Type	The evaluation metric type in the training set, which must correspond to the objective function type and are exported to stdout of the coordinator in a logview. For more information, see Usage notes.	For more information, see Usage notes.	Optional. By default, this parameter is empty.
treeCount	Trees	The number of trees. The training time is proportional to this number.	Positive integer	Optional. Default value: 1.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
maxDepth	Maximum Tree Depth	The maximum depth of a tree. We recommend that you set the parameter to 5, indicating that the tree can contain up to 32 leaf nodes.	A positive integer in the range of [1, 20]	Optional. Default value: 5.
sampleRatio	Data Sampling Fraction	The data sampling rate when trees are built. The sample data is used to build a weak learner to accelerate training.	(0,1]	Optional. Default value: 1.0. The default value indicates that data sampling is disabled.
featureRatio	Feature Sampling Fraction	The feature sampling rate when trees are built. The sample features are used to build a weak learner to accelerate training.	(0,1]	Optional. Default value: 1.0. The default value indicates that feature sampling is disabled.
l1	L1 Penalty Coefficient	This parameter determines the number of leaf nodes. The greater the value, the less the leaf nodes. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 0.
l2	L2 Penalty Coefficient	This parameter determines the size of a leaf node. The greater the value, the more evenly the leaf nodes are distributed. You can set this parameter to a greater value if overfitting occurs.	Non-negative real number	Optional. Default value: 1.0.
shrinkage	Learning Rate	N/A	(0,1]	Optional. Default value: 0.3.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
sketchEps	Sketch-based Approximate Precision	The threshold for selecting quantiles when you build a sketch. The number of bins is O(1.0/sketchEps). The smaller the parameter value, the more bins are generated. Typically, you do not need to change this value.	(0,1)	Optional. Default value: 0.03.
minSplitLoss	Minimum Split Loss Change	The minimum split loss changes required for splitting a node. The greater the value, the more conservatively the node splits.	Non-negative real number	Optional. Default value: 0.
featureNum	Features	The number of features or the maximum feature ID. Specify this parameter for resource usage estimation.	Positive integer	Optional.
baseScore	Global Offset	The initial predicted values of all samples.	Real number	Optional. Default value: 0.5.
featureImportanceType	Feature Importance Type	The type of feature importance. **weight** indicates the number of times that a feature splits. **gain** indicates information gain brought by the feature. **cover** indicates the number of samples that the feature covers on the splitting nodes.	**weight**, **gain**, and **cover**	Optional. Default value: **gain**.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
tweedieVarPower	N/A	The relationship between the variance and mean value of Tweedie distribution. Example: `$Var(y) ~ E(y)^tweedie_variance_power$`.	(1,2)	Optional. Default value: 1.5.

- The following table describes the tuning parameters in PAI commands.

Parameter in PAI commands	Corresponding parameter in the console	Description	Valid value	Required/Default value
coreNum	Cores	The number of cores. The greater the value, the faster the computing algorithm runs.	Positive integer	Optional. By default, the system determines the value.
memSizePerCore	Memory Size per Core (MB)	The memory size of each core. A value of 1024 represents 1 GB of memory.	Positive integer	Optional. By default, the system determines the value.

Usage notes

When you set algorithm parameters, take note of the following items:

- Specify different values for the objective parameter in different learning models. On the web UI, the PS-SMART Regression component provides multiple types of objective functions.

```
reg:linear (Linear regression) // The value range of the label column is (-∞, +∞).
reg:logistic (Logistic regression) // The value range of the label column is [0, 1].
count:poisson (Poisson regression for count data, output mean of poisson distribution) // The values of the label column must be greater than or equal to 0.
reg:gamma (Gamma regression for modeling insurance claims severity, or for any outcome that might be [gamma-distributed](https://en.wikipedia.org/wiki/Gamma_distribution#Applications)) // The values of the label column must be greater than or equal to 0.
reg:tweedie (Tweedie regression for modeling total loss in insurance, or for any outcome that might be [Tweedie-distributed](https://en.wikipedia.org/wiki/Tweedie_distribution#Applications).)  // The values of the label column must be greater than or equal to 0.
```

- Metrics for these objective function types are:
  - rmse: Rooted Mean Square Error for the `reg:linear` objective function type.
  - mae: Mean Absolute Error for the `reg:linear` objective function type.
  - poisson-nloglik: Negative Loglikelihood for Poisson Regression for the `count:poisson` objective function type.
  - gamma-deviance: Residual Deviance for Gamma Regression for the `reg:gamma` objective function type.
  - gamma-nloglik: Negative Log-Likelihood for Gamma Regression for the `reg:gamma` objective function type.

- tweedie-nloglik: Negative Log-Likelihood for Tweedie Regression for the `reg:tweedie` objective function type.

FAQ

- Q: Does PS_SMART support non-numerical features and tags?
- A: No.
- Q: What is the scale of features supported by PS-SMART? Can I use large-scale 0-1 features?
- A: Although PS-SMART supports tasks that contain hundreds of thousands of features, such tasks consume a large number of resources and run slowly. Therefore, we recommend that you do not use such a large number of features. The GBDT algorithm is suitable for training with continuous features. The categorical features require one-hot coding to filter out infrequent features before they can be used for training. The continuous numerical features can be directly used for training with the GBDT algorithm. Discretization is not recommended for numerical features.
- Q: Why is the result different every time even though the SMART algorithm has the same data and the same parameter settings?
- A: The PS-SMART algorithm applies randomness in many scenarios. For example, the data_sample_ratio and fea_sample_ratio parameters introduce data and feature sampling respectively. In addition, the PS-SMART algorithm uses histograms to show similarity. When multiple workers run in a cluster in distributed mode, local sketches are merged to global sketches in a random order. Different merging orders result in different tree structures, but this does not introduce too much variation to the output model. Therefore, it is a normal situation to obtain different results after the algorithm runs multiple times with the same data and same parameter settings.

> **Note**
>
> - The label column in a PS-SMART regression model supports only numerical values. Even if values in the MaxCompute table are strings, they are saved as numerical values.
> - In the key-value format, feature IDs must be positive integers, and feature values must be real numbers. If feature IDs are strings, use the serialization component to serialize them. If the feature values are classification type strings, perform feature engineering, such as discretization.

4.1.5.2.6.5. Collaborative filtering (etrec)

etrec is an item-based collaborative filtering algorithm that takes two input columns and provides the top N items that have the highest similarity.

Set the user and item columns.

- You can configure three similarity types.
- topN indicates the first N items with the highest similarity.
- Calculation method: the method used to calculate items that appear multiple times.

PAI command

```
PAI -name pai_etrec
-project algo_public
-DsimilarityType="wbcosine"
-Dweight="1"
-DminUserBehavior="2"
-Dlifecycle="28"
-DtopN="2000"
-Dalpha="0.5"
-DoutputTableName="etrec_test_result"
-DmaxUserBehavior="500"
-DinputTableName="etrec_test_input"
-Doperator="add"
-DuserColName="user"
-DitemColName="item"
```

Parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	N/A	N/A
userColName	Required. The name of the input table column selected as the user column.	N/A	N/A
itemColName	The name of the input table column selected as the item column.	N/A	N/A
payloadColName	Optional. The name of the input table column selected as the payload column.	N/A	No payload column is set by default.
inputTablePartitions	Optional. The partitions selected from the input table for training.	N/A	The whole table is selected by default.
outputTableName	Required. The name of the output table.	N/A	N/A
outputTablePartition	Optional. The partitions in the output table.	N/A	The output table is non-partitioned by default.
similarityType	Optional. The type of similarity.	wbcosine, asymcosine, and jaccard	wbcosine
topN	Optional. N items with the highest similarity.	[1, 10000]	2000
minUserBehavior	Optional. The minimum user behavior.	[2,)	2
maxUserBehavior	Optional. The maximum user behavior.	[2, 100000]	500

Parameter	Description	Valid value	Default value
itemDelimiter	Optional. The delimiter used to separate items in the output table.	N/A	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values in the output table.	N/A	The default delimiter is a colon (:).
alpha	Optional. The value of the smoothing factor for asymcosine.	N/A	0.5
weight	Optional. The weight used for asymcosine.	N/A	1.0
operator	Optional. The action to be performed when the same items exist for one user.	add, mul, min, and max	add
lifecycle	Optional. The lifecycle of the output table.	N/A	1

Examples

- SQL statement to generate data:

```
drop table if exists etrec_test_input;
create table etrec_test_input as select * from
(
select cast(0 as string) as user,
cast(0 as string) as item from dual
union all
select cast(0 as string) as user,
cast(1 as string) as item from dual
union all
select cast(1 as string) as user,
cast(0 as string) as item from dual
union all
select cast(1 as string) as user,
cast(1 as string) as item from dual ) a;
```

- PAI command

```
drop table if exists etrec_test_result;
PAI -name pai_etrec
-project algo_public
-DsimilarityType="wbcosine"
-Dweight="1"
-DminUserBehavior="2"
-Dlifecycle="28"
-DtopN="2000"
-Dalpha="0.5"
-DoutputTableName="etrec_test_result"
-DmaxUserBehavior="500"
-DinputTableName="etrec_test_input"
-Doperator="add"
-DuserColName="user"
-DitemColName="item"
```

- Input description etrec_test_input

User	Item
0	0
0	1
1	0
1	1

- Output description etrec_test_result

Item ID	Similarity
0	1:1
1	0:1

4.1.5.2.6.6. Evaluation

Regression model evaluation

You can evaluate a regression model based on the predicted and actual results. Indicators include SST, SSE, SSR, R2, R, MSE, RMSE, MAE, MAD, MAPE, count, yMean, and predictMean.

PAI command

```
Pai -name regression_evaluation
-project algo_public
-DinputTableName=input_table
-DyColName=y_col
-DpredictionColName=prediction_col
-DoutputTableName=output_table;
```

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	-

Parameter	Description	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training.	All partitions of the input table are selected by default.
yColName	Required. The name of the original dependent variable column in the input table. It must be a numerical value.	-
predictionColName	Required. The name of the predicted dependent variable column. It must be a numerical value.	-
outputTableName	Required. The name of the output table.	-
inputTablePartitions	Optional. The partitions selected from the input table.	-
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.

Output

The following table describes the JSON columns.

Column description

Column	Description
SST	The sum of squares total.
SSE	The sum of squares error.
SSR	The sum of squares regression.
R2	The coefficient of determination.
R	The coefficient of multiple correlations.
MSE	The mean squared error.
RMSE	The root-mean-square error.
MAE	The mean absolute error.
MAD	The mean absolute difference.
MAPE	The mean absolute percentage error.
count	The number of rows.
yMean	The mean of original dependent variables.
predictionMean	The mean of prediction results.

Clustering model evaluation

You can evaluate clustering models, including metrics and icons, based on raw data and clustering models.

PAI command

```
PAI     -name cluster_evaluation
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DmodelName=pai_kmeans_test_model
-DoutputTableName=pai_ft_cluster_evaluation_out;
```

Parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
selectedColNames	Optional. The names of columns selected from the input table for evaluation. The column names must be separated with commas (,). The column names must be the same as the feature names saved in the model.	Column name	All columns are selected by default.
inputTablePartitions	Optional. The partitions selected from the input table for evaluation, in the `name1=value1/name2=value2` format. Separate multiple partitions with commas (,).	N/A	All partitions are selected by default.
enableSparse	Optional. This parameter specifies whether data in the input table is in sparse format.	true and false	false
itemDelimiter	Optional. The delimiter used to separate key-value pairs when data in the input table is in sparse format.	N/A	The default delimiter is a space.
kvDelimiter	Optional. The delimiter used to separate keys and values when data in the input table is in sparse format.	N/A	The default delimiter is a colon (:).
modelName	Required. The name of the input clustering model.	Model name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Evaluation formula

The Calinski-Harabasz metric is also known as the variance ratio criterion (VRC), which is defined as follows:

$$VRC_k = \frac{SS_B}{SS_W} \times \frac{(N-k)}{(k-1)},$$

- SS_B represents the inter-clustering variance. The definition is as follows:

  $$SS_B = \sum_{i=1}^{k} n_i \|m_i - m\|^2,$$

  - `k` represents the number of cluster centers.
  - m_i represents the center of cluster i.
  - `m` represents the mean of the input data.
- SS_W represents the intra-clustering variance. The definition is as follows:

  $$SS_W = \sum_{i=1}^{k} \sum_{x \in c_i} \|x - m_i\|^2,$$

  - `k` represents the number of cluster centers.
  - `x` represents a data point.
  - c_i represents the number i cluster.
  - m_i represents the center of cluster i.
- `N` represents the total number of records. `k` represents the number of cluster centers.

Examples

- Test data

```
create table if not exists pai_cluster_evaluation_test_input
as select * from ( select 1 as id,
1 as f0,2 as f3 from dual union all
select 2 as id, 1 as f0,3 as f3 from dual union all
select 3 as id, 1 as f0,4 as f3 from dual union all
select 4 as id, 0 as f0,3 as f3 from dual union all
select 5 as id, 0 as f0,4 as f3 from dual )tmp;
```

- Clustering model building

```
pai -name kmeans
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DcenterCount=3
-Dloop=10
-Daccuracy=0.00001
-DdistanceType=euclidean
-DinitCenterMethod=random
-Dseed=1
-DmodelName=pai_kmeans_test_model
-DidxTableName=pai_kmeans_test_idx
```

- PAI command

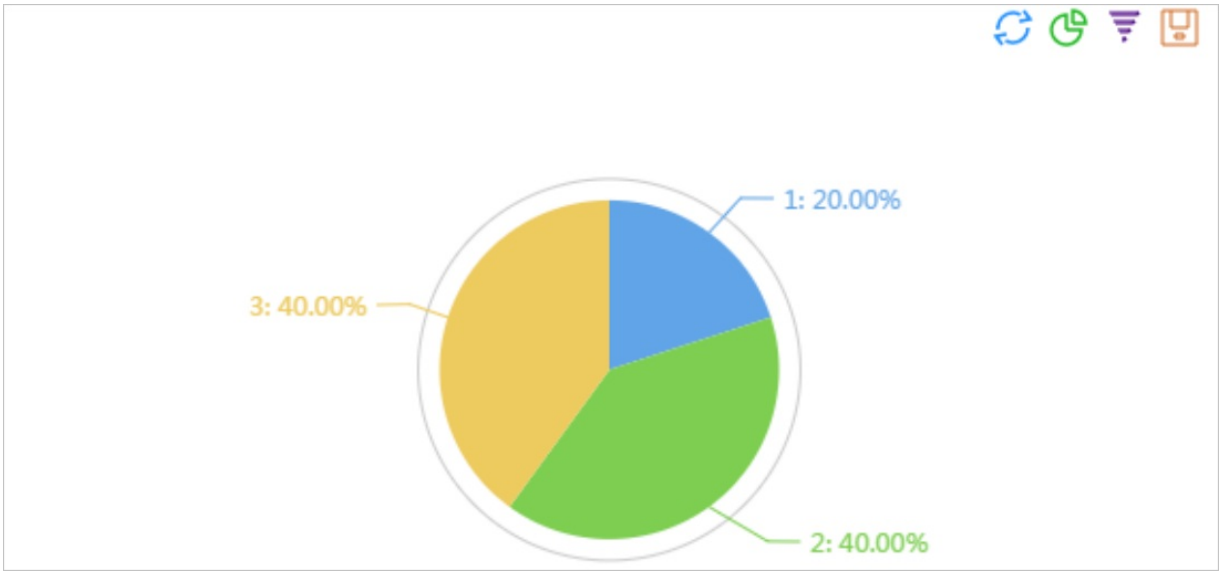
```
PAI -name cluster_evaluation
-project algo_public
-DinputTableName=pai_cluster_evaluation_test_input
-DselectedColNames=f0,f3
-DmodelName=pai_kmeans_test_model
-DoutputTableName=pai_ft_cluster_evaluation_out;
```

- Output description Output table (outputTableName)

Column	Description
count	The total number of records.
centerCount	The number of cluster centers.
calinhara	The Calinski Harabasz metric.
clusterCounts	The number of points included in each cluster.

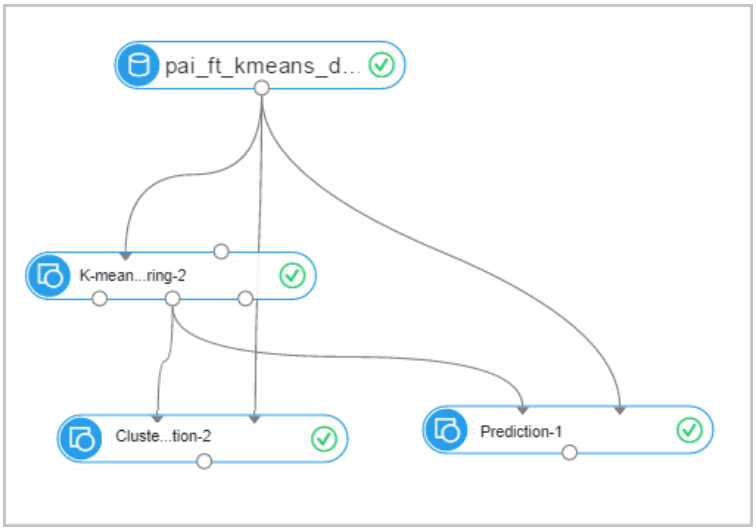
PaiWeb demonstration

Clustering model evaluation



PaiWeb-Pipeline

PaiWeb-Pipeline



Binary classification evaluation

You can evaluate a regression algorithm model based on its predicted and actual results. The metrics include MSE, MAE, and MAPE.

PAI command

```
pai -name evaluation
-DinputTableName=input_table
-DlabelColName=label_name
-DpredictionColName=prediction_score
-DoutputTableName=output_table;
```

Algorithm parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	N/A	N/A
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	N/A	All partitions of the input table are selected by default.
labelColName	Required. The name of the original label column in the input table. It must be a numerical value.	N/A	N/A
predictionColName	Required. The name of the label column in the prediction result table. It must be a numerical value.	N/A	N/A
outputTableName	Required. The name of the output table.	N/A	N/A
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Output table

Output column description

Column	Description
MSE	The mean square error, which is used to measure the mean error and evaluate data changes. The smaller the MSE, the more accurately a prediction model describes the test data.
MAE	The mean absolute error, which is used to measure the mean difference between the predicted value and the actual value.
MAPE	The mean absolute percentage error, which is used to measure prediction accuracy. The value is expressed in percentage. If MAPE is set to 15, the mean absolute percentage error is 15%.

Confusion matrix

The Confusion Matrix component is a visualization tool typically used in supervised learning. This tool is used to calculate the classification accuracy of a confusion matrix model by comparing its results with measured values.

Procedure

1. Configure the confusion matrix parameters.

   The default settings are typically used. You can also select a target column and a prediction probability column. A prediction probability column is the target column generated by the Prediction component.

2. Connect the Confusion Matrix component and the Prediction component.

   > **Note** The parent node of the Confusion Matrix component must be a Prediction component. You can perform confusion matrix analysis only when a classification model is used.

3. Right-click the Confusion Matrix component and choose **View Evaluation Report**.

PAI command

```
PAI -name confusionmatrix
-project algo_public
-DoutputTableName="pai_temp_2954_24178_1"
-DlabelColName="age"
-DpredictionColName="prediction_result"
-DinputTableName="pai_temp_2954_24176_1";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
outputTableName	The name of the output table.
labelColName	The name of the label column selected from the input table.
predictionColName	The name of the prediction result column.
inputTableName	The name of the input table for predicting results.

Multiclass classification evaluation

You can evaluate a multiclass classification model based on its predicted and actual results. The indicators include accuracy, kappa, and F1-Score.

Component description

The Multiclass Classification Evaluation component must be connected to a Prediction component and does not support regression models.

PAI command

```
PAI -name MultiClassEvaluation -project algo_public
    -DinputTableName="test_input"
    -DoutputTableName="test_output"
    -DlabelColName="label"
    -DpredictionColName="prediction_result"
    -Dlifecycle=30;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training.	-	All partitions of the input table are selected by default.
labelColName	Required. The name of the original label column in the input table. It must be a numerical value.	-	-
predictionColName	Required. The name of the label column in the prediction result table. It must be a numerical value.	-	-
outputTableName	Required. The name of the output table.	-	-
predictionColName	Optional. The name of the probability column that lists prediction results. It must be in the {"A":0.2,"B":0.3} format.	-	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

4.1.5.2.6.7. Prediction

The Prediction component is used to make model-based predictions. The component has two inputs (training model and prediction data) and one output (prediction result). Conventional data mining algorithms often use this component for prediction.

Procedure

1. Connect all components.
2. Configure column settings. Parameters

Parameter	Description
Feature Columns	The feature columns used for prediction. All feature columns are selected by default.
Reserved Columns	The columns reserved and exported to the prediction result.
Output Result Column	The default value is used.
Output Score Column	The default value is used.
Output Detail Column	The default value is used.

> **Note** Feature columns must be selected if data is in sparse format such as `k1:v1,k2:v2`.

3. After you configure the preceding parameters, right-click the Prediction component and choose **View Data** from the shortcut menu.

   The following three columns are appended to the prediction data:

   - predict_result: the prediction result column.
   - predict_score: the probability score in prediction results. This column is only appended onto the outputs of binary classification models.
   - predict_detail: the prediction result of each category. This column is only appended onto the outputs of binary classification models.

PAI command

```
PAI -name Prediction
-project algo_public
-DdetailColName="prediction_detail"
-DsplitCharacteristic="2"
-DappendColNames="age,campaign,pdays,previous,poutcome,emp_var_rate,cons_price_idx,cons_conf_idx,euribor3m,nr_employed,y"
-DmodelName="xlab_m_random_forests_6036"
-DresultColName="prediction_result"
-DoutputTableName="pai_temp_675_6048_1"
-DscoreColName="prediction_score"
-DinputTableName="bank_data";
```

Parameters

Parameter	Description
name	The name of the component.
project	The name of the project. This parameter is used to specify the workspace of the algorithm. The default value is algo_public. If you change the name, the system reports an error.
detailColName	Optional. The name of the detail column in the output table. The default value is prediction_detail.
splitCharacteristic	Optional. The type of classification. The value *1* indicates binary classification. The value *2* indicates multiclass classification.

Parameter	Description
appendColNames	Optional. The names of columns in the input prediction table to be appended to the output table.
modelName	The name of the random forest model.
resultColName	Optional. The name of the result column in the output table. The default value is *prediction_result*.
outputTableName	The name of the output prediction table.
scoreColName	Optional. The name of the score column in the output table. The default value is *prediction_score*.
inputTableName	The name of the input prediction table.

4.1.5.2.7. Deep learning (must be separately activated)

Note The deep learning components are applicable only to Intel servers, but not to Hygon servers.

4.1.5.2.7.1. Activate deep learning

The deep learning service is not a basic function of Apsara Stack Machine Learning Platform for AI. You must purchase it separately.

If you have already deployed the deep learning service, activate it by using the following procedure:

1. Log on to the Apsara Stack Machine Learning Platform for AI console.
2. Click **Settings** in the left-side navigation pane.
3. Click **General**. Under **Deep Learning**, select **Enable GPU Compute**.

4.1.5.2.7.2. Read OSS buckets

When using the **Read OSS Bucket** component on Machine Learning Platform for AI, you must assign the default system role **AliyunODPSPAIDefaultRole** to your DTplus service account. OSS buckets can be correctly read and written by algorithms of the machine learning platform only when the role is correctly assigned.

Note The machine learning platform shares service accounts with MaxCompute, because it runs on the MaxCompute framework. During authorization, you must assign the default role to your MaxCompute service account.

You can use RAM authorization to grant OSS access permissions to Machine Learning Platform for AI. Click **Settings** to grant permission to read and write OSS data. For more information, see RAM authorization.

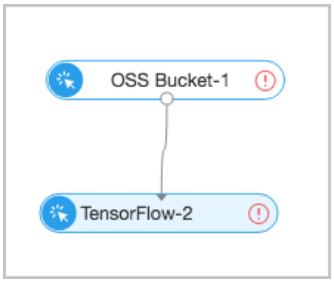
RAM authorization

1. Log on to the Machine Learning Platform For AI console, click **Settings** in the left-side navigation pane, and select **General**.
2. Under **OSS Authorization**, select **Authorize Machine Learning Platform for AI to access my OSS resources**.
3. The following page is displayed. Click **Click here to authorize access in RAM**. The RAM page is displayed.
4. Click **I Agree**.

> **Note** To view details about the AliyunODPSPAIDefaultRole policy, log on to the RAM console. The default role AliyunODPSPAIDefaultRole contains the following permission information.

Permission (Action)	Description
oss:PutObject	Upload a file or folder object.
oss:GetObject	Obtain a file or folder object.
oss:ListObjects	Query file information.
oss:DeleteObjects	Delete an object.

5. Go back to the machine learning page and click **Refresh**. RAM information is automatically recorded to the components.
6. Use the deep learning framework. Connect the **Read OSS Bucket** component to the corresponding deep learning component to obtain permissions to read and write OSS data.



4.1.5.2.7.3. TensorFlow 1.4

TensorFlow (TF) is an open-source machine learning framework. It is easy to use for algorithm developers. The TF framework is integrated into Apsara Stack Machine Learning Platform for AI. You can write code and adjust computing resources flexibly by using the TF compute engine. The TF computing engine is a Graphics Processing Unit (GPU) cluster.

Parameters

- Parameter settings Parameter settings

Parameter	Description
Python Code Files	The program execution files. Multiple files can be packaged and uploaded in the tar.gz format.
Primary Python File	Optional. The primary file in a compressed code file package.
Data Source Directory	The path of data sources. You can select Object Storage Service (OSS) data sources.
Configuration File Hyperparameters and Custom Parameters	Machine Learning Platform for AI Tensorflow allows you to use commands to pass in hyperparameter settings and try different learning rates and batch sizes during model testing.
Output Directory	The path of the output model.

- Tuning

  You can specify the number of GPUs based on the complexity of jobs.

PAI command

> **Note** You do not need to set all parameters. For the definitions of these parameters, see Parameters. We recommend that you do not directly copy the following command.

```
PAI -name tensorflow_ext140
-Dbuckets="oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/"
-DgpuRequired="100"
-Darn="acs:ram::166408185518****:role/aliyunodpspaidefaultrole"
-Dscript="oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist_ext.py";
```

The following table lists the descriptions of the parameters.

Parameters

Parameter	Description	Valid values	Default value
script	Required. The TF algorithm file. This file can be a single file or compressed as a tar.gz format package.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist_ext.py	N/A
entryFile	Optional. The name of the primary Python file. If the script is a compressed package in the tar.gz format, this parameter is required.	train.py	Null
buckets	Required. The input OSS buckets. You can specify multiple buckets separated with commas (,). Each bucket must end with a forward slash (/).	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/	Null
arn	Required. The Alibaba Cloud Resource Name (ARN) of an OSS object.	N/A	Null
gpuRequired	Required. This parameter indicates the number of GPUs to be used.	200	100
checkpointDir	Optional. The TF checkpoint directory.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/	Null
cluster	Optional.	A JSON format value. Quotation marks must be escaped.	Null

Parameter	Description	Valid values	Default value
hyperParameters	Optional. The path of the command line hyperparameters.	oss://imagenet.oss-cn-shanghai-internal.aliyuncs.com/smoke_tensorflow/mnist/hyper_parameters.txt	Null

- script and entryFile are used to specify the TF algorithm script to be executed. If the algorithm is complex and divided into multiple files, you can package the files into a tar.gz file and use entryFile to specify the primary Python file.
- checkpointDir is used to specify the OSS path to be written by algorithms. You must specify the OSS path when you save TensorFlow models.
- buckets is used to specify the OSS path to be read by algorithms. To use OSS, you must specify arn.
- Distributed Machine Learning Platform for AI TensorFlow supports cluster. You can use cluster to specify the number of parameter servers and workers. cluster is in JSON format, and the quotation marks must be escaped. The JSON code must contain two keys: ps and worker. Both the ps and worker parameters contain count, gpu, cpu, and memory.

Keyword	Description	Default value	Remarks
count	Required. The number of parameter servers or workers.	-	None
gpu	Optional. The number of GPUs allocated to each parameter server or worker. 100 represents a single GPU card.	For parameter servers, the default value is 0. For workers, the default value is 100.	If the number of GPUs allocated to each worker is set to 0, Machine Learning Platform for AI will reset the value to 100 to ensure the task is scheduled properly.
cpu	Optional. The number of CPUs allocated to each parameter server or worker. 100 represents a single CPU card.	600	None
memory	The memory size allocated to each parameter server or worker. 100 represents 100 MB.	30000	None

Examples

The MNIST digit classification set is a set of handwritten digits 1 through 9 that contains training and test sets for machine learning models.

1. Upload the Python execution files and training datasets to OSS. In this case, create a bucket on OSS in China (Shanghai) and name the bucket as tfmnist001. Upload the Python script and training data.
2. Drag and drop the **Read OSS Bucket** and **TensorFlow** components onto the canvas to create the following experiment. Set the region for the OSS bucket and configure RAM authorization.
3. Set the TensorFlow parameters. Set the paths for **Python Code Files**, **Primary Python File**, and **Data Source Directory**.

4. Click **Run** and wait for the experiment to complete running.
5. Right-click the **TensorFlow** component and view the running log.

4.1.5.2.8. Time series

4.1.5.2.8.1. x13_arima

Autoregressive Integrated Moving Average Model (ARIMA) is a well-known time series prediction method defined by Box and Jenkins in the early 1970s. This model is also called the Box-Jenkins model or the Box-Jenkins method. x13-arima is an ARIMA algorithm for seasonal adjustment based on the open-source X-13ARIMA-SEATS algorithm.

PAI command

```
pai -name x13_arima
    -project algo_public
    -DinputTableName=pai_ft_x13_arima_input
    -DseqColName=id
    -DvalueColName=number
    -Dorder=3,1,1
    -Dstart=1949.1
    -Dfrequency=12
    -Dseasonal=0,1,1
    -Dperiod=12
    -DpredictStep=12
    -DoutputPredictTableName=pai_ft_x13_arima_out_predict
    -DoutputDetailTableName=pai_ft_x13_arima_out_detail
```

Algorithm parameters

Parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
inputTablePartitions	Optional. The partitions selected from the input table for training, in the `partition_name=value` format. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
seqColName	Required. The name of the time series column.	Column name	This parameter is only used to sort the column specified by valueColName. The value does not affect the calculated results.

Parameter	Description	Valid value	Default value
valueColName	Required. The name of the value column.	Column name	N/A
groupColNames	Optional. The name of the stratification column. Separate multiple columns with commas (,), such as `col0,col1;`. A time series is created for each stratum.	Column name	N/A
order	Required. *p*, *d*, and *q* indicate the autoregressive coefficient, difference, and moving regression coefficient, respectively.	*p*, *d*, and *q* must be non-negative integers in the range of [0, 36].	N/A
start	Optional. The start date of a time series.	A string in the `year.seasonal` format, such as 1986.1 For more information, see the time series format section.	1.1
frequency	Optional. The frequency of a time series. Unit: months/year	A positive integer in the range of (0, 12) For more information, see the time series format section.	12
seasonal	Optional. *sp*, *sd*, and *sq* indicate the seasonal autoregressive coefficient, seasonal difference, and seasonal moving regression coefficient, respectively.	*sp*, *sd*, and *sq* must be non-negative integers in the range of [0, 36].	*seasonal* is not set by default.
period	Optional. The seasonal period.	A number in the range of (0, 100]	frequency
maxiter	Optional. The maximum number of iterations.	A positive integer	1500
tol	Optional. The degree of tolerance.	A double type value	1e-5
predictStep	Optional. The number of prediction items.	A number in the range of (0, 365]	12
confidenceLevel	Optional. The prediction confidence level.	A number in the range of (0, 1)	0.95

Parameter	Description	Valid value	Default value
outputPredictTableName	Required. The name of the output prediction table.	Table name	N/A
outputDetailTableName	Required. The name of the output detail table.	Table name	N/A
outputTablePartition	Optional. The partition in the output table.	Partition name	The output table is non-partitioned by default.
coreNum	Optional. The number of cores.	A positive integer used with memSizePerCore	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Time series format

- The start and frequency parameters specify the two time dimensions of data (valueColName): TS1 and TS2.
- The frequency parameter indicates the data frequency within a period, which equals the frequency of TS2 in each TS1.
- The start parameter must be in the `n1.n2` format. This indicates that the start date is the N2 TS2 in the N1 TS1.

Unit time	TS1	TS2	Frequency	Start date
12 months/year	Year	Month	12	1949.2 indicates the second month of year 1949.
Four quarters/year	Year	Quarter	4	1949.2 indicates the second quarter of year 1949.
Seven days/week	Day	Week	7	1949.2 indicates the second day of the1949th week.
1	Any time unit	1	1	1949.1 indicates the 1949th (year, day, or hour).

Example: value=[1,2,3,5,6,7,8,9,10,11,12,13,14,15]

- `start=1949.3` and `frequency=12` indicate that the data frequency is monthly, and the prediction start date is 1950.06.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1949			1	2	3	4	5	6	7	8	9	10
1950	11	12	13	14	15							

- `start=1949.3` and `frequency=4` indicate that the data frequency is quarterly, and the prediction start

date is 1953.02.

Year	Qtr1	Qtr2	Qtr3	Qtr4
1949			1	2
1950	3	4	5	6
1951	7	8	9	10
1952	11	12	13	14
1953	14			

- `start=1949.3` and `frequency=7` indicate that the data frequency is daily, and the prediction start date is 1951.04.

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1949			1	2	3	4	5
1950	6	7	8	9	10	11	12
1951	13	14	15				

- `start=1949.1` and `frequency=1` indicate that the prediction start date is 1963.00 regardless of the time unit used.

Cycle	p1
1949	1
1950	2

Examples

- Data used for testing: AirPassengers. The data set contains the number of passengers for international airlines each month from 1949 to 1960. It can be downloaded from https://stat.ethz.ch/R-manual/R-devel/library/datasets/html/AirPassengers.html .

```
create table pai_ft_x13_arima_input(id bigint,number bigint);
tunnel upload data/airpassengers.csv pai_ft_x13_arima_input -h true;
```

- PAI command

```
pai -name x13_arima
  -project algo_public
  -DinputTableName=pai_ft_x13_arima_input
  -DseqColName=id
  -DvalueColName=number
  -Dorder=3,1,1
  -Dseasonal=0,1,1
  -Dstart=1949.1
  -Dfrequency=12
  -Dperiod=12
  -DpredictStep=12
  -DoutputPredictTableName=pai_ft_x13_arima_out_predict
  -DoutputDetailTableName=pai_ft_x13_arima_out_detail
```

- Output description

- The columns of the output table specified by outputPredictTableName are as follows.

Column	Description
pdate	The prediction date.
forecast	The prediction result.
lower	The lower threshold of the prediction result when the confidence level is specified (default value: 0.95).
upper	The upper threshold of the prediction result when the confidence level is specified (default value: 0.95).

Output data

1	196101	444.445401291661	422.354385657496	466.536416925825

4.1.5.2.8.2. x13_auto_arima

ARIMA is described in x13_arima. The x13_auto_arima algorithm includes a process of automatic model selection.

The x13_auto_arima selection process is as follows:

- **Default model estimation**

  In the case of `frequency = 1`, the default model is `(0,1,1)`.

  In the case of `frequency > 1`, the default model is `(0,1,1)(0,1,1)`.

- **Identification of differencing orders**

  Skip this step if you have configured diff and SeasonalDiff.

  Use `Unit root test (wiki )` to determine the difference d and the seasonal difference D.

- **Identification of ARMA model orders**

  Select the optimal model based on BIC (wiki). The maxOrder and maxSeasonalOrder parameters are used in this step.

- **Comparison of identified model with default model**

  Use Ljung-Box Q statistic(wiki) to compare the models. If both models are unacceptable, use the `(3,d,1)(0,D,1)` model.

- **Final model checks**

PAI command

```
pai -name x13_auto_arima
    -project algo_public
    -DinputTableName=pai_ft_x13_arima_input
    -DseqColName=id
    -DvalueColName=number
    -Dstart=1949.1
    -Dfrequency=12
    -DpredictStep=12
    -DoutputPredictTableName=pai_ft_x13_arima_out_predict2
    -DoutputDetailTableName=pai_ft_x13_arima_out_detail2
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
seqColName	Required. The name of the time series column.	Column name	This parameter is only used to sort valueColNames. It is not relevant to the calculated output.
valueColName	Required. The name of the value column.	Column name	-

Parameter	Description	Valid values	Default value
groupColNames	Optional. The name of the stratification column. Separate multiple columns with commas (,), such as `col0,col1;`. A time series is created for each group.	Column name	-
start	Optional. The start date of a time series.	A string in the format of `year.seasonal`, such as 1986.1 For more information, see the time series format section.	1.1
frequency	Optional. The frequency of a time series.	A positive integer in the range of (0, 12) For more information, see the time series format section.	The frequency is 12 months/year by default.
maxOrder	Optional. The maximum values of p and q.	A positive integer in the range of [0, 4]	2
maxSeasonalOrder	Optional. The seasonal maximum values of p and q.	A positive integer in the range of [0, 2]	1
maxDiff	Optional. The maximum value of differential d.	A positive integer in the range of [0, 2]	2
maxSeasonalDiff	Optional. The maximum value of seasonal differential d.	A positive integer in the range of [0, 1]	1
diff	Optional. The differential d.	A positive integer in the range of [0, 2] If both diff and maxDiff are set, maxDiff is ignored. If diff is set, then seasonalDiff must also be set.	Default value: -1. This value indicates that diff is not specified by default.
seasonalDiff	Optional. The seasonal differential d.	A positive integer in the range of [0, 1] If both seasonalDiff and maxSeasonalDiff are set, maxSeasonalDiff is ignored.	Default value: -1. This value indicates that seasonalDiff is not specified by default.

Parameter	Description	Valid values	Default value
maxiter	Optional. The maximum number of iterations.	A positive integer	1500
tol	Optional. The degree of tolerance.	A double type value	1e-5
predictStep	Optional. The number of prediction items.	A number in the range of (0, 365]	12
confidenceLevel	Optional. The prediction confidence level.	A number in the range of (0, 1)	0.95
outputPredictTableName	Required. The name of the output prediction table.	Table name	-
outputDetailTableName	Required. The name of the output detail table.	Table name	-
outputTablePartition	Optional. The partitions in the output table.	Partition name	No partition is specified by default.
coreNum	Optional. The number of cores.	A positive integer used with memSizePerCore	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Time format

- The start and frequency parameters specify the two time dimensions of data (valueColName): TS1 and TS2.
- The frequency parameter indicates the data frequency within a period, which equals the frequency of TS2 in each TS1.
- The start parameter is in the format of `n1.n2`. This indicates that the start date is the N2 TS2 in the N1 TS1.

Unit time	ts1	ts2	Frequency	Start date
12	Year	Month	12	1949.2 indicates the second month of year 1949.
4	Year	Quarter	4	1949.2 indicates the second quarter of year 1949.
7	Day	Week	7	1949.2 indicates the second day of a week in year 1949.
1	Any time unit	1	1	1949.1 indicates the 1949th (year, day, or hour).

For example, value=[1,2,3,5,6,7,8,9,10,11,12,13,14,15].

- `start=1949.3` and `frequency=12` indicate that the data frequency is monthly, and the prediction start date is 1950.06.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1949			1	2	3	4	5	6	7	8	9	10
1950	11	12	13	14	15							

- `start=1949.3` and `frequency=4` indicate that the data frequency is quarterly, and the prediction start date is 1953.02.

Year	Qtr1	Qtr2	Qtr3	Qtr4
1949			1	2
1950	3	4	5	6
1951	7	8	9	10
1952	11	12	13	14
1953	14			

- `start=1949.3` and `frequency=7` indicate that the data frequency is daily, and the prediction start date is 1951.04.

Week	Sun	Mon	Tue	Wed	Thu	Fri	Sat
1949			1	2	3	4	5
1950	6	7	8	9	10	11	12
1951	13	14	15				

- `start=1949.1` and `frequency=1` indicate that the end date is 1963.00.

Period	p1
1949	1
1950	2
1951	3
1951	4
1952	5
1953	6
1954	7
1955	8
1956	9
1957	10

Period	p1
1958	11
1959	12
1960	13
1961	14
1962	15

Examples

- Data used for testing: AirPassengers. This data set contains the number of passengers for international airlines each month from 1949 to 1960. It can be downloaded from https://stat.ethz.ch/R-manual/R-devel/library/datasets/html/AirPassengers.html.

summary	Storage details.

4.1.5.2.9. Text analysis

4.1.5.2.9.1. Word splitting

Based on Alibaba Word Segmenter (AliWS), this component performs word splitting on documents specified by columns. Segmented words are separated with spaces. If you have set the part-of-speech (POS) tagging or semantic tagging parameters, the component outputs the word splitting results, POS tagging results, and semantic tagging results. Forward slashes `(/)` are used as delimiters for POS tagging. Vertical bars `(|)` are used as delimiters for semantic tagging. Only Chinese Taobao word segmentation and Internet word segmentation are supported.

Parameter settings

Word segmentation algorithms: CRF and UNIGRAM.

Parameters

Parameter	Description
Recognition Options	Specifies whether to recognize nouns with special meanings during word splitting.
Merge Options	Considers the terms used in certain industries as a whole without splitting.
Tokenizer	Allows you to select the Taobao word segmentation or Internet word segmentation. Taobao word segmentation is recommended.
Pos Tagger	Specifies whether to mark the part of speech for each word. If this parameter is specified, the part of speech for each word is marked in the output.

Examples

The following input table consists of the id column (document IDs) and the text column (document content).

PAI command

```
pai -name split_word
-project algo_public
-DinputTableName=doc_test
-DselectedColNames=content1,content2
-DoutputTableName=doc_test_split_word
-DinputTablePartitions="region=cctv_news"
-DoutputTablePartition="region=news"
-Dtokenizer=TAOBAO_CHN
-DenableDfa=true
-DenablePersonNameTagger=false
-DenableOrgnizationTagger=false
-DenablePosTagger=false
-DenableTelephoneRetrievalUnit=true
-DenableTimeRetrievalUnit=true
-DenableDateRetrievalUnit=true
-DenableNumberLetterRetrievalUnit=true
-DenableChnNumMerge=false
-DenableNumMerge=true
-DenableChnTimeMerge=false
-DenableChnDateMerge=false
-DenableSemanticTagger=true
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	The name of the input table.	-	-
selectedColNames	The names of the columns selected from the input table for word segmentation.	Separate multiple columns with commas (,).	-
outputTableName	The name of the output table.	-	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.
outputTablePartition	The partition in the output table.	-	The output table is non-partitioned by default.
tokenizer	The type of the classifier.	TAOBAO_CHN and INTERNET_CHN	Default value: TAOBAO_CHN. *TAOBAO_CHN* represents Taobao word segmentation. *INTERNET_CHN* represents Internet word segmentation.
enableDfa	Specifies whether to enable simple entity recognition.	true and false	true
enablePersonNameTagger	Specifies whether to enable personal name recognition.	true and false	false
enableOrgnizationTagger	Specifies whether to enable organization name recognition.	true and false	false
enablePosTagger	Specifies whether to enable part-of-speech tagging.	true and false	false
enableTelephoneRetrievalUnit	Specifies whether to enable retrieval unit configuration for telephone number recognition.	true and false	true
enableTimeRetrievalUnit	Specifies whether to enable retrieval unit configuration for time ID recognition.	true and false	true
enableDateRetrievalUnit	Specifies whether to enable retrieval unit configuration for date ID recognition.	true and false	true

Parameter	Description	Valid values	Default value
enableNumberLetterRetrievalUnit	Specifies whether to enable retrieval unit configuration for number and letter recognition.	true and false	true
enableChnNumMerge	Specifies whether to merge Chinese numbers into a retrieval unit.	true and false	false
enableNumMerge	Specifies whether to merge regular numbers into a retrieval unit.	true and false	true
enableChnTimeMerge	Specifies whether to merge Chinese time into a semantic unit.	true and false	false
enableChnDateMerge	Specifies whether to merge Chinese dates into a semantic unit.	true and false	false
enableSemanticTagger	Specifies whether to enable semantic tagging.	true and false	false

4.1.5.2.9.2. Deprecated word filtering

Deprecated word filtering is a preprocessing method in text analysis. This method is used to filter out the noise in word splitting results, such as of, yes, and ah.

Parameter settings

The left and right input ports are as follows:

- Input table, which is a word splitting result table for filtering. Parameter: inputTableName
- Deprecated word table, which is a one-column table with each row containing a deprecated word. Parameter: noiseTableName

PAI command

```
PAI -name FilterNoise
-project algo_public
-DinputTableName="test_input"
-DnoiseTableName="noise_input"
-DoutputTableName="test_output"
-DselectedColNames="words_seg1,words_seg2"
-Dlifecycle=30
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
noiseTableName	Required. The name of the deprecated word table.	A one-column table with each row containing a deprecated word	-
noiseTablePartitions	Optional. The partitions selected from the deprecated word table.	-	All partitions in the table are selected by default.
outputTableName	Required. The name of the output table.	-	-
selectedColNames	Required. The name of the column to be filtered. Separate multiple columns with commas (,).	-	-
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

4.1.5.2.9.3. String similarity

String similarity calculation is a basic operation in machine learning that is used in information retrieval, natural language processing, and bioinformatics. This algorithm supports five methods to calculate similarity: Levenshtein distance, longest common substring, string subsequence kernel, cosine, and simhash_hamming. It also supports two input methods: string-to-string calculation and top N calculation.

PAI command

```
PAI -name string_similarity
-project algo_public
-DinputTableName="pai_test_string_similarity"
-DoutputTableName="pai_test_string_similarity_output"
-DinputSelectedColName1="col0"
-DinputSelectedColName2="col1";
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
outputTableName	Required. The name of the output table.	-	-

Parameter	Description	Valid values	Default value
inputSelectedColName1	Optional. The name of the first column for similarity calculation.	-	By default, the first string type column in the table is selected.
inputSelectedColName2	Optional. The name of the second column for similarity calculation.	-	The second string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table.	-	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	The whole table is selected by default.
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein, levenshtein_sim, lcs, lcs_sim, ssk, cosine, simhash_hamming, simhash_hamming_sim, minhash_sim, and hash_jaccard_sim	levenshtein_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.

Parameter	Description	Valid values	Default value
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
create table pai_ft_string_similarity_input
as select * from
(select 0 as id, "Beijing" as col0,
"Beijing" as col1 from dual union all
select 1 as id,
"Beijing" as col0,
"Beijing Shanghai" as col1 from dual union all
select 2 as id,
"Beijing" as col0,
"Beijing Shanghai Hongkong" as col1 from dual )tmp;
```

- PAI command

```
PAI -name string_similarity
-project sre_mpi_algo_dev
-DinputTableName=pai_ft_string_similarity_input
-DoutputTableName=pai_ft_string_similarity_output
-DinputSelectedColName1=col0
-DinputSelectedColName2=col1
-Dmethod=simhash_hamming
-DinputAppendColNames=col0,col1;
```

- Output description
  - Output obtained by using the simhash_hamming method:

col0	col1	output
beijing	beijing	0
beijing	beijing shanghai	6
beijing	beijing shanghai xianggang	13

  - Output obtained by using the simhash_hamming_sim method:

col0	col1	output
beijing	beijing	1
beijing	beijing shanghai	0.90625
beijing	beijing shanghai xianggang	0.796875

4.1.5.2.9.4. Convert row, column, and value to KV pair

This component converts rows, columns, and values into KV pairs. A row, column, and value set is defined as XXD or XXL, where X can represent any type, D represents Double, and L represents Bigint. The row, column, and value set is converted into KV format (row,[col_id:value]). The row and value types are consistent with the original input data. The col_id type is Bigint, and the column is mapped to col_id based on the index table.

PAI command

```
PAI -name triple_to_kv
-project algo_public
-DinputTableName=test_data
-DoutputTableName=test_kv_out
-DindexOutputTableName=test_index_out
-DidColName=id
-DkeyColName=word
-DvalueColName=count
-DinputTablePartitions=ds=test1
-DindexInputTableName=test_index_input
-DindexInputKeyColName=word
-DindexInputKeyIdColName=word_id
-DkvDelimiter=:
-DpairDelimiter=;
-Dlifecycle=3
```

Parameters

Parameters

Parameter	Description	Default value
inputTableName	Required. The name of the input table.	The input table cannot be empty.
idColName	Required. The name of the column to be retained after the table is converted into a KV table.	-
keyColName	Required. The name of the key column in the KV table.	-
valueColName	Required. The name of the value column in the KV table.	-
outputTableName	Required. The name of the output KV table.	-
indexOutputTableName	Required. The name of the index table for the output keys.	-
indexInputTableName	Optional. The name of the input index table.	No index table is set by default. The table cannot be empty and it does not need to contain indexes for all of the output keys.
indexInputKeyColName	Optional. The name of the key column in the input index table.	No key column is specified by default. This parameter is required if indexInputTableName is set.
indexInputKeyIdColName	Optional. The name of the index column in the input index table.	No index column is specified by default. This parameter is required if indexInputTableName is set.
inputTablePartitions	Optional. The partitions in the input table.	No partition is specified by default. Only one partition can be input.

Parameter	Description	Default value
kvDelimiter	Optional. The delimiter used to separate the key and value.	The default delimiter is a colon (:).
pairDelimiter	Optional. The delimiter used to separate KV pairs.	The default delimiter is a semicolon (;).
lifecycle	Optional. The lifecycle of the output table.	No lifecycle is set by default.
coreNum	Optional. The number of cores.	-1
memSizePerCore	Optional. The memory size of each core. Valid values: 100 to 65536.	-1

Examples

- SQL statement to generate data:

```
drop table if exists triple2kv_test_input;
create table triple2kv_test_input as
select        *     from
(       select '01' as id, 'a' as word,
10 as count from dual         union all
select '01' as id, 'b' as word,
20 as count from dual         union all
select '01' as id, 'c' as word,

Input description

Input table

Input description

id	word	count
01	a	10

id	word	count
01	b	20
01	c	30

Output description

- The output KV table is as follows, where custom KV delimiters can be used.Output description

id	key_value
01	1:10;2:20;3:30

- The output index table that contains indexes for the words is as follows.Output index table

key	key_id
a	1
b	2
c	3

4.1.5.2.9.5. String similarity - Top N

String similarity calculation is a basic operation in machine learning that is used in information retrieval, natural language processing, and bioinformatics. This algorithm supports five methods to calculate similarity: Levenshtein distance, longest common substring, string subsequence kernel, cosine, and simhash_hamming. It also supports two input methods: string-to-string calculation and top N calculation.

PAI command

```
PAI -name string_similarity_topn
-project algo_public
-DinputTableName="pai_test_string_similarity_topn"
-DoutputTableName="pai_test_string_similarity_topn_output"
-DmapTableName="pai_test_string_similarity_map_topn"
-DinputSelectedColName="col0"
-DmapSelectedColName="col1";
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
mapTableName	Required. The name of the mapping table.	-	-
outputTableName	Required. The name of the output table.	-	-

Parameter	Description	Valid values	Default value
inputSelectedColName	Optional. The name of the column selected from the left table for similarity calculation.	-	The first string type column in the table is selected by default.
mapSelectedColName	Optional. The name of the column selected from the mapping table for similarity calculation. The similarities between each row in the left table and all strings in the mapping table are calculated, and the top N entries are output.	-	The first string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table from the input table.	-	No column is appended by default.
inputAppendRenameColNames	Optional. The aliases of columns appended to the output table from the input table. This parameter takes effect when inputAppendColNames is specified.	-	No alias is specified by default.
mapAppendColNames	Optional. The names of columns appended to the output table from the mapping table.	-	No column is appended by default.
mapAppendRenameColNames	Optional. The aliases of columns appended to the output table from the mapping table.	-	No alias is specified by default.
inputTablePartitions	Optional. The partitions selected from the input table.	-	The whole table is selected by default.
mapTablePartitions	Optional. The partitions in the mapping table.	-	The whole table is selected by default.
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output

Parameter	Description	Valid values	Default value
method	Optional. The similarity calculation method.	levenshtein_sim, lcs_sim, ssk, cosine, simhash_hamming_sim, minhash_sim, and hash_jaccard_sim	levenshtein_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0
topN	Optional. The number of similarity maximums to be output.	(0, +∞)	10
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
create table pai_ft_string_similarity_topn_input
as select * from
(select 0 as id,
"Beijing" as col0 from dual union all
select 1 as id,
"Beijing Shanghai" as col0 from dual union all
select 2 as id,
"Beijing Shanghai Hongkong" as col0 from dual )tmp;
```

- PAI command

```
PAI -name string_similarity_topn
-project sre_mpi_algo_dev
-DinputTableName=pai_ft_string_similarity_topn_input
-DmapTableName=pai_ft_string_similarity_topn_input
-DoutputTableName=pai_ft_string_similarity_topn_output
-DinputSelectedColName=col0
-DmapSelectedColName=col0
-DinputAppendColNames=col0
-DinputAppendRenameColNames=input_col0
-DmapAppendColNames=col0
-DmapAppendRenameColNames=map_col0
-Dmethod=simhash_hamming_sim;
```

- Output.

input_col0	map_col0	output
beijing	beijing	1
beiji beijing	beijing shanghai	0.90625
beijing	beijing shanghai xianggang	0.796875
beijing shanghai	beijing shanghai	1
beijing shanghai	beijing	0.90625
beijing shanghai	beijing shanghai xianggang	0.828125
beijing shanghai xianggang	beijing shanghai xianggang	1
beijing shanghai xianggang	beijing shanghai	0.828125
beijing shanghai xianggang	beijing	0.796875

4.1.5.2.9.6. N-gram counting

N-gram counting is a step in language model training. N-grams are generated based on words.The number of the corresponding N-grams in all corpora is counted. The N-gram counting model counts the number of N-grams in all documents rather than in a single document. For more information, see ngram-count.

PAI command

```
PAI -name ngram_count
    -project algo_public
    -DinputTableName=pai_ngram_input
    -DoutputTableName=pai_ngram_output
    -DinputSelectedColNames=col0
    -DweightColName=weight
    -DcoreNum=2
    -DmemSizePerCore=1000;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A

Parameter	Description	Valid values	Default value
inputSelectedColNames	Optional. The names of columns selected from the input table.	Column name	The first character type column is selected by default.
weightColName	Optional. The name of the weight column.	Column name	1
inputTablePartitions	Optional. The partitions selected from the input table.	Partition name	The whole table is selected by default.
countTableName	Optional. The name of the former N-gram counting output table. This table is merged into the output result.	Table name	N/A
countWordColName	Optional. The name of the word column in the counting table.	Column name	The second column is selected by default.
countCountColName	Optional. The name of the counting column in the counting table.	Column name	The third column is selected by default.
countTablePartitions	Optional. The partitions in the counting table.	Partition name	N/A
vocabTableName	Optional. The name of the bag-of-words table. The words that are not contained in the bag-of-words table are marked with \<unk\>.	Table name	N/A
vocabSelectedColName	Optional. The name of the bag-of-words column.	Column name	The first character type column is selected by default.
vocabTablePartitions	Optional. The partitions in the bag-of-words table.	Partition name	N/A
order	Optional. The maximum length of N-grams.	N/A	3
lifecycle	Optional. The lifecycle of the output table.	A positive integer	N/A
coreNum	Optional. The number of cores.	A positive integer	N/A
memSizePerCore	Optional. The memory size of each core.	A positive integer	N/A

4.1.5.2.9.7. Text summarization

Automatic summarization uses computers to automatically extract summaries from a source document. A summary is a simple, concise, and short document that completely and accurately describes the content of a certain document. This TextRank-based algorithm generates summaries by extracting existing sentences in the document.

PAI command

```
PAI -name TextSummarization
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DdocIdCol="doc_id"
-DsentenceCol="sentence"
-DtopN=2
-Dlifecycle=30;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	-	-
sentenceCol	Required. The sentence column.	Only one column can be specified.	-
topN	Optional. The top N key sentences to be output.	-	3
similarityType	Optional. The method used to calculate sentence similarity.	lcs_sim, levenshtein_sim, cosine, and ssk	lcs_sim
lambda	Optional. The weight of the matching string. This parameter takes effect when similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect when similarityType is set to ssk or cosine.	(0, 100)	2
dampingFactor	Optional. The damping factor.	(0, 1)	0.85

Parameter	Description	Valid values	Default value
maxIter	Optional. The maximum number of iterations.	[1, +]	100
epsilon	Optional. The convergence coefficient.	(0, ∞)	0.000001
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

The sentence similarity options are as follows:

- lcs_sim: The formula is `1.0 - (Length of the longest common subsequence)/max(len(A), len(B))` .
- levenshtein_sim: The formula is `1.0 - (Levenshtein distance)/max(len(A), len(B))` .
- cosine: See `Lodhi, Huma; Saunders, Craig; Shawe-Taylor, John; Cristianini, Nello; Watkins, Chris (2002). "Text classification using string kernels". Journal of Machine Learning Research: 419-444` .
- ssk: See `Leslie, C.; Eskin, E.; Noble, W.S. (2002), The spectrum kernel: A string kernel for SVM protein classification 7, pp. 566-575` .

> **Note** `A` and `B` indicate two strings, and `len(A)` indicates the length of string A.

Output format description

The output table contains the doc_id and abstract columns, as shown in Output table example.

Output table example

doc_id	abstract
1000894	In 2008, the Shanghai Stock Exchange published disclosure guidelines for the corporate social responsibility of listed companies. Three types of companies were urged to disclose their CSR reports, and other qualified listed companies were encouraged to voluntarily disclose their CSR reports. In 2012, a total of 379 listed companies making up a 40% of all listed companies disclosed CSR reports. Of those companies, 305 were mandated to disclose CSR reports and and 75 voluntarily disclosed CSR reports. According to Hu Ruyin, Shanghai Stock Exchange will explore how to expand the scope of CSR report disclosure, revise and refine the guidelines on disclosure of the CSR reports, and encourage more organizations to promote CSR product innovation.

4.1.5.2.9.8. Keyword extraction

Keyword extraction is one of the important technologies in natural language processing. It is used to extract keywords from a document. This algorithm is based on TextRank, a variation of the PageRank algorithm used to describe the relationship between webpages. This algorithm uses the relationship between certain words to construct a network, calculate the importance of each word, and determine words with larger weights as keywords.

PAI command

```
PAI -name KeywordsExtraction
-DinputTableName=maple_test_keywords_basic_input
-DdocIdCol=docid -DdocContent=word
-DoututTableName=maple_test_keywords_basic_output
-DtopN=19;
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	Only one column can be specified.	-
docContent	Required. The word column.	Only one column can be specified.	-
topN	Optional. The number of top N keywords to be output. If this number is smaller than the number of keywords, all keywords are output.	-	5
windowSize	Optional. The window size of the TextRank algorithm.	-	2
dumpingFactor	Optional. The damping factor of the TextRank algorithm.	-	0.85

Parameter	Description	Valid values	Default value
maxIter	Optional. The maximum number of iterations of the TextRank algorithm.	-	100
epsilon	Optional. The convergence residual threshold of the TextRank algorithm.	-	0.000001
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

The words in the input table are separated with spaces, and deprecated words and all punctuations are filtered out.

Examples

docid: string	word: string

docid: string	word: string
doc0	The blended-wing-body aircraft is a new direction for the future development in the aviation field Many research institutions inside and outside China have carried out research on the blended-wing-body aircraft while its fully automated shape optimization algorithm has become a new hot topic Based on the existing research achievements inside and outside China common modeling and flow solver tools have been analyzed and compared The geometric modeling grid flow field solver and shape optimization modules have been designed The pros and cons between different algorithms have been compared to achieve the optimized shape of the blended-wing-body aircraft in the conceptual design stage Geometric modeling and grid generation module are achieved based on the transfinite interpolation algorithm and spline based grid generation method The flow solver module includes the finite difference solver the finite element solver and the panel method solver The finite difference solver includes mathematical modeling of the potential flow the derivation of the Cartesian grid based variable step length difference scheme Cartesian grid generation and indexing algorithm the Cartesian grid based Neumann boundary conditions expression form derivation are achieved based on finite element difference solver The aerodynamic parameters of a two-dimensional airfoil are calculated based on the finite difference solver The finite element solver includes potential flow modeling based on the variational principle of the finite element theory the derivation of the two-dimensional finite element Kutta conditional least squares based speed solving algorithm Gmsh based two-dimensional field grid generator of airfoil with wakes design The aerodynamic parameters of a two-dimensional airfoil are calculated based on the finite element solver The panel method solver includes modeling and automatic wake generation the design of the three-dimensional flow solver of the blended-wing-body drag estimation based on the Blasius solution solver implemented in the Fortran language a mixed compilation of Python and Fortran OpenMP and CUDA based acceleration algorithm The aerodynamic parameters of a three-dimensional wing body are calculated based on the panel method solver The shape optimization module includes free form deformation algorithm genetic algorithms differential evolution algorithm Aircraft surface area calculation algorithm is based on the moments integration algorithm The volume of an aircraft calculation algorithm is based on VKT data visualization format tool

4.1.5.2.9.9. Sentence splitting

You can split sentences in a document by punctuation. This component is used to preprocess text summarizations. It splits text such that each row contains only a single sentence.

PAI command

```
PAI -name SplitSentences
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DdocIdCol="doc_id"
-DdocContent="content"
-Dlifecycle=30
```

Parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
docIdCol	Required. The name of the document ID column.	-	-
docContent	Required. The name of the document content column.	Only one column can be specified.	-
delimiter	Optional. A set of characters used to determine the end of a sentence.	-	The default delimiter set contains the period (.), question mark (!), and exclamation mark (?).
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Output format description

The output table contains the doc_id and sentence columns, as shown in Output table example.

Output table example

doc_id	sentence
1000894	In 2008, the Shanghai Stock Exchange published disclosure guidelines for the corporate social responsibility of listed companies. Three types of companies were urged to disclose their CSR reports, and other qualified listed companies were encouraged to voluntarily disclose their CSR reports.
1000894	In 2012, a total of 379 listed companies making up a 40% of all listed companies disclosed CSR reports. Of those companies, 305 were mandated to disclose CSR reports and and 75 voluntarily disclosed CSR reports.

4.1.5.2.9.10. Semantic vector distance

You can calculate the extension words or sentences of the specified words or sentences based on the calculated semantic vectors, such as word vectors calculated by the Word2Vec component. The extension words or sentences are a set of vectors closest to a certain vector. The following example shows how to generate a list of words that are most similar to the word that you entered based on the word vectors calculated by the Word2Vec component.

PAI command

```
PAI -name SemanticVectorDistance
-project algo_public
-DinputTableName="test_input"
-DoutputTableName="test_output"
-DidColName="word"
-DvectorColNames="f0,f1,f2,f3,f4,f5"
-Dlifecycle=30
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for calculation.	-	All partitions in the input table are selected by default.
outputTableName	Required. The name of the output table.	-	-
idTableName	Optional. The name of the vector ID table for vector calculation. The table contains only one column and each row stores a vector ID.	-	No vector ID table is specified by default. This means that all vectors in the input table are calculated.
idTablePartitions	Optional. The partitions selected from the ID table for calculation.	-	All partitions are selected by default.
idColName	Required. The name of the ID column.	-	3
vectorColNames	Optional. A list of vector column names, such as f1, f2,...	-	-
topN	Optional. The number of the closest vectors to output.	[1, +∞]	5
distanceType	Optional. The distance calculation method.	euclidean, cosine, and manhattan	euclidean

Parameter	Description	Valid values	Default value
distanceThreshold	Optional. The distance threshold. Only the distances between two vectors that do not exceed this threshold are output.	(0, +∞)	∞
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core.	A positive integer	Automatically calculated.

Examples

The output table contains the original_id, near_id, distance, and rank columns.

original_id	near_id	distance	rank
hello	hi	0.2	1
hello	xxx	xx	2
Man	Woman	0.3	1
Man	xx	xx	2
..	...	...	...

4.1.5.2.9.11. Document similarity

This algorithm calculates the similarity between two text documents by comparing the similarities of documents or sentences separated by spaces. This algorithms functions similar to how the similarity of strings is calculated.

PAI command

```
PAI -name doc_similarity
-project algo_public
-DinputTableName="pai_test_doc_similarity"
-DoutputTableName="pai_test_doc_similarity_output"
-DinputSelectedColName1="col0"
-DinputSelectedColName2="col1"
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	-	-

Parameter	Description	Valid values	Default value
outputTableName	Required. The name of the output table.	-	-
inputSelectedColName1	Optional. The name of the first column for similarity calculation.	-	By default, the first string type column in the table is selected.
inputSelectedColName2	Optional. The name of the second column for similarity calculation.	-	The name of the second string type column in the table is selected by default.
inputAppendColNames	Optional. The names of columns appended to the output table.	-	No column is appended by default.
inputTablePartitions	Optional. The partitions selected from the input table.	-	The whole table is selected by default.
outputColName	Optional. The name of the similarity column in the output table. The column name can be up to 128 characters in length and can contain letters, digits, and underscores (_). It must start with a letter.	-	output
method	Optional. The similarity calculation method.	levenshtein, levenshtein_sim, lcs, lcs_sim, ssk, cosine, simhash_hamming, and simhash_hamming_sim	levenshtein_sim
lambda	Optional. The weight of the matching word pair. This parameter takes effect if similarityType is set to ssk.	(0, 1)	0.5
k	Optional. The length of the substring. This parameter takes effect if similarityType is set to ssk or cosine.	(0, 100)	2
kVec	Optional. The number of MinHash instances.	A positive integer	2
b	Optional. The number of buckets.	A positive integer	1
seed	Optional. The random seed used in a MinHash instance.	A positive integer	0

Parameter	Description	Valid values	Default value
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	A positive integer	Automatically calculated.
memSizePerCore	Optional. The memory size of each core. Unit: MB.	A positive integer in the range of (0, 65536)	Automatically calculated.

Examples

- SQL statement to generate data:

```
drop table if exists pai_doc_similarity_input;
create table pai_doc_similarity_input as
select * from  (
select 0 as id,
"Beijing and Shanghai" as col0,
"Beijing and Shanghai" as col1 from dual union all
select 1 as id,
"Beijing and Shanghai" as col0,
"Beijing, Shanghai, and Hong Kong" as col1 from dual )tmp;
```

- PAI command

```
drop table if exists pai_doc_similarity_output;
PAI -name doc_similarity
-project algo_public
-DinputTableName=pai_doc_similarity_input
-DoutputTableName=pai_doc_similarity_output
-DinputSelectedColName1=col0
-DinputSelectedColName2=col1
-Dmethod=levenshtein_sim
-DinputAppendColNames=id,col0,col1;
```

- Input description: pai_doc_similarity_input

ID	col0	col1
1	Beijing and Shanghai	Beijing, Shanghai, and Hong Kong
0	Beijing and Shanghai	Beijing and Shanghai

- Output description: pai_doc_similarity_output

ID	col0	col1	Output
1	Beijing and Shanghai	Beijing, Shanghai, and Hong Kong	0.6666666666666667
0	Beijing and Shanghai	Beijing and Shanghai	1.0

4.1.5.2.9.12. PMI

Mutual information (MI) is a measure of information in the information theory. It can be regarded as the amount of information contained in a random variable about another variable, or the reduction in uncertainty of a random variable due to the known random variable.

This algorithm is used to count the co-occurrence of all words in several documents and calculate the point mutual information (PMI). PMI definition: `PMI(x,y)=ln(p(x,y)/(p(x)p(y)))=ln(#(x,y)D/(#x#y))`.

- `#(x,y)` indicates the number of pair(x,y).
- D indicates the total number of pairs.
- If x and y appear in the same window, the output is #x+=1;#y+=1;#(x,y)+=1.

PAI command

```
PAI -name PointwiseMutualInformation
    -project algo_public
    -DinputTableName=maple_test_pmi_basic_input
    -DdocColName=doc
    -DoutputTableName=maple_test_pmi_basic_output
    -DminCount=0
    -DwindowSize=2
    -DcoreNum=1
    -DmemSizePerCore=110;
```

Parameters

Parameter	Description	Valid values	Default value
inputTableName	Required. The name of the input table.	Table name	-
outputTableName	Required. The name of the output table.	Table name	-
docColName	Required. The name of the document column after word splitting, where words are separated with spaces.	Column name	-
windowSize	Optional. The window size. For example, the value 5 refers to the five words adjacent on the right of the current word. Words that appear in the window are considered related to the current word.	[1, sentence length]	The whole row is selected by default.
minCount	The minimum word truncation frequency. Words that appear for a number of times less than this value are filtered out.	[0, 2e63]	5

Parameter	Description	Valid values	Default value
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Partition name	All partitions are selected by default.
lifecycle	Optional. The lifecycle of the output table.	A positive integer	No lifecycle is set by default.
coreNum	Optional. The number of cores.	This parameter is used with memSizePerCore. The value must be a positive integer in the range of [1, 9999].	Automatically calculated.
memSizePerCore	The memory size of each core. Unit: MB.	A positive integer in the range of [1024, 65536]	Automatically calculated.

Examples

4.1.5.2.9.13. Word frequency statistics

Based on the word splitting results, this component outputs the words in their original order and calculates the frequency that a word occurs in the document (docContent) specified by the document ID column (docId).

Parameter settings

Input parameters: docId column and docContent column generated by the Word Splitting component.

Two output parameters:

- Output port 1: The output table contains the id, word, and count columns.

  count: indicates the frequency that a word occurs in each document.
- Output port 2: The output table contains the id and word columns.

  The table output by the second output port lists words in order of occurrence in the document. The table does not calculate the frequency of the occurrence. Therefore, a word may have multiple table entries in the same document. The output table format is compatible with the Word2Vec component.

Examples

In the Alibaba Cloud word splitting data, the two columns in the output table are used as the input parameters for word frequency calculation.

- Select the docId column: id.
- Select the docContent column: After the word frequency calculation is performed, the result is displayed by output port 1 on this component.

PAI command

```
pai -name doc_word_stat
-project algo_public
-DinputTableName=doc_test_split_word
-DdocId=id
-DdocContent=content
-DoutputTableNameMulti=doc_test_stat_multi
-DoutputTableNameTriple=doc_test_stat_triple
-DinputTablePartitions="region=cctv_news"
```

Algorithm parameters

Parameters

Parameter	Description	Valid values	Default value
inputTableName	The name of the input table.	-	-
docId	The name of the document ID column.	Only one column can be specified.	-
docContent	The name of the document content column.	Only one column can be specified.	-
outputTableNameMulti	The name of the output table that lists words in the document content after word splitting. Documents are specified by the docId column and their contents are specified by the docContent column. The words are listed in the order that they occur within the documents.	-	-
outputTableNameTriple	The name of the output table that lists the words and the frequency of the occurrence of these words in the documents. The documents are specified by the docId column and their contents are specified by the docContent column.	-	-
inputTablePartitions	Optional. The partitions selected from the input table for training, in the format of `partition_name=value`. To specify multiple partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	-	All partitions in the input table are selected by default.

4.1.5.2.9.14. TF-IDF

Term Frequency-Inverse Document Frequency (TF-IDF) is a common weighting technique for information retrieval and text mining. TF-IDF is used by search engines as a tool in scoring and ranking the relevance of a document for a given search query.

TF-IDF is also a statistical method to evaluate the importance of a word for a document in a collection or corpus. The importance of a word increases as the frequency that it occurs within the document increases. The importance decreases as the frequency that the word occurs in the corpus increases. The TF-IDF component is used to calculate the TF-IDF value of each word that appears in a collection of documents based on word frequency statistics.

Example

The output table in the example of the Word Frequency Statistics component is used as the input table for the TF-IDF component. Set the following parameters for the TF-IDF component.

- Document ID Column: id
- Word Column: word
- Word Counting Column: count

The output table contains the following columns: docid, word, word_count, total_word_count, doc_count, total_doc_count, tf, idf, and tfidf. word_count indicates the number of times a word appears in a document. total_word_count indicates the total number of words in a document. doc_count indicates the number of documents that contain a word. total_doc_count indicates the total number of documents.

PAI command

You can run the following PAI command to use the component:

```
pai -name tfidf
-project algo_public
-DinputTableName=rgdoc_split_triple_out
-DdocIdCol=id
-DwordCol=word
-DcountCol=count
-DoutputTableName=rg_tfidf_out;
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameter	Description	Valid value	Required/Default value
inputTableName	The name of the input table.	Table name	Required.
inputTablePartitions	The partitions that are selected from the input table for word splitting.	This value must be in the `partition_name=value` format. If you want to specify multiple levels of partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Optional. By default, all partitions in the input table are selected.
docIdCol	The name of the document ID column.	Only one column can be specified.	Required.
wordCol	The name of the word column.	Only one column can be specified.	Required.

Parameter	Description	Valid value	Required/Default value
countCol	The name of the count column.	Only one column can be specified.	Required.
outputTableName	The name of the output table.	Table name	Required.
outputTablePartition	The partitions in the output table.	Partition name	Optional. By default, the output table is non-partitioned.

4.1.5.2.9.15. PLDA

Latent Dirichlet allocation (LDA) is a topic model that provides topics of each document based on probability distribution. LDA is an unsupervised learning algorithm. You need only to specify the number of topics in a document set by using K. You do not need to manually annotate training sets. K is the Topics parameter of the PLDA component. LDA is used to recognize texts, classify texts, and calculate the similarity between texts in the text mining field.

Input parameters

The following figure shows the parameters of the PLDA component on the Parameters Setting tab. The following table describes the parameters.

Parameter	Description
Topics	The number of topics that are generated by LDA.
Alpha	The prior Dirichlet distribution parameter of `P(z/d)`.
Beta	The prior Dirichlet distribution parameter of `P(w/z)`.
Burn-in Iterations	The number of burn-in iterations. The parameter value must be less than the total number of iterations. The default value is 100.
Total Iterations	Optional. The total number of iterations. The value must be a positive integer. Default value: 150.

Note z represents topics, w represents words, and d represents documents.

Input and output settings

- **Input**:

  The data must be sparse arrays and can be converted by using the Convert Row, Column, and Value to KV Pair component.

  The following figure shows the input format.

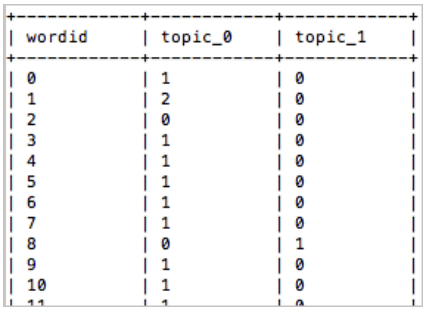
```
| id          | features |
+-------------+----------+
| 2           | 38:3.0,39:1.0,40:3.0,41:1.0,42:1.0,43:2.0,44:1.0,45:1.0,46:1.0,47:1.0,48:1.0,49:2.0,50:1.0,51:1.0,52:1.0,53:1.0,54:1.0,55:1.0,5
6:1.0,57:1.0,58:1.0,59:1.0,60:1.0,61:1.0,62:1.0,63:1.0,64:1.0,65:1.0,66:1.0,67:1.0,68:1.0,69:1.0,70:1.0,71:1.0,72:1.0,73:1.0,74:1.0,75:1.0,76:
1.0,77:2.0 |
| 1           | 0:1.0,1:2.0,3:1.0,4:1.0,5:1.0,6:1.0,7:1.0,8:1.0,9:1.0,10:1.0,11:1.0,12:1.0,13:1.0,14:2.0,15:1.0,16:1.0,17:1.0,18:1.0,19:1.0,20:
1.0,21:1.0,22:1.0,23:1.0,24:1.0,25:1.0,26:1.0,27:1.0,28:1.0,29:1.0,30:1.0,31:1.0,32:1.0,33:1.0,34:1.0,35:1.0,36:2.0,39:2.0,77:3.0 |
+-------------+----------+
```

  - Column 1: the ID of a document.
  - Column 2: key-value data of words and word frequencies.

- **Output**:

  The following tables are generated in sequence: topic-word frequency contribution table, P(w/z) table, P(z/w) table, P(d/z) table, P(z/d) table, and P(z) table.

  The following figure shows the output format of the topic-word frequency contribution table.



wordid	topic_0	topic_1
0	1	0
1	2	0
2	0	0
3	1	0
4	1	0
5	1	0
6	1	0
7	1	0
8	0	1
9	1	0
10	1	0

PAI command

You can run the following PAI command to use the component:

```
pai -name PLDA
-project algo_public
-DinputTableName=lda_input
-DtopicNum=10
-topicWordTableName=lda_output;
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameter	Description	Valid value	Required/Default value
inputTableName	The name of the input table.	Table name	Required.
inputTablePartitions	The partitions that are selected from the input table for word splitting.	This value must be in the `partition_name=value` format. If you want to specify multiple levels of partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Optional. By default, all partitions in the input table are selected.
selectedColNames	The names of the columns that are selected from the input table for LDA.	Separate column names with commas (,).	Optional. By default, all columns in the input table are selected.
topicNum	The number of topics.	[2, 500]	Required.
kvDelimiter	The delimiter that is used to separate keys and values.	Space, comma (,), colon (:)	Optional. Default value: colon (:).
itemDelimiter	The delimiter that is used to separate keys.	Space, comma (,), colon (:)	Optional. By default, keys are separated by spaces.

Parameter	Description	Valid value	Required/Default value
alpha	The prior Dirichlet distribution parameter of P(z/d).	(0, ∞)	Optional. Default value: 0.1.
beta	The prior Dirichlet distribution parameter of P(w/z).	(0, ∞)	Optional. Default value: 0.01.
topicWordTableName	The name of the topic-word frequency contribution table.	Table name	Required.
pwzTableName	The name of the P(w/z) table.	Table name	Optional. By default, no P(w/z) table is generated.
pzwTableName	The name of the P(z/w) table.	Table name	Optional. By default, no P(z/w) table is generated.
pdzTableName	The name of the P(d/z) table.	Table name	Optional. By default, no P(d/z) table is generated.
pzdTableName	The name of the P(z/d) table.	Table name	Optional. By default, no P(z/d) table is generated.
pzTableName	The name of the P(z) table.	Table name	Optional. By default, no P(z) table is generated.
burnInIterations	The number of burn-in iterations.	Positive integer	Optional. This value must be smaller than the total number of iterations. Default value is 100.
totalIterations	The number of iterations.	Positive integer	Optional. Default value: 150.

4.1.5.2.9.16. Word2Vec

Word2Vec is an open-source algorithm used to convert words into vectors. The Word2Vec component uses a neural network to map words to vectors in the K-dimensional space based on extensive training. The component supports operations on the vectors to show the semantics of the vectors.

For more information about the tool kit provided by Google Word2Vec, see word2vec.

Input parameters

The Word2Vec component has the following core settings:

- Word Feature Dimension: We recommend that you specify a value from 0 to 1000.
- Downsampling Threshold: We recommend that you specify a value from 1e-3 to 1e-5.
- Input: uses a word column and a word list as the input data.
- Output: generates a word vector table and a word list.

PAI command

You can run the following PAI command to use the component:

```
pai -name Word2Vec
-project algo_public
-DinputTableName=w2v_input
-DwordColName=word
-DoutputTableName=w2v_output;
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameters

Parameter	Description	Valid value	Required/Default value
inputTableName	The name of the input table.	Table name	Required.
inputTablePartitions	The partitions that are selected from the input table for word splitting.	This value must be in the `partition_name=value` format. If you want to specify multiple levels of partitions, use the following format: `name1=value1/name2=value2`. Separate multiple partitions with commas (,).	Optional. By default, all partitions in the input table are selected.
wordColName	The name of the word column. Each row in the word column contains a single word. `</s>` is used to break lines in the corpus.	Column name	Required.
inVocabularyTableName	The name of the input word list, which contains the wordcount output of inputTableName.	Table name	Optional. By default, word count is performed for the input table.
inVocabularyPartitions	The partitions in the input word list.	Partition name	Optional. By default, all partitions in the table specified by inVocabularyTableName are selected.
layerSize	The dimension of word features.	0-1000	Optional. Default value: 100.
cbow	The language model.	1: cbow 0: skip-gram	Optional. Default value: 0.
window	The window size of words.	Positive integer	Optional. Default value: 5.
minCount	The minimum frequency of words.	Positive integer	Optional. Default value: 5.

Parameter	Description	Valid value	Required/Default value
hs	Specifies whether to use hierarchical softmax.	1: Hierarchical softmax is used. 0: Hierarchical softmax is not used.	Optional. Default value: 1.
negative	NEGATIVE SAMPLING	0: Negative sampling is disabled. Recommended value range: 5 to 10.	Optional. Default value: 0.
sample	The downsampling threshold.	0 or smaller values: Downward sampling is disabled. Recommended value range: 1e-3 to 1e-5.	Optional. Default value: 0.
alpha	The initial learning rate.	A value greater than 0	Optional. Default value: 0.025.
iterTrain	The number of training iterations.	A value greater than or equal to 1	Optional. Default value: 1.
randomWindow	Specifies whether to randomly set the size of the window.	1: The window size is randomly generated in a range from 1 to 5. 0: The window size is determined by the window parameter.	Optional. Default value: 1.
outVocabularyTableName	Optional. The name of the output word list.	Table name	Optional. By default, the **output word list** is generated.
outVocabularyPartition	The partition in the output word list.	Partition name	Optional. By default, the output word list is non-partitioned.
outputTableName	Output table	Table name	Required.
outputPartition	The information about partitions in the output table.	Partition name	Optional. By default, the output table is non-partitioned.

4.1.5.2.10. Network analysis

4.1.5.2.10.1. K-Core

The k-core of a graph is the subgraph that remains after all vertices with a degree less than or equal to K are removed. If a vertex belongs to the k-core but is not included in the (k+1)-core, the coreness of the vertex is k. Therefore, the coreness of a vertex whose degree is 1 must be 0. The largest coreness among the corenesses of all vertices is considered to be the coreness of the graph.

Input parameters

The core parameter k of the K-Core component specifies the coreness. This parameter is required. The default value is 3.

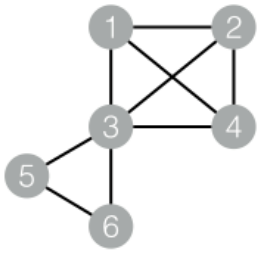
Sample test data

Execute the following SQL statements to generate test data:

```
drop table if exists KCore_func_test_edge;
create table KCore_func_test_edge as
select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '1' as flow_out_id,
'3' as flow_in_id from dual   union all
select '1' as flow_out_id,
'4' as flow_in_id from dual   union all
select '2' as flow_out_id,
'3' as flow_in_id from dual   union all
select '2' as flow_out_id,
'4' as flow_in_id from dual   union all
select '3' as flow_out_id,
'4' as flow_in_id from dual   union all
select '3' as flow_out_id,
'5' as flow_in_id from dual   union all
select '3' as flow_out_id,
'6' as flow_in_id from dual   union all
select '5' as flow_out_id,
'6' as flow_in_id from dual )tmp;
```

The Graph structure figure shows the graph structure of the test data.

Graph structure



Set the k parameter to 2. The Output figure shows the output.

Output

node1	node2
1	2
1	3
1	4
2	1
2	3
2	4
3	1
3	2
3	4
4	1
4	2
4	3

PAI command

You can run the following PAI command to use the component:

```
pai -name KCore
-project algo_public
-DinputEdgeTableName=KCore_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=KCore_func_test_result
-Dk=2;
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	All partitions
fromVertexCol	The start vertex column in the edge table.	Yes	N/A
toVertexCol	The end vertex column in the edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of processes.	No	N/A
workerMem	The memory size of each process. Unit: MB.	No	4096
splitSize	The size of each part after data is split. Unit: MB.	No	64
k	The coreness.	Yes	3

4.1.5.2.10.2. Single-source Shortest Path

The single-source shortest path (SSSP) refers to the shortest path between a vertex and all other vertices. The shortest path is calculated by using the Dijkstra algorithm.

Parameter settings

The core parameter of the Single-source Shortest Path component is Start Vertex ID. You must set this parameter to specify the start vertex that is used to calculate the shortest path.

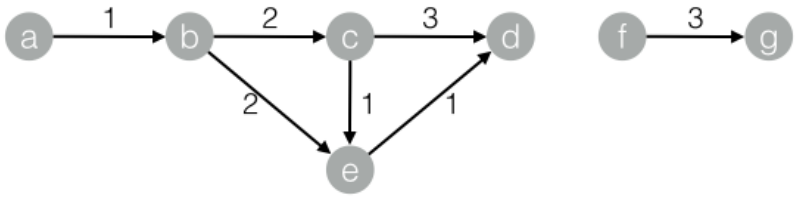
Sample test data

Execute the following SQL statements to generate test data:

```
drop table if exists SSSP_func_test_edge;
create table SSSP_func_test_edge
as select
flow_out_id,flow_in_id,edge_weight from (
select "a" as flow_out_id,
"b" as flow_in_id,
1.0 as edge_weight from dual     union all
select "b" as flow_out_id,
"c" as flow_in_id,
2.0 as edge_weight from dual     union all
select "c" as flow_out_id,
"d" as flow_in_id,
1.0 as edge_weight from dual     union all
select "b" as flow_out_id,
"e" as flow_in_id,
2.0 as edge_weight from dual     union all
select "e" as flow_out_id,
"d" as flow_in_id,
1.0 as edge_weight from dual     union all
select "c" as flow_out_id,
"e" as flow_in_id,
1.0 as edge_weight from dual     union all
select "f" as flow_out_id,
"g" as flow_in_id,
3.0 as edge_weight from dual     union all
select "a" as flow_out_id,
"d" as flow_in_id,
4.0 as edge_weight from dual ) tmp ;
```

The Graph structure figure shows the graph structure of the test data.

Graph structure



Output

The following figure shows the output of the Single-source Shortest Path component that is run based on the preceding test data.

start_node	dest_node	distance	distance_cnt
a	b	1.0	1
a	c	3.0	1
a	d	4.0	3
a	a	0.0	0
a	e	3.0	1

PAI command

You can run the following PAI command to use the component:

```
pai -name SSSP
-project algo_public
-DinputEdgeTableName=SSSP_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=SSSP_func_test_result
-DhasEdgeWeight=true
-DedgeWeightCol=edge_weight
-DstartVertex=a;
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	All partitions
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of processes.	No	N/A
workerMem	The memory size of each process. Unit: MB.	No	4096
splitSize	The size of each part after data is split. Unit: MB.	No	64
startVertex	The ID of the start vertex.	Yes	N/A
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	N/A

4.1.5.2.10.3. Page Rank

PageRank is an algorithm that is used to sort and calculate the rankings of web pages based on their links.

Introduction

The PageRank algorithm implements ranking based on the following principle: The more links that direct to a web page, the more importance or higher quality the web page has. In addition to the number of links directing to a web page, the weight of the web page and the number of outgoing links are also considered during page ranking. For a social network of users, the edge weight is an important factor in addition to the influence of the users. For example, a Sina Weibo user is more likely to have an influence on their family, friends, classmates, and colleagues than they will on followers with a weaker relationship. In the social network, the edge weight is equivalent to the user-to-user relationship strength index. The following picture shows the PageRank formula with the link weight.

$$W(A) = (1 - d) + d * (\sum_{i} W(i) * C(Ai))$$

In the formula, W(i) indicates the weight of Node i, C(Ai) indicates the link weight, and d indicates the damping coefficient. W(A) indicates the influence index of each user and represents the node weight after the algorithm iteration becomes stable.

Input parameters

The core parameter of the Page Rank component is **Maximum Iterations**. You can use this parameter to specify the number of iterations before the algorithm automatically converges. The default value is 30 and this parameter is optional.

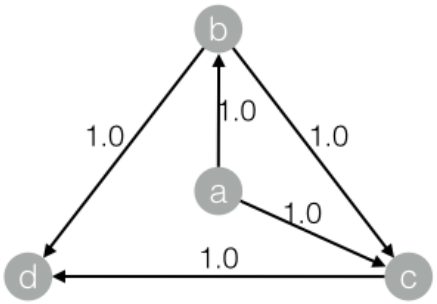
Sample test data

You can execute the following SQL statements to generate test data:

```
drop table if exists PageRankWithWeight_func_test_edge;
create table PageRankWithWeight_func_test_edge
as select * from (
select 'a' as flow_out_id,
'b' as flow_in_id,
1.0 as weight from dual     union all
select 'a' as flow_out_id,
'c' as flow_in_id,
1.0 as weight from dual     union all
select 'b' as flow_out_id,
'c' as flow_in_id,
1.0 as weight from dual     union all
select 'b' as flow_out_id,
'd' as flow_in_id,
1.0 as weight from dual     union all
select 'c' as flow_out_id,
'd' as flow_in_id,1.0 as weight from dual )tmp ;
```

The Graph structure figure shows the graph structure of the test data.

Graph structure



Output

The following figure shows the output of the Page Rank component that is run based on the preceding test data.

node	weight
a	0.0375
b	0.06938
c	0.12834
d	0.20556

PAI command

You can run the following PAI command to use the component:

```
pai -name PageRankWithWeight
-project algo_public
-DinputEdgeTableName=PageRankWithWeight_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=PageRankWithWeight_func_test_result
-DhasEdgeWeight=true
-DedgeWeightCol=weight
-DmaxIter 100;
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	All partitions
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A

Parameter	Description	Required	Default value
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of processes.	No	N/A
workerMem	The memory size of each process. Unit: MB.	No	4096
splitSize	The size of each part after data is split. Unit: MB.	No	64
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	N/A
maxIter	The maximum number of iterations.	No	30

4.1.5.2.10.4. Label propagation clustering

Graph clustering is used to divide a graph into subgraphs based on the topology of the graph so that the links between the nodes in a subgraph are more than the links between the subgraphs. The label propagation algorithm (LPA) is a graph-based semi-supervised machine learning algorithm. The labels of a node (community) depend on those of the neighboring nodes. The degree of dependence is determined by the similarity between nodes. Data becomes stable by iterative propagation updates.

Parameter settings

The core parameter of this component is maxIter, which indicates the maximum number of iterations. This parameter is optional. Default value: 30.

Examples - Testing data

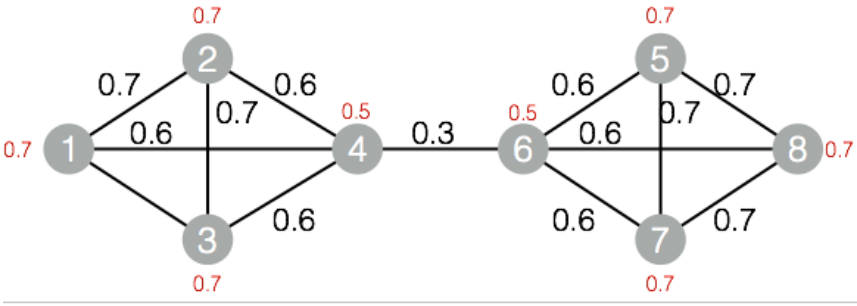
Execute the following SQL statements to generate testing data:

```
drop table if exists LabelPropagationClustering_func_test_edge;
create table LabelPropagationClustering_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id,
0.7 as edge_weight from dual     union all
select '1' as flow_out_id,
'3' as flow_in_id,
0.7 as edge_weight from dual     union all
select '1' as flow_out_id,
'4' as flow_in_id,
0.6 as edge_weight from dual     union all
select '2' as flow_out_id,
```

```
'3' as flow_in_id,
0.7 as edge_weight from dual     union all
select '2' as flow_out_id,
'4' as flow_in_id,
0.6 as edge_weight from dual     union all
select '3' as flow_out_id,
'4' as flow_in_id,
0.6 as edge_weight from dual     union all
select '4' as flow_out_id,
'6' as flow_in_id,
0.3 as edge_weight from dual     union all
select '5' as flow_out_id,
'6' as flow_in_id,
0.6 as edge_weight from dual     union all
select '5' as flow_out_id,
'7' as flow_in_id,
0.7 as edge_weight from dual     union all
select '5' as flow_out_id,
'8' as flow_in_id,
0.7 as edge_weight from dual     union all
select '6' as flow_out_id,
'7' as flow_in_id,
0.6 as edge_weight from dual     union all
select '6' as flow_out_id,
'8' as flow_in_id,
0.6 as edge_weight from dual     union all
select '7' as flow_out_id,
'8' as flow_in_id,
0.7 as edge_weight from dual )tmp ;
drop table if exists LabelPropagationClustering_func_test_node;
create table LabelPropagationClustering_func_test_node
as select * from (
select '1' as node,
0.7 as node_weight from dual     union all
select '2' as node,
0.7 as node_weight from dual     union all
select '3' as node,
0.7 as node_weight from dual     union all
select '4' as node,
0.5 as node_weight from dual     union all
select '5' as node,
0.7 as node_weight from dual     union all
select '6' as node,
0.5 as node_weight from dual     union all
select '7' as node,
0.7 as node_weight from dual     union all
select '8' as node,
0.7 as node_weight from dual )tmp ;
```

Group structure shows the group structure.

Group structure



Output

The following figure shows the output based on the testing data.

node	group_id
1	1
2	1
3	1
4	1
5	5
6	5
7	5
8	5

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use this component:

```
pai -name LabelPropagationClustering
-project algo_public
-DinputEdgeTableName=LabelPropagationClustering_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DinputVertexTableName=LabelPropagationClustering_func_test_node
-DvertexCol=node
-DoutputTableName=LabelPropagationClustering_func_test_result
-DhasEdgeWeight=true
-DedgeWeightCol=edge_weight
-DhasVertexWeight=true
-DvertexWeightCol=node_weight
-DrandSelect=true
-DmaxIter=100;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A

Parameter	Description	Required	Default value
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
inputVertexTableName	The name of the input vertex table.	Yes	N/A
inputVertexTablePartitions	The partitions in the input vertex table.	No	The whole table is selected by default.
vertexCol	The vertex column in the input vertex table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	N/A
hasVertexWeight	Specifies whether the vertices in the input vertex table have weights.	No	false
vertexWeightCol	The vertex weight column in the input vertex table.	No	N/A
randSelect	Specifies whether the maximum label value is to be randomly selected.	No	false
maxIter	The maximum number of iterations.	No	30

4.1.5.2.10.5. Label propagation classification

Label propagation classification is a semi-supervised classification algorithm. It uses the label information of labeled nodes to predict the label information for unlabeled nodes.

Features

During algorithm execution, the labels of each node are propagated to the neighboring nodes based on the similarity between the nodes. In each step of propagation, a node updates its labels based on the labels of the neighboring nodes so that the node is more similar to the neighboring nodes. The higher the similarity, the more labeling influences the neighboring nodes have on that node, and the easier it is for the labels to be propagated. During label propagation, the labels of the labeled data remain unchanged. These labels serve as sources for propagation to the unlabeled data.

After the iterations end, the probability distributions of similar nodes tend to be similar. These nodes can be classified into the same category. This completes the label propagation.

Parameter settings

This algorithm component uses the following core parameters:

- alpha: the damping coefficient. Default value: 0.8.
- epsilon: the convergence coefficient. Default value: 0.000001.

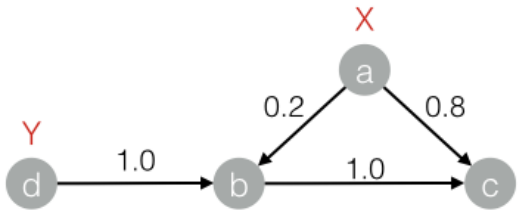
Examples - Testing data

Execute the following SQL statements to generate testing data:

```
drop table if exists LabelPropagationClassification_func_test_edge;
create table LabelPropagationClassification_func_test_edge
as select * from (
select 'a' as flow_out_id,
'b' as flow_in_id,
0.2 as edge_weight from dual     union all
select 'a' as flow_out_id,
'c' as flow_in_id,
0.8 as edge_weight from dual     union all
select 'b' as flow_out_id,
'c' as flow_in_id,
1.0 as edge_weight from dual     union all
select 'd' as flow_out_id,
'b' as flow_in_id,
1.0 as edge_weight from dual )tmp ;
drop table if exists LabelPropagationClassification_func_test_node;
create table LabelPropagationClassification_func_test_node
as select * from (
select 'a' as node,
'X' as label,
1.0 as label_weight from dual     union all
select 'd' as node,
'Y' as label,
1.0 as label_weight from dual )tmp ;
```

Graph structure shows the graph structure.

Graph structure



Output

The following figure shows the output based on the testing data.

node	tag	weight
a	X	1.0
b	X	0.16667
b	Y	0.83333
c	X	0.53704
c	Y	0.46296
d	Y	1.0

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use this algorithm component:

```
pai -name LabelPropagationClassification
-project algo_public
-DinputEdgeTableName=LabelPropagationClassification_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DinputVertexTableName=LabelPropagationClassification_func_test_node
-DvertexCol=node
-DvertexLabelCol=label
-DoutputTableName=LabelPropagationClassification_func_test_result
-DhasEdgeWeight=true
-DedgeWeightCol=edge_weight
-DhasVertexWeight=true
-DvertexWeightCol=label_weight
-Dalpha=0.8
-Depsilon=0.000001;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A

Parameter	Description	Required	Default value
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
inputVertexTableName	The name of the input vertex table.	Yes	N/A
inputVertexTablePartitions	The partitions in the input vertex table.	No	The whole table is selected by default.
vertexCol	The vertex column in the input vertex table.	Yes	N/A
vertexLabelCol	The vertex label column in the input vertex table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64
hasEdgeWeight	Specifies whether the edges in the input edge table have weights.	No	false
edgeWeightCol	The edge weight column in the input edge table.	No	N/A
hasVertexWeight	Specifies whether the vertices in the input vertex table have weights.	No	false
vertexWeightCol	The vertex weight column in the input vertex table.	No	N/A
alpha	The damping coefficient.	No	0.8
epsilon	The convergence coefficient.	No	0.000001
maxIter	The maximum number of iterations.	No	30

4.1.5.2.10.6. Modularity

Modularity is used to measure the structure of the community network. It measures the closeness of the communities divided from a network structure. A value larger than 0.3 represents an obvious community structure.

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use this component:

```
pai -name Modularity
-project algo_public
-DinputEdgeTableName=Modularity_func_test_edge
-DfromVertexCol=flow_out_id
-DfromGroupCol=group_out_id
-DtoVertexCol=flow_in_id
-DtoGroupCol=group_in_id
-DoutputTableName=Modularity_func_test_result;
```

Algorithm parameters

Parameters

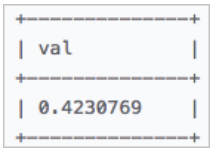
Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
fromGroupCol	The start vertex group in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
toGroupCol	The end vertex group in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64

Examples - Testing data

The testing data is the same as that in Label propagation clustering.

Output

The following figure shows the output.



val
0.4230769

4.1.5.2.10.7. Maximum connected subgraph

In Undirected Graph G, Vertex A is connected to Vertex B if a path exists between the two vertices. Graph G contains several subgraphs. Each vertex is connected to other vertices in the same subgraph. Vertices in different subgraphs are not connected. In this case, the subgraphs of Graph G are called maximum connected subgraphs.

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use this component:

```
pai -name MaximalConnectedComponent
-project algo_public
-DinputEdgeTableName=MaximalConnectedComponent_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=MaximalConnectedComponent_func_test_result;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of workers.	No	N/A

Parameter	Description	Required	Default value
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64

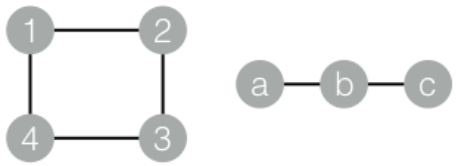
Examples - Testing data

Execute the following SQL statements to generate input data:

```
drop table if exists MaximalConnectedComponent_func_test_edge;
create table MaximalConnectedComponent_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '2' as flow_out_id,
'3' as flow_in_id from dual   union all
select '3' as flow_out_id,
'4' as flow_in_id from dual   union all
select '1' as flow_out_id,
'4' as flow_in_id from dual   union all
select 'a' as flow_out_id,
'b' as flow_in_id from dual   union all
select 'b' as flow_out_id,
'c' as flow_in_id from dual )tmp;
drop table if exists MaximalConnectedComponent_func_test_result;
create table MaximalConnectedComponent_func_test_result (   node string,   grp_id string );
```

shows the graph structure.

Graph structure



Output

The following figure shows the output based on the testing data.

```
+-------+-------+
| node  | grp_id|
+-------+-------+
| 1     | 4     |
| 2     | 4     |
| 3     | 4     |
| 4     | 4     |
| a     | c     |
| b     | c     |
| c     | c     |
+-------+-------+
```

4.1.5.2.10.8. Vertex clustering coefficient

A vertex clustering coefficient is used to calculate the peripheral density of a vertex in Undirected Graph G. The density of a star network is 0, and that of a fully meshed network is 1.

Parameter settings

The core parameter of this component is maxEdgeCnt. If the node degree is larger than the value of this parameter, sampling is performed. This parameter is optional. Default value: 500.

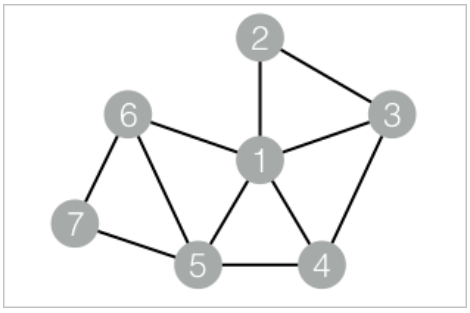
Examples - Testing data

Execute the following SQL statements to generate testing data:

```
drop table if exists NodeDensity_func_test_edge;
create table NodeDensity_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '1' as flow_out_id,
'3' as flow_in_id from dual   union all
select '1' as flow_out_id,
'4' as flow_in_id from dual   union all
select '1' as flow_out_id,
'5' as flow_in_id from dual   union all
select '1' as flow_out_id,
'6' as flow_in_id from dual   union all
select '2' as flow_out_id,
'3' as flow_in_id from dual   union all
select '3' as flow_out_id,
'4' as flow_in_id from dual   union all
select '4' as flow_out_id,
'5' as flow_in_id from dual   union all
select '5' as flow_out_id,
'6' as flow_in_id from dual   union all
select '5' as flow_out_id,
'7' as flow_in_id from dual   union all
select '6' as flow_out_id,
'7' as flow_in_id from dual )tmp;
drop table if exists NodeDensity_func_test_result;
create table NodeDensity_func_test_result (   node string,   node_cnt bigint,   edge_cnt bigint,   d
ensity double,   log_density double );
```

Graph structure shows the graph structure.

Graph structure



Output

```
1,5,4,0.4,1.45657
2,2,1,1.0,1.24696
3,3,2,0.66667,1.35204
4,3,2,0.66667,1.35204
5,4,3,0.5,1.41189
6,3,2,0.66667,1.35204
7,2,1,1.0,1.24696
```

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use the algorithm component:

```
pai -name NodeDensity
-project algo_public
-DinputEdgeTableName=NodeDensity_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=NodeDensity_func_test_result
-DmaxEdgeCnt=500;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command.

Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
maxEdgeCnt	If the node degree is larger than the value of this parameter, sampling is required.	No	500
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096

Parameter	Description	Required	Default value
splitSize	The data split size, in MB.	No	64

4.1.5.2.10.9. Edge clustering coefficient

An edge clustering coefficient is used to calculate the edge density in Undirected Graph G.

Examples - Testing data

Execute the following SQL statements to generate testing data:

```
drop table if exists EdgeDensity_func_test_edge;
create table EdgeDensity_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '1' as flow_out_id,
'3' as flow_in_id from dual   union all
select '1' as flow_out_id,
'5' as flow_in_id from dual   union all
select '1' as flow_out_id,
'7' as flow_in_id from dual   union all
select '2' as flow_out_id,

-DoutputTableName=EdgeDensity_func_test_result;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command. Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A

Parameter	Description	Required	Default value
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64

4.1.5.2.10.10. Counting triangle

This component generates all triangles in Undirected Graph G.

Parameter settings

The core parameter of this component is maxEdgeCnt. If the node degree is larger than the value of the maxEdgeCnt parameter, sampling is performed. This parameter is optional. Default value: 500.

Examples - Testing data

Execute the following SQL statements to generate testing data:

```
drop table if exists TriangleCount_func_test_edge;
create table TriangleCount_func_test_edge
as select * from (
select '1' as flow_out_id,
'2' as flow_in_id from dual   union all
select '1' as flow_out_id,
'3' as flow_in_id from dual   union all
select '1' as flow_out_id,
'4' as flow_in_id from dual   union all
select '1' as flow_out_id,
'5' as flow_in_id from dual   union all
select '1' as flow_out_id,
'6' as flow_in_id from dual   union all

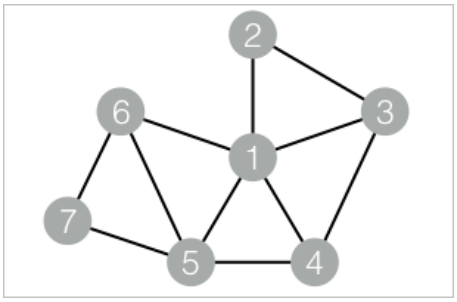
'3' as flow_in_id from dual   union all
select '3' as flow_out_id,
'4' as flow_in_id from dual   union all
select '4' as flow_out_id,
'5' as flow_in_id from dual   union all
select '5' as flow_out_id,
'6' as flow_in_id from dual   union all
select '5' as flow_out_id,
'7' as flow_in_id from dual   union all
select '6' as flow_out_id,
'7' as flow_in_id from dual )tmp;
drop table if exists TriangleCount_func_test_result;
create table TriangleCount_func_test_result (   node1 string,   node2 string,   node3 string );
```

Graph structure shows the graph structure.

Graph structure



Output

```
1,2,3
1,3,4
1,4,5
1,5,6
5,6,7
```

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use this component:

```
pai -name TriangleCount
-project algo_public
-DinputEdgeTableName=TriangleCount_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=TriangleCount_func_test_result;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command. Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
maxEdgeCnt	If the node degree is larger than the value of this parameter, sampling is required.	No	500
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64

4.1.5.2.10.11. Tree depth

In a tree network, this component generates the depth of each node in a tree and the tree ID.

Examples - Testing data

Execute the following SQL statements to generate testing data:

```
drop table if exists TreeDepth_func_test_edge;
create table TreeDepth_func_test_edge
as select * from (

```

PAI command

You can run the following Machine Learning Platform for AI (PAI) command to use this component:

```
pai -name TreeDepth
-project algo_public
-DinputEdgeTableName=TreeDepth_func_test_edge
-DfromVertexCol=flow_out_id
-DtoVertexCol=flow_in_id
-DoutputTableName=TreeDepth_func_test_result;
```

Algorithm parameters

The following table describes the parameters that are used in the PAI command. Parameters

Parameter	Description	Required	Default value
inputEdgeTableName	The name of the input edge table.	Yes	N/A
inputEdgeTablePartitions	The partitions that are selected from the input edge table.	No	The whole table is selected by default.
fromVertexCol	The start vertex column in the input edge table.	Yes	N/A
toVertexCol	The end vertex column in the input edge table.	Yes	N/A
outputTableName	The name of the output table.	Yes	N/A
outputTablePartitions	The partitions in the output table.	No	N/A
lifecycle	The lifecycle of the output table.	No	N/A
workerNum	The number of workers.	No	N/A
workerMem	The memory size per worker, in MB.	No	4096
splitSize	The data split size, in MB.	No	64

4.1.5.2.11. Tools

4.1.5.2.11.1. SQL Script

The SQL script component allows you to write SQL statements in the SQL script editor.

1. Go to a Machine Learning Studio project. For more information, see Data preparation.
2. In the left-side navigation pane, click **Components**.
3. Drag the **SQL Script** component in the **Tools** folder to the canvas.
4. After you connect the component that generates the input table and the **SQL Script** component, click the **SQL Script** component to open the **Parameters Setting** panel.

5. In the SQL Script section, enter the SQL script that is used to implement the required feature. Take note of the following items:
   - The component supports one to four inputs and one output.
   - You can write only one SQL statement.
   - Input tables are automatically mapped to tables t1 to t4. You can directly use ${t1}, ${t2}, ${t3}, and ${t4} without the need to specify the table names.
   - The sample SQL script calculates the number of rows in the input table.

4.1.5.2.12. Financials

4.1.5.2.12.1. Binning

The Binning component supports data binning in equal frequency or equal width.

PAI command

You can run the following PAI command to use the Binning component.

```
PAI -name binning
    -project algo_public
    -DinputTableName=input
    -DoutputTableName=output
```

Parameters

The following table describes the parameters in the PAI command.

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input table.	Table name	N/A
outputTableName	Required. The name of the output table.	Table name	N/A
selectedColNames	Optional. The columns that are selected from the input table for binning.	Column name	All columns except the label column (If no label column exists, all columns are selected.)
labelColumn	Required. The name of the label column.	Column name	Empty
validTableName	Optional. The name of the validation table. This parameter is required if the binningMethod parameter is set to auto.	Table name	Empty
validTablePartitions	Optional. The partitions that are selected from the validation table.	Partition name	All partitions
inputTablePartitions	Optional. The partitions that are selected from the input table.	Partition name	All partitions

Parameter	Description	Valid value	Default value
inputBinTableName	Optional. The input binning table.	Table name	Empty
selectedBinColNames	Optional. The columns that are selected from the input binning table.	Column name	Empty
positiveLabel	Optional. The label of the output positive samples.	N/A	1
nDivide	Optional. The number of bins.	Positive integer	10
colsNDivide	Optional. The numbers of bins for specific columns. Specify this parameter in the format of Column name 1:Number of bins,Column name 2:Number of bins. Example: col0:3,col2:5. If the columns that are specified for the colsNDivide parameter are not included in those specified for the selectedColNames parameter, the columns are also used in binning. For example, the selectedColNames parameter is set to col0,col1, the colsNDivide parameter is set to col0:3,col2:5, and the nDivide parameter is set to 10. In this case, binning is performed based on col0:3,col1:10,col2:5.	N/A	Empty
isLeftOpen	Optional. Specifies whether the interval is left-open and right-closed. A value of false indicates a left-closed, right-closed interval.	true and false	true
stringThreshold	Optional. The threshold for discrete values in the else bin.	N/A	Empty
colsStringThreshold	Optional. The threshold for specific columns. Specify this parameter in the same format as the colsNDivide parameter.	N/A	Empty

Parameter	Description	Valid value	Default value
binningMethod	Optional. The binning mode. A value of quantile indicates data binning in equal frequency. A value of bucket indicates data binning in equal width. A value of auto indicates the system automatically selects a binning mode.	quantile, bucket, and auto	quantile
lifecycle	Optional. The lifecycle of the output table.	Positive integer	Empty
coreNum	Optional. The number of cores.	Positive integer	Determined by the system
memSizePerCore	Optional. The memory size of each core.	Positive integer	Determined by the system

Constraints

If you want to specify constrains, the Binning component must be used with the Scorecard Training component. During scorecard training, the Binning component converts continuous features into multiple discrete dummy variables to achieve feature engineering. You can specify constraints for the weights of the dummy variables. The following information describes the constraints:

- Ascending order: Weights must be added to the dummy variables of a feature based on index values in ascending order. This indicates that a dummy variable with a large index value has a high weight.
- Descending order: Weights must be added to the dummy variables of a feature based on index values in descending order. This indicates that a dummy variable with a large index value has a low weight.
- Same weight: The weights of two dummy variables of a feature must be the same.
- Zero weight: The weight of a dummy variable must be 0.
- Specific weight: The weight of a dummy variable must be a specific floating-point value.
- WOE order: Weights must be added to the dummy variables of a feature based on the weight of evidence (WOE) values in ascending order. This indicates that a dummy variable with a large WOE value has a high weight.

4.1.5.2.12.2. Data Conversion Module

The Data Conversion Module component uses binning results to convert the input features that you provide. You can use this component to perform normalization, Weight of Evidence (WoE) conversion, and discretization.

Parameters

The following table describes the command parameters of the Data Conversion Module component.

Parameter	Description
inputFeatureTableName	Required. The name of the input feature table.
inputBinTableName	Required. The name of the binning result table.
inputFeatureTablePartitions	Optional. The partitions that are selected from the input feature table. By default, all partitions are selected.
outputTableName	Required. The name of the output table.

Parameter	Description
featureColNames	Optional. The feature columns that are selected from the input table. By default, all feature columns are selected.
metaColNames	The columns that do not need to be converted. These columns in the output are the same as those in the input. By default, the metaColNames parameter is left empty. You can specify the label and sample_id columns.
transformType	Optional. The type of data conversion. Valid values: normalize, dummy, and woe. A value of normalize indicates normalization. A value of dummy indicates discretization. A value of woe indicates WOE conversion. Default value: dummy.
itemDelimiter	Optional. The delimiter that is used to separate features. The default delimiter is the comma (,). This parameter is valid only if the transformType parameter is set to dummy.
kvDelimiter	Optional. The delimiter that is used to separate keys and values. The default delimiter is the comma (,). This parameter is valid only if the transformType parameter is set to dummy.
lifecycle	Optional. The lifecycle of the output table. By default, this parameter is left empty.
coreNum	Optional. The number of CPU cores that are required. By default, the system determines the value.
memSizePerCore	Optional. The memory size of each CPU core. By default, the system determines the value.

Example

PAI command

You can run the following PAI command to call the Data Conversion Module component.

```
PAI -name data_transform
-project algo_public
-DinputFeatureTableName=feature_table
-DinputBinTableName=bin_table
-DoutputTableName=output_table
-DmetaColNames=label
-DfeatureColNames=feaname1,feaname2
```

Normalization algorithm

To implement normalization, the Data Conversion Module component converts variable values into values between 0 and 1 based on input binning information, and imputes missing values with 0. The following algorithm is used:

```
if feature_raw_value == null or feature_raw_value == 0 then
    feature_norm_value = 0.0
else
    bin_index = FindBin(bin_table, feature_raw_value)
    bin_width = round(1.0 / bin_count * 1000) / 1000.0
    feature_norm_value = 1.0 - (bin_count - bin_index - 1) * bin_width
```

Output format

The Data Conversion Module component generates regular output tables for normalization and WOE conversion.

During discretization in which data is converted into dummy variables, the component generates a table in the key-value format. Each variable in the table is in the `[${feaname}]\_bin\_${bin_id}` format. In this example, the variable is sns.

- If sns falls into the second bin, the generated variable is `[sns]_bin_2`.
- If sns does not have a value, it falls into the empty bin, and the generated variable is `[sns]_bin_null`.
- If sns has a value but does not fall into a defined bin, it falls into the else bin, and the generated variable is `[sns]_bin_else`.

4.1.5.2.12.3. Scorecard Training

The scorecard is a modeling tool that is commonly used in credit risk evaluation. Scorecard modeling performs discretization on original variables by using binning and uses linear models such as logistic regression and linear regression, to conduct model training. The scorecard supports feature selection and score conversion. In addition, it allows you to add constraints to variables during model training.

> **Note** If you use the scorecard without binning, scorecard training is equivalent to logistic or linear regression.

Feature engineering

The main difference between the scorecard and normal linear models is that the scorecard performs feature engineering before it trains linear models. The Scorecard Training component supports two methods for feature engineering. Both methods use the Binning component for feature discretization. Then, one method performs one-hot encoding for each variable based on binning results to generate N dummy variables. N represents the number of bins. The other method performs weight of evidence (WOE) conversion to replace the original value of a variable with the WOE value of the bin into which the variable falls.

> **Note** When you convert original variables into dummy variables, you can specify constraints for these dummy variables.

Score transformation

In scenarios such as credit scoring, you must perform a linear transformation to convert the predicted sample odds into a score. The following formula is used for linear transformation:

```
log(odds) = \sum(wx) = a scaled_score + b
```

You can use the following parameters to specify the linear transformation relationship:

- scaledValue: a scaled score.
- odds: the odds of the scaled score.
- pdo: the points at which the odds are doubled.

For example, the value of scaledValue is 800, that of odds is 50, and that of pdo is 25. In this case, the following two dots are determined for a line:

```
log(40) = a * 800 + b
log(80) = a * 825 + b
```

Calculate the values of a and b. Then, perform a linear transformation to obtain the scores of a and b.

The scaling information is specified in the JSON format by using the -Dscale parameter.

```
null
```

If you specify a value for the -Dscale parameter, you must also specify a value for each of the scaledValue, odds, and pdo parameters.

Constraint addition during training

During scorecard training, you can add constraints to variables. For example, you can set the score of a specific bin to a fixed value, specify the scores of two bins to a specific proportion, or limit the scores between bins, such as sorting bin scores by WOE value. The implementation of constraints depends on the underlying optimization algorithm that contains constraints. You can specify the constraints in the Binning component in the PAI console. After the constraints are specified, the Binning component generates JSON-formatted constraints and automatically transfers them to its connected training component.

- <: The weights of variables must be sorted in ascending order.
- >: The weights of variables must be sorted in descending order.
- =: The weight of a specific variable must be a fixed value.
- %: The weights of two variables must meet a proportional relationship.
- UP: the upper limit for the weights of variables.
- LO: the lower limit for the weights of variables.

Each JSON-formatted constraint is stored in a table as a JSON string. The table contains only one row and one column. The following code shows a sample JSON string:

```
{
    "name": "feature0",
    "<": [
        [0,1,2,3]
    ],
    ">": [
        [4,5,6]
    ],
    "=": [
        "3:0","4:0.25"
    ],
    "%": [
        ["6:1.0","7:1.0"]
    ]
}
```

Built-in constraints

Each original variable has a built-in constraint. For each variable, the average score of a population must be 0. Due to the constraint, the value of scaled_weight in the intercept options of the scorecard model equals the average score of the population in terms of all variables.

Optimization algorithms

On the Parameters Setting tab, select Advanced Options. Then, you can configure the optimization algorithm that is used during scorecard training. The system supports the following optimization algorithms:

- L-BFGS
- Newton's method
- Barrier method
- SQP

The L-BFGS algorithm is a first-order optimization algorithm that is used to process large amounts of feature data. The Newton's method algorithm is a classic second-order optimization algorithm. It is fast in convergence and accurate. However, the Newton's method algorithm is not suitable for processing large amounts of feature data because it needs to calculate a second-order Hessian matrix. Both algorithms do not contain constraints. If you select one of the two algorithms, the system automatically ignores the constraints that you specify.

If you require constraints in training, you can select the barrier method and SQP algorithms. Both algorithms are second-order optimization algorithms. If the algorithm does not contain constraints, it is completely equivalent to the Newton's method algorithm. The barrier method algorithm provides almost the same computing performance and accuracy as the SQP algorithm. In most cases, we recommend that you select SQP. If you are not familiar with optimization algorithms, we recommend that you set the Optimization Algorithm parameter to Auto-selected by default. In this case, the system selects the most appropriate algorithm based on the data amount and constraints.

Feature selection

The Scorecard Training component supports stepwise feature selection. Stepwise feature selection is a fusion of forward and backward selection. Each time the system performs a forward selection to select a new variable and adds it to the model, the system also performs a backward selection. The backward selection is used to remove the variables whose significance does not meet the requirements. Stepwise feature selection supports various functions and feature transformation methods. Therefore, stepwise feature selection also supports multiple selection standards. The following standards are supported:

- Marginal contribution: This standard can be applied to all functions and feature engineering methods.
- Score test: This standard supports only WOE conversion and logistic regression without feature engineering.
- F test: This standard supports only WOE conversion and linear regression without feature engineering.

Marginal contribution

This standard needs two models to be trained: Model A and Model B. Model A does not contain Variable X, and Model B contains Variable X in addition to all the variables of Model A. The difference between the functions of the two models in final convergence is the marginal contribution of Variable X to all the other variables in Model B. In scenarios where variables are converted into dummy variables, the marginal contribution of Variable X is the difference between the functions of all dummy variables in Model A and the functions of all dummy variables in Model B. Therefore, marginal contribution is supported by all feature engineering methods.

Marginal contribution is flexible and is not limited to a specific type of model. Only variables that contribute to functions are passed to the model. Marginal contribution has disadvantages when compared with statistical significance. Typically, 0.05 is used as the threshold for statistical significance. Marginal contribution does not provide a recommended threshold for beginners. We recommend that you set the threshold to 10E-5.

Score test

This standard is applicable only to feature selection with logistic regression. During a forward selection, a model that has only intercept options is trained first. In each subsequent iteration, the score chi-squares of the variables that are not passed to the model are measured. The variable with the largest score chi-square is passed to the model. In addition, the p-value of the variable with the largest score chi-square is calculated based on chi-square distribution. If the p-value of the variable is greater than the given SLENTRY value, the variable is not passed to the model, and feature selection is terminated.

After the forward selection is complete, a backward selection is performed for the variable that is passed to the model. The Wald chi-square of the variable and the related p-value are calculated. If the p-value is greater than the given SLSTAY value, the variable is removed from the model. Then, the system starts a new iteration.

F test

This standard is applicable to feature selection with linear regression. During a forward selection, a variable that has only intercept options is trained first. In each subsequent iteration, the F-values of the variables that are not passed to the model are calculated. F-value calculation is similar to marginal contribution calculation. Two models must be trained to calculate the F-value of a variable. The F-value follows F distribution. The related p-value can be calculated based on the probability density function of F distribution. If the p-value is greater than the given SLENTRY value, the variable is not passed to the model, and the forward selection is terminated.

During the backward selection, the F-value is used to calculate the significance of a variable in a way similar to a score test.

Forced selection of the variables that you want to pass to a model

Before a feature selection is performed, you can specify the variables that you want to forcibly pass to the model. These variables are directly passed to the model regardless of their significance. No forward or backward selection is performed for the specified variables.

You can specify the number of iterations and significance thresholds by using the -Dselected parameter. Specify this parameter in the JSON format. Example:

```
{"max_step":2, "slentry": 0.0001, "slstay": 0.0001}
```

If the -Dselected parameter is left empty or the max_step parameter is set to 0, no feature selection is performed.

Model report

The Scorecard Training component generates data to a model report. The model report contains basic model evaluation statistics, such as binning information of variables, binning constraints, WOE values, and marginal contribution information. The following table describes the columns in a model report that is generated in the PAI console.

Column name	Data type	Description
feaname	string	The name of the feature.
binid	bigint	The ID of the bin.
bin	string	The description of the bin, which indicates the interval of the bin.
constraint	string	The constraints that are added to the bin during training.
weight	double	The weight of a binning variable. For a non-scorecard model without binning, this field indicates the weight of a model variable.
scaled_weight	double	The score that is linearly transformed from the weight of a binning variable in scorecard training.
woe	double	A statistical metric. It indicates the WOE value of a bin in the training set.

Column name	Data type	Description
contribution	double	A statistical metric. It indicates the marginal contribution value of a bin in the training set.
total	bigint	A statistical metric. It indicates the total number of samples in a bin in the training set.
positive	bigint	A statistical metric. It indicates the number of positive samples in a bin in the training set.
negative	bigint	A statistical metric. It indicates the number of negative samples in a bin in the training set.
percentage_pos	double	A statistical metric. It indicates the proportion of positive samples in a bin to total positive samples in the training set.
percentage_neg	double	A statistical metric. It indicates the proportion of negative samples in a bin to total negative samples in the training set.
test_woe	double	A statistical metric. It indicates the WOE value of a bin in the testing set.
test_contribution	double	A statistical metric. It indicates the marginal contribution value of a bin in the testing set.
test_total	bigint	A statistical metric. It indicates the total number of samples in a bin in the testing set.
test_positive	bigint	A statistical metric. It indicates the number of positive samples in a bin in the testing set.
test_negative	bigint	A statistical metric. It indicates the number of negative samples in a bin in the testing set.
test_percentage_pos	double	A statistical metric. It indicates the proportion of positive samples in a bin to total positive samples in the testing set.
test_percentage_neg	double	A statistical metric. It indicates the proportion of negative samples in a bin to total negative samples in the testing set.

The following table describes the algorithm parameters.

Algorithm parameters

Parameter	Description	Valid value	Default value
inputTableName	Required. The name of the input feature table.	N/A	N/A
inputTablePartitions	Optional. The partitions selected from the input table.	N/A	All partitions
inputBinTableName	Optional. The name of the binning result table. If you specify a value for this parameter, the system automatically performs discretization for features based on the binning rules in the binning result table.	N/A	N/A
featureColNames	Optional. The feature columns that are selected from the input feature table.	N/A	All columns except the label column
labelColName	Required. The label column.	N/A	N/A
outputTableName	Required. The output model table.	N/A	N/A
inputConstraintTableName	Optional. The name of the table that stores constraints. The constraints are a JSON string that is stored in a cell of the table.	N/A	N/A
optimization	Optional. The optimization algorithm.	lbfgs, newton, barrier_method, sqp, and auto. Only sqp and barrier_method support constraints. If you set the optimization parameter to auto, the system automatically selects an appropriate optimization algorithm based on user data and related parameter settings. If you are not familiar with optimization algorithms, we recommend that you set the optimization parameter to auto.	auto
loss	Optional. The loss type.	logistic_regression and least_square	logistic_regression
iterations	Optional. The maximum number of iterations of optimizations.	N/A	100

Parameter	Description	Valid value	Default value
l1Weight	Optional. The parameter weight of L1 regularization. Only the L-BFGS algorithm supports this parameter.	N/A	0
l2Weight	Optional. The parameter weight of L2 regularization.	N/A	0
m	Optional. The historical step size for optimization that is performed by using the L-BFGS algorithm. Only the L-BFGS algorithm supports this parameter.	N/A	10
scale	Optional. The weight scaling information of the scorecard.	N/A	Empty
selected	Optional. Specifies whether to enable feature selection during scorecard training.	N/A	Empty
convergenceTolerance	Optional. The convergence tolerance.	N/A	1e-6
positiveLabel	Optional. The label of the positive samples.	N/A	"1"
lifecycle	Optional. The lifecycle of the output table.	N/A	N/A
coreNum	Optional. The number of cores.	N/A	Determined by the system
memSizePerCore	Optional. The memory size of each core.	N/A	Determined by the system

4.1.5.2.12.4. Scorecard Prediction

The Scorecard Prediction component uses the model that is generated by a training component to predict scores. The following training components are supported: the Scorecard Training, Logistic Regression for Binary Classification, and Linear Regression components.

Input parameters

The Scorecard Prediction component has the following parameters:

- **Feature Columns**: the feature columns to be used for prediction. By default, all columns are selected.
- **Reserved Columns**: the columns that are appended to the prediction result table without processing, such as the ID and label columns.
- **Output Variable Score**: specifies whether to generate a score for each feature variable. The total predicted score is the score of intercept options plus the score of each variable.

Sample score table

The churn column is a reserved column. The data in this column does not affect the prediction results.

Column name	Data type	Description
prediction_score	double	The column that contains predicted scores. In a linear model, the feature values and model weight values are multiplied and summed up to obtain the predicted scores. In a scorecard model, if score transformation is performed, the transformed scores are generated in this column.
prediction_prob	double	The column that contains the probability values of positive samples in binary classification. The probability values are transformed from the original scores (without score transformation) by using the sigmoid function.
prediction_detail	string	The column that contains the probability values of positive and negative samples. The probability values are described in JSON strings. The value 0 represents negative and the value 1 represents positive. Example: { “0” :0.1813110520,” 1” :0.8186889480}.

PAI command

You can run the following PAI command to use the component:

```
pai -name=lm_predict
    -project=algo_public
    -DinputFeatureTableName=input_data_table
    -DinputModelTableName=input_model_table
    -DmetaColNames=sample_key,label
    -DfeatureColNames=fea1,fea2
    -DoutputTableName=output_score_table
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameter	Description	Default value
inputFeatureTableName	Required. The name of the input feature table.	N/A
inputFeatureTablePartitions	The partitions that are selected from the input feature table.	All partitions
inputModelTableName	Required. The name of the input model table.	N/A

Parameter	Description	Default value
featureColNames	Optional. The feature columns that are selected from the input feature table.	All columns
metaColNames	The columns that do not need to be converted. These columns in the output are the same as those in the input.	By default, this parameter is left empty. You can specify the label and sample_id columns.
outputFeatureScore	Optional. Specifies whether to generate the scores of variables in the prediction results. Valid values: true and false.	false
outputTableName	Required. The name of the output table.	N/A
lifecycle	Optional. The lifecycle of the output table.	Empty
coreNum	Optional. The number of cores.	Determined by the system
memSizePerCore	Optional. The memory size per core.	Determined by the system

4.1.5.2.12.5. Population Stability Index

Population stability index (PSI) is an important metric to identify a shift in two samples of a population.

For example, PSI can measure the stability of samples over the past two months. A PSI value less than 0.1 indicates insignificant changes. A PSI value between 0.1 and 0.25 indicates changes that are relatively significant. A PSI value greater than 0.25 indicates sharp changes and requires special attention.

When the changes in a population over time are unstable, you can use charts to identify the changes. You can use binning to discretize variables into multiple bins, calculate the number and proportion of the samples in each bin, and then display the statistics in a column chart.

The preceding method can directly show whether a variable in two samples changes significantly. However, the shift in these changes cannot be measured by using this method. Therefore, the population stability cannot be automatically monitored. To resolve this issue, you can use the Binning and Population Stability Index components.

PAI command

You can run the following PAI command to use the component:

```
PAI -name psi
-project algo_public
-DinputBaseTableName=psi_base_table
-DinputTestTableName=psi_test_table
-DoutputTableName=psi_bin_table
-DinputBinTableName=pai_index_table
-DfeatureColNames=fea1,fea2,fea3
-Dlifecycle=7
```

Algorithm parameters

The following table describes the parameters in the PAI command.

Parameter	Description	Default value
inputBaseTableName	Required. The name of the base table. The shift of the population is calculated based on the samples in the base and test tables.	N/A
inputBaseTablePartitions	Optional. The partitions that are selected from the base table.	All partitions
inputTestTableName	Required. The name of the test table. The shift of the population is calculated based on the samples in the base and test tables.	N/A
inputTestTablePartitions	Optional. The partitions that are selected from the test table.	All partitions
inputBinTableName	Required. The name of the binning result table.	N/A
featureColNames	Optional. The feature columns that are required for PSI value calculation.	All feature columns
outputTableName	Required. The name of the output table.	N/A
lifecycle	Optional. The lifecycle of the output table.	Empty
coreNum	Optional. The number of cores.	Determined by the system
memSizePerCore	Optional. The memory size of each core.	Determined by the system

4.1.5.2.13. Video intelligence platform (must be separately activated)

Note Video intelligence platforms are applicable only to Intel servers, but not to Hygon servers.

4.1.5.2.13.1. Video preprocessing

Convert datasets to TFRecord files

EasyVision of Machine Learning Platform for AI (PAI) allows you to convert datasets that are labeled by the data labeling module to TFRecord files. TFRecord files can be used to train models. You can use the TFRecord conversion component of EasyVision to convert labeled datasets that are stored in Object Storage Service (OSS) to TFRecord files and store the TFRecord files in OSS. If the datasets are labeled by using a method other than the data labeling module, you must first convert the labeled datasets to a format that is required by PAI.

PAI command

Convert a labeled dataset for classification

```
pai -name easy_vision
      -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
      -Dcmd  convert
      -Dlabel_file 'oss://pai-vision-data-hz/data/pai_test/watchdog.csv'
      -Dconvert_param_config '
        --class_list_file oss://pai-vision-data-hz/data/pai_test/watchdog_class_list.txt
        --max_image_size 600
        --write_parallel_num 8
        --num_samples_per_tfrecord 128
        --test_ratio 0.1
        --model_type CLASSIFICATION
      '
      -Doutput_tfrecord 'oss://pai-vision-data-hz/test/convert/watchdog_tfrecord/watchdog'
      -Dcluster='{
              \"worker\" : {
                \"count\" : 3,
                \"cpu\" : 800
              }
            }'
```

Convert a labeled dataset for text detection or recognition

```
pai -name easy_vision
      -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
      -Dcmd  convert
      -Dlabel_file 'oss://pai-vision-data-hz/data/recipt_text/qince_data/qince_receipt_test.csv'
      -Dconvert_param_config '
        --model_type TEXT_END2END
        --default_class text
        --max_image_size 2000
        --char_replace_map_path oss://pai-vision-data-hz/data/recipt_text/qince_data/char_replace_map.csv
        --default_char_dict_path oss://pai-vision-data-hz/data/recipt_text/qince_data/char_dict
        --test_ratio 0.1
        --write_parallel_num 8
        --num_samples_per_tfrecord 64
      '
      -Doutput_tfrecord 'oss://pai-vision-data-hz/test/convert/recipt_text_end2end/'
```

Parameters

Parameter	Required	Description	Value type or sample value	Default value
cmd	Yes	Set the value to convert.	String	convert

Parameter	Required	Description	Value type or sample value	Default value
buckets	No	The OSS bucket in which the input data is stored. You can specify multiple OSS buckets by separating them with commas (,). Each bucket name must end with a forward slash (/).	`"oss://bucket_name/?role_arn=xxx&host=yyy"` `"oss://bucket_1/?role_arn=xxx&host=yyy,oss://bucket_2/"`	""
label_file	Yes	The OSS path of the labeled CSV file.	`oss://your_bucket/xxx.csv`	Required
convert_param_config	No	The information about the conversion task. For more information, see the following table. You can also replace the convert_param_config parameter with the convert_config parameter.	--parama valuea --paramb valueb	""
convert_config	No	The OSS path of the conversion task profile.	String	""
output_tfrecord	No	The OSS path of the TFRecord file.	`oss://your_dir/prefix`	""
cluster	No	The information about the workers that are used to perform conversion in a distributed manner.	JSON string	`"{\"worker\":{\"count\":3,\"cpu\": 800,\"gpu\":0,\"memory\":20000}}"`

convert_param_config

Parameter	Required	Description	Value type or sample value	Default value

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of model to which the converted data applies. Valid values: • CLASSIFICATION: single-label or multi-label image classification • DETECTION: object detection • POLYGON_SEGMENTATION: semantic segmentation based on polygon labeling • SEGMENTATION: semantic segmentation • INSTANCE_SEGMENTATION: instance segmentation • TEXT_END2END: end-to-end optical character recognition (OCR) • TEXT_RECOGNITION: single-line text recognition • TEXT_DETECTION: text detection • VIDEO_CLASSIFICATION: video classification • SELF_DEFINED: custom conversion If the value of the model_type parameter is set to TEXT_END2END or TEXT_RECOGNITION, the char_replace_map_path and default_char_dict_path parameters take effect. If the value of the model_type parameter is set to VIDEO_CLASSIFICATION, the decode_type, sample_fps, reshape_size, decode_batch_size, and decode_keep_size parameters take effect.	String	N/A

Parameter	Required	Description	Value type or sample value	Default value
class_list_file	No	The OSS path of the category file. The file contains a list of category names. The category name in each line may be presented in one of the following formats: • Category name • Category name:Name of the mapping category If the default_class parameter is set, you must set the class_list_file or class_list parameter.	oss://path/to/your/classlit	""
class_list	No	The list of category names. Separate category names with commas (,). If the default_class parameter is set, you must set the class_list_file or class_list parameter.	String list	""
test_ratio	No	The ratio that is used to divide the set of test data into different subsets. Valid values: 0 to 1. If the value is set to 0, the total set of test data is used for training. If the value is set to 0.1, 10% of the test data is used for verification.	0.1	0.1
max_image_size	No	The maximum pixel value for the longer side of the images. If you have set this parameter and the size of an image exceeds the upper limit, the image is resized and saved to the TFRecord file. This reduces storage space and accelerates data reading.	INT	N/A
max_test_image_size	No	The maximum pixel value for the longer side of the image that is used for testing. The value of this parameter is the same as that of the max_image_size parameter. This parameter is used to configure test data.	INT	${max_image_size}

Parameter	Required	Description	Value type or sample value	Default value
default_class	No	The name of the default category. Category names that are not included in the class_list parameter will be specified as the default category.	STRING	""
error_class	No	The name of the invalid category. Objects or bounding boxes that belong to this category are not used for training.	STRING	""
ignore_class	No	The name of the category that is used only to detect models. Bounding boxes that belong to this category are not used for training.	STRING	""
converter_class	No	The name of the conversion class. Valid values: • PaiConverter: converts the datasets to the PAI format • QinceConverter: converts the datasets to the traditional labeling format • A custom class name	STRING	PaiConverter
seperator	No	The separator that is used in the split() method to break the label file into substrings.	STRING	""
image_format	No	The encoding format of the images in the TFRecord file.	STRING	jpg
read_parallel_num	No	The number of concurrent reads.	INT	10
write_parallel_num	No	The number of concurrent writes to the TFRecord file.	INT	1
num_samples_per_tfrecord	No	The number of images that are saved in each TFRecord file.	INT	256
user_defined_converter_path	No	The HTTP or OSS path of the user-defined converter code. Example: http://path/to/your/converter.py.	STRING	""
user_defined_generator_path	No	The HTTP or OSS path of the user-defined generator code. Example: http://path/to/your/generator.py.	STRING	""

Parameter	Required	Description	Value type or sample value	Default value
generator_class	No	The name of the user-defined generator class.	STRING	""
char_replace_map_path	No	The OSS path of the CSV file for character map replacement. The CSV file contains two columns named original and replaced. The strings in the original column are replaced by the strings in the replaced column.	STRING	""
default_char_dict_path	No	The OSS path of the file that is used to map characters to IDs. In the file, each character occupies a line. The ID of a character equals the line number minus 1.	STRING	""
decode_type	No	The method that is used to decode the videos. Valid values: • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	5
reshape_size	No	The size of the output frames, in pixels.	INT	224
decode_batch_size	No	The number of frames that are decoded at a time.	INT	0
task_id	No	The ID of the PAI labeling job, in the format of label-xxxx. If the manifest file contains a labeling job, this parameter is not required.	STRING	""

Custom conversion

PAI command

```
pai -name easy_vision
      -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
      -Dcmd  convert
      -Dlabel_file 'oss://pai-vision-data-hz/data/image_mat/qince/imagemat.txt'
      -Dconvert_param_config '
        --model_type SELF_DEFINED
        --converter_class ImageMatConverter
        --user_defined_converter_path  oss://pai-vision-data-hz/samples/code/imagemat_converter.py
        --user_defined_generator_path oss://pai-vision-data-hz/samples/code/custom_generator_example.py
        --generator_class CustomGenerator
        --max_image_size 1200
        --write_parallel_num 2
        --num_samples_per_tfrecord 6
        --test_ratio 0.0
```

To customize dataset conversion to TFRecord files, you must implement the following classes:

- A row class that inherits the DataRow class. The row class is used to parse data in each line of the label file and obtain image URLs and label information.
- A generator class that inherits the TFRecordGenerator class. The generator class is used to convert the data that is parsed by the row class to the tf.train.Example protocol buffers and specify the data format in TFRecord.
- A converter class that inherits the MultiProcConvert class. The converter class is used to load label files and configure train-test split policies to complete the conversion.

Example on custom_converter

```

General video preprocessing

This topic provides an example on how to run a Machine Learning Platform for AI (PAI) command to train a model to preprocess videos. This topic also describes the command parameters.

You can run the `ev_video_process` command to train a model to preprocess videos. When you run this command, you need only to set the common parameters without the need to know the rules or logic of the EasyVision profile.

PAI command

```
pai -name ev_video_process
             -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/video_decode_test.list'
             -Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_video_decode_result.txt'
             -Doutput_dir='oss://pai-vision-data-hz/data/ucf101_train/frames/'
             -Ddecode_type=4
             -Dsample_fps=5
             -Dreshape_size=224
             -Ddecode_batch_size=10
             -Ddecode_keep_size=0
             -Dqueue_size=256
             -Dnum_worker=4
             -DcpuRequired=400
             -DgpuRequired=100
             -Dbuckets='YOUR_OSS_BUCKET_CONFIG'
```

Parameters

Parameter	Required	Description	Value type or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket in which your model is stored. This parameter is required when you use your own model to perform prediction.	`"oss://bucket_name/?role_arn=xxx&host=yyy"`	N/A
input_oss_file	Yes	The path of the input OSS file. Each line of the OSS object includes a video path.	`oss://your_bucket/filelist.txt`	N/A
output_oss_file	Yes	The path of the output OSS file in which the preprocessing result is stored. The system may generate multiple result files and merge these result files into an output OSS file. The result files are prefixed with the name of the output OSS file. The number of result files is the same as the number of workers, which is specified by the num_worker parameter.	`oss://your_bucket/result.txt`	N/A
output_dir	Yes	The directory that is used to store the frames extracted from the videos.	`oss://your_bucket/your_dir`	N/A

Parameter	Required	Description	Value type or sample value	Default value
decode_type	No	The method that is used to decode the videos. Valid values: • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	5
reshape_size	No	The size of the output frames, in pixels. If you set this parameter to -1, the frames are not resized.	INT	224
decode_batch_size	No	The number of frames that are decoded at a time.	INT	10
decode_keep_size	No	The number of overlapped frames in different batches.	INT	0
queue_size	No	The length of the preprocessing queue.	INT	256
thread_num	No	The number of threads on each worker.	INT	4
num_worker	No	The number of prediction workers.	INT	2
cpuRequired	No	The number of CPUs for a worker.	A value of 100 indicates one CPU.	800
gpuRequired	No	The number of GPUs for a worker.	A value of 100 indicates one GPU.	100

4.1.5.2.13.2. Offline training

Train a model for semantic image segmentation

This topic provides an example on how to run a Machine Learning Platform for AI (PAI) command to train a model for semantic image segmentation in EasyVision. This topic also describes the command parameters.

A semantic segmentation model based on DeepLabv3 is implemented. For more information, see Encoder-Decoder with Atrous Separable Convolution for Semantic Image Segmentation.

PAI command

The following code provides an example on the training of semantic image segmentation with a single GPU:

```
pai -name easy_vision
           -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
           -DgpuRequired=100
           -Dcmd train
           -Dparam_config '
             --model_type DeeplabV3
             --backbone  resnet_v1_50
             --backbone_feature_stride 16
             --bn_trainable true
             --num_classes 21
             --num_epochs 1
             --model_dir oss://pai-vision-data-hz/test/deeplab_stage1
             --train_data oss://pai-vision-data-hz/data/test/pascal_voc_seg_aug/voc_ev_train.tfrecor
d
             --test_data oss://pai-vision-data-hz/data/test/pascal_voc_seg_aug/voc_ev_train.tfrecord
             --num_test_example 2
             --train_batch_size 6
             --test_batch_size 1
             --image_crop_size 513
             --lr_type polynomial_decay
             --initial_learning_rate 0.007
             --power 0.9
           '
```

Parameters

Parameter	Required	Description	Value type or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket.	oss://pai-vision-data-hz/?role_arn=acs:ram::1217060697xxxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	""
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	100	100
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	train	N/A
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see param_config.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example of the param_config parameter:

```
-Dparam_config = '
--backbone resnet_v1_50
--num_classes 200
--model_dir oss://your/bucket/exp_dir
'
```

Note Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

The following table describes all parameters that are contained in the param_config parameter.

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. Set this parameter to DeeplabV3.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: • resnet_v1_50 • resnet_v1_101 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1d_50 • resnet_v1d_101 • xception_41 • xception_65 • xception_71	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	Yes	The number of categories, including background categories.	21	N/A
backbone_feature_stride	No	The feature downsampling step size of the backbone network.	INT	16
bn_trainable	No	Specify whether the batch normalization (BN) layer is trainable. If the value of the train_batch_size parameter is greater than 8, set the bn_trainable parameter to true.	BOOL	true
image_crop_size	No	The size of the image after cropping, in pixels.	INT	513

Parameter	Required	Description	Value type or sample value	Default value
optimizer	No	The type of the optimizer. Valid values: • momentum: stochastic gradient descent (SGD) with momentum • adam	STRING	momentum
lr_type	No	The policy that is used to adjust the learning rate. Valid values: • exponential_decay: The learning rate is subject to exponential decay. • polynomial_decay: The learning rate is subject to polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. • manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed. • cosine_decay: The learning rate of each epoch is adjusted based on the cosine curve until the learning rate decreases to 0. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for each specified epoch. This parameter is required if you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The OSS path of the data that is used to train the model.	`oss://path/to/train_*.tfrecord`	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	`oss://path/to/test_*.tfrecord`	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	`oss://path/to/model`	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	`oss://pai-vision-data-hz/pretrained_models/inception_v4.ckpt`	`""`
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

Parameter	Required	Description	Value type or sample value	Default value
num_epochs	Yes	The number of times the data is iterated for the training. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	`""`

Train an image detection model

This topic provides an example on how to run a Machine Learning Platform for AI (PAI) command to train an image detection model. This topic also describes the command parameters.

EasyVision allows you to run a command to train an image detection model. You can use the `-Dparam_config` parameter to set common parameters without the need to know the rules or logic of the EasyVision profile. If you need advanced parameters to train an image detection model, you can use the `-Dconfig` parameter to pass the profile to EasyVision. The following table describes the models that are supported for image detection training.

Model	Backbone	Whether FPN is supported
Faster R-CNN	• resnet_v1_50 • resnet_v1_101 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1d_50 • resnet_v1d_101 • resnet_v1d_152	Yes

Model	Backbone	Whether FPN is supported
R-FCN	• resnet_v1_50 • resnet_v1_101 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1d_50 • resnet_v1d_101 • resnet_v1d_152	No
SSD	• resnet_v1_50 • resnet_v1d_50	Yes
SSD	vgg16_reduce_fc	No
SSD	mobilenet_v1	No

PAI command

- The following code provides an example on how to train a single-shot detection (SSD) model by using a single GPU:

```
pai -name easy_vision
           -Dbuckets='oss://YOUR_BUCKET_NAME/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
           -DgpuRequired=100
           -Dcmd train
           -Dparam_config '
             --model_type SSD
             --backbone  resnet_v1_50
             --num_classes 20
             --model_dir oss://YOUR_BUCKET_NAME/test/ssd_resnet50
             --train_data oss://pai-vision-data-hz/data/voc0712_tfrecord/voc0712_part_*.tfrecord
             --test_data oss://pai-vision-data-hz/data/voc0712_tfrecord/VOC2007_test.tfrecord
             --num_test_example 2
             --train_batch_size 32
             --test_batch_size 1
             --image_sizes 300
             --lr_type exponential_decay
             --initial_learning_rate 0.001
             --decay_epochs 20
             --staircase true
           '
```

- The following code provides an example on how to train a Faster R-CNN model or an R-FCN model by using a single GPU:

```
pai -name easy_vision
           -Dbuckets='oss://YOUR_BUCKET_NAME/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
           -DgpuRequired=100
           -Dcmd train
           -Dparam_config '
             --model_type FasterRCNN
             --backbone  resnet_v1_50
             --num_classes 20
             --model_dir oss://YOUR_BUCKET_NAME/test/ssd_fpn_resnet50
             --train_data oss://pai-vision-data-hz/data/voc0712_tfrecord/voc0712_part_*.tfrecord
             --test_data oss://pai-vision-data-hz/data/voc0712_tfrecord/VOC2007_test.tfrecord
             --num_test_example 2
             --train_batch_size 32
             --test_batch_size 1
             --image_min_sizes 600
             --image_max_sizes 1024
             --lr_type exponential_decay
             --initial_learning_rate 0.001
             --decay_epochs 20
             --staircase true
           '
```

- The following code provides an example on how to train an SSD model by using multiple GPUs:

```
pai -name easy_vision
           -Dbuckets='oss://YOUR_BUCKET_NAME/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
           -Dcmd train
           -Dcluster='{
             \"ps\": {
                 \"count\" : 1,
                 \"cpu\" : 600
             },
             \"worker\" : {
                 \"count\" : 3,
                 \"cpu\" : 800,
                 \"gpu\" : 100
             }
           }'
           -Dparam_config '
             --model_type SSD
             --backbone  resnet_v1_50
             --num_classes 20
             --model_dir oss://YOUR_BUCKET_NAME/test/ssd_fpn_resnet50
             --train_data oss://pai-vision-data-hz/data/voc0712_tfrecord/voc0712_part_*.tfrecord
             --test_data oss://pai-vision-data-hz/data/voc0712_tfrecord/VOC2007_test.tfrecord
             --num_test_example 2
             --train_batch_size 32
             --test_batch_size 1
             --image_sizes 300
             --lr_type exponential_decay
             --initial_learning_rate 0.001
             --decay_epochs 20
             --staircase true
           '
```

Parameters

Parameter	Required	Description	Value type or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket.	`oss://pai-vision-data-hz/?role_arn=acs:ram::1217060697 1xxxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com`	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	`""`
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	INT	100
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	train	N/A
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see param_config.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example of the param_config parameter:

```
-Dparam_config = '
--backbone resnet_v1_50
--num_classes 200
--model_dir oss://your/bucket/exp_dir
'
```

Note Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameter	Required	Description	Value type or sample value	Default value

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. Valid values: • SSD • FasterRCNN • RFCN	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: • mobilenet_v1 • resnet_v1_50 • resnet_v1_101 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1d_50 • resnet_v1d_101 • vgg16 _reduce_fc	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
use_fpn	No	Specifies whether to use Feature Pyramid Network (FPN).	BOOL	false
num_classes	No	The number of categories, excluding background categories.	INT. Sample value: 21.	N/A
anchor_scales	No	The size of the anchor box. The size of the anchor box is the same as that of the input image in which the anchor box resides after the image is resized. If you use an SSD model, this parameter is not required. If you use FPN, set this parameter to the size of the anchor box in the layer that has the highest resolution. The total number of layers is five. The size of the anchor box in a layer is twice as that in the previous layer. For example, if the size of the anchor box in the first layer is 32, the sizes of the anchor boxes in the next four layers are 64, 128, 256, and 512. If you use the FasterRCNN model or the RFCN model without FPN support, you can specify multiple anchor sizes as needed. For example, you can set the anchor_scales parameter to 128 256 512.	FLOAT list. Sample value: 32 (single scale) or 128 256 512 (multiple scales).	• SSD: The default value is 0.1, 0.2, 0.37, 0.54, 0.71, 0.88, 0.96, or 1.0 times of the size of the input image. • FNP: 32 • Faster R-CNN with FNP support: 32 • Faster R-CNN or R-FCN: [128 256 512]
anchor_ratios	No	The ratios of the width to the height of the anchor boxes.	FLOAT list	0.5 1 2

Parameter	Required	Description	Value type or sample value	Default value
image_sizes	No	The size of the images after they are resized. This parameter takes effect only when an SSD model is used. The value of this parameter is a list that contains two numbers, which indicate the height and width.	FLOAT list	300 300
image_min_sizes	No	The length of the shorter side of images after they are resized. This parameter is used for Faster R-CNN and R-FCN models. If you specify multiple lengths for the shorter sides of the images in the value of this parameter, the last one is used to evaluate the model, whereas one of the others is randomly selected to train the model. This way, the multi-scale training is supported. If you specify only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	600
image_max_sizes	No	The length of the longer side of images after they are resized. This parameter is used for Faster R-CNN and R-FCN models. If you specify multiple lengths for the longer sides of the images in the value of this parameter, the last one is used to evaluate the model, whereas one of the others is randomly selected to train the model. This way, the multi-scale training is supported. If you specify only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	1024
optimizer	No	The type of the optimizer. Valid values: • momentum: stochastic gradient descent (SGD) with momentum • adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: • exponential_decay: The learning rate is subject to exponential decay. • polynomial_decay: The learning rate is subject to polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. • manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate of each epoch as needed. • cosine_decay The learning rate of each epoch is adjusted based on the cosine curve until the learning rate decreases to 0. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. If you set the lr_type parameter to cosine_decay, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	Floating point	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for each specified epoch. This parameter is required if you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The OSS path of the data that is used to train the model.	`oss://path/to/train_*.tfrecord`	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	`oss://path/to/test_*.tfrecord`	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	`oss://path/to/model`	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	`oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt`	`""`
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

Parameter	Required	Description	Value type or sample value	Default value
num_epochs	Yes	The number of training iterations. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	`""`

Train an image classification model

This topic provides examples on how to run a Machine Learning Platform for AI (PAI) command to train an image classification model in EasyVision. This topic also describes the command parameters.

EasyVision allows you to run a command to train an image classification model. When you run the command, you need only to set the common classification parameters without the need to know the rules or logic of the EasyVision profile.

PAI command

- Training on a single server

```
pai -name easy_vision
           -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx&host=oss-cn-zhangjiakou.aliyuncs.com'
           -DgpuRequired=100
           -Dcmd train
           -Dparam_config '
             --model_type Classification
             --backbone  inception_v4
             --num_classes 10
             --num_epochs 1

```

Parameters

Parameter	Required	Description	Value type or sample value	Default value
buckets	Yes	The endpoint of the Object Storage Service (OSS) bucket.	`oss://pai-vision-data-hz/?role_arn=acs:ram::1217060697 1xxxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com`	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	""
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	100	100
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	train	N/A
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see the following table.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example of the param_config parameter:

```
-Dparam_config = '
--model_type Classification
--backbone inception_v4
--num_classes 200
--model_dir oss://your/bucket/exp_dir
'
```

Note Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameter	Required	Description	Value type or sample value	Default value

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. To train a model for multi-label image classification, set this parameter to Classification.	STRING	N/A
backbone	No	The name of the backbone network that is used by the model. Valid values: • vgg_16 • vgg_19 • inception_v1 • inception_v2 • inception_v3 • inception_v4 • mobilenet_v1 • mobilenet_v2 • mobilenet_v3 • resnet_v1_50 • resnet_v1_101 • resnet_v1_152 • resnet_v2_50 • resnet_v2_101 • resnet_v2_152 • resnet_v1a_18 • resnet_v1a_34 • resnet_v1a_50 • resnet_v1a_101 • resnet_v1a_152 • resnet_v1b_50 • resnet_v1b_101 • resnet_v1b_152 • resnet_v1c_50 • resnet_v1c_101 • resnet_v1c_152 • resnet_v1d_50 • resnet_v1d_101 • resnet_v1d_152 • efficientnet-b0 • efficientnet-b1 • efficientnet-b2 • efficientnet-b3 • efficientnet-b4 • efficientnet-b5 • efficientnet-b6 • efficientnet-b7 • efficientnet-b8	STRING	inception_v4

Parameter	Required	Description	Value type or sample value	Default value
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	Yes	The number of categories.	INT	N/A
hidden_size	No	The size of the custom Fiber Channel (FC) layer. A value of -1 indicates that the size of the original FC layer is used.	INT	-1
image_size	No	The size of the images after they are resized, in pixels.	INT	224
use_crop	No	Specifies whether to crop images for data enhancement.	BOOL	true
crop_min_area	No	The minimum proportion of the original image area that is occupied by the crop box when you set the use_crop parameter to true.	FLOAT	0.7
eval_each_category	No	Specifies whether to separately evaluate each category.	BOOL	false
optimizer	No	The type of the optimizer. Valid values: • momentum: stochastic gradient descent (SGD) with momentum • adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: • exponential_decay: The learning rate is subject to exponential decay. • polynomial_decay: The learning rate is subject to polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. • manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed. • cosine_decay: The learning rate of each epoch is adjusted based on the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for each specified epoch. This parameter is required if you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The OSS path of the data that is used to train the model.	`oss://path/to/train_*.tfrecord`	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	`oss://path/to/test_*.tfrecord`	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	`oss://path/to/model`	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	`oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt`	`""`
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

Parameter	Required	Description	Value type or sample value	Default value
num_epochs	Yes	The number of times the data is iterated for the training. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	`""`

Train a video classification model

This topic provides an example on how to run a Machine Learning Platform for AI (PAI) command to train a video classification model. This topic also describes the command parameters.

You can run the `ev_video_classification` command to train a model to classify videos. When you run this command, you need only to set the common classification parameters without the need to know the rules or logic of the EasyVision profile.

PAI command

- Training on a single server

```
pai -name ev_video_classification
             -Dbackbone='resnet_3d_50'
             -Dnum_classes=101
             -Dnum_epochs=2
             -Ddecay_epochs=1
             -Dsave_checkpoints_epochs=1
             -Dmodel_dir=oss://pai-vision-data-hz/test/UCF101_resnet_3d_50
             -Dpretrained_model='oss://pai-vision-data-hz/pretrained_models/resnet_3d_50/resent_3d
_50_model.ckpt'

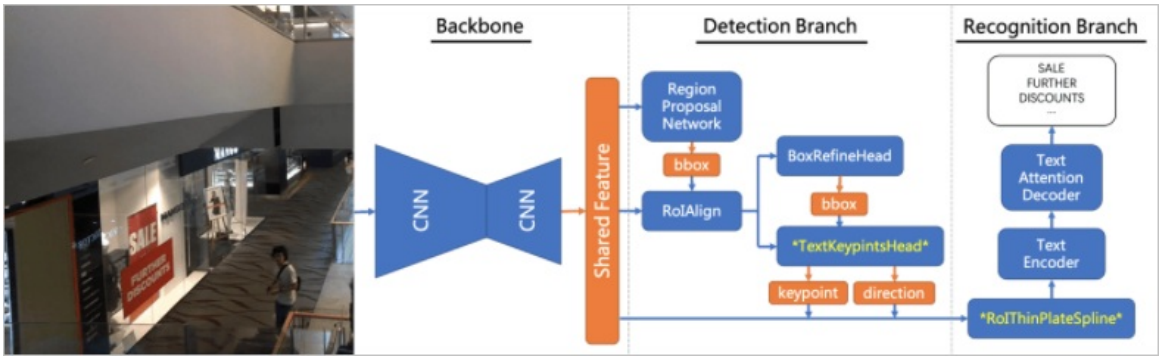
Training of end-to-end text recognition

EasyVision of Machine Learning Platform for AI (PAI) allows you to train models for end-to-end text recognition and use the trained models to make predictions. This topic shows you how to use PAI commands to train a model for end-to-end text recognition. This topic also provides sample PAI commands and describes related parameters.

EasyVision simplifies the training configuration. You can use the `-Dparam_config` parameter to set common parameters. This way, you do not need to know the rules or logic of the configuration files of EasyVision. If you need advanced parameters to train a model for end-to-end text recognition, you can use the `-Dconfig` parameter to pass the configuration file to EasyVision. The following figure shows the algorithm framework of the models for end-to-end text recognition.



Training of end-to-end text recognition

```
pai -name easy_vision
           -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
           -DgpuRequired=100
           -Dcmd train
           -Dparam_config '
             --model_type TextEnd2End
             --backbone  resnet_v1_50
             --num_classes 1
             --use_pretrained_model true
             --train_batch_size 1
             --test_batch_size 1
             --image_min_sizes 960
             --image_max_sizes 1440
             --initial_learning_rate 0.0001
             --optimizer adam
             --lr_type exponential_decay

             --model_dir oss://pai-vision-data-hz/test/recipt_text/text_end2end_krcnn_resnet50_attn
           '
```

Parameters

Parameter	Required	Description	Value type or value format	Default Value
		The information about the Object Storage Service (OSS) buckets. This parameter supports three value formats. Set the following variables in the value formats to their actual values and keep the remaining part unchanged. • <your_bucket>: Set this variable to the name of the OSS bucket that you created. • <your_arn>: You can obtain the value of this variable by	The following three value formats are	

Parameter	Required	Description	Value type or value format	Default Value
buckets	Yes	performing the following operations: i. In the top navigation bar of the Apsara Uni-manager Management Console, click **Configurations**. ii. On the **Service-linked Roles** page, view the role identifier in the **Role Identifier** column. The role identifier is the Apsara Stack resource name that globally and uniquely identifies a RAM role. If no role exists, you can create a role on the page. • <your_host>: Set this variable to the endpoint of your OSS bucket. You can obtain the endpoint in the OSS console.	supported: • "oss://<your_bucket>/?role_arn=<your_arn>&host=<your_host>" • "oss://<your_bucket1>/?role_arn=<your_arn>,oss://<your_bucket2>/?role_arn=<your_arn>&host=<your_host>" • "oss://<your_bucket1>/?role_arn=<your_arn>&host=<your_host>,oss://<your_bucket2>/"	N/A
cluster	No	The configuration of parameters that are used for distributed training.	JSON string	""
gpuRequired	No	Specifies whether to use GPUs. By default, each worker uses one GPU. If you set this parameter to 200, each worker uses two GPUs.	INT	100

Parameter	Required	Description	Value type or value format	Default Value
cmd	Yes	The type of the EasyVision task. To train a model, you must set this parameter to train.	STRING	N/A
param_config	Yes	The configuration of parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. For more information, see param_config.	STRING	N/A

param_config

The param_config parameter contains the parameters that are used for model training. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following code provides an example of the param_config parameter:

```
-Dparam_config = '
--backbone resnet_v1_50
--model_dir oss://your/bucket/exp_dir
'
```

Note The values of all string parameters in the param_config parameter are not enclosed in double quotation marks (") or single quotation marks (').

Parameter	Required	Description	Value type or value format	Default Value
model_type	Yes	The type of the model to train. Set this parameter to TextEnd2End when you train a model for end-to-end text recognition.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: • resnet_v1_50 • resnet_v1_101	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	No	The number of categories. By default, the value is obtained by analyzing the dataset that is used for model training.	INT	-1

Parameter	Required	Description	Value type or value format	Default Value
anchor_scales	No	The size of the anchor box. The size of the anchor box is the same as that of the input image where the anchor box resides after the image is resized. Set this parameter to the size of the anchor box in the layer that has the highest resolution. The total number of layers is five. The size of the anchor box in a layer is twice as that in the previous layer. For example, if the size of the anchor box in the first layer is 32, the sizes of the anchor boxes in the next four layers are 64, 128, 256, and 512.	FLOAT list. Example value: 32 (single scale).	24
anchor_ratios	No	The ratios of the width to the height of the anchor boxes.	FLOAT list	0.2 0.5 1 2 5
predict_text_direction	No	Specifies whether to predict the text orientation.	BOOL	false
text_direction_trainable	No	Specifies whether to train the model to predict the text orientation.	BOOL	false
text_direction_type	No	The type of the prediction of text orientation. Valid values: • normal: greedy prediction. • unified: The orientation of the most text lines is determined as the text orientation. • smart_unified: The orientation of the most text lines excluding the lines of which the height is twice the width is determined as the text orientation.	STRING	normal
feature_gather_type	No	The type of the extractor that is used to extract features of the text lines. Valid values: • fixed_size: extracts features based on the specified width and height. • fixed_height: extracts features based on the specified height and the specified ratio of the width to the height. • fixed_height_pyramid: extracts features from multi-scale features based on the specified height and the specified ratio of the width to the height.	STRING	fixed_height

Parameter	Required	Description	Value type or value format	Default Value
feature_gather_aspect_ratio	No	The ratio of the width to the height of the text lines. If you set the feature_gather_type parameter to fixed_size, this parameter specifies the ratio of the specified height to width after the features are resized. If you set the feature_gather_type parameter to fixed_height, this parameter specifies the maximum ratio of the specified height to the custom width after the features are resized.	FLOAT	40
feature_gather_batch_size	No	The size of the current batch of the text lines that are used to train the model.	INT	160
recognition_norm_type	No	The type of the normalization that is used by the encoder and feature extractor. Valid values: • batch_norm • group_norm	STRING	group_norm
recognition_bn_trainable	No	Specifies whether the batch normalization value that is obtained by the encoder and feature extractor can be used for the training. This parameter takes effect only when the norm_type parameter is set to batch_norm.	BOOL	false
encoder_type	No	The type of the encoder. Valid values: • crnn: hybrid Convolutional Neural Network (CNN)-Recurrent Neural Network (RNN) encoder. • cnn_line: CNN encoder. • cnn_spatial: the encoder that uses spatial attention CNN.	STRING	crnn
encoder_cnn_name	No	The type of CNN that is used by the encoder. Valid values: • conv5_encoder • senet5_encoder	STRING	senet5_encoder
encoder_num_layers	No	The number of RNN layers in the encoder. CNN layers are not counted.	INT	2
encoder_rnn_type	No	The type of RNN that is used by the encoder. Valid values: • bi: bidirectional RNN. • uni: unidirectional RNN.	STRING	uni
encoder_hidden_size	No	The number of neurons in the hidden layer of the encoder.	INT	512

Parameter	Required	Description	Value type or value format	Default Value
encoder_cell_type	No	The type of RNN cells in the encoder. Valid values: • basic_lstm • gru • layer_norm_basic_lstm • nas	STRING	basic_lstm
decoder_type	No	The type of the decoder. Valid values: • attention • ctc	STRING	attention
decoder_num_layers	No	The number of layers in the decoder.	INT	2
decoder_hidden_size	No	The number of neurons in the hidden layer of the decoder.	INT	512
decoder_cell_type	No	The type of RNN cells in the decoder. Valid values: • basic_lstm • gru • layer_norm_basic_lstm • nas	STRING	basic_lstm
embedding_size	No	The embedding size of the dictionary.	INT	64
beam_width	No	The beam width of the beam search.	INT	0
length_penalty_weight	No	The length penalty score of the beam search. This prevents shorter sentences from receiving higher scores.	FLOAT	0.0
attention_mechanism	No	The type of the attention mechanism of the decoder. Valid values: • luong • scaled_luong • bahdanau • normed_bahdanau	STRING	normed_bahdanau
aspect_ratio_min_jitter_coef	No	The minimum ratio of the width to the height at which images can be resized during the training. The value 0 indicates that the ratios of the width to the height of images remain unchanged during the training.	FLOAT	0.8

Parameter	Required	Description	Value type or value format	Default Value
aspect_ratio_max_jitter_coef	No	The maximum ratio of the width to the height at which images can be resized during the training. The value 0 indicates that the ratios of the width to the height of images remain unchanged during the training.	FLOAT	1.2
random_rotation_angle	No	The maximum angle to which images can be randomly rotated during the training, in the clockwise or anticlockwise direction. The value 0 indicates that images are not randomly rotated during the training.	FLOAT	10
random_crop_min_area	No	The minimum ratio of the size of an image after it is randomly cropped to the size of the original image. The value 0 indicates that images are not randomly cropped during the training.	FLOAT	0.1
random_crop_max_area	No	The maximum ratio of the size of an image after it is randomly cropped to the size of the original image. The value 0 indicates that images are not randomly cropped during the training.	FLOAT	1.0
random_crop_min_aspect_ratio	No	The minimum ratio of the width to the height of images after they are randomly cropped during the training. The value 0 indicates that images are not randomly cropped during the training.	FLOAT	0.2
random_crop_max_aspect_ratio	No	The maximum ratio of the width to the height of images after they are randomly cropped during the training. The value 0 indicates that images are not randomly cropped during the training.	FLOAT	5
image_min_sizes	No	The length of the shorter side of images after they are resized. If you specify multiple lengths for the shorter sides of the images in the value of this parameter, the last one is used to evaluate the model, whereas one of the others is randomly selected to train the model. This way, the multi-scale training is supported. If you set only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	800

Parameter	Required	Description	Value type or value format	Default Value
image_max_sizes	No	The length of the longer side of images after they are resized. If you specify multiple lengths for the longer sides of the images in the value of this parameter, the last one is used to evaluate the model, whereas one of the others is randomly selected to train the model. This way, the multi-scale training is supported. If you set only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	1200
random_distort_color	No	Specifies whether to randomly change the brightness, contrast, and saturation of images during the training.	BOOL	true
optimizer	No	The type of the optimizer. Valid values: • momentum: stochastic gradient descent (SGD) with momentum • adam	STRING	momentum

Parameter	Required	Description	Value type or value format	Default Value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: • exponential_decay: the exponential decay. • polynomial_decay: the polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. • manual_step: specifies to manually adjust the learning rate for each epoch. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed. • cosine_decay adjusts the learning rate by following the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. If you set the lr_type parameter to cosine_decay, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rates.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or value format	Default Value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or value format	Default Value
learning_rates	No	The learning rate that you want to set for the specified epochs. This parameter is required when you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and that of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The OSS path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	`oss://path/to/model`	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	`oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt`	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true
num_epochs	Yes	The number of training iterations. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A

Parameter	Required	Description	Value type or value format	Default Value
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.1.5.2.13.3. Offline prediction

General image prediction

The general image prediction component is used to make predictions. It reads data from MaxCompute tables or Object Storage Service (OSS) files for prediction, and writes the prediction results to the MaxCompute tables or OSS files. This topic provides examples on how to run a Machine Learning Platform for AI (PAI) command to use the general image prediction component. This topic also describes how to define the input and output files and customize the process and prediction classes for different types of models.

PAI command

- Detect objects based on a region of interest

```
pai -name ev_predict
   -Dmodel_path='oss://pai-vision-data-hz/pretrained_models/saved_models/faster_rcnn_with_roi_features_coco/'
   -Dmodel_type='detector'
   -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/predict_oss_io_test.list'
   -Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_predict_result.txt'
   -Dimage_type='url'
   -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx:role/pai-vision-hz&host=cn-hangzhou.oss.aliyun-inc.com'
```

- Customize the process and predictor classes

```
pai -name ev_predict
   -Dmodel_path='oss://pai-vision-data-hz/pretrained_models/pipeline_text_models/'
   -Dmodel_type='self_define'
   -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/predict_oss_io_test.list'
   -Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_predict_result.txt'
   -Dimage_type='url'
   -Duser_resource='oss://pai-vision-data-hz/data/pai_test/ev_predict/test_data/self_define/user_res.tar.gz'
   -Duser_predictor_cls='user_predictor.MyPredictor'
   -Duser_process_config='
      [
        {
         \"job_name\":\"myprocess\",
         \"num_threads\":2,
         \"batch_size\":1,
         \"class\":\"user_process.MyProcess\"
       }
      ]'
   -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
```

The code file that is used to customize the process class is *user_process.py*. The class name is MyProcess. The code file that is used to customize the predictor class is *user_predictor.py*. The class name is MyPredictor. The *user_process.py* and *user_predictor.py* code files are compressed in the *user_res.tar.gz* package.

- Specify the input and output OSS files

```
pai -name ev_predict
   -Dmodel_path='oss://pai-vision-data-hz/pretrained_models/pipeline_text_models/'
   -Dmodel_type='self_define'
   -Duser_resource='oss://your_predictor_res.tar.gz'
   -Duser_predictor_cls='your_predictor.DummyModalPredictor'
   -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/predict_oss_io_test.list'
   -Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_predict_multi_modal_result.json'
   -Doutput_dir='oss://pai-vision-data-hz/test/tmp/multi_modal_output'
   -Dimage_type='url'
   -Dbuckets='oss://pai-vision-data-hz/?role_arn=xxx/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
```

The code file that is used to customize the predictor class is *user_predictor.py*. The class name is DummyModalPredictor.

- Customize the process class

  You can specify the input tables to read and process, and the output table to which the processed data is written. The following content provides an example on how to extract video features. In this example, two input tables are used. One of them contains the information about video frames. The other contains the IDs of the videos from which you want to extract features. You can use the following PAI command to read data from the input tables and write the prediction results to the output table.

- Input table 1

```
+-------------------------------------------------------------------------------------+
| Field           | Type       | Label | Comment                                      |
+-------------------------------------------------------------------------------------+
| video_id        | bigint     |       |                                              |
| frame_id        | bigint     |       |                                              |
| image           | string     |       |                                              |
| shot_id         | bigint     |       |                                              |

```

Parameters

Parameter	Required	Description	Value type	Default value
model_path	Yes	The OSS path of the model. Example: "oss://your_bucket/your_model_dir".	STRING	N/A

Parameter	Required	Description	Value type	Default value
model_type	Yes	The type of the model. Valid values: • feature_extractor: feature extraction • classifier: image classification • detector: object detection • text_detector: text detection • text_recognizer: text line recognition • text_spotter: end-to-end text recognition • segmentor: semantic image segmentation • self_define: custom prediction If the model_type parameter is set to self_define, the predictor class that is specified by the user_predictor_cls parameter is loaded.	STRING	N/A
buckets	No	The information about the OSS buckets. If you use a custom model, you must specify the OSS bucket in which your model is stored. Example: "oss://bucket_name/?role_arn=xxx&host=yyy".	STRING	""
feature_name	No	The name of the feature to extract. This parameter is required if the model_type parameter is set to feature_extractor. Example: resnet_v1_50/logits.	STRING	""
input_table	No	The name of the input table. For example, you can use a non-partitioned table "odps://prj_name/tables/table_name" or a partitioned table "odps://prj_name/tables/table_name/pt=xxx".	STRING	""
image_col	No	The name of the column that contains the image data.	STRING	"image"
image_type	No	The format of the image data. Valid values: • base64: indicates that the table stores the image data in the Base64 format. • url: indicates that the table stores the URLs or OSS paths of the images.	STRING	"base64"

Parameter	Required	Description	Value type	Default value
reserved_columns	No	The names of reserved data columns. Separate multiple names with commas (,). Example: "col1,col2,col3".	STRING	""
result_column	No	The name of the result column.	STRING	"prediction_result"
output_table	No	The output table. The value format is the same as that of the input_table parameter. If the specified output table does not exist, an output table is automatically created and partitioned. You can also create a partitioned table as the output table before you make the prediction.	STRING	""
lifecycle	No	The lifecycle of the output table.	INT	10
num_worker	No	The number of prediction workers. More workers can accelerate offline prediction.	INT	2
cpuRequired	No	The number of CPUs for a worker. A value of 100 indicates one CPU.	INT	1600
gpuRequired	No	The number of GPUs for each worker. A value of 100 indicates one GPU. You can use up to 100 GPUs for a worker. A value of 0 indicates that a CPU cluster is used.	INT	100
memory	No	The memory size of each worker, in MB.	INT	30000
input_oss_file	No	The path of the input OSS file. Each line in the input file can be in one of the following formats: • The OSS path or URL of an image to predict. Example: oss://your_bucket/filelist.txt. • A JSON string.	STRING	""
output_oss_file	No	The path of the output OSS file that is used to store the prediction results. The system may generate multiple result files and merge these result files into an output OSS file. The result files are prefixed with the name of the output OSS file. The number of result files is the same as the number of workers, which is specified by the num_worker parameter.	STRING	""

Parameter	Required	Description	Value type	Default value
output_dir	No	The directory of the output file. If you customize the output format, all the result images are stored in this directory.	STRING	""
user_resource	No	The path to which you want to upload your resources. You can upload tar.gz, .zip, and .py files. OSS paths and HTTP URLs are supported. Example: oss://xxx/a.tar.gz or http://a.com/c.zip.	STRING	""
user_predictor_cls	No	The module path of the custom predictor class. For example, if you implement Predictor A in *module.py*, the module path of Predictor A is module.A.	STRING	""
user_process_config	No	The configurations of the custom process class. You can use the following fields to configure the process class. You can also configure other custom fields. • job_name: the name of the custom process class. • num_threads: the number of concurrent threads that are used by the custom process class. • batch_size: the batch size of the data to be processed. • user_process_cls: the module path of the custom process class. For example, if you implement Process A in *module.py*, the module path of Process A is module.A. Example: '{["job_name":"myprocess","user_process_cls": module.ClassA"num_threads":2, "batch_size":1]}'	JSON string	""
queue_size	No	The length of the cache queue.	INT	1024
batch_size	No	The size of data that is used for prediction in the current batch.	INT	1
preprocess_thread_num	No	The number of concurrent threads that are used for preprocessing, such as image decoding and download.	INT	4
predict_thread_num	No	The number of concurrent threads that are used for prediction.	INT	2

Parameter	Required	Description	Value type	Default value
is_input_video	No	Specifies whether the input files are video files.	BOOL	false
use_image_predictor	No	Specifies whether the predictor supports only image input.	BOOL	true
decode_type	No	The method that is used to decode the videos. Valid values: • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	5
reshape_size	No	The size of the output frames, in pixels. If you set this parameter to -1, the frames are not resized.	INT	-1
decode_batch_size	No	The number of frames that are decoded at a time.	INT	10
decode_keep_size	No	The number of overlapped frames in different batches.	INT	0
float_digits	No	The number of FLOAT digits for JSON serialization. For example, if you set this parameter to 3, the generated string contains three decimal places. A value of -1 indicates that the generated string uses the original precision.	INT	-1
mediaflow_class_name	No	The path of the Mediaflow class. Example: demo.mediaflow_caller.	STRING	""
self_defined_result_formater	No	The class that is used to format the custom results. Example: a.table_result_format.	STRING	""
user_build_process_fn	No	The custom process function. Example: a.build_process_fn.	STRING	""
enableDynamicCluster	No	Specifies whether to enable the dynamic cluster feature. If this feature is enabled, the failover of a single worker is allowed. If task exceptions frequently occur, we recommend that you enable this feature.	BOOL	false

Parameter	Required	Description	Value type	Default value
useSparseClusterSchema	No	If the enableDynamicCluster parameter is set to true, you must also set the useSparseClusterSchema parameter to true.	BOOL	false
enable_elastic_inference	No	Specifies whether to enable the elastic inference feature.	BOOL	false
restore_works_dir	No	The cache directory that is used to store the data being processed by each worker. When a worker fails, the data can be used to recover the worker. You can set this parameter to an OSS path or an Apsara File Storage for HDFS directory. If the enable_elastic_inference parameter is set to true, this parameter is required. Example: egoss://path/to/dir/hdfs://path/to/dir/. **Note** The value must end with a forward slash (/).	STRING	""
slice_size	No	The size of a data shard that a worker processes at a time. A large value may lead to out of memory (OOM) errors, whereas a small value may lead to low reading efficiency. We recommend that you set this parameter to 1024 for image processing and 16 for video processing.	INT	N/A

Input data formats

- Input table

  An input table can contain one or more columns. One of the columns must contain the image URLs or Base64-encoded binary image data. The data type of the column must be STRING. The following example shows a table schema:

```
+------------------------------------------------------------------------------------+
| Field           | Type       | Label | Comment                                     |
+------------------------------------------------------------------------------------+
| id              | STRING     |       |                                             |
| url             | STRING     |       |                                             |
+------------------------------------------------------------------------------------+
```

- Input OSS file

  Each line of the input OSS file is a URL or an OSS path, for example:

```
oss://your/path/to/image.jpg
http://your.path/to/image.jpg
```

- Custom input format

  By default, only image URLs or Base64-encoded image data entries are read from the input tables. Only image URLs are read from the input OSS files to download and decode images. Both of the two methods generate only the numPy arrays of images in the {"image": np.ndarry} format. The numPy arrays are used by the process and predictor classes to make predictions. More and more users customize the predictor and process classes. A single input data format cannot satisfy user needs. To support custom formats, the method for reading data from OSS files is improved.

  The custom format can be the original OSS file format or JSON string format. Each line in the input files is a JSON string. You can enter multiple key-value pairs. All key-value pairs are saved in a dictionary and passed to the custom predictor and process classes. You can obtain the corresponding values based on custom keys.

  If the values are OSS paths or URLs, the system automatically uses multiple threads to download the file content, and saves the values in a Python file-like object. You can call methods such as `read()` or `readlines()` to obtain the content of the Python file-like object. If a value points to a file with an image extension, the system automatically decodes the image. You can obtain the value from the input_data dictionary based on the corresponding key. The value is of the numpy.ndarray type.

  The following code provides an example of the input data:

  ```
  {"image":"http://your/path/to/image.jpg", "prior":"oss://your/path/to/prior.txt", "config": {"key1":1, "key2":"value2"}}
  {"image":"http://your/path/to/image.jpg", "prior":"oss://your/path/to/prior.txt", "config": {"key2":1, "key2":"value2"}}
  ```

  The preceding input data is converted into data in the input_data dictionary with the following fields:

  - image: the decoded data of an image.
  - prior: the file-like object.
  - config: a dictionary of JSON strings.

  The input_data dictionary is in the following format. For all custom process and predictor classes, you can query image data based on the key.

  ```
  input_dict = {
    "image": np.ndarray,
    "prior" : file_like_object,
    "config": null
  }
  ```

  Note All built-in predictor classes of EasyVision use the image key to obtain input images. If you want to use a custom input format to call the built-in predictor classes of EasyVision, you must set the image key for image data.

Custom third-party library

The offline prediction framework is implemented based on PAI-TensorFlow. Therefore, the framework does not allow you to use PyTorch models to make custom predictions. In addition, if you make a custom prediction by using a third-party library that does not exist in the preset Python environment, the prediction fails. To resolve this issue, PAI allows you to use the *requirements.txt* file to install a custom Python library.

You must add the *requirements.txt* file to the top-level code directory:

```
user_resource
├── pytorch_sr_script.py
├── requirements.txt
├── user_predictor.py
├── user_process.py
```

Then, you must package the entire code directory and upload it to OSS. The following code provides an example:

```
tar -zcf user_resource.tar.gz user_resource
osscmd put user_resource.tar.gz oss://your/path/user_resource.tar.gz
```

You can specify the address of the code package in the PAI command parameter `-Duser_resource`. When the prediction task runs, PAI automatically installs the dependencies that are specified in the *requirements.txt* file.

Custom predictor class

The custom predictor class must inherit `easy_vision.python.inference.predictor.PredictorInterface` or `easy_vision.python.inference.predictor.PredictorInterfaceV2`. The names and default values of all functions and parameters of the custom predictor class must be the same as those in the definition of the UserProcess operation.

The general image prediction component is compatible with V1 and V2 operation definitions of the custom predictor class.

- V1 (only serializes all prediction results to JSON strings)

  The following code shows the operation definition:

```
class PredictorInterface(six.with_metaclass(abc.ABCMeta, object)):
  def __init__(self, model_path, model_config=None):
    """
    init tensorflow session and load tf model
    Args:
      model_path  init model from this directory
      model_config config string for model to init, in json format
    """
    pass
  @abc.abstractmethod
  def predict(self, input_data, batch_size):
    """
    using session run predict a number of samples using batch_size
    Args:
      input_data:  a list of numpy array, each array is a sample to be predicted
      batch_size: batch_size passed by the caller, you can also ignore this param and
        use a fixed number if you do not want to adjust batch_size in runtime
    Return:
      result: a list of dict, each dict is the prediction result of one sample
        eg, {"output1": value1, "output2": value2}, the value type can be
        python int str float, and numpy array
    """
    pass
```

  The following code provides an example of the custom predictor class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_predictor.py
# Author: Qianyan (wenmeng.zwm@alibaba-inc.com)
# Date: 2019-06-10
# Description:
from easy_vision.python.inference import predictor
import tensorflow as tf
class MyPredictor(predictor.PredictorInterface):
  def __init__(self, model_path, model_config=None):
    """
    init tensorflow session and load tf model
    Args:
      model_path  init model from this directory
      model_config config string for model to init, in json format
    """
    tf.logging.info('my predictor init done')
  def predict(self, input_data, batch_size):
    """
    using session run predit a number of samples using batch_size
    Args:
      input_data:  a list of numpy array, each array is a sample to be predicted
      batch_size: batch_size passed by the caller, you can also ignore this param and
        use a fixed number if you do not want to adjust batch_size in runtime
    Return:
      result: a list of dict, each dict is the prediction result of one sample
        eg, {"output1": value1, "output2": value2}, the value type can be
        python int str float, and numpy array
    """
    results = [{'result1':'my_predictor_result1', 'result2':'my_predictor_result2'}
               for i in range(len(input_data))]
    return results
```

- V2

  The custom predictor class has the following limits:

  - You can use the custom predictor class to pass only the list of images. No other information can be passed.
  - The output dictionary is converted into only JSON strings and cannot save image files.

  To remove the limits, PAI provides V2 operation definition to enable you to specify the output format. V2 is developed based on V1 by adding the get_output_type function. This function returns a dictionary that indicates how to save the values in the key-value pairs in the dictionary returned by the prediction. The values can be saved in the following ways:

  - json: All the output JSON data of keys is aggregated into a dictionary and serialized to a JSON string. Then, the JSON string is written to the output OSS file.
  - image: The output data of the keys that correspond to values of the image type is saved in an OSS file *output_dir/key/filename.jpg*. The value of the filename variable is obtained from the input URL. If the output data of a key is a list of images, each image in the list is saved as *output_dir/key/filename_idx.jpg*, where, idx is the index number of each image.
  - video: not supported.

  To pass more information, you can also pass a list of dictionaries to the predictor class by using custom input data types.

  The following code shows the operation definition:

```
class PredictorInterfaceV2(six.with_metaclass(abc.ABCMeta, object)):
  def __init__(self, model_path, model_config=None):
    """
    init tensorflow session and load tf model
    Args:
      model_path  init model from this directory
      model_config config string for model to init, in json format
    """
    pass
  def get_output_type(self):
    """
    in this function user should return a type dict, which indicates
    which type of data should the output of predictor be converted to
    * type json, data will be serialized to json str
    * type image, data will be converted to encode image binary and write to oss file,
      whose name is output_dir/${key}/${input_filename}_${idx}.jpg, where input_filename
      is extracted from url, key corresponds to the key in the dict of output_type,
      if the type of data indexed by key is a list, idx is the index of element in list, otherwhil
e ${idx} will be empty
    * type video, data will be converted to encode video binary and write to oss file,
    eg:  return  {
      'ret_image': 'image',
      'feature': 'json'
    }
    indicating that the image data in the output dict will be save to image
    file and feature in output dict will be converted to json
    """
    return {}
  @abc.abstractmethod
    def predict(self, input_data_dict, batch_size):
    """
    using session run predict a number of samples using batch_size
    Args:
      input_data_dict:  a list of dict, each dict is a sample data to be predicted
      batch_size: batch_size passed by the caller, you can also ignore this param and
        use a fixed number if you do not want to adjust batch_size in runtime
    Return:
      result: a list of dict, each dict is the prediction result of one sample
        eg, {"output1": value1, "output2": value2}, the value type can be
        python int str float, and numpy array
    """
    pass
```

The following code provides an example of the custom predictor class:

```
  class DummyMultiModalPredictor(ev_predictor.PredictorInterfaceV2):
    def __init__(self, model_path, model_config=None):
      pass
    def get_output_type(self):
      return {'result1': 'json',
              'result2':'json',
              'result_image': 'image',
              'result_image_list':'image',
              }
    def predict(self, images, batch_size=1):
      results = [{
                  'result1':'dummy',
                  'result2':'dummy',
                  'result_image': np.zeros([224,224,3],dtype=np.uint8),
                  'result_image_list': [255* np.ones([224,224,3],dtype=np.uint8) for i in range(2
))]
                } for i in range(len(images))]
      return results
```

Custom process class

The custom process class must inherit `easy_vision.python.pai_utils.ev_process.UserProcess`. The names and default values of all functions and parameters of the custom process class must be the same as those in the definition of the UserProcess operation.

The following code shows the operation definition:

```
class UserProcess(Process):
  def __init__(self,
               job_name,
               num_threads=1,
               input_queue=None,
               output_queue=None,
               process_config=None,
               batch_size=1):
    """
    Args:
      job_name:  job name for this process
      num_threads: number of threads to run your process
      input_queue:  a queue containing input data, you should not read input_queue by
        yourself
      output_queue:  you can push data to output_queue or just return data in process
        which will be pushed into output queue automatically
      process_config:  config for your process, dict type
      batch_size:  if batch_size is 1, input_data passed to in_data is a dict of one sample data
        if batch_size greater than 1, input_data passed to process is a list of dict, each dict
                contains one sample data
    """
    super(UserProcess, self).__init__(
        job_name,
        num_threads,
        input_queue=input_queue,
        output_queue=output_queue,
        batch_size=batch_size)
  def process(self, in_data):
    """
    method need to be reimplemented, one can add result to output_queue in this func
    or just return the result which will be pushed to output queue automatically.
    you should add the process result to input_data dict, and push it to the output
    queue or just return it. You can refer to easy_vision.python.pai_utils.ev_process.DataFields
    attribute to acquire what information you can get from input_dict, you can only
    write data with key like DataFields.image or DataFields.clip
    Args:
      in_data   if self.batch_size is 1, input_data is a dict of one sample data
                if self.batch_size greater than 1, input_data is a list of dict, each dict
                  contains one sample data
    Return
      if None, result should be added to output_queue by yourself in this func
      if not None, the returned result will be add to output_queue automatically
    """
    return input_data
  def destroy(self):
    """
    destroy resources that has been used for this process
    """
    pass
```

The following code provides an example of the custom process class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_process.py
# Author: Qianyan (wenmeng.zwm@alibaba-inc.com)
# Date: 2019-06-10
# Description:
from easy_vision.python.pai_utils import ev_process
import logging
class MyProcess(ev_process.UserProcess):
  def __init__(self,
               job_name,
               num_threads=1,
               input_queue=None,

    """
    logging.info('my process destroyed')
```

Result format

This section describes the result format of various models.

- feature_extractor

  Sample result:

  ```
  {"feature": [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.4583122730255127, 0.0]}
  ```

  The following table describes the fields in the sample result.

Field	Description	Shape	Type
feature	The extracted feature.	[feature_dim]	FLOAT

- classifier

  Sample result:

  ```
  {
  "class": 3,
  "class_name": "coho4",
  "class_probs": {"coho1": 4.028851974258174e-10,
            "coho2": 0.48115724325180054,
            "coho3": 5.116515922054532e-07,
            "coho4": 0.5188422446937221}
  }
  ```

  The following table describes the fields in the sample result.

Field	Description	Shape	Type
class	The ID of the category.	[]	INT 32
class_name	The name of the category.	[]	STRING
class_probs	The matching probabilities of all categories.	[num_classes]	DICT{key: STRING, value: FLOAT}

- detector

  Sample result:

  ```
  {
    "detection_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.724777221679
  7], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],
    "detection_scores": [0.9942291975021362, 0.9940272569656372],
    "detection_classes": [1, 1],
    "detection_classe_names": ["text", "text"]
   }
  ```

  The following table describes the fields in the sample result.

Field	Description	Shape	Type

Field	Description	Shape	Type
detection_boxes	The bounding boxes that mark the recognized objects. The coordinates of each bounding box are specified in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probabilities that the commodities are recognized.	num_detections	FLOAT
detection_classes	The IDs of the categories to which the objects belong.	num_detections	INT
detection_class_names	The names of the categories to which the commodities belong.	num_detections	ISTRING
detection_masks	The segmentation masks of the object. Optional.	[num_detection, image_height, image_width]	FLOAT
detection_keypoints	The landmarks of the object. Optional.	[num_detection, num_keypoints, 2]	FLOAT
detection_roi_features	The local features of the object. Optional.	[num_detection, roi_height, roi_width, channels]	FLOAT

- segmentor

  Sample result:

```
{
  "probs" : [[[0.8, 0.8], [0.6, 0.7]],[[0.8, 0.5], [0.4, 0.3]]],
  "preds" : [[[1,1], [0, 0]], [[0, 0], [1,1]]]
}
```

  The following table describes the fields in the sample result.

Field	Description	Shape	Type
probs	The probability that each pixel obtained through segmentation belongs to a specific category.	[output_height, output_width, num_classes]	FLOAT
preds	The IDs of the categories to which the pixels obtained after segmentation belong.	[output_height, output_widths]	INT

- text_detector

  Sample result:

```
{
  "detection_keypoints": [[[243.57516479492188, 198.84210205078125], [243.91038513183594, 247.62425231933594], [385.5513916015625, 246.61660766601562], [385.2197570800781, 197.79345703125]], [[292.2718200683594, 114.44700622558594], [292.2237243652344, 164.684814453125], [571.1962890625, 164.931640625], [571.2444458007812, 114.67433166503906]]],
  "detection_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.7247772216797], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],
  "detection_scores": [0.9942291975021362, 0.9940272569656372],
  "detection_classes": [1, 1],
  "detection_classe_names": ["text", "text"],
   "image_shape": [1024, 968, 3]
 }
```

The following table describes the fields in the sample result.

Field	Description	Shape	Type
detection_boxes	The detected text area with coordinates in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probabilities that the text areas are detected.	num_detections	FLOAT
detection_classes	The IDs of the categories to which the text areas belong.	num_detections	INT
detection_class_names	The names of the categories to which the text areas belong.	num_detections	STRING
detection_keypoints	The (y, x) coordinates of the four vertices of the detected text area.	[num_detections, 4, 2]	FLOAT
image_shape	The information about the input image. The value is a list that contains the following information in order: height, width, and channel.	[3]	LIST

- text_recognizer

  Sample result:

```
{
  "sequence_predict_ids": [1,2,2008,12],
  "sequence_predict_texts": "This is an example",
  "sequence_probability": 0.88
}
```

The following table describes the fields in the sample result.

Field	Description	Shape	Type

Field	Description	Shape	Type
sequence_predict_ids	The ID of the category to which a single line of the recognized text belongs.	[text_length]	INT
sequence_predict_texts	The recognition result of each single-line text.	[]	STRING
sequence_probability	The probability that each single-line text is recognized.	[]	FLOAT

- text_spotter

  Sample result:

```
{
  "detection_keypoints": [[[243.57516479492188, 198.84210205078125], [243.91038513183594, 247.6242
5231933594], [385.5513916015625, 246.61660766601562], [385.2197570800781, 197.79345703125]], [[292

7], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],
  "detection_scores": [0.9942291975021362, 0.9940272569656372],
  "detection_classes": [1, 1],
  "detection_classe_names": ["text", "text"],
  "detection_texts_ids" : [[1,2,2008,12], [1,2,2008,12]],
  "detection_texts": ["This is an example", "This is an example"],
  "detection_texts_scores" : [0.88, 0.88],
  "image_shape": [1024, 968, 3]
 }
```

  The following table describes the fields in the sample result.

Field	Description	Shape	Type
detection_boxes	The detected text area with coordinates in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probabilities that the text areas are detected.	num_detections	FLOAT
detection_classes	The IDs of the categories to which the text areas belong.	num_detections	INT
detection_class_names	The names of the categories to which the text areas belong.	num_detections	STRING
detection_keypoints	The (y, x) coordinates of the four vertices of the detected text area.	[num_detections, 4, 2]	FLOAT

Field	Description	Shape	Type
detection_texts_ids	The ID of the category to which a single line of the recognized text belongs.	[num_detections, max_text_length]	INT
detection_texts	The recognition result of each single-line text.	[num_detections]	STRING
detection_texts_scores	The probability that each single-line text is recognized.	[num_detections]	FLOAT
image_shape	The information about the input image. The value is a list that contains the following information in order: height, width, and channel.	[3]	LIST

- Custom result format

  By default, `ev_predict` extracts the dictionary from the cache queue, obtains the value of `prediction_result`, serializes the value to a JSON string, and then writes the JSON string to the result column. To write results to different columns by field, you can set the `self_defined_result_formater` parameter to the path of the custom result formatting class and the user_resource parameter to the path of your code.

  The process class is a derived class. For more information about the operation definition of this class, see the "Custom process class" section of this topic. You need only to save the formatted results in the input_data dictionary with the key as result_to_save. Then, TableWriter automatically writes the prediction results to the specified table.

  The following code provides an example on how to write the decoded data of a video to a table by frame. Each line is the encoded data of a frame.

```
class SelfDefineTableFormatProcess(ev_process.Process):
  def __init__(self,
               input_queue,
               output_queue,
               reserved_col_names=[],
               output_col_names=[]):
    """
    extract data from dict to preprare result dict which will be written to table or oss file
    Args:
      reserved_col_names list of str column names for reserved col
      output_col_names  list of column name for output table
      input_queue  the python queue for input
      output  the python queue for output
      float_digits: The number of digits of precision when writing floats out
    Return:
      push a k-v pair {'result_to_save': result_dict} into data_dict and return
      a result dict or a tuple, or a list of tuple or a list of dict
        if dict is returned, each key should be the same as column name of output table
        if tuple is returned, this tuple corespond to one table record
        if list of tuple is returned, they correspond to a list of table record
        if list of dict is returned, each element in list will be automatically converted to table
record in table writer
    """
    super(SelfDefineTableFormatProcess, self).__init__('SelfDefineTableFormatProcess', 1,
                                                       input_queue=input_queue,
                                                      output_queue=output_queue)
  def process(self, input_data):
    output_record = []
    frames = input_data['frames']
    frames = [base64.urlsafe_b64encode(np.array(frame)) for frame in frames]
    frame_ids = input_data['frame_id']
    url = input_data['url']
    video_records = []
    for url, fid, frame in zip(url, frame_ids, frames):
      video_records.append((url, fid, frame))
    # result should be returned with key result_to_save
    input_data['result_to_save'] = video_records
    return input_data
```

Add the preceding code to *oss://path/to/you/code.py*. Then, use the following PAI command parameters to customize the logic for writing data to the table.

```
pai -name ev_predict
   ...
   -Duser_resource=oss://path/to/you/code.py
   -Dself_defined_result_formater=code.SelfDefineTableFormatProcess
```

General video prediction

This topic provides examples on how to run a Machine Learning Platform for AI (PAI) command to use the video prediction component. This topic also describes the command parameters and provides the operation definitions of and examples on custom process and predictor classes.

You can run the `ev_video_predict` command to make video predictions. When you run this command, you need only to set the common parameters without the need to know the rules or logic of the EasyVision profile.

PAI command

- Input OSS file

```
pai -name ev_video_predict
             -Dinput_oss_file='oss://pai-vision-data-hz/data/pai_test/video_decode_test.list'
             -Doutput_oss_file='oss://pai-vision-data-hz/test/tmp/ev_video_predict_result.txt'
             -Dmodel_path='oss://pai-vision-data-hz/data/pai_test/ev_predict/test_data/models/ucf1
01_resnet3d_50'
             -Dtask_type='video_classifier'
             -Dfeature_name=''
             -Ddecode_type=4
             -Dsample_fps=-1
             -Dreshape_size=-1
             -Dsample_duration=16
             -Dbatch_size=16
             -Dpredict_thread_num=1
             -Dqueue_size=256
             -Dnum_worker=4
             -DcpuRequired=400
             -Dbuckets='YOUR_OSS_BUCKET_CONFIG'
```

- Input Swift file

```
pai -name ev_video_predict
             -Dswift_end_point='SWIFT_END_POINT'
             -Dinput_topic='INPUT_TOPIC'
             -Doutput_topic='OUTPUT_TOPIC'
             -Dmodel_path='oss://pai-vision-data-hz/data/pai_test/ev_predict/test_data/models/ucf1
01_resnet3d_50'
             -Dtask_type='video_classifier'
             -Dfeature_name=''
             -Ddecode_type=4
             -Dsample_fps=-1
             -Dreshape_size=-1
             -Dsample_duration=16
             -Dbatch_size=16
             -Dpredict_thread_num=1
             -Dqueue_size=256
             -Dnum_worker=4
             -DcpuRequired=400
             -Dbuckets='YOUR_OSS_BUCKET_CONFIG'
```

- Custom process and predictor classes

```
pai -name ev_video_predict
             -Dswift_end_point='SWIFT_END_POINT'
             -Dinput_topic='INPUT_TOPIC'
             -Doutput_topic='OUTPUT_TOPIC'
             -Dmodel_path='oss://pai-vision-data-hz/data/pai_test/ev_predict/test_data/models/ucf101_resnet3d_50'
             -Dtask_type='self_define'
             -Dfeature_name=''
             -Ddecode_type=4
             -Dsample_fps=-1
             -Dreshape_size=-1
             -Dsample_duration=16
             -Dbatch_size=1
             -Dpredict_thread_num=1
             -Dqueue_size=256
             -Dnum_worker=4
             -DcpuRequired=400
             -Duser_resource='oss://pai-vision-data-hz/data/pai_test/ev_predict/test_data/self_define/video_res.tar.gz'
             -Duser_predictor_cls='user_predictor.MyPredictor'
             -Duser_process_config='
                [
                  {
                   \"job_name\":\"myprocess\",
                   \"num_threads\":4,
                   \"batch_size\":1,
                   \"class\":\"user_process.MyProcess\"
                  }
                ]'
             -Dbuckets='oss://pai-vision-data-hz/?role_arn=acs:ram::1217060697l8XXXX:role/pai-vision-hz&host=oss-cn-zhangjiakou.aliyuncs.com'
```

The code file that is used to customize the predictor class is *user_predictor.py*. The class name is `MyPredictor`. The code file that is used to customize the process class is *user_process.py*. The class name is `MyProcess`. The *user_predictor.py* and *user_process.py* code files are compressed in the `video_res.tar.gz` package.

Parameters

Parameter	Required	Description	Value type or sample value	Default value
buckets	Yes	The information about the Object Storage Service (OSS) buckets.	`"oss://bucket_name/?role_arn=xxx&host=yyy"`	N/A

Parameter	Required	Description	Value type or sample value	Default value
model_path	Yes	The OSS path of the model.	`"oss://your_bucket/your_model_dir"` The OSS path of the model that EasyVision provides is `oss://pai-vision-data-hz/pretrained_models/saved_models/ucf101_resnet3d_50/`.	N/A
task_type	Yes	The type of the model. Only the video classification model is supported. Set this parameter to video_classifier.	STRING	N/A
input_oss_file	Yes	The path of the input OSS file. Each line in the input file can be in one of the following formats: • The path of a video. • A JSON string. Example: {"video_binary_data": VIDEO_URL, "xxx":xxx}	`oss://your_bucket/filelist.txt`	N/A
output_oss_file	Yes	The path of the output OSS file that is used to store the prediction results. The system may generate multiple result files and merge these result files into an output OSS file. The result files are prefixed with the name of the output OSS file. The number of result files is the same as the number of workers, which is specified by the num_worker parameter.	`oss://your_bucket/result.txt`	N/A
output_dir	No	The directory of the output file. If you customize the output format, all the result files are stored in this directory.	`oss://your_bucket/dir`	`""`
swift_end_point	No	The URL of the online ZooKeeper server.	STRING	`""`

Parameter	Required	Description	Value type or sample value	Default value
input_topic	No	The input topic. Each element in the topic is the OSS path of a video or a JSON string, for example, {"url":xxx, "user_define": xxx}.	STRING	""
output_topic	No	The output topic.	STRING	""
feature_name	No	The name of the output feature. Example: "resnet_3d_50/poo2","resnet_3d_50/scale5/conv5","resnet_3d_50/scale4/conv4","resnet_3d_50/scale3/conv3","resnet_3d_50/scale2/conv2","resnet_3d_50/pool1","resnet_3d_50/scale1/conv1".	STRING	""
decode_type	No	The method that is used to decode the videos. Valid values: • 1: intra only • 2: keyframe only • 3: without bidir • 4: decode all	INT	4
sample_fps	No	The number of frames that are extracted for sampling per second.	FLOAT	-1, which indicates that 25 frames are extracted per second.
reshape_size	No	The size of the output frames, in pixels.	INT	If you set this parameter to -1, the frames are not resized.
sample_duration	No	The length of consecutive frames that are imported to the model.	INT	16
batch_size	No	The number of clips that are imported to the model.	INT	16
predict_thread_num	No	The number of threads that are used for prediction.	INT	1
queue_size	No	The length of the processing queue.	INT	256
num_worker	No	The number of prediction workers.	INT	2

Parameter	Required	Description	Value type or sample value	Default value
cpuRequired	No	The number of CPUs for a worker. A value of 100 indicates one CPU.	INT	400
gpuRequired	No	The number of CPUs for a worker. A value of 100 indicates one GPU.	INT	100
user_resource	No	The path to which you want to upload your resources. You can upload tar.gz, .zip, and .py files. OSS paths and HTTP URLs are supported.	`oss://xxx/a.tar.gzhttp://a.com/c.zip`	`""`
user_predictor_cls	No	The module path of the custom predictor class. For example, if you implement Predictor A in module.py, the module path of Predictor A is module.A.	`module.PredictorA`	`""`
user_process_config	No	The configurations of the custom process class, in the JSON string format. You can use the following fields to configure the process class. You can also configure other custom fields. • job_name: the name of the custom process class. • num_threads: the number of concurrent threads that are used by the custom process class. • batch_size: the batch size of the data to be processed. • user_process_cls: the module path of the custom process class. For example, if you implement Process A in module.py, the module path of Predictor A is module.A.	`'{["job_name":"myprocess","user_process_cls":module.ClassA"num_threads":2,"batch_size":1]}'`	`""`

Result format

The result of each video is a JSON string, which includes the URL or OSS path and the prediction result of the video. The following code provides an example:

```

```

If you want to obtain video features, the result contains the feature field with the corresponding feature value. The following code provides an example:

```
{"feature": [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.4583122730255127, 0.0]}
```

Parameter	Description	Shape	Value type
class	The ID of the category.	[]	INT32
class_name	The name of the category.	[]	STRING
probs	The matching probabilities of all categories.	[num_classes]	DICT{Key: STRING, Value: FLOAT}
feature	The video feature.	[]	FLOAT

Custom process class

The custom process class must inherit `easy_vision.python.pai_utils.ev_process.UserProcess`. The names and default values of all functions and parameters of the custom process class must be the same as those in the definition of the UserProcess operation.

The following code shows the operation definition:

```
class UserProcess(Process):
  def __init__(self,
               job_name,
               num_threads=1,
               input_queue=None,
               output_queue=None,
               process_config=None,
               batch_size=1):
    """
    Args:
      job_name:  job name for this process
      num_threads: number of threads to run your process
      input_queue:  a queue containing input data, you should not read input_queue by
        yourself
      output_queue:  you can push data to output_queue or just return data in process
        which will be pushed into output queue automatically
      process_config:  config for your process, dict type
      batch_size:  if batch_size is 1, input_data passed to in_data is a dict of one sample data
        if batch_size greater than 1, input_data passed to process is a list of dict, each dict
                contains one sample data
    """
    super(UserProcess, self).__init__(
        job_name,
        num_threads,
        input_queue=input_queue,
        output_queue=output_queue,
        batch_size=batch_size)
  def process(self, in_data):
    """
    method need to be reimplemented, one can add result to output_queue in this func
    or just return the result which will be pushed to output queue automatically.
    you should add the process result to input_data dict, and push it to the output
    queue or just return it. You can refer to easy_vision.python.pai_utils.ev_process.DataFields
    attribute to acquire what information you can get from input_dict, you can only
    write data with key like DataFields.image or DataFields.clip
    Args:
      in_data   if self.batch_size is 1, input_data is a dict of one sample data
                if self.batch_size greater than 1, input_data is a list of dict, each dict
                  contains one sample data
    Return
      if None, result should be added to output_queue by yourself in this func
      if not None, the returned result will be add to output_queue automatically
    """
    return in_data
  def destroy(self):
    """
    destroy resources that has been used for this process
    """
    pass
```

To use the custom process class for video prediction, you must pass a dictionary that contains the following fields:

- url: the URL of the video.
- video_binary_data: the original video stream, in the STRING format.
- frames: the frames that are decoded from the video, in the LIST format. In the list, each element indicates a frame in the STRING format.
- time_stamp: the timestamps, in the LIST format. In the list, each element indicates a timestamp in the FLOAT format.
- xxx: the custom information.

The following code provides an example of the custom process class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_process.py
from easy_vision.python.pai_utils import ev_process
import logging
class MyProcess(ev_process.UserProcess):
  def __init__(self,
               job_name,
               num_threads=1,
               input_queue=None,
               output_queue=None,
               process_config=None,
               batch_size=1):
    """
    Args:
      job_name:  job name for this process
      num_threads: number of threads to run your process
      input_queue:  a queue containing input data, you should not read input_queue by
        yourself
      output_queue:  you can push data to output_queue or just return data in process
        which will be pushed into output queue automatically
      process_config:  config for your process, dict type
      batch_size:  if batch_size is 1, input_data passed to in_data is a dict of one sample data
        if batch_size greater than 1, input_data passed to process is a list of dict, each dict
                contains one sample data
    """
    super(MyProcess, self).__init__(job_name, num_threads,
        input_queue = input_queue,
        output_queue = output_queue,
        batch_size = batch_size)
  def process(self, in_data):
    """
    method need to be reimplemented, one can add result to output_queue in this func
    or just return the result which will be pushed to output queue automatically.
    you should add the process result to input_data dict, and push it to the output
    queue or just return it. You can refer to easy_vision.python.pai_utils.ev_process.DataFields
    attribute to acquire what information you can get from input_dict, you can only
    write data with key like DataFields.image or DataFields.clip
    Args:
      in_data   if self.batch_size is 1, input_data is a dict of one sample data
                if self.batch_size greater than 1, input_data is a list of dict, each dict
                  contains one sample data
    Return
      if None, result should be added to output_queue by yourself in this func
      if not None, the returned result will be add to output_queue automatically
    """
    logging.info('my process process data')
    return in_data
  def destroy(self):
    """
    destroy resources that has been used for this process
    """
    logging.info('my process destroyed')
```

Custom predictor class

The custom predictor class must inherit `easy_vision.python.inference.predictor.PredictorInterface`. The names and default values of all functions and parameters of the custom predictor class must be the same as those in the definition of the UserProcess operation.

The general video prediction component is compatible with V1 and V2 operation definitions of the custom predictor class.

- V1

  The following code shows the operation definition:

```
class PredictorInterface(six.with_metaclass(abc.ABCMeta, object)):
  def __init__(self, model_path, model_config=None):
    """
    init tensorflow session and load tf model
    Args:
      model_path  init model from this directory
      model_config config string for model to init, in json format
    """
    pass
  @abc.abstractmethod
  def predict(self, input_data, batch_size):
    """
    using session run predict a number of samples using batch_size
    Args:
      input_data:  a list of numpy array, each array is a sample to be predicted
      batch_size: batch_size passed by the caller, you can also ignore this param and
        use a fixed number if you do not want to adjust batch_size in runtime
    Return:
      result: a list of dict, each dict is the prediction result of one sample
        eg, {"output1": value1, "output2": value2}, the value type can be
        python int str float, and numpy array
    """
    pass
```

  The following code provides an example of the custom predictor class:

```
#!/usr/bin/env python
# -*- encoding:utf-8 -*-
# Filename: user_predictor.py
# Description:
from easy_vision.python.inference import predictor
import tensorflow as tf
class MyPredictor(predictor.PredictorInterface):
  def __init__(self, model_path, model_config=None):
    """
    init tensorflow session and load tf model
    Args:
      model_path  init model from this directory
      model_config config string for model to init, in json format
    """
    tf.logging.info('my predictor init done')
  def predict(self, input_data, batch_size):
    """
    using session run predit a number of samples using batch_size
    Args:
      input_data:  a list of numpy array[l*h*w*c], each array is a sample to be predicted
      batch_size: batch_size passed by the caller, you can also ignore this param and
        use a fixed number if you do not want to adjust batch_size in runtime
    Return:
      result: a list of dict, each dict is the prediction result of one sample
        eg, {"output1": value1, "output2": value2}, the value type can be
        python int str float, and numpy array
    """
    results = []
    for i in range(len(input_data)):
      output = {'result1':'my_predictor_result1'}
      if 'url' in input_data:
        output['url'] = input_data['url']
      if 'user_define' in input_data:
        output['user_define'] = input_data['user_define']
      results.append(output)
    return results
```

- V2

  The custom predictor class has the following limits:

  - You can use the custom predictor class to pass only the list of images. No other information can be passed.
  - The output dictionary is converted into only JSON strings and cannot save image files.

  To remove the limits, PAI provides V2 operation definition to enable you to specify the output format. V2 is developed based on V1 by adding the get_output_type function. This function returns a dictionary that indicates how to save the values in the key-value pairs in the dictionary returned by the prediction. The values can be saved in the following ways:

  - json: All the output JSON data of keys is aggregated into a dictionary and serialized to a JSON string. Then, the JSON string is written to the output OSS file.
  - image: The output data of the keys that correspond to values of the image type is saved in an OSS file *output_dir/key/filename.jpg*. The value of the filename variable is obtained from the input URL. If the output data of a key is a list of images, each image in the list is saved as *output_dir/key/filename_idx.jpg*, where, idx is the index number of each image.
  - video: not supported.

  To pass more information, you can also pass a list of dictionaries to the predictor class by using custom input data types.

The following code shows the operation definition:

```
class PredictorInterfaceV2(six.with_metaclass(abc.ABCMeta, object)):
  def __init__(self, model_path, model_config=None):
    """
    init tensorflow session and load tf model
    Args:
      model_path  init model from this directory
      model_config config string for model to init, in json format
    """
    pass
  def get_output_type(self):
    """
    in this function user should return a type dict, which indicates
    which type of data should the output of predictor be converted to
    * type json, data will be serialized to json str
    * type image, data will be converted to encode image binary and write to oss file,
      whose name is output_dir/${key}/${input_filename}_${idx}.jpg, where input_filename
      is extracted from url, key corresponds to the key in the dict of output_type,
      if the type of data indexed by key is a list, idx is the index of element in list, otherwhil
e ${idx} will be empty
    * type video, data will be converted to encode video binary and write to oss file,
    eg:  return  {
      'image': 'jpg',
      'feature': 'json'
    }
    indicating that the image data in the output dict will be save to image
    file and feature in output dict will be converted to json
    """
    return {}
  @abc.abstractmethod
    def predict(self, input_data_dict, batch_size):
    """
    using session run predict a number of samples using batch_size
    Args:
      input_data_dict:  a list of dict, each dict is a sample data to be predicted
      batch_size: batch_size passed by the caller, you can also ignore this param and
        use a fixed number if you do not want to adjust batch_size in runtime
    Return:
      result: a list of dict, each dict is the prediction result of one sample
        eg, {"output1": value1, "output2": value2}, the value type can be
        python int str float, and numpy array
    """
    pass
```

The following code provides an example of the custom predictor class:

```
  class DummyMultiModalPredictor(ev_predictor.PredictorInterfaceV2):
    def __init__(self, model_path, model_config=None):
      pass
    def get_output_type(self):
      return {'result1': 'json',
              'result2':'json',
              'result_image': 'image',
              'result_image_list':'image',
              }
    def predict(self, images, batch_size=1):
      results = [{
                  'result1':'dummy',
                  'result2':'dummy',
                  'result_image': np.zeros([224,224,3],dtype=np.uint8),
                  'result_image_list': [255* np.ones([224,224,3],dtype=np.uint8) for i in range(2
))]
                } for i in range(len(images))]
      return results
```

ASR prediction

This topic provides an example on how to run a Machine Learning Platform for AI (PAI) command to use the automatic speech recognition (ASR) prediction component. This topic also describes the command parameters.

You must specify a MaxCompute table that contains the URL of the raw data as the input. Then, the ASR prediction component returns all the input data with an extra row at the end that contains the ASR result.

> **Note** You must create an empty table in advance as the output table. The schema of the output table must be the same as that of the input table. The last row of the output table contains the prediction result in the STRING format.

PAI command

```
PAI -name asr_predict_180 -project sre_mpi_algo_dev
-Dbuckets='oss://pai-audio-zjk/?role_arn=xxx&host=yyy'
-Dinput_tables='odps://sre_mpi_algo_dev/tables/video_asr_dev'
-Doutput_tables='odps://sre_mpi_algo_dev/tables/video_asr_dev_output'
-Durl_col_index=0
-Dmerge=1
-Dnum_workers=1
-Dnum_processes=6
-Dnum_download=7
-Dnum_memory=10000
-Doversubscription=false;
```

Set the buckets, input_tables, and output_tables parameters as needed.

Parameters

Parameter	Required	Description	Value type	GraphKey

Parameter	Required	Description	Value type	GraphKey
buckets	Yes	The information about the Object Storage Service (OSS) buckets. Set this parameter to the path of a directory in an OSS bucket. The value format is the same as that of the buckets parameter of PAI-TensorFlow. Example: oss://pai-audio-zjk/?role_arn=xxx&host=yyy.	STRING	N/A
input_tables	Yes	The input tables. Example: odps://sre_mpi_algo_dev/tables/video_asr_dev.	STRING	N/A
output_tables	Yes	The output tables. Example: odps://sre_mpi_algo_dev/tables/video_asr_dev_output.	STRING	N/A
url_col_index	No	The serial number of the column that contains the data URL. The serial number starts from 0.	INT	0
merge	No	Specifies whether to return the merged recognition result. If you set this parameter to 0, the recognition result contains the speech segments and their start and stop timestamps. Example: {"detection_texts": ["你看人家想妈了吧小妈了", "小妈了", "太好了", "你呀赶紧给你妈打电话话"], "time": [["0", "2660"], ["4040", "4660"], ["5800", "6560"], ["6840", "10069"]]}.	INT	1
num_workers	No	The number of workers that are used for prediction.	INT	1
num_processes	No	The number of threads that are used by each worker for prediction. We recommend that you set this parameter to 12 or less.	INT	6
num_download	No	The number of threads that are used by each worker to download videos. We recommend that you set this parameter to 10 or less.	INT	7
num_memory	No	The size of the memory that each worker consumes, in MB.	INT	10000
oversubscription	No	The value format of this parameter is the same as that of the oversubscription parameter of PAI-TensorFlow. • true • false	BOOL	true

If an error occurs during ASR, the system returns the corresponding error code as a string in the output table. The

following table describes the error codes.

Error message	Description
data_convert_error	An error occurred during data download or transcoding. Check whether the data source is normal.
data_download_error	An error occurred during data download. Check whether the URL is valid.
predict_error	An error occurred during the model prediction.

4.1.5.3. Online model service (must be activated separately)

4.1.5.3.1. Deploy a model as an online service

This topic describes how to deploy the generated experiment model as an online service for prediction by using Elastic Algorithm Service (EAS). You can adjust your business strategy in real time based on predicted results.

Prerequisites

Before you deploy a model as an online service, make sure that the preceding steps are performed and the components are run as expected. A green check means that the component runs as expected.

Procedure

1. Log on to Apsara Stack Machine Learning Platform for AI.
2. In the left-side navigation pane, choose **Model Training > Studio-Modeling Visualization**.
3. On the **PAI Visualization Modeling** page, find your project and click **Machine Learning** in the **Operation** column.
4. In the left-side navigation pane, click **Experiments**.
5. Click **My Experiments** and click the experiment that you want to manage.

   > **Notice** Make sure that all components are run as expected in the experiment. A green tick means that the component is successful.

6. In the upper-left corner of the canvas, choose **Deploy > Online Model Service**.
7. In the Select Model dialog box, select the model to deploy and click **Next**.
8. Select a deployment mode. You can select one of the following modes:
   - Deploy a new service
   - Add a version to an existing service
   - Implement a blue-green deployment

4.1.5.3.2. Create a service

This topic describes how to use the **New Service** mode to deploy online prediction services.

Procedure

1. Complete Preparations for online model prediction.
2. Set **Processes** and **Quota**.

> **Note** **Processes** determines the maximum number of concurrently running programs. **Quota** determines the running speed and the parameters such as RT and QPS.

3. Click **Deploy**.

   It takes several minutes to create the model.
4. After the model is created, click the model name to view information about the model invocation.
5. Click the icons under **Monitor** to view statistics about QPS, response, RT, traffic, CPU utilization, memory usage, and daily invocation.
6. > **Note** Perform this step when resources are insufficient and need to be expanded.

   Click **Update** to expand resources.
7. Click **Online Debugging** in the upper-right corner of the page and select the current model.

4.1.5.3.3. Add an existing service version

This topic describes how to use the **Add Existing Service Version** mode to deploy online prediction services.

Prerequisites

Before you use the **Add Existing Service Version** mode to deploy online prediction services, ensure that you have deployed one version of online prediction services through the New Service mode.

Procedure

1. Complete Preparations for online model prediction.
2. Select **Add Existing Service Version**.
3. Select a deployed model. It takes several minutes to add a version.
4. After the model is deployed, select the added version from the **Current Version** drop-down list.

4.1.5.3.4. Create a blue-green deployment

This topic describes how to use the **Create Blue-green Deployment** mode to deploy online prediction services.

Prerequisites

Before you use the **Create Blue-green Deployment** mode to deploy online prediction services, ensure that you have deployed two versions of online prediction services through the New Service and Add Existing Service Version modes.

Context

In the blue-green deployment mode, you can deploy and test the target version without stopping the source version. After confirming that the target version is running normally, switch all traffic to the target version. Blue-green deployment is safe and does not interrupt services.

Procedure

1. Complete Preparations for online model prediction.
2. Select the deployed model service and click **Deploy**.

   The deployment may take several minutes.
3. Click **Switch Traffic** and adjust the ratio of traffic forwarded to the two models.

The initial ratio is 100% for both models.

4. Perform online debugging.
   i. Click **Online Debugging** in the upper-right corner of the page and select the deployed model.
   ii. Enter data (feature input) in **Body**. For example, the body information of the logistic regression model for heart disease prediction is as follows:

```
[{"sex":0,"cp":0,"fbs":0,"restecg":0,"exang":0,"slop":0,"thal":0,"age":0,"trestbps":0,"chol"
:0,"thalach":0,"oldpeak":0,"ca":0}]
```

   iii. Click **Run** and check the result.

4.1.6. DSW user guide

4.1.6.1. Overview

This topic describes the features and user interfaces of Data Science Workshop (DSW).

Features

PAI supports visualized modeling and allows you to create models in Notebook or an online integrated development environment (IDE). This way, native code can be used to create custom models to better meet your requirements. You can select a programming environment as needed on the Notebook Modeling page to create and train models. DSW provides the following features:

- Allows you to start and stop DSW instances on demand, save images with a few clicks, restore development environments, and access resources over virtual private clouds (VPCs).
- Provides integrated AI development environments.
- Provides built-in big data development packages and algorithm packages, and grants sudo permissions to you for installing third-party libraries.
- Provides official images that support different versions of mainstream computing frameworks, such as TensorFlow and PyTorch.
- Provides built-in WebIDE that allows you to install all plug-ins.

Interfaces related to modeling in DSW

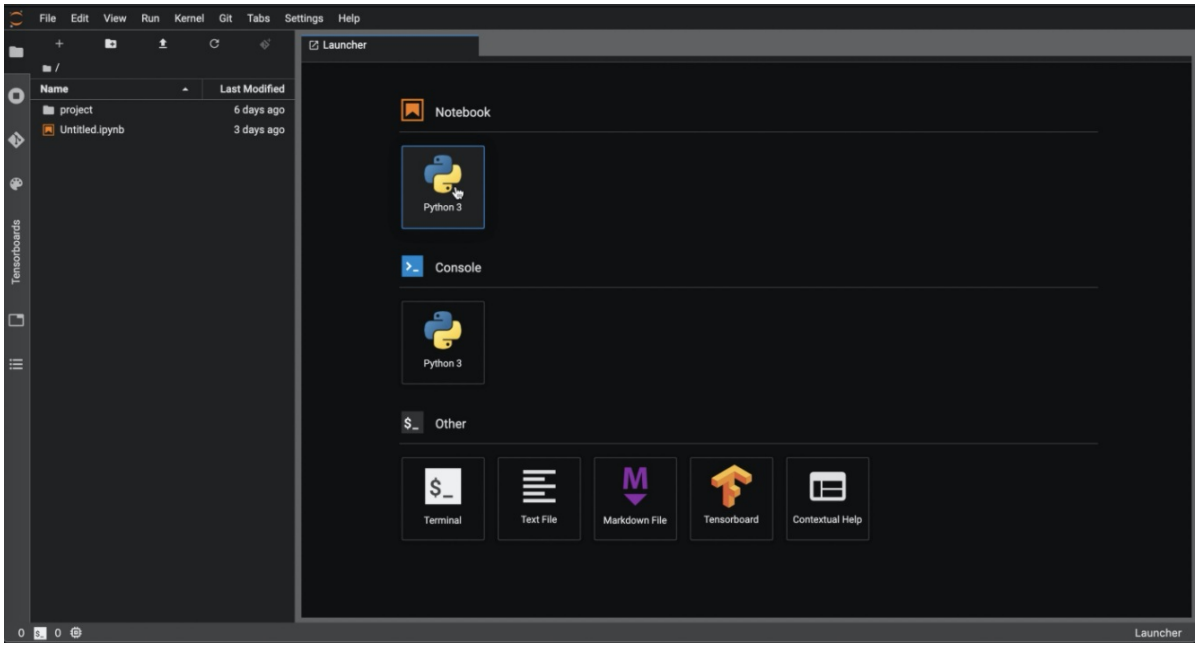
Modeling in DSW involves the following interfaces:

- DSW-Notebook Service page in the PAI console

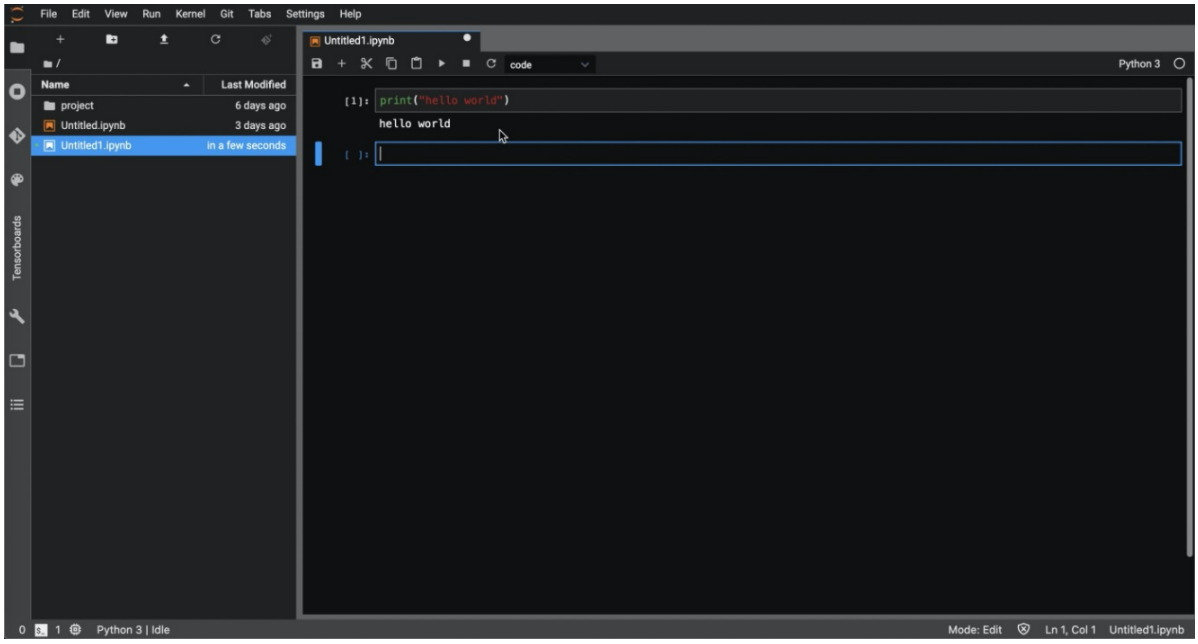
  In the PAI console, you can view the information about all created DSW instances and their statuses. You can create, stop, or delete DSW instances. In addition, you can click Lab in the Actions column to create models in Notebook. Alternatively, you can click IDE or Terminal in the Actions column to create models in WebIDE based on native code, or create models on online terminals.

- Notebook modeling interface

You can create, upload, or open an existing notebook in the Notebook modeling interface, as shown in the following figure. Notebook supports various data formats. This facilitates data exploration and modeling.

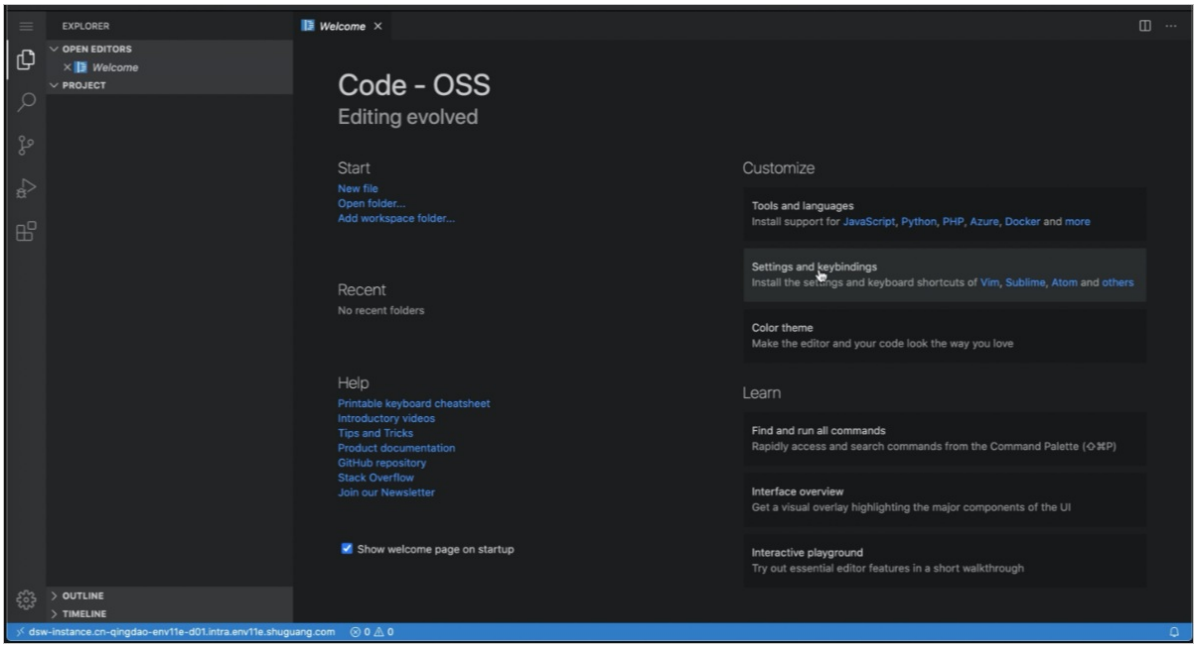


The following figure shows how to create a model in Notebook.



- WebIDE interface

You can use native code to create models in WebIDE.



- Online terminal interface

  You can use command lines to create models on online terminals.

Persistent storage

If the DSW environment contains a distributed storage system such as a bucket in Object Storage Service (OSS) or a file system in Apsara File Storage NAS (NAS), PAI automatically creates a disk for each logon user in OSS or NAS. The disk is a remote disk that is bound to each logon user and mounted to the fixed directory */home/admin/workspace*. After a DSW instance is created, DSW mounts the created disk to the fixed directory */home/admin/workspace*.

By default, all operations related to modeling in Notebook or WebIDE or on terminals are performed in this directory. The operation data that is generated when you write code, obtain data files, and export training results in this directory is permanently stored on the remote disk.

The remote disk separates computing from storage, and provides the following benefits:

- If your log off from your DSW instance for specific reason, user data is not lost.
- When you start your DSW instance for computing, the disk is automatically mounted to your instance, and you are connected to the data stored on the disk.

4.1.6.2. Manage instances

This topic describes how to manage Data Science Workshop (DSW) instances. You can create, stop, start, and delete DSW instances.

Create an instance

1. Go to the Notebook Models page.
2. On the **Notebook Modeling** page, click **Create Instance**.
3. In the **Create Instance** panel, set the parameters.

Parameter	Description
Instance	The instance name cannot exceed 27 characters in length and can contain only letters, digits, and underscores (_).
Compute Resource Type	Valid values: **CPU** and **GPU**.
Resource Type	The instance type. You can an instance type with appropriate resource specifications.
Image Source	The image based on which the instance is created. Only official images are supported. You can select one as needed.

4. Click **OK**.

Stop an instance

1. Go to the Notebook Models page.
2. On the **Notebook Models** page, find the instance that you want to stop and click **Stop** in the **Actions** column.

Start an instance

You can manually start an instance that is in the Stopped state.

1. Go to the Notebook Models page.
2. On the **Notebook Models** page, find the instance that you want to start and click **Start** in the **Actions** column.

   After the instance is started, its status changes to **Running**.

Delete an instance

You can delete instances that are not in use. After an instance is deleted, its data cannot be recovered.

1. Go to the Notebook Models page.
2. On the **Notebook Models** page, find the instance that you want to delete, and click **Delete** in the **Actions** column.
3. In the **Delete** message, click **OK**.

Go to the Notebook Models page

1. Log on to the Machine Learning Platform for AI (PAI) console. For more information, see Log on to the PAI console.
2. In the left-side navigation pane, choose **Model Training > DSW-Notebook Service**.

4.1.6.3. Work with the development environments of DSW

This article describes how to go to the development environments of Data Science Workshop (DSW), including JupyterLab, WebIDE, and Terminal.

Prerequisites

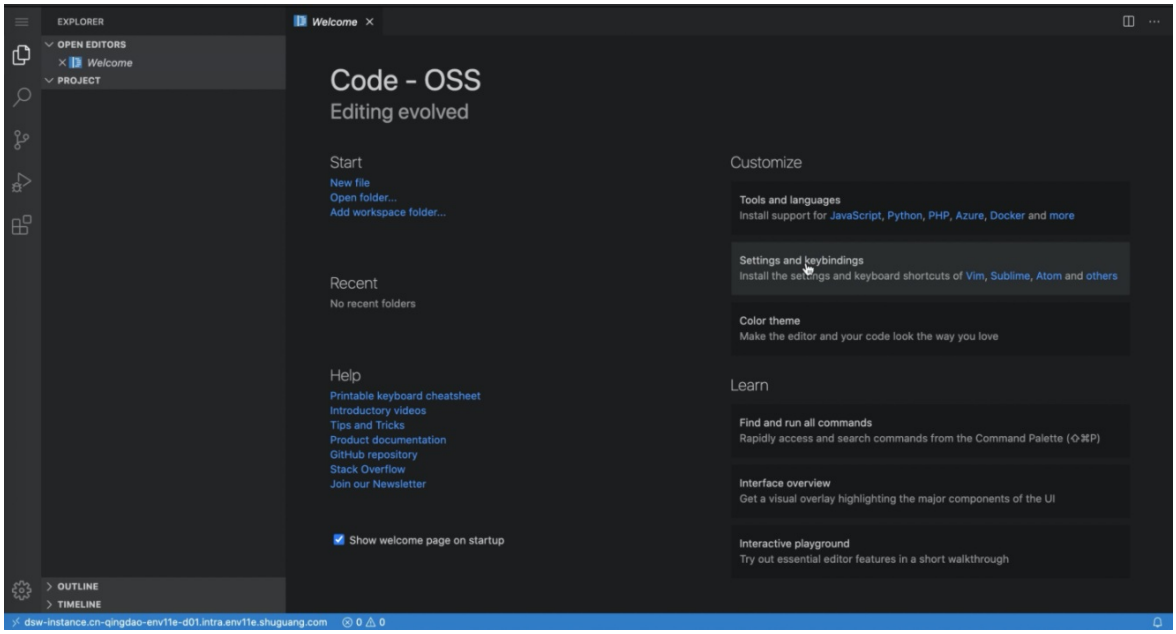
A DSW instance is created. For more information, see the "Create an instance" section of the Manage instances" topic.

Go to JupyterLab

1. Log on to the Machine Learning Platform for AI (PAI) console. For more information, see Log on to the PAI console.
2. In the left-side navigation pane, choose **Model Training > DSW-Notebook Service**.
3. On the **Notebook Models** page, find the instance that you want to manage and click **Lab** in the **Actions** column.
4. In JupyterLab, you can build Notebook models. For more information about how to build Notebook models, see JupyterLab Documentation.

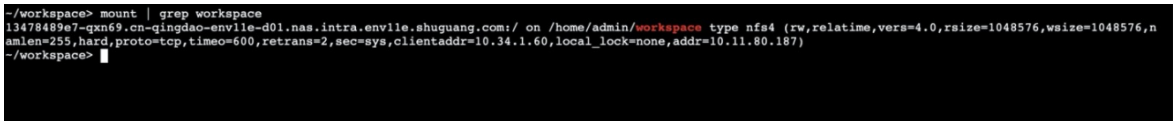
Go to WebIDE

1. Log on to the Machine Learning Platform for AI (PAI) console. For more information, see Log on to the PAI console.
2. In the left-side navigation pane, choose **Model Training > DSW-Notebook Service**.
3. On the **Notebook Models** page, find the instance that you want to manage and click **IDE** in the **Actions** column.
   The following figure shows the user interface of WebIDE.



Go to Terminal

1. Log on to the PAI console. For more information, see Log on to the PAI console.
2. In the left-side navigation pane, choose **Model Training > DSW-Notebook Service**.
3. On the **Notebook Models** page, find the instance that you want to manage and click **Terminal** in the **Actions** column.
   The following figure shows the user interface of Terminal.



4.1.6.4. Video intelligence platform (must be separately activated)

The video intelligent platform (VIP) is a one-stop platform for intelligent video analysis. VIP supports the following features for a large amount of video data: data preprocessing, feature extraction, training, and prediction. VIP integrates the storage, decoding, model training, and video algorithm analysis features for video data.

VIP supports a distributed compute engine with high performance and advanced algorithms for images, videos, audio, and natural language processing (NLP). This feature allows you to obtain and analyze video data in a flexible way. This way, you can implement an end-to-end video analysis solution to meet the needs in different scenarios.

Machine Learning Platform for AI (PAI) provides three types of upper-layer application algorithm libraries: EasyVision for images and videos, EasyTransfer for text, and EasyASR for speech recognition. You can train, evaluate and predict models in various fields by calling the API for Python in Data Science Workshop (DSW).

For more information about EasyVision, how to use EasyVision, and the API operations of EasyVision, see the topics related to EasyVison in the SDK Reference chapter.

4.1.7. Manage models

You can manage models on the Model Management page. For a registered model, you can deploy it to EAS, download the model, or delete the model.

Register a model

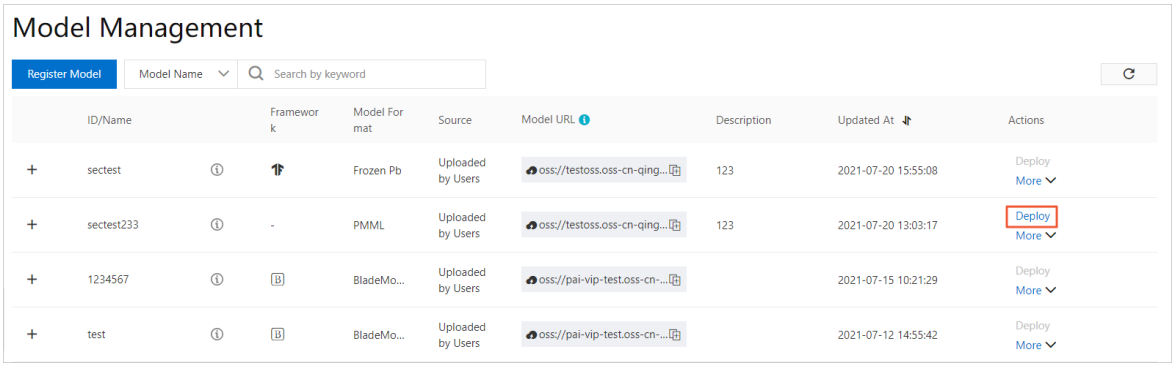
1. Go to the Model Management page.
2. On the **Model Management** page, click **Register Model**.
3. In the **Register Model** panel, set the parameters.

Parameter	Description
Model Name	The name of the model. The name must be 1 to 27 characters in length and can contain underscores (_) and hyphens (-). It must start with a letter or digit.
Description	The description of the model. Enter an informational description based on your business requirements to facilitate model management.
Model Format	Valid values: ○ SavedModel ○ Frozen Pb ○ Keras H5 ○ Caffe Prototxt ○ ONNX ○ BladeModel ○ PMML ○ Torchscript ○ TFLite
Model Framework	The system automatically select the framework based on the selected **model format**. You do not need to set this parameter.
Model URL	Model files are stored in OSS. To register a model, you must authorize PAI to access OSS. You can select **User-defined OSS Path** or **Upload to Specified OSS Path**.

4. Click **Confirm Operation**.

Deploy a model

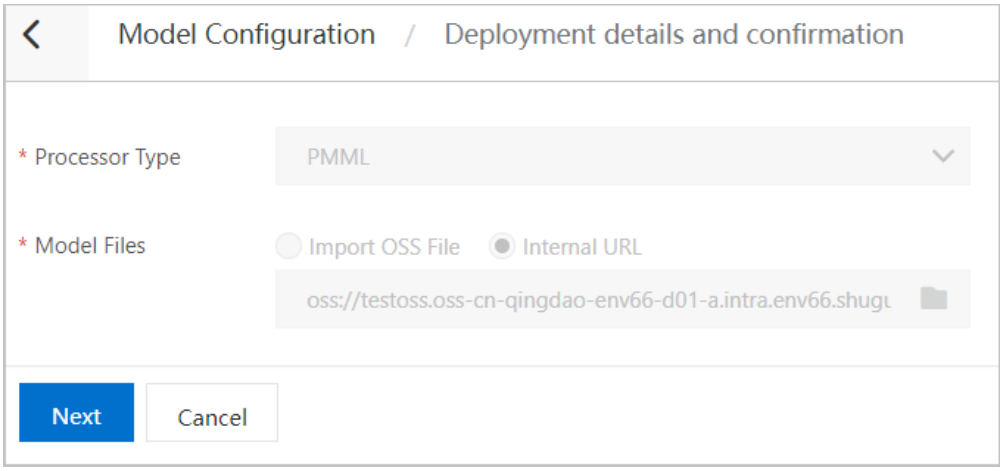
1. Go to the Model Management page.
2. On the **Model Management** page, find the model that you want to deploy and click **Deploy** in the **Actions** column.



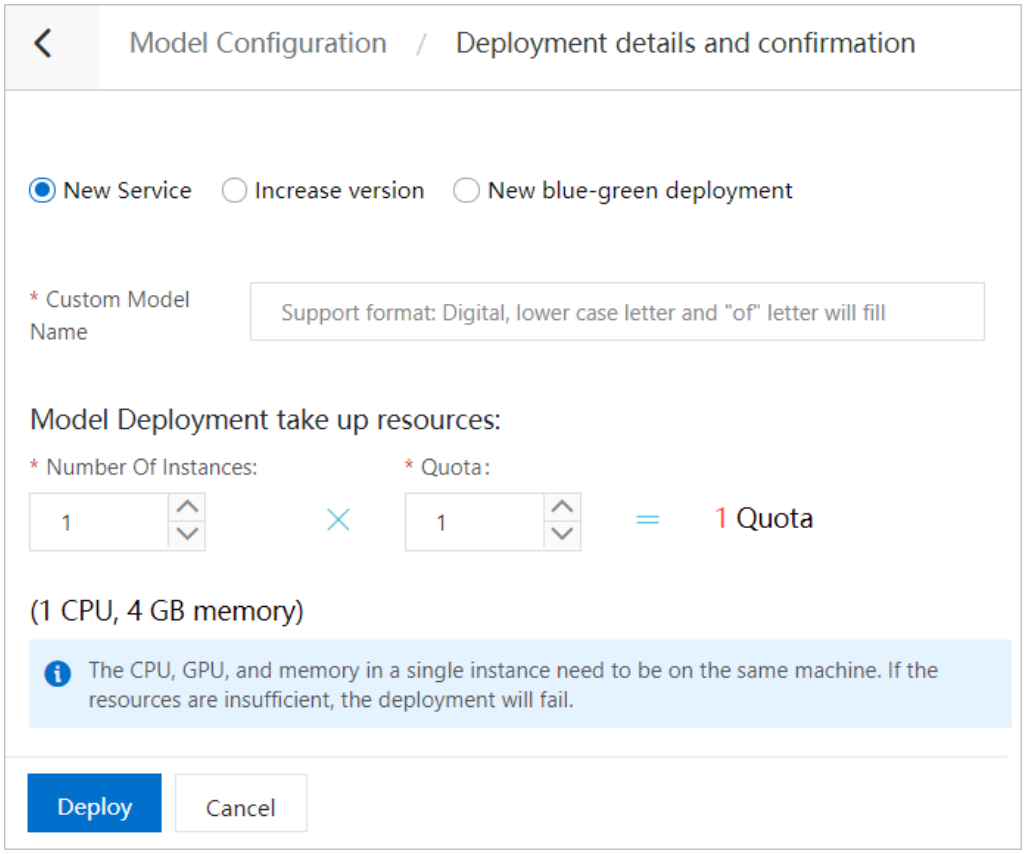
On the Model Management page, you can deploy only models in the SavedModel, PMML, and Torchscript formats to EAS. The **Deploy** button is dimmed for models in other formats. If you need to deploy models in other formats, you can use custom processors in EAS to deploy models. For more information, see Create a service by uploading a model to the PAI console.

3. Confirm the region where the model is deployed and click **OK**.

4. In the **Model Configuration** panel, the system automatically sets the **Processor Type** and **Model Files** parameters. You can directly click **Next**.



5. In the **Deployment details and confirmation** panel, set the parameters.

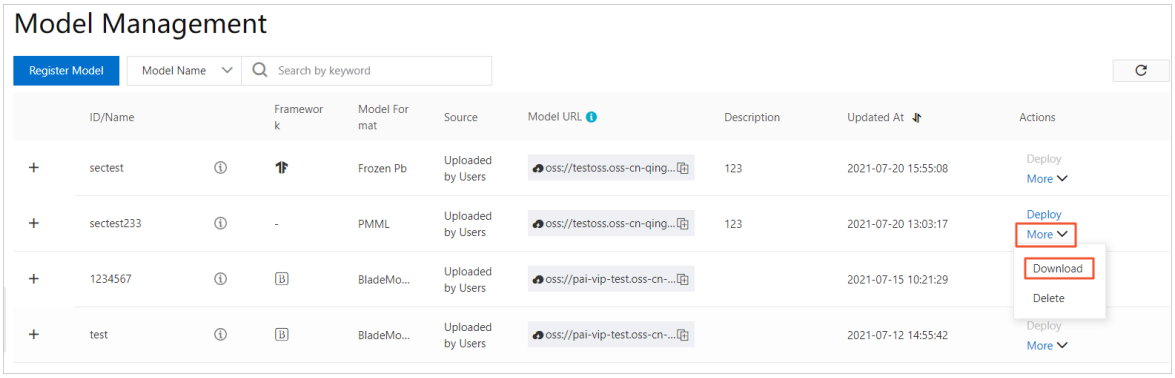


Parameter		Description
Deployment mode		EAS supports the following three deployment modes: ○ **New Service**: Deploy a new service. If you want to deploy a model that is registered on the Model Management page, select this mode to deploy the registered model as a new service. ○ **Increase version**: Add a new version to an existing service. The version number of the existing service increases by one. ○ **New blue-green deployment**: Deploy an associated service for an existing service. You can configure the traffic allocation between the two services.
Custom Model Name		The name can contain digits, lowercase letters, and underscores (_). It must start with a letter.
Model Deployment take up resources	**Number Of Instances**	We recommend that you use multiple service instances to prevent risks caused by single-machine deployment.
	Quota	One quota contains 1 core and 4 GB of memory.

6. Click **Deploy**.

Download a model

1. Go to the Model Management page.
2. On the **Model Management** page, find the model that you want to download and choose **More > Download** in the **Actions** column.



Delete a model

1. Go to the Model Management page.
2. On the **Model Management** page, choose **More > Delete** in the **Actions** column.
3. In the **Delete** message, click **Delete**.

Go to the Model Management page

1. Log on to the Machine Learning Platform for AI console.
2. In the left-side navigation pane, click **Model Management and Optimization**.

4.1.8. EAS user guide

4.1.8.1. Overview

EAS allows you to deploy machine learning models as online services with simple configurations.

EAS allows you to deploy machine learning models, such as PMML, PAI-OfflineModel, TensorFlow, and Caffe models, as online services with simple configurations. You can also develop custom online services based on the API standards defined by EAS. You can simply use a JSON file to describe the service that you want to deploy, such as the path of the model, the region where the service is deployed, and the resources used by the service. After the JSON file is prepared, you can use the EASCMD client or PAI SDK for Java to deploy it as an online service. The service can be accessed from the production environment and the Internet. EAS supports various regions and different types of hardware resources, including CPUs and GPUs.

4.1.8.2. EASCMD client

This topic describes how to download the EASCMD client.

You can use the EASCMD client to manage services, including creating, deleting, and modifying services, and view the service status. In Machine Learning Platform for AI (PAI), the EASCMD client is stored in the eas-utils bucket. You can download the EASCMD client by using the wget or curl command. Perform the following steps:

1. Obtain the endpoint of the storage service.

   MinIO is an easy-to-use service that provides storage for Elastic Algorithm Service (EAS). The Internet endpoint of MinIO is the endpoint of the storage service for EAS. Sample Internet endpoint: `eas.minio.cn-hangzhou-env50-d01.inter.env50e.shuguang.com`. You can run the following command to obtain the Internet endpoint.

   ```
   kubectl get cm -n eas-system eas-config -oyaml
   ```

2. Download the EASCMD client by running the following `wget` command:

   ```
   wget eas.minio.cn-hangzhou-env50-d01.inter.env50e.shuguang.com/eas-utils/eascmd64
   ```

Replace `eas.minio.cn-hangzhou-env50-d01.inter.env50e.shuguang.com` with the endpoint of the storage service that you actually obtain in the preceding step. The following figure shows the output of the wget command.

4.1.8.3. User authentication

You can use the EASCMD client to manage the services in Elastic Algorithm Service (EAS). This topic shows you how to download the EASCMD client and complete user authentication.

In Machine Learning Platform for AI (PAI), prediction services use JSON Web Token (JWT) for user authentication. When you use the EASCMD client, run the following command to configure an AccessKey pair for the EASCMD client:

```
./eascmd64 config -i <AccessKeyId> -k <AccessKeySecret> -e {{Domain name of EAS in PAI}}
// New users can use the admin account to pass authentication.
./eascmd64 config -i admin -k admin -e {{Domain name of EAS in PAI}}
```

You can use the following methods to obtain the domain name of EAS in PAI:

- Concatenate a domain name:
  - To call the API for service management, you can concatenate a domain name in the following format:

    ```
    eas.${global:region}.${global:internet-domain}
    ```

  - To call the API for service calls, you can concatenate a domain name in one of the following formats based on whether the prediction service is deployed across regions:
    - Secondary region: `eas.pai.${global:region}.${global:internet-domain}`
    - Primary region: `eas.pai.${global:internet-domain}`
- Use the EAS Meta Server to obtain the access information by performing the following steps:
  i. Run the following command to obtain the string with Region as the key:

  ```
  curl http://easmeta.pai.${global:internet-domain}/regions
  ```

  ii. Find the access information of the current region.

4.1.8.4. Upload files

When you create a service, you must specify the HTTP addresses of the model and processor files. You can store the model and processor files on any HTTP servers.

4.1.8.5. Create a service

To create a service, you can use the EASCMD client tool or upload a model in the Machine Learning Platform for AI console.

Create a service by using the EASCMD client

You can run the `create` command to create a service. When you create the service, you need to configure resources such as the model or processor by specifying HTTP URLs. You can upload resources to Object Storage Service (OSS) and obtain the HTTP URL provided by OSS.

```
eascmd create <service_desc_json>
```

In the preceding command, <service_desc_json> indicates the name of the service description file. The file includes information about the service. The metadata parameter in the file specifies the region where the cluster is deployed and the information about resources.

> **Note** The metadata parameter specifies only the deployment information about the cluster. When you run the test command to debug the on-premises model, the system ignores the metadata parameter.

The following code provides an example of the <service_desc_json> file:

```
{
  "name": "mnist_saved_model_example",
  "generate_token": "true",
  "model_path": "http://eas-data.oss-cn-shanghai.aliyuncs.com/models%2Fmnist_saved_model.tar.gz",
  "processor": "tensorflow_cpu",
  "metadata": {
    "instance": 1,
    "cpu": 1,
  }
}
```

The following table describes the parameters in the service description file.

Key	Value
name	The name of the service. The name of the service must be unique in a region. You can specify the region where the service is deployed in the metadata parameter.
generate_token	Specifies whether a token is generated. If you set the parameter to true, you must include the token in the HTTP URL that is used to access the prediction service. If you set the parameter to false, the service is a public service and can be accessed without authentication.
token	Optional. The token string that is used for authentication. If this parameter is not specified, the system automatically generates a token when the generate_token parameter is set to true.
model_path	The path of the model package. For more information, see the note that follows this table.
model_entry	Optional. The entry file of the model package. If this parameter is not specified, the file name in the value of the model_path parameter is used. The path of the main file is passed to the Load() function in the processor.
model_config	Optional. The configurations of the model. The value is of the TEXT type. The value of this parameter is passed to the second parameter of the LoadWithConfig() function in the processor.
processor	Optional. The built-in processor that is to be used for prediction. When this parameter is specified, the processor_path, processor_entry, processor_mainclass, and processor_type parameters are ignored.

Key	Value
processor_path	Optional. The package path of the custom processor to be used. For more information, see the note that follows this table.
processor_entry	Optional. The main file of the processor package. The main file contains the implementations of the Load() and process() functions that are required for prediction. This parameter is required when the language used to implement the custom processor is C or C++.
processor_mainclass	Optional. The main class in the JAR package of the processor. This parameter is required when the language used to implement the custom processor is Java.
processor_type	Optional. The language that is used to implement the custom processor. Valid values: cpp, java, and python.
metadata	The metadata of the service. For more information, see Description of the metadata parameter.

Note The model_path parameter specifies the path in which the input model package is stored. The processor_path parameter specifies the path in which the input processor package is stored. The values of the two parameters can be HTTP URLs or OSS URLs. If you want to run the test command to perform on-premises debugging, you can use an on-premises path.

If an HTTP URL is used, the input package must be in the TAR.GZ, TAR, BZ2, or ZIP format.

Description of the metadata parameter

Category	Parameter	Description
Common parameters	workers	Optional. Default value: 5. This parameter specifies the number of threads that are used to concurrently process requests on each instance.
	instance	The number of instances that are required to run the service.
	cpu	The number of CPUs that are required by each instance.
	gpu	The number of GPUs that are required by each instance.
	resource	The name of the resource group. You can ignore this parameter if the service uses only CPUs. If the service uses only GPUs, you can specify the P4_4CORE or P4_8CORE resource group.

Category	Parameter	Description
Advanced parameters (modify them with caution)	rpc.batching	Optional. Default value: false. This parameter specifies whether batch processing is enabled on the server to improve the speed of a GPU-based model.
	rpc.keepalive	Optional. Default value: 5000. Unit: milliseconds. This parameter specifies the maximum processing time for a single request. If the request processing time exceeds this value, the server returns the timeout error code 408 and closes the connection.
	rpc.io_threads	Optional. Default value: 4. This parameter specifies the number of threads that are used to process the input and output network data on each instance.
	rpc.max_batch_size	Optional. Default value: 16. This parameter specifies the maximum size of each batch. This parameter takes effect only when the rpc.batching parameter is set to true.
	rpc.max_batch_timeout	Optional. Default value: 50. Unit: milliseconds. This parameter specifies the maximum timeout period of each batch. This parameter takes effect only when the rpc.batching parameter is set to true.
	rpc.max_queue_size	Optional. The size of the request queue. Default value: 64. When the queue is full, the server returns the error code 450 and closes the connection. To prevent the server from being overloaded, the request queue instructs the client to send requests to other instances when the queue is full. If the response time is too long, set this parameter to a smaller value to prevent a request from timing out.
	rpc.worker_threads	Optional. Default value: 5. This parameter specifies the number of threads that are used to concurrently process requests on each instance. This parameter works in the same way as the workers parameter.

The following code provides an example on how to configure the metadata parameter:

```
{
 ...
"metadata": {
  "cpu": 4,
"rpc.max_queue_size": 32,
...
 }
```

For example, if the service description file pmml.json is created, you can run the following command to create a service:

```
eascmd create pmml.json
```

The system displays information similar to the following output:

```
[RequestId]: 1651567F-8F8D-4A2B-933D-F8D3E2DD****

```

Create a service by uploading a model to the Machine Learning Platform for AI console

On the **Elastic Algorithm Service** page, you can upload trained models and deploy them as online model services. Perform the following steps:

1. Go to the **Elastic Algorithm Service** page.
   i. Log on to the PAI console.
   ii. In the left-side navigation pane, choose **Model Deployment > EAS-Model Serving**.
2. In the upper-left corner of the page, select the region where you want to create a service.

3. On the **Elastic Algorithm Service** page, click **Model Deploy**.
4. In the **Model Configuration** step of the panel that appears, set the parameters.

Parameter	Description
Processor Type	Valid values: **PMML**, **TensorFlow1.12**, and **Self-definition processor**.

Parameter	Description
Processor Language	This parameter takes effect only when the **Processor Type** parameter is set to **Self-definition processor**. Valid values: **Cpp**, **Java**, and **python**.
Processor package	This parameter takes effect only when the **Processor Type** parameter is set to **Self-definition processor**. In the **Processor package** field, enter a public URL.
Processor Master File	This parameter takes effect only when the **Processor Type** parameter is set to **Self-definition processor**. This parameter specifies the main file of the custom processor package.
Model Files	You can set this parameter in one of the following ways: ○ **Import OSS File** Select **Import OSS File**. Then, select the OSS path where the model file resides. ○ **Internal URL** Select **Internal URL**. Then, enter a public URL.

5. Click **Next**.
6. In the **Deployment details and confirmation** step, set the parameters.
   i. Select **New Service**.

      EAS supports the following deployment modes:

      - **New Service**: Deploy a new service. In this example, this deployment mode is used.
      - **Increase version**: Add a new version to an existing model service. The version number of the existing model service increases by one.
      - **New blue-green deployment**: Deploy an associated service for an existing service. You can configure the traffic allocation between the two services.

   ii. Set the **Custom Model Name** parameter and other parameters.

Parameter		Description
Model Deployment take up resources	**Number Of Instances**	We recommend that you use multiple service instances to prevent risks caused by single-machine deployment.
	Quota	One quota contains 1 core and 4 GB of memory.

> **Note**
>
> - The CPU, GPU, and memory of a single service instance must belong to the same machine. If the resources are insufficient, the deployment fails.
> - To deploy the model as an online service with high stability requirements, we recommend that you use a resource group that includes multiple machines and deploy multiple service instances.

   iii. Click **Deploy**.

4.1.8.6. Perform on-premises debugging

Before you deploy a service to a cluster, you can use the on-premises debugging feature to start an on-premises service for debugging. This topic describes how to perform on-premises debugging.

This feature requires a Docker container and Internet access. You must install Docker on the machine where the EASCMD client runs and run the following command to debug the service:

```
sudo eascmd test [service_desc_json]
```

Specify the JSON file that is used to deploy the service. Run the following sample command:

```
bin/eascmd test tf.json
```

The system displays information similar to the following output:

```
[OK] Pulling image: registry.cn-shanghai.aliyuncs.com/eas/eas-worker-amd64:0.1.4
[OK] Pull image done
[OK] Creating container from: registry.cn-shanghai.aliyuncs.com/eas/eas-worker-amd64:0.1.4
[OK] Created container: e39176f85cf41a161bbb2896f76f1c0db0ad4f50e1d78a********
[OK] Serving At: [http://localhost:6942/api/predict/savedmodel_exanple]
[2019-02-24 00:16:27] [172.17.0.2] Fetching model from [http://eas-data.oss-cn-shanghai.aliyuncs.com
/models%2Fflypig_scorecard.pmml]
[2019-02-24 00:16:27] [172.17.0.2] Fetching processor from [http://eas-data.oss-cn-shanghai.aliyuncs
.com/eas-pmml-processor-0.1-jar-with-dependencies.jar]
[2019-02-24 00:16:28] [172.17.0.2] ----------------------------SERVICE LOG--------------------------
------
...
[2019-02-24 00:16:30] [172.17.0.2] [INFO] Token: [WIzMFW5Jb8kckYj****]
...
[2019-02-24 00:16:30] [172.17.0.2] [INFO] Service start successfully
```

In this example, the command starts an on-premises TensorFlow model service. The endpoint of the service is `http://localhost:6942/api/predict/savedmodel_exanple`.

4.1.8.7. Modify configurations

This topic describes how to modify the configurations of a service, such as the instance, CPU, and memory configurations.

You can specify the -D parameter in the `modify` command to modify the metadata configurations, such as the instance, CPU, and memory configurations.

```
eascmd modify <service_name> -Dmetadata.[attr_name]=[attr_value]
```

For example, you can run the following command to set the number of instances to 10:

```
eascmd modify service_test -Dmetadata.instance=10
```

You can set multiple properties at a time. For example, you can run the following command to set the number of instances to 10 and the memory size to 2,000 MB:

```
eascmd modify service_test -Dmetadata.instance=10 -Dmetadata.memory=2000
```

4.1.8.8. Modify a service

You can run the modify command to modify a deployed service.

```
eascmd modify [service_name] -s [service_desc_json]
```

Note You cannot use this command to modify the region where the service is deployed. Note: If you only want to modify the resources used by the service, specify the metadata configurations in the service description file.

4.1.8.9. Delete a service

This topic describes how to delete a service.

You can run the `delete` command to delete a service.

```
eascmd delete <service_name>
```

When you delete a service, you must specify the service name and the region where the service is deployed.

For example, to delete the savedmodel_exanple service, run the following command:

```
eascmd delete savedmodel_exanple
```

The system returns the following confirmation message:

```
Are you sure to delete the service [savedmodel_exanple] in [cn-shanghai]? [Y/n]
```

Enter Y. The system displays information similar to the following output:

```
[RequestId]: 1651567F-8F8D-4A2B-933D-F8D3E2DD****
[OK] Service [savedmodel_exanple] in region [cn-shanghai] is terminating
[OK] Service is terminating
[OK] Service is terminating
[OK] Service was deleted successfully
```

4.1.8.10. Switch service version

You can run the desc command to view the version of the current service and the latest version, and run the version command to switch the service to a version earlier than the latest version.

```
eascmd version [service_name] [version_id]
```

4.1.8.11. Enable HTTPS

To meet the requirements for encrypted transmission, (EAS) allows you to access services over HTTPS. This topic describes how enable or disable HTTPS.

You can enable HTTPS when you create a service. You can also enable HTTPS after a service is deployed. The following content describes the methods used to enable HTTPS for a new service or a deployed service:

- Enable HTTPS when you create a service.

  When you configure the service description file, set the enable_https parameter in metadata to true. The following code provides an example of the service description file. For more information about the parameters in the service description file, see Create a service.

```
  "name": "test",
  "token": "test-token",
  "model_path": "http://xxx/echo_processor_release.tar.gz",
  "processor_path": "http://xxx/echo_processor_release.tar.gz",
  "processor_entry": "libecho.so",
  "processor_type": "cpp",
  "metadata": {
    "instance": x,
    "memory": xxx,
    "enable_https": "true"
  }
}
```

- Enable HTTPS for a deployed service by running the following command:

```
eascmd modify <servicename> -Dmetadata.enable_https=true
```

Replace <servicename> with the name of the deployed service.

Note You cannot use both HTTPS and HTTP to access the service. If HTTPS is enabled, the service can be accessed only over HTTPS rather than HTTP.

If you want to disable HTTPS for a service, run the following command:

```
eascmd modify <servicename> -Dmetadata.enable_https=false
```

Replace <servicename> with the name of the service.

4.1.8.12. View services

This topic describes how to view deployed services.

You can run the `list(ls)` command to view the services that you deploy.

```
eascmd ls
```

The system displays information similar to the following output:

```
[RequestId]: 83945D4EED3E-4D35-A989-831E6BB****
+--------------------------+-------------+----------+---------------------+---------------------+--
-------+--------+-----------------------------------------+
|        SERVICENAME       |   REGION    | INSTANCE |     CREATETIME      |     UPDATETIME      | S

unning |      0 | /api/predict/mnist_saved_model_example |
```

4.1.8.13. View the details of a service

This topic describes how to view the details of a deployed service.

You can run the `desc` command to view the details of a deployed service.

```
eascmd desc [service_name]
```

For example, to view the details of the mnist_saved_model_example service, you can run the following command:

```
eascmd desc mnist_saved_model_example
```

The system displays information similar to the following output:

```
+--------------------+-----------------------------------------------------------------------------------

|                      |   "name":
|
|                      | "mnist_saved_model_example",
|
|                      |   "processor":
|
|                      | "tensorflow_cpu"
|
|                      | }
```

4.1.8.14. View service processes

This topic describes how to view the status of service processes.

You can run the `showworkers(w)` command to view the status of the service processes.

```
eascmd w <service_name>
```

Replace <service_name> with the name of the service.

For example, to view the process status of the mnist_saved_model_example service, run the following command:

```
eascmd w mnist_saved_model_example
```

The system displays information similar to the following output:

```
[RequestId]: 4E905404-E617-4BD8-85D6-EC5C6A0D****
+--------------+----------------+---------------------+----------+---------+-------+---------+
|   INNERIP    |     HOSTIP     |       STARTAT       | RESTARTS | STATUS  | READY | REASON |
+--------------+----------------+---------------------+----------+---------+-------+---------+
| 172.24.5.183 | 192.168.65.121 | 2019-02-21 16:35:58 |        0 | Running | [1/1] |        |
+--------------+----------------+---------------------+----------+---------+-------+---------+
```

4.1.8.15. Call a prediction service

This topic describes how to call a prediction service.

To call a prediction service, you must use the HTTP URL that is generated when you create the prediction service. The HTTP URLs for on-premises testing services are generated in the same format as those for cluster-based prediction services, except that the HTTP URLs use different hosts. When you send a request to call a service, you must add a token to the HTTP header of the request. The token is generated when you create an image. The following example shows how to call a PMML prediction service by running the curl command:

```
curl http://{{Domain name of EAS in the environment}}/api/predict/pmml_example -H 'Authorization: NG
E3MzM4YmRhODZjMTE2NmZjZjNlNTJlNDgyNzM3YzdjMmIwOD****==' -d '[{}]'
[{"prediction_score":0.0902926730924553}]
```

You can use the following methods to obtain the domain name of EAS in PAI:

- Concatenate a domain name:
  - To call the API for service management, you can concatenate a domain name in the following format:

    ```
    eas.${global:region}.${global:internet-domain}
    ```

  - To call the API for service calls, you can concatenate a domain name in one of the following formats based on whether the prediction service is deployed across regions:
    - Secondary region: `eas.pai.${global:region}.${global:internet-domain}`
    - Primary region: `eas.pai.${global:internet-domain}`
- Use the EAS Meta Server to obtain the access information by performing the following steps:
  i. Run the following command to obtain the string with Region as the key:

  ```
  curl http://easmeta.pai.${global:internet-domain}/regions
  ```

  ii. Find the access information of the current region.

The input and output formats of a prediction service are determined by the processor of the service.

4.1.8.16. Use Java or C++ to develop a model service

4.1.8.16.1. What are processors?

A processor is a package that contains the online prediction logic. This topic describes how processors work.

A processor is a package that contains online prediction logic. Your requests are processed by processors and then returned to clients. A processor contains the logic for loading models and making predictions upon requests. PAI supports general processors, such as PMML and TensorFlow. If you want to customize the prediction logic, you must follow the processor development standards to develop a processor.

You can develop a processor in C, C++, and Java without the need to use an SDK. To develop a processor, you only need to define the relevant classes and functions. This facilitates on-premises debugging.

4.1.8.16.2. Processors in C or C++

This topic describes how to develop custom processors in C or C++.

If you want to develop a processor by using C or C++, you must define the initialize() and Process() functions. The initialize() function is used to load the model during the initialization process. The Process() function is used to process service calls and return the processing results to clients. You can declare the two functions based on the following information:

- initialize()

```
void *initialize(const char *model_entry, const char *model_config, int *state)
```

Parameter	Type	Description
model_entry	Input parameter	The entry file of the model package. This parameter corresponds to the model_entry field in the configuration file when the service is created. You can specify a file name such as randomforest.pmml, or a directory such as ./model.
model_config	Input parameter	The custom configuration information of the model. This parameter corresponds to the model_config field in the configuration file when the service is created.
state	Output parameter	The status of model loading. If the return value is 0, the model is loaded. Otherwise, the model fails to be loaded.
-	Return value	The memory address of the model, which supports all types. The model is specified in the model variable.

- Process()

```
int process(void *model_buf, const void *input_data, int input_size,
            void **output_data, int *output_size)
```

Parameter	Type	Description
model_buf	Input parameter	The model memory address that is returned by the initialize() function.
input_data	Input parameter	The input data, which can be a string or of the BINARY type.
input_size	Output parameter	The length of the input data.
output_data	Output parameter	The data that is returned by the processor. The heap memory must be allocated for the data. The model releases the memory as configured.
output_size	Output parameter	The length of the data that is returned by the processor.
-	Return value	If 0 or 200 is returned, the request is successful. Otherwise, an HTTP error code can be returned. If an undefined HTTP status code is returned, it is automatically converted to http 400 error.

Example for developing a processor in C or C++

In the following sample code, no model data is loaded. The prediction service returns the user request to the client.

```
#include <stdio.h>
#include <string.h>
extern "C" {
    void *initialize(const char *model_entry, const char *model_config, int *state)
    {
        *state = 0;
        return NULL;
    }
    int process(void *model_buf, const void *input_data, int input_size,
            void **output_data, int *output_size)
    {
        if (inputSize == 0) {
            const char *errmsg = "input data should not be empty";
            *outputData = strndup(errmsg, strlen(errmsg));
            *outputSize = strlen(errmsg);
            return 400;
        }
        *outputData = strndup((char *)inputData, inputSize);
        *outputSize = inputSize;
        return 200;
    }
}
```

In the following sample code, the processor does not read model information and returns the input data without changes. You can compile the input data as an SO file based on the following Makefile:

```
CC=g++
CCFLAGS=-I./ -D_GNU_SOURCE -Wall -g -fPIC
LDFLAGS= -shared -Wl,-rpath=./
OBJS=processor.o
TARGET=libpredictor.so
all: $(TARGET)
$(TARGET): $(OBJS)
	$(CC) -o $(TARGET) $(OBJS) $(LDFLAGS) -L./
%.o: %.cc
	$(CC) $(CCFLAGS) -c $< -o $@
clean:
	rm -f $(TARGET) $(OBJS)
```

If other dependent SO files exist, you must package both the dependent SO files and the SO file that is generated after compilation and then deploy the package as a processor.

4.1.8.16.3. Processors in Java

This topic describes the prototype of the processors in Java.

To develop a processor by using Java, you must define only one class. In addition to the constructor, this class requires only the Load() and Process() functions. The following information specifies the prototype of the class:

```
package com.alibaba.eas;
import java.util.*;
public class TestProcessor {
  public TestProcessor(String modelEntry, String modelConfig) {
    /* Pass the model file name for initialization.*/
  }
  public void Load() {
    /* Load model information based on the model name.*/
  }
  public String Process(String input) {
    /* /* Predict the input data and return the prediction result. The input data and output data can only be strings* /
  }
  public static void main(String[] args) {
    /* /* The main function is optional, and its class functions can be verified on an on-premises standalone machine.* /
  }
}
```

If an exception occurs, the framework captures the exception and returns the message in the exception as an error message to the client. In addition, the HTTP status code 400 is returned. You can also capture exceptions and return corresponding error messages, as shown in the following example:

```
try{
} catch (com.alibaba.fastjson.JSONException e) {
  throw new RuntimeException("bad json format, " + e.getMessage());
}
```

4.1.9. Automatic parameter tuning with AutoML (must be separately activated)

Note The AutoML feature is applicable only to Intel servers, but not to Hygon servers.

4.1.9.1. Automatic parameter tuning with AutoML

This topic describes the automatic parameter tuning feature of AutoML.

Parameter

1. Log on to the PAI console. In the left-side navigation pane, click **Experiments**.
2. Click an experiment to go to the canvas of the experiment.

   Note This topic uses air quality prediction as an example.

3. In the upper-left corner of the canvas, choose **Auto ML > Auto Parameter Tuning**.
4. On the **Auto Parameter Tuning** page, select an algorithm for parameter tuning, and click **Next**.

   Note You can select only one algorithm to tune at a time.

5. In the **Configure Parameter Tuning** module, set the **Parameter Tuning Method** parameter and click **Next**.

Alibaba Cloud Machine Learning Platform for AI provides four **parameter tuning methods**. For more information, see Parameter adjustment method.

6. In the **Configure Model Output** module, set the model output parameters and click **Next**.

Parameter	Description
Evaluation Criteria	You can select one evaluation standard from the following four dimensions: **AUC**, **F1-score**, **PRECISION**, and **RECALL**.
Saved Models	You can save up to five models. The system ranks models based on the **Evaluation Criteria** setting you select and save the top ranked models according to the number entered in the **Saved Models** field.
Pass Down Model	This switch is turned on by default. If the switch is turned off, the model generated by the default parameters of the current component are passed down to the node of the subsequent component. If the switch is turned on, the optimal model generated by automatic parameter tuning are passed down to the node of the subsequent component.

7. In the upper-left corner of the canvas, click **Run** to run the automatic parameter tuning algorithm, as shown in the following figure.

> **Note** After the preceding configuration is complete, the Auto ML switch of the related algorithm is turned on. You can turn the switch on or off as needed.

8. Right-click a model component and choose **Edit AutoML Parameters** from the shortcut menu to modify its AutoML configuration parameters.

Output model display

1. During parameter tuning, right-click the target model component and choose **Parameter Tuning Details** from the shortcut menu.
2. On the **AutoML-Parameter Tuning Details** page, click the **Metrics** tab to view the current tuning progress and the running status of each model.
3. You can sort candidate models according to indicators (**AUC**, **F1-score**, **Accuracy**, and **Recall Rate**).
4. In the **View Details** column, you can click **Log** or **Parameter** to view the logs and parameters of each candidate model.

Parameter tuning effect display

1. On the **AutoML-Parameter Tuning Details** page, you can click the **Charts** tab to view the **Model Evaluation and Comparison** and **Hyperparameter Iteration Result Comparison** charts.
2. You can view the growth trend of the evaluation indicators of updated parameters in the **Hyperparameter Iteration Result Comparison** chart.

Model storage

1. Log on to the PAI console. In the left-side navigation pane, click **Models**.
2. Click **Experiment Model** to open the experiment model folder.
3. Click the corresponding experiment folder to view the model saved with Auto ML.
4. (Optional) You can apply a model to other experiments by dragging the model to the canvas of the target

experiment.

4.1.9.2. Parameter tuning methods

AutoML supports four parameter tuning methods.

Evolutionary Optimizer

Principle:

1. Randomly selects A parameter candidate sets. A indicates the **number of exploration samples**.
2. Takes the N parameter candidate sets with higher evaluation indicators as the parameter candidate sets of the next iteration.
3. Continues the exploration within R times as the standard deviation range around these parameters to explore new parameter sets. R indicates the **convergence coefficient**. The new parameter sets replace the last A-N parameter sets by the evaluation indicator in the previous round.
4. Iterates the exploration for M rounds based on the preceding logic until the optimal parameter set is found. M indicates the **number of explorations**.

Based on the preceding principle, the final number of models is A + (A - N) × M.

> **Note** The first value of N is A/2 - 1. During iteration, the default value is N/2 - 1. If the result of N/2 - 1 is a decimal number, the number is rounded up.

Parameter	Description
Data Splitting Ratio	You can set this parameter to split input data sources into training and evaluation sets. A value of 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Exploration Samples	The number of parameter sets of each iteration. The higher the number, the higher the accuracy, the more the consumed computing resources. This parameter must be set to a positive integer in the range of 5 to 30.
Explorations	The number of iterations. The higher the number of iterations, the higher the exploration accuracy, the more the consumed computing resources. This parameter must be set to a positive integer in the range of 1 to 10.
Convergence Coefficient	You can set this parameter to adjust the exploration ranges (R times the standard deviation range search). The smaller the parameter value, the faster the convergence. However, optimal parameters may be missed if the convergence is fast. Valid values: 0.1 to 1. The value can contain only one decimal place.

> **Note** You must enter the tuning range for each parameter. If the current parameter range is not specified, the parameter range is specified by default.

Random Search

Principle:

1. Randomly selects a value for each parameter within the parameter range.

2. Enters random values into a set of parameters for model training.
3. Performs M rounds and then sorts the output models. M indicates the **number of iterations**.

Parameter	Description
Data Splitting Ratio	You can set this parameter to split input data sources into training and evaluation sets. A value of 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Iterations	The number of searches in the specified range. Valid values: 2 to 50.

Note You must enter the tuning range for each parameter. If the current parameter range is not specified, the parameter range is specified by default.

Grid Search

Principle:

1. Splits the value range of each parameter into N segments. N indicates the **number of split grids**.
2. Randomly selects a value from the N segments. If M parameters exist, N^M parameter sets can be combined.
3. Generates N^M models by training based on the N^M parameter sets and then sorts the models.

Parameter	Description
Data Splitting Ratio	You can set this parameter to split input data sources into training and evaluation sets. A value of 0.7 indicates that 70% of the data is used for model training and 30% for evaluation.
Grids	The number of grids after splitting. Valid values: 2 to 10.

Note You must enter the tuning range for each parameter. If the current parameter range is not specified, the parameter range is specified by default.

Custom Parameters

The following figure shows the configurations if you use the Custom Parameters method.

- You can enumerate parameter candidate sets. Then, the system helps score all the combinations of the candidate sets.
- You can define enumeration ranges. Separate parameters with commas (,). If the ranges are not specified, the default ranges of parameters are tuned.

4.1.10. OpenAPI

4.1.10.1. Query PMML models

This topic how to use the ListPMMLModels operation to query Predictive Model Markup Language (PMML) models.

Operation name

ListPMMLModels

Description

You can call this operation to query the PMML models that belong to a specified owner in a specified project. You can also query the PMML models that are generated from a specified experiment.

Request parameters

Parameter	Type	Required	Example	Description
OnwerId	String	Yes	11769368777159105	The UID of a model owner.
ProjectId	Long	Yes	10009	The ID of the project to which a model belongs.
ExperimentId	Long	No	4294	The ID of the experiment from which a model is generated.
Action	String	Yes	ListPMMLModels	The operation that you want to perform. Set the value to ListPMMLModels.

Response parameters

Parameter	Type	Description
Experiments	List<ExperimentModelInfo>	An array of experiment properties returned.
Experiment	ExperimentModelInfo	The returned experiment information.
ExpId	Long	The ID of the experiment from which the models are generated.
Models	List<ModelInfo >	An array of model properties returned.
Model	ModelInfo	The returned model information.
Name	String	The display name of the model.
Owner	String	The ID of the model owner.
Description	String	The description of the model.
ModelId	String	The ID of the model.
ModelName	String	The name of the underlying model that is generated by the corresponding algorithm.
CreateTime	Date	The time when the model was generated.

Parameter	Type	Description
ExperimentId	String	The ID of the experiment from which the model is generated.
UpdateTime	Date	The time when the model was updated.
Project	String	The name of the project to which the model belongs.
ProjectId	String	The ID of the project to which the model belongs.
Action	String	The operation that you want to perform.
AccessKeyId	String	The AccessKey ID provided to you by Apsara Stack.
Signature	String	The signature string.
SignatureMethod	String	The signature method.
SignatureVersion	String	The version of the signature encryption algorithm.
SignatureNonce	String	A unique, random number used to prevent replay attacks.
Timestamp	String	The timestamp of the request.
Version	String	The version number of the API. The value must be in the YYYY-MM-DD format.
Format	String	The language of the response.

4.1.10.2. Query the details of a PMML model

This topic describes the API operation that is used to query the details of a PMML model.

API operation

DescribePMMLMode

Description

You can call this operation to query the details of a model.

Request parameters

Parameter	Type	Required	Example	Description
ModelId	Integer	Yes	6200	The ID of the model.
Action	String	Yes	DescribePMMLMode	The operation that you want to perform. Set the value to DescribePMMLMode.

Response parameters

Parameter	Type	Description
Models	List<ModelInfo >	An array of model properties. For more information about the structure of each element, see the sample code.
Model	ModelInfo	The details of a model.
Name	String	The display name of the model.
Owner	String	The ID of the model owner.
Description	String	The description of the model.
ModelId	String	The ID of the model.
ModelName	String	The name of the underlying model that is generated by the corresponding algorithm.
CreateTime	Date	The time when the model was generated.
ExperimentId	String	The ID of the experiment from which the model is generated.

Parameter	Type	Description
UpdateTime	Date	The time when the model was last updated.
Project	String	The name of the project to which the model belongs.
ProjectId	String	The ID of the project to which the model belongs.

Sample request

```

4.1.10.3. Download PMML models

4.1.10.3.1. Generate a download URL for a model

This topic describes how to use the GeneratePMMLModelUrl operation to generate a download URL for a model.

Operation name

GeneratePMMLModelUrl

Description

You can call this operation to generate a Predictive Model Markup Language (PMML) download URL for a model in asynchronous mode. After you call this operation, the system starts a task in the background to generate a download URL and returns the JobId parameter. The system uses the JobId parameter to query the execution status of the task. If the task is successful, a download URL, which is an Object Storage Service (OSS) endpoint, of the model is returned.

Request parameters

Parameter	Type	Required	Example	Description
ModelId	Integer	Yes	6200	The ID of the model.
Action	String	Yes	GeneratePMMLModelUrl	The operation that you want to perform. Set the value to GeneratePMMLModelUrl.

Response parameters

Parameter	Type	Description
Data	Data	The returned data.
JobId	String	The ID of the task that is used to generate a download URL.

Sample requests

```
http://pop.pai.idst.inter.env8d.com/?Action=GeneratePMMLModelUrl&ModelId=6200&<Common request parameters>
```

Sample responses

```
<GeneratePMMLModelUrlResponse>
<Data>
<JobId>
asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c
</JobId>
</Data>
<RequestId>0a948186156950130543566 97d0059</RequestId>
<ErrMsg>Successful</ErrMsg>
<ErrCode>success</ErrCode>
</GeneratePMMLModelUrlResponse>{
  "GeneratePMMLModelUrlResponse": {
    "Data": {
      "JobId": "
asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c
"
    },
    "RequestId": "0a948186156950130543566 97d0059",
    "ErrMsg": "Successful",
    "ErrCode": "success"
  }
}
```

4.1.10.3.2. Poll the status of a download URL generation task

This topic describes the API operation that is used to poll the status of a download URL generation task.

API operation

QueryAsynJobStatus

Description

You can call this operation to poll the status of a download URL generation task and obtain the generated OSS URL for you to download models when the task is successful.

Request parameters

Parameter	Type	Required	Example	Description
JobId	String	Yes	asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c	The ID of the download URL generation task. The ID is returned by the GeneratePMMLModelUrl operation.
Action	String	Yes	QueryAsynJobStatus	The operation that you want to perform. Set the value to QueryAsynJobStatus.

Response parameters

Parameter	Type	Description
Data	Data	The return data in a structure.

Parameter	Type	Description
Status	String	The status of the download URL generation task. Valid values: done, failed, and running.
Info	String	A URL is returned if the task is successful. An error message is returned if the task fails.

Sample request

```
http://pop.pai.idst.inter.env8d.com/?Action=QueryAsynJobStatus&JobId=asynUploadModel2Oss_395fd769-1568-4015-8aa8-a56b2e0da11c&<Common request parameters>
```

Sample success response

```
<QueryAsynJobStatusResponse>

  }
}
```

4.1.10.4. SDK

This topic describes how to use Alibaba Cloud SDK.

Alibaba Cloud SDK

```
https://developer.aliyun.com/sdk?spm=5176.10695662.1kquk9v2l.2.1e734735x9Gptc&aly_as=m3lFQpXP<dependency>
<groupId>com.aliyun</groupId>
<artifactId>aliyun-java-sdk-core</artifactId>
<version>{$version}</version></dependency>
```

SDK use cases

Example: Call a remote procedure call (RPC) API operation.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>",           // The region ID.
            "<your-access-key-id>",       // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and specify its parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("ecs.aliyuncs.com");
        request.setVersion("2014-05-26");
        request.setAction("DescribeInstanceStatus");
        request.putQueryParameter("PageNumber", "1");
        request.putQueryParameter("PageSize", "30");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

Example: Call a RESTful API operation.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>",           // The region ID.
            "<your-access-key-id>",       // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and specify its parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("cs.aliyuncs.com");
        request.setVersion("2015-12-15");
        request.setUriPattern("/clusters");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

SDK parameters

The Domain parameter must be in the pop.${pai_domain} format. Set the pai_domain parameter to the domain of the Machine Learning Platform for AI console.

The Version parameter must be set to 2019-09-25.

The Action parameter specifies an API operation.

The QueryParameter parameter specifies API request parameters, excluding the Action parameter.

Example:

```
        CommonRequest request = new CommonRequest();
        request.setDomain("pop.${pai_domain}");
        request.setVersion("2019-09-25");
        request.setAction("DescribePMMLMode");
        request.putQueryParameter("ModelId", "***");
```

4.1.11. SDK Reference

4.1.11.1. Overview

Machine Learning Platform for AI (PAI) provides EasyVision, which is an enhanced algorithm framework for visual intelligence. EasyVision provides a variety of features for model training and prediction. You can use EasyVision to train and apply computer vision (CV) models for your CV applications.

Background information

The rapid development of deep learning technologies promotes large-scale commercial use of CV. As CV developers, you may encounter the following difficulties when you use deep learning technologies to build CV models:

- High costs are required to develop and debug deep learning algorithms.
- Models are frequently updated. You must spend much time understanding how the models work and other details of the models.
- To train algorithms and improve the inference performance, you must master professional and systematic knowledge.
- High costs are required for data annotation.
- To use open source algorithms in PAI, you must spend time learning and rebuilding the algorithms.

To overcome the preceding difficulties, PAI provides EasyVision, which is a simple and easy-to-use algorithm framework that allows you to train models. You can use EasyVision to build and apply CV models with ease.

Benefits

EasyVision has the following benefits:

- Ease of use

  EasyVision supports pluggable API operations that can be called to complete various tasks of various modules. In addition, EasyVision provides rich features, such as data I/O, preprocessing, model training, and offline prediction, to support the entire modeling process. You can use EasyVision in multiple modules such as Machine Learning Studio or Data Science Workshop (DSW) of PAI.

- High performance

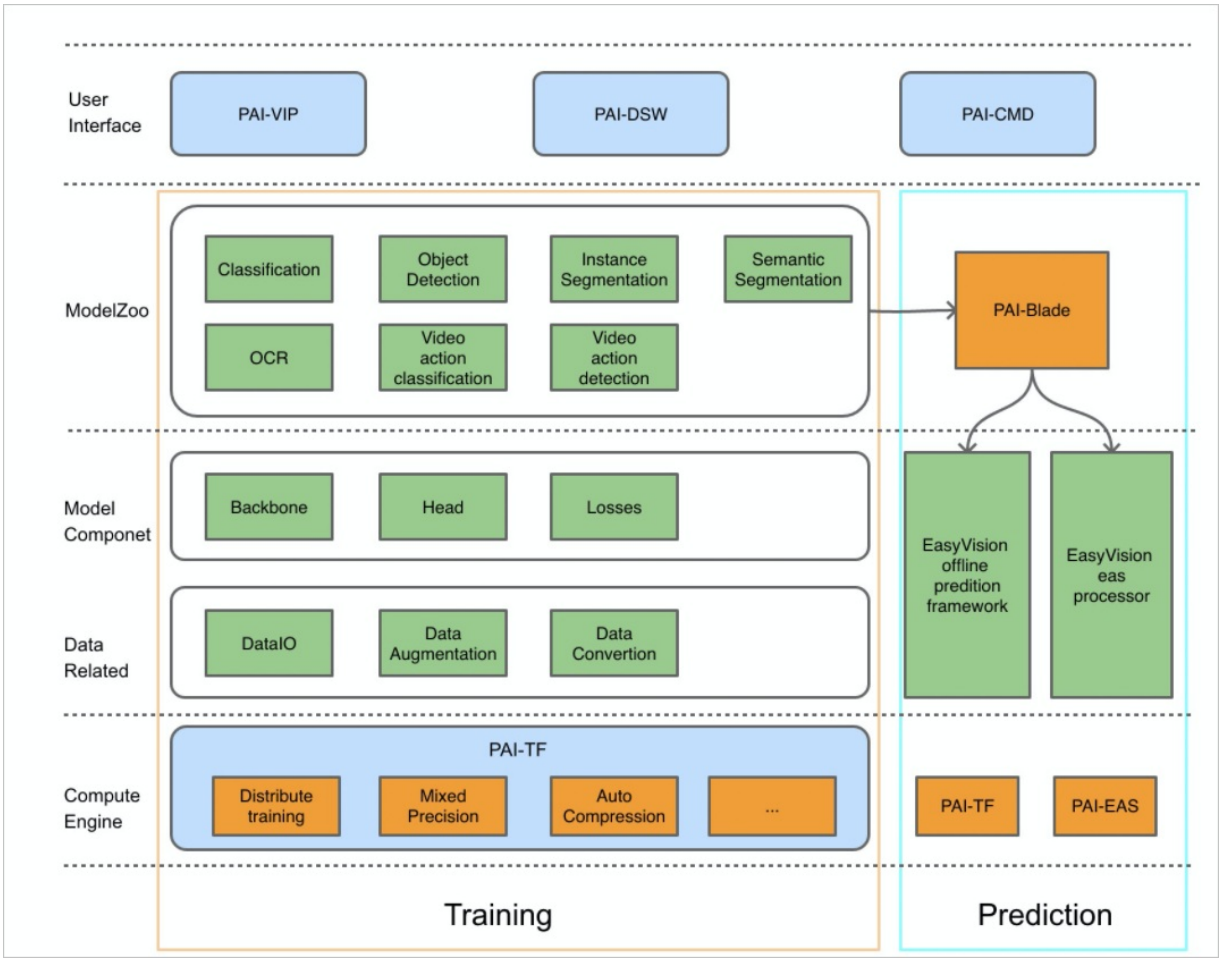
  EasyVision encapsulates a variety of optimization engines of PAI-TensorFlow, such as the optimization engines for compiling, distributed training, and mixed precision training. You can use these optimization engines to improve the system performance by configuring the related configuration files. You can also use EasyVision in open source TensorFlow systems.

- Rich models

  EasyVision provides a variety of models, such as the optical character recognition (OCR) model. The models are trained based on open source datasets. This reduces the development and training costs.

Architecture

EasyVision builds a model zoo with plenty of models. In addition, EasyVision provides a variety of model training and prediction capabilities and is compatible with the commands, Video Intelligence Platform (VIP), and DSW of PAI. This way, EasyVision can meet various modeling requirements. EasyVision uses a distributed pipeline architecture for offline prediction. This is a flexible and highly available architecture that allows EasyVision to process hundreds of millions of data records offline within a short period. Models can be used to make predictions in Elastic Algorithm Service (EAS) of PAI. The system and model optimization features of PAI allow you to make predictions with fewer parameters more efficiently. In addition, you can use EasyVision to customize operations of model training and prediction. This way, you can reuse existing features and optimize models. The following figure shows the architecture of EasyVision.



Features

- Usability

  You may have different requirements on model training and prediction. For example, you may want to train models by performing simple operations, run model training and prediction tasks as scheduled, and reuse existing models and algorithms. To meet these requirements, EasyVision is compatible with the commands, VIP, and DSW of PAI.

- Performance optimization

  EasyVision optimizes distributed training based on PAI-TensorFlow. EasyVision allows you to train a model on one or more multi-GPU servers. EasyVision also improves the inference performance, including graph optimization and model compression.

- Connection to Smart Labeling of PAI

EasyVision is connected to Smart Labeling of PAI, which is used to label data. PAI provides a conversion tool to convert files that contain labeled data to TFRecord files. You can use the TFRecord files to train EasyVision models. In addition, EasyVision provides rich data enhancement modules to dynamically inject data during training.

- Efficient offline predictions

  EasyVision allows you to use multiple servers to concurrently make predictions. Each server separately processes data. This way, you can use offline data to make predictions based on the models that are trained by EasyVision. Each processing job in a prediction task can be run in an accelerated manner by using multiple threads on multiple servers. All jobs are asynchronously run one by one. This improves the processing efficiency. You can also customize jobs.

- Connection to EAS

  A SavedModel file is generated during training. You can use the SavedModel file in your own system or EAS to make online predictions. EasyVision provides a processor that supports the powerful online prediction capabilities of EAS. You can use this processor to process data in real time after you specify the model information such as the endpoint and type in the configuration file.

4.1.11.2. Quick start

This topic describes how to install EasyVision, which is an enhanced algorithm framework provided by Machine Learning Platform for AI (PAI). This topic also describes how to use EasyVision to train computer vision (CV) models.

Prerequisites

Python and TensorFlow are installed. For more information about the limits on the versions of Python and TensorFlow, see Limits.

Limits

You can install and use EasyVision only by using Python and TensorFlow of the following versions:

- Python 2.7, or Python 3.4 or later
- TensorFlow 1.8 or later, or PAI-TensorFlow

Procedure

1. Prepare the test data.
   i. Use one of the following methods to download the Pascal dataset to the current directory:

   ```
   # Method 1: Use osscmd.
   osscmd downloadallobject oss://pai-vision-data-hz/data/voc0712_tfrecord/ data/voc0712_tfrecord --host=oss-cn-zhangjiakou.aliyuncs.com
   # Method 2: Use ossutil. To use ossutil to download the Pascal dataset, you must set the host parameter to oss-cn-zhangjiakou.aliyuncs.com in the configuration file.
   ossutil  cp -r  oss://pai-vision-data-hz/data/voc0712_tfrecord/ data/voc0712_tfrecord
   ```

   ii. Create a folder in the current directory and download the ResNet50 pre-trained model to the folder.

   ```
   mkdir -p pretrained_models/
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1d_50/ pretrained_models/resnet_v1d_50
   ```

2. Use one of the following methods to start a training task:
   - Use the configuration file

   ```
   import easy_vision
   easy_vision.train_and_evaluate(easy_vision.RFCN_SAMPLE_CONFIG)
   ```

- Set parameters

```
import easy_vision
param_config = """
  --model_type RFCN
  --backbone  resnet_v1d_50
  --num_classes 20
  --model_dir experiments/pascal_voc/resnet50_rfcn_model
  --train_data data/voc0712_tfrecord/voc0712_part_*.tfrecord
  --test_data data/voc0712_tfrecord/VOC2007_test.tfrecord
  --num_test_example 2
  --train_batch_size 32
  --test_batch_size 1
  --image_min_sizes 600
  --image_max_sizes 1024
  --lr_type exponential_decay
  --initial_learning_rate 0.001
  --decay_epochs 20
  --staircase true"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

- Use multiple servers

  You can use multiple servers to train the model. Make sure that each server has at least two GPUs. If you use this method, you must start the following child processes:

  - ps: the parameter server.
  - master: the master that writes summaries, saves checkpoints, and periodically evaluates the model.
  - worker: the worker that processes specific data.

  Run the following code to start a training task:

```
#-*- encoding:utf-8 -*-
import multiprocessing
import sys
import os
import easy_vision
import json
import logging
import subprocess
import time
# train config under distributed settings
config=easy_vision.RFCN_DISTRIBUTE_SAMPLE_CONFIG
print('config path: %s' % config)
# The configuration of the cluster.
TF_CONFIG={'cluster':{
             'ps': ['localhost:12921'],
             'master': ['localhost:12922'],
             'worker': ['localhost:12923']
            }
          }
def job(task, gpu):
  task_name = task['type']
  # redirect python log and tf log to log_file_name
  # [logs/master.log, logs/worker.log, logs/ps.log]
  log_file_name = "logs/%s.log" % task_name
  TF_CONFIG['task'] = task
  os.environ['TF_CONFIG'] = json.dumps(TF_CONFIG)
  os.environ['CUDA_VISIBLE_DEVICES'] = gpu
  train_cmd = 'python -m easy_vision.python.train_eval --pipeline_config_path %s' % config
```

```
  logging.info('%s > %s 2>&1 ' % (train_cmd, log_file_name))
  with open(log_file_name, 'w') as lfile:
    return subprocess.Popen(train_cmd.split(' '), stdout= lfile, stderr=subprocess.STDOUT)
if __name__ == '__main__':
  procs = {}
  # start ps job on cpu
  task = {'type':'ps', 'index':0}
  procs['ps'] = job(task, '')
  # start master job on gpu 0
  task = {'type':'master', 'index':0}
  procs['master'] = job(task, '0')
  # start worker job on gpu 1
  task = {'type':'worker', 'index':0}
  procs['worker'] = job(task, '1')
  num_worker = 2
  for k, proc in procs.items():
    logging.info('%s pid: %d' %(k, proc.pid))
  task_failed = None
  task_finish_cnt = 0
  task_has_finished = {k:False for k in procs.keys()}
  while True:
    for k, proc in procs.items():
      if proc.poll() is None:
        if task_failed is not None:
          logging.error('task %s failed, %s quit' % (task_failed, k))
          proc.terminate()
          if k != 'ps':
            task_has_finished[k] = True
            task_finish_cnt += 1
          logging.info('task_finish_cnt %d' % task_finish_cnt)
      else:
        if not task_has_finished[k]:
          #process quit by itself
          if k != 'ps':
            task_finish_cnt += 1
            task_has_finished[k] = True
          logging.info('task_finish_cnt %d' % task_finish_cnt)
          if proc.returncode != 0:
            logging.error('%s failed' %k)
            task_failed = k
          else:
            logging.info('%s run successfuly' % k)
    if task_finish_cnt >= num_worker:
      break
    time.sleep(1)
```

3. Use TensorBoard to monitor the training task.

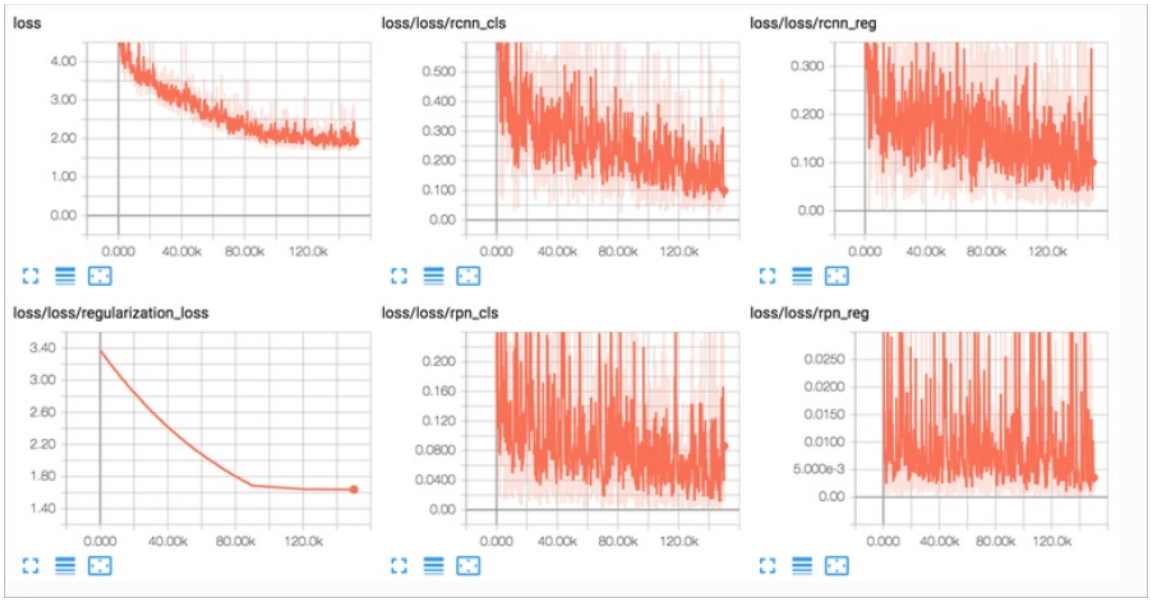
   The checkpoints and event files of the model are saved in the model directory. You can run the following command in TensorBoard to view the loss and mean average precision (mAP) of the training:

   ```
   tensorboard --port 6006 --logdir <model_dir>  [ --host 0.0.0.0 ]
   ```

   Replace <model_dir> with the directory of your model.

   In TensorBoard, you can view the following information:

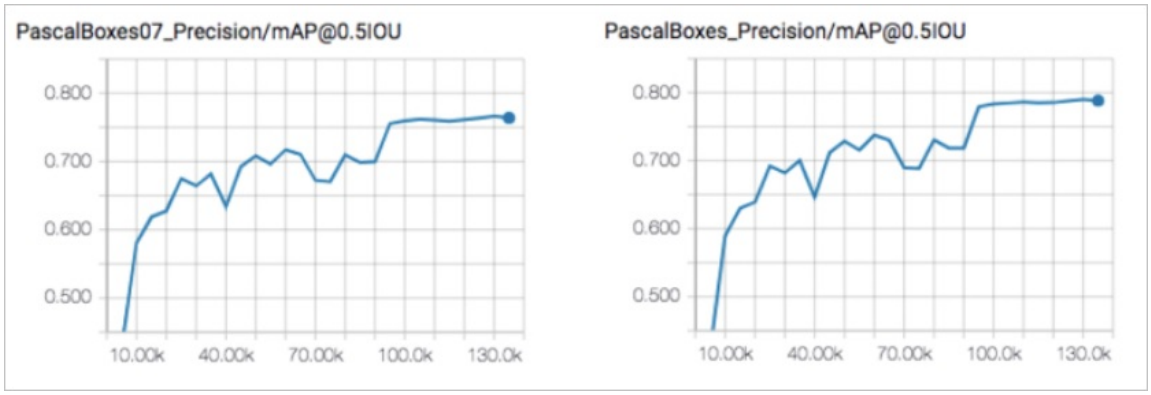
   - Training loss



TensorBoard provides the following metrics about the training loss:

- loss: the total loss of the training.
- loss/loss/rcnn_cls: the classification loss.
- loss/loss/rcnn_reg: the regression loss.
- loss/loss/regularization_loss: the regularization loss.
- loss/loss/rpn_cls: the classification loss of region proposal network (RPN).
- loss/loss/rpn_reg: the regression loss of RPN.

- Test mAP



PascalBoxes07 and PascalBoxes are used as metrics to calculate the test mAP, as shown in the preceding figure. PascalBoxes07 is commonly used in studies.

4. Test and evaluate the model.

   After the training task is complete, you can test and evaluate the trained model.

   - Use other datasets to test the model. Then, check the detection result of each image.

```
import easy_vision
test_filelist = 'path/to/filelist.txt' # each line is a image file path.
detect_results = easy_vision.predict(easy_vision.RFCN_SAMPLE_CONFIG, test_filelist=test_fileli
st)
```

   The detection result of each image is returned in the detect_results parameter in the format of [detection_boxes, box_probability, box_class]. In the format, detection_boxes and box_class indicate the

location and category of the detected object. box_probability indicates the confidence level of the detection result.

- Evaluate the trained model.

```
import easy_vision
eval_metrics = easy_vision.evaluate(easy_vision.RFCN_SAMPLE_CONFIG)
```

The eval_metrics parameter indicates evaluation metrics, including PascalBoxes07, PascalBoxes, global_step, and the following loss metrics: loss, loss/loss/rcnn_cls, loss/loss/rcnn_reg, loss/loss/rpn_cls, loss/loss/rpn_reg, and loss/loss/total_loss.

5. Export the model.

EasyVision allows you to export the model as a SavedModel file. Then, you can use the SavedModel file in Python or C++ to make predictions.

Run the following code to export the model as a SavedModel file:

```
import easy_vision
easy_vision.export(export_dir, easy_vision.RFCN_SAMPLE_CONFIG, checkpoint_path)
```

After you run the preceding code, a model directory is created in the export_dir directory. The name of the model directory contains the UNIX timestamp that indicates the time when the directory is created. All checkpoints of the model are exported to a SavedModel file in the model directory.

6. Use the model to make predictions.

EasyVision provides the predictor in Python for SavedModel files. You can run the following code to start model prediction based on a detection model. For more information about the predictors for classification, segmentation, and optical character recognition (OCR), see Offline prediction.

```
import easy_vision
detector = ev.Detector(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
output_dict = detector.predict([image])
```

The prediction result is returned in the output_dict parameter. The parameter value is in the format of a JSON list. The number of elements in the list is equal to the number of images in the datasets for testing. The following code shows the sample response in the JSON format:

```
{
  "detection_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.7247772216
797], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],
  "detection_scores": [0.9942291975021362, 0.9940272569656372],
  "detection_classes": [1, 1],
  "detection_classe_names": ["text", "text"]
}
```

7. Evaluate the SavedModel file.

Run the following code to evaluate the exported SavedModel file. All metrics of the model are contained in the evaluation result file and logs.

```
from easy_vision.python.main import predictor_evaluate
predictor_evaluate(predictor_eval_config)
```

In the preceding code, predictor_eval_config specifies the .proto file that is used for the evaluation. For more information, see SavedModel file evaluation.

4.1.11.3. Model export and prediction

EasyVision allows you to export a trained model as a SavedModel file. Then, you can use the SavedModel file in Python or C++ to make predictions. This topic describes how to export a model as a SavedModel file and the input and output of model prediction. This topic also provides an example on how to make offline prediction.

Model export

You can run the following Python code to export a model:

```
import easy_vision
easy_vision.export(export_dir, pipeline_config_path, checkpoint_path)
```

By default, If you do not specify the checkpoint_path parameter, the checkpoints in the model directory specified by the model_dir parameter under the configuration path specified by the pipeline_config_path parameter are used.

Input and output of model prediction

To make predictions based on a SavedModel file, you must obtain the TensorFlow input and output operations.

Parameters in a placeholder in the input

Parameter	Description	Dimension	Type
image	The batched tensor of the image. The channels are in the RGB sequence.	[batch_size, None, None, 3]	tf.uint8
true_image_shape	The size of the image. The last dimension must be in the sequence of [height, width, channel], such as [[224,224,3], [448, 448, 3]].	[batch_size, 3]	tf.int32

The value of the batch_size parameter is specified in export_config in *pipeline_config* when you export the model. If the batch_size parameter is set to -1, its value is dynamically assigned. Only classification models support dynamic value assignment of the batch_size parameter.

Parameters in an output tensor

The output of a prediction model is in the format of a JSON list. The number of elements in the list is equal to the number of images in the input datasets. The following part provides the sample outputs of different types of models in the JSON format and describes the output parameters:

- **feature_extractor**

  The following code shows a sample output:

  ```
  {"feature": [0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.4583122730255127, 0.0]}
  ```

  Parameters

Parameter	Description	Dimension	Type
feature	The extracted features. The coordinates of each feature are specified in the following order: [top, left, bottom, right].	[feature_dim]	FLOAT

- **classifier**

  The following code shows a sample output:

```
{
"class": 3,
"class_name": "coho4",
"class_probs": {"coho1": 4.028851974258174e-10,
          "coho2": 0.48115724325180054,
          "coho3": 5.116515922054532e-07,
          "coho4": 0.5188422446937221}
}
```

Parameters

Parameter	Description	Dimension	Type
class	The ID of the category.	[]	INT32
class_name	The name of the category.	[]	STRING
class_probs	The probabilities for all categories.	[num_classes]	Dict{Key: STRING, Value: FLOAT}

- **multilabel_classifier**

  The following code shows a sample output:

```
{
"class": [3, 4],
"class_names": ["coho3", "coho4"],
"class_probs": {"coho1": 4.028851974258174e-10,
          "coho2": 0.10115724325180054,
          "coho3": 0.6188422446937221,
          "coho4": 0.5188422446937221}
}
```

  Parameters

Parameter	Description	Dimension	Type
class	The ID of the category.	[None]	INT32
class_names	The name of the category.	[None]	STRING
class_probs	The probabilities for all categories.	[num_classes]	Dict{Key: STRING, Value: FLOAT}

- **detector** (supports instance segmentation)

  The following code shows a sample output:

```
{
  "detection_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.724777221679
7], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],
  "detection_scores": [0.9942291975021362, 0.9940272569656372],
  "detection_classes": [1, 1],
  "detection_classe_names": ["text", "text"]
 }
```

  Parameters

Parameter	Description	Dimension	Type
detection_boxes	The bounding boxes that mark the recognized objects. The coordinates of each bounding box are specified in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probabilities that the objects are recognized.	num_detections	FLOAT
detection_classes	The IDs of the categories to which the objects belong.	num_detections	INT
detection_class_names	The names of the categories to which the objects belong.	num_detections	STRING
detection_masks	Optional. The segmentation masks of the objects.	[num_detection, image_height, image_width]	FLOAT
detection_keypoints	Optional. The landmarks of the objects.	[num_detection, num_keypoints, 2]	FLOAT
detection_roi_features	Optional. The local features of the objects.	[num_detection, roi_height, roi_width, channels]	FLOAT

- **detector_with_rpn**

  The following code shows a sample output:

```
{
  "proposal_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.7247772216797
], 243.5308074951172, 197.69570922851562, 385.59625244140625, 247.7247772216797],
  "proposal_scores": [0.88, 0.56],
  "detection_boxes": [[243.5308074951172, 197.69570922851562, 385.59625244140625, 247.724777221679
7], [292.1929931640625, 114.28043365478516, 571.2748413085938, 165.09771728515625]],
  "detection_scores": [0.9942291975021362, 0.9940272569656372],
  "detection_classes": [1, 1],
  "detection_classe_names": ["text", "text"]
 }
```

  Parameters

Parameter	Description	Dimension	Type
proposal_boxes	The areas that cover the proposals.	[num_proposal, 4]	FLOAT
proposal_scores	The scores of the proposals.	num_proposal	FLOAT

Parameter	Description	Dimension	Type
detection_boxes	The bounding boxes that mark the recognized objects. The coordinates of each bounding box are specified in the following order: [top, left, bottom, right].	[num_detections, 4]	FLOAT
detection_scores	The probabilities that the objects are recognized.	num_detections	FLOAT
detection_classes	The IDs of the categories to which the objects belong.	num_detections	INT
detection_class_names	The names of the categories to which the objects belong.	num_detections	STRING

- segmentor

  The following code shows a sample output:

```
{
  "probs" : [[[0.8, 0.8], [0.6, 0.7]],[[0.8, 0.5], [0.4, 0.3]]],
  "preds" : [[[1,1], [0, 0]], [[0, 0], [1,1]]]
}
```

  Parameters

Parameter	Description	Dimension	Type
probs	The probabilities that the pixels obtained after segmentation belong to specific categories.	[output_height, output_width, num_classes]	FLOAT
preds	The IDs of the categories to which the pixels obtained after segmentation belong.	[output_height, output_widths]	INT

- text_detector

  The following code shows a sample output:

```
{

Offline prediction

EasyVision provides an operation in Python for predictions. You can call this operation to use an exported SavedModel file to make predictions. For more information about the operation, see easy_vision.python.inference. The following code shows examples of offline prediction jobs:

```
import easy_vision as ev
import numpy as np
# Recognition.
saved_model_path = 'xxx/xxx'
classifier = ev.Classifier(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
output_dict = classifier.predict([image])
# Detection.
saved_model_path = 'xxx/xxx'
detector = ev.Detector(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
output_dict = detector.predict([image])
# Text recognition.
saved_model_path = 'xxx/xxx'
text_recognizer = ev.TextRecognizer(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
output_dict = text_recognizer.predict([image])
# Text detection.
saved_model_path = 'xxx/xxx'
text_detector = ev.TextDetector(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
output_dict = text_detector.predict([image])
# End-to-End text recognition.
saved_model_path = 'xxx/xxx'
text_spotter = ev.TextSpotter(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
output_dict = text_spotter.predict([image])
# Basic predictor.
saved_model_path = 'xxx/xxx'
predictor = ev.Predictor(saved_model_path)
image = np.zeros([640, 480, 3],  dtype=np.float32)
image_list = [image for i in range(10)]
batched_images, origin_shapes = predictor.batch(images)
input_data = {
  'image': batched_images,
  'true_image_shape', origin_shapes
}
output_data_dict = predictor.predict(input_data)
```

4.1.11.4. Model library

4.1.11.4.1. Image classification

This topic describes how to use EasyVision that is provided by Machine Learning Platform for AI (PAI) to train an image classification model. In this example, a CIFAR-10 dataset is used to train a resnet_v1d_50 model.

Context

The module of image classification provides multiple major convolutional neural networks (CNNs) for training image classification models. The following types of models are supported:

- Residual Neural Network (ResNet) models
- SE-ResNet models
- Inception models
- VGG models
- MobileNet models
- EfficientNet models
- DarkNet models

The following table describes the performance benchmarks for the preceding models. Benchmark

Model	EasyVisionTop1 Acc	EasyVisionTop5 Acc
resnet_v1a_18	70.94	89.88
resnet_v1a_34	74.26	91.97
resnet_v1_50	75.20	92.20

darknet53	0.7664	0.9342
cspdarknet53-mish	0.7794	0.9425

Step 1: Prepare data

1. Download a dataset.

   EasyVision provides the CIFAR-10 dataset that is converted to a TFRecord file. You can run the following command to download the CIFAR-10 dataset to the *data* folder:

   ```
   ossutil cp -r oss://pai-vision-data-hz/data/cifar10/ data/cifar10
   ```

2. Run the following command to download the pretrained ResNet50 model to the *pretrained_models* folder:

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1d_50/ pretrained_models/resnet_v1d_50
   ```

Step 2: Train the model

EasyVision allows you to train a model by referencing a configuration file or setting parameters.

- **Reference a configuration file**

You can set the parameters that are used for model training and evaluation in a configuration file and reference the file in Python code. For more information about sample configuration files, see Image classification. If you want to know the configuration details, submit a ticket to contact the customer service representatives of PAI. Run the following Python code that references a configuration file to start model training and evaluation:

```
import easy_vision
easy_vision.train_and_evaluate(easy_vision.RESNET50_FINETUNE_PRETRAINED_MODELS_SAMPLE_CONFIG)
```

If you use a custom configuration file, you must modify the preceding code by replacing `easy_vision.RESNET50_FINETUNE_PRETRAINED_MODELS_SAMPLE_CONFIG` with the path of the custom configuration file.

- **Set parameters**

  You can set the parameters that are used for model training and evaluation in Python code. Run the following Python code that contains related parameters to start model training and evaluation:

```
import easy_vision
param_config = """
    --model_type Classification
  --backbone  resnet_v1d_50
  --num_classes 10
  --num_epochs 1
  --model_dir experiments/cifar10/resnet50_imagenet_pretrain
  --use_pretrained_model true
  --train_data data/cifar10/cifar10_train_part_*.tfrecord
  --test_data data/cifar10/cifar10_test.tfrecord
  --train_batch_size 96
  --test_batch_size 96
  --image_size 224
  --lr_type manual_step
  --initial_learning_rate 0.001
  --learning_rates 0.0003 0.0001
  --decay_epochs 35 40
  --save_checkpoint_epochs 5
  --staircase true"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

In the preceding code, the param_config structure contains the parameters that are used for model training and evaluation. The format of the param_config structure is the same as that of the ArgumentParser() object in Python. The following table describes the parameters in the param_config structure.

> **Note** Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameters in the param_config structure

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. To train an image classification model, set this parameter to Classification.	STRING	N/A

Parameter	Required	Description	Value type or sample value	Default value
backbone	No	The name of the backbone network that is used by the model. Valid values: ○ vgg_16 ○ vgg_19 ○ inception_v1 ○ inception_v2 ○ inception_v3 ○ inception_v4 ○ mobilenet_v1 ○ mobilenet_v2 ○ mobilenet_v3 ○ resnet_v1_50 ○ resnet_v1_101 ○ resnet_v1_152 ○ resnet_v2_50 ○ resnet_v2_101 ○ resnet_v2_152 ○ resnet_v1a_18 ○ resnet_v1a_34 ○ resnet_v1a_50 ○ resnet_v1a_101 ○ resnet_v1a_152 ○ resnet_v1b_50 ○ resnet_v1b_101 ○ resnet_v1b_152 ○ resnet_v1c_50 ○ resnet_v1c_101 ○ resnet_v1c_152 ○ resnet_v1d_50 ○ resnet_v1d_101 ○ resnet_v1d_152 ○ efficientnet-b0 ○ efficientnet-b1 ○ efficientnet-b2 ○ efficientnet-b3 ○ efficientnet-b4 ○ efficientnet-b5 ○ efficientnet-b6 ○ efficientnet-b7 ○ efficientnet-b8	STRING	inception_v4
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	Yes	The number of categories.	100	N/A

Parameter	Required	Description	Value type or sample value	Default value
image_size	No	The size of the images after they are resized.	INT	224
use_crop	No	Specifies whether to crop images for data enhancement.	BOOL	true
crop_min_area	No	The minimum proportion of the original image area that is occupied by the crop box if you set the use_crop parameter to true.	FLOAT	0.7
eval_each_category	No	Specifies whether to separately evaluate each category.	BOOL	false
optimizer	No	The type of the optimizer. Valid values: ◦ momentum: stochastic gradient descent (SGD) with momentum ◦ adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: ◦ exponential_decay: The learning rate is subject to exponential decay. ◦ polynomial_decay: The learning rate is subject to polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. ◦ manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate of each epoch as needed. ◦ cosine_decay: The learning rate of each epoch is adjusted based on the cosine curve until the learning rate decreases to 0.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for each specified epoch. This parameter is required if you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The Object Storage Service (OSS) path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

Parameter	Required	Description	Value type or sample value	Default value
num_epochs	Yes	The number of times the data is iterated for the training. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.1.11.4.2. Object detection

This topic describes how to use EasyVision to train an object detection model. In this example, a Visual Object Classes (VOC) dataset is used and a FasterRCNN model is trained.

Context

EasyVision provides multiple types of models for common object detection tasks that return the position information of the detected objects in images. The following types of models are supported:

- FasterRCNN models
- Single Shot Detector (SSD) models
- You Only Look Once (YOLO) models

The following table describes the expected performance of the preceding models when they are trained by using a VOC dataset or the COCO 2017 dataset.

Benchmark datasets based on VOC datasets

- Train set: the trainvals of VOC 2007 and VOC 2012
- Test set: the test set of VOC 2007

Model name	Input image size	mAP@IOU0.5
faster-rcnn-resnet50	600 × 1024	0.790
faster-rcnn-resnet50-ohem	600 × 1024	0.796
faster-rcnn-resnet50-fpn	600 × 1024	0.798
rfcn-resnet50	600 × 1024	0.764
ssd-vgg16	300 × 300	0.777
ssd-vgg16	512 × 512	0.801
ssd-resnet50	300 × 300	0.749
ssd-resnet50-fpn	300 × 300	0.762

Benchmark datasets based on the COCO 2017 dataset

- Train set: train 118k
- Test set: test 5k

Model name	Input image size	mAP@IOU0.5
faster-rcnn-resnet50	800 × 1333	0.34
ssd-mobilenet-v1	512 × 512	0.21

Step 1: Prepare data

1. Download a dataset.

   EasyVision provides a VOC dataset that is converted to TFRecord files. You can download the dataset to the *data* folder by running the following command:

   ```
   ossutil  cp -r  oss://pai-vision-data-hz/data/voc0712_tfrecord/ data/voc0712_tfrecord
   ```

2. Download the ResNet50 pretrained model to the *pretrained_models* folder by running the following command:

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1d_50/ pretrained_models/resnet_v1d_50
   ```

Step 2: Train the model

EasyVision allows you to train a model by referencing a configuration file or setting parameters.

- **Reference a configuration file**

  You can set parameters related to training and evaluation in a configuration file and reference the file in the Python code. For more information about sample configuration files, see Object detection. If you want to know the configuration details, submit a ticket to contact the customer service representatives of Machine Learning Platform for AI (PAI). Run the following Python code that references a configuration file to start training and evaluation:

  ```
  import easy_vision
  easy_vision.train_and_evaluate(easy_vision.FASTER_RCNN_SAMPLE_CONFIG)
  ```

  If you want to use a custom configuration file, replace `easy_vision.FASTER_RCNN_SAMPLE_CONFIG` in the

preceding code with the path of the custom configuration file.

- Set parameters

  You can set the parameters related to training and evaluation in the Python code. Run the following Python code that contains related parameters to start training and evaluation:

```
import easy_vision
param_config = """
  --model_type FasterRCNN
  --backbone  resnet_v1d_50
  --num_classes 20
  --model_dir experiments/pascal_voc/resnet50_frcnn_model
  --train_data data/voc0712_tfrecord/voc0712_part_*.tfrecord
  --test_data data/voc0712_tfrecord/VOC2007_test.tfrecord
  --num_test_example 2
  --train_batch_size 32
  --test_batch_size 1
  --image_min_sizes 600
  --image_max_sizes 1024
  --lr_type exponential_decay
  --initial_learning_rate 0.001
  --decay_epochs 20
  --staircase true"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

In the preceding code, the param_config parameter contains the parameters that are used for training and evaluation. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following table describes the parameters.

> **Note** Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameters in the param_config structure

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. Valid values: ○ SSD ○ FasterRCNN ○ RFCN	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: ○ mobilenet_v1 ○ resnet_v1_50 ○ resnet_v1_101 ○ resnet_v1a_18 ○ resnet_v1a_34 ○ resnet_v1d_50 ○ resnet_v1d_101 ○ vgg16 _reduce_fc	STRING	N/A

Parameter	Required	Description	Value type or sample value	Default value
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
use_fpn	No	Specifies whether to use Feature Pyramid Network (FPN).	BOOL	false
num_classes	No	The number of categories, excluding background categories.	INT	N/A
anchor_scales	No	The size of the anchor box. The size of the anchor box is the same as that of the input image where the anchor box resides after the image is resized. If you use an SSD model, this parameter is not required. If you use FPN, set this parameter to the size of the anchor box in the layer that has the highest resolution. The total number of layers is five. The size of the anchor box in a layer is twice as that in the previous layer. For example, if the size of the anchor box in the first layer is 32, the sizes of the anchor boxes in the next four layers are 64, 128, 256, and 512. If you use the Faster R-CNN model or the R-FCN model without FPN support, you can specify multiple anchor sizes as needed. For example, you can set the anchor_scales parameter to 128 256 512.	FLOAT list Sample value: 32 (single scale) or 128 256 512 (multiple scales)	◦ SSD: The default value is 0.1, 0.2, 0.37, 0.54, 0.71, 0.88, 0.96, or 1.0 times of the size of the input image. ◦ FPN: 32 ◦ Faster R-CNN with FNP support: 32 ◦ Faster R-CNN or R-FCN: [128 256 512]
anchor_ratios	No	The ratios of the width to the height of the anchor boxes.	FLOAT list	0.5 1 2
image_sizes	No	The size of the images after they are resized. This parameter takes effect only when an SSD model is used. The value of this parameter is a list that contains two numbers, which indicate the height and width. Unit: pixel.	FLOAT list	300 300
image_min_sizes	No	The length of the shorter side of images after they are resized. This parameter is used for Faster R-CNN and R-FCN models. Unit: pixel. If you specify multiple lengths for the shorter sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the shorter sides of images, this length is used for both training and evaluation.	FLOAT list	600

Parameter	Required	Description	Value type or sample value	Default value
image_max_sizes	No	The length of the longer side of images after they are resized. This parameter is used for Faster R-CNN and R-FCN models. Unit: pixel. If you specify multiple lengths for the longer sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	1024
optimizer	No	The type of the optimizer. Valid values: ◦ momentum: stochastic gradient descent (SGD) with momentum ◦ adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: ◦ exponential_decay: the exponential decay. ◦ polynomial_decay: the polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. ◦ manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed. ◦ cosine_decay The learning rate of each epoch is adjusted based on the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. If you set the lr_type parameter to cosine_decay, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rates.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	Floating point	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for the specified epochs. This parameter is required when you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The Object Storage Service (OSS) path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true
num_epochs	Yes	The number of training iterations. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A

Parameter	Required	Description	Value type or sample value	Default value
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.1.11.4.3. Image segmentation

This topic describes how to use EasyVision that is provided by Machine Learning Platform for AI (PAI) to train an image segmentation model. In this example, a Visual Object Classes (VOC) dataset is used to train a DeepLab v3+ model.

Context

Image segmentation refers to the process of partitioning an image into multiple segments. Each segment consists of pixels that share specific characteristics. The mean Intersection-Over-Union (mIOU) is used to evaluate how well an image segmentation model performs. EasyVision implements image segmentation based on DeepLab v3+.

Step 1: Prepare data

1. Download a dataset.

   EasyVision provides the VOC dataset that is converted to a TFRecord file. You can run the following command to download the VOC dataset to the *data* folder:

   ```
   # Download the dataset to the pascal_voc_seg folder.
   ossutil cp -r  oss://pai-vision-data-hz/data/pascal_voc_seg/ data/pascal_voc_seg
   # Download the dataset to the pascal_voc_seg_aug folder.
   ossutil cp -r  oss://pai-vision-data-hz/data/pascal_voc_seg_aug/ data/pascal_voc_seg_aug
   ```

2. Run the following command to download the pretrained ResNet101 model to the *pretrained_models* folder:

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1d_101/ pretrained_models/resnet_v1d_101
   ```

Step 2: Train the model

EasyVision allows you to train a model by referencing a configuration file or setting parameters.

- **Reference a configuration file**

  You can set the parameters that are used for model training and evaluation in a configuration file and reference the file in Python code. For more information about sample configuration files, see Image semantic segmentation. If you want to know the configuration details, submit a ticket to contact the customer service representatives of PAI. Run the following Python code that references a configuration file to start model training and evaluation:

```
import easy_vision
# The first step of model training and evaluation.
easy_vision.train_and_evaluate(easy_vision.DEEPLAB_SAMPLE_CONFIG_STEP1)
# The second step of model training and evaluation.
easy_vision.train_and_evaluate(easy_vision.DEEPLAB_SAMPLE_CONFIG_STEP2)
```

  If you use a custom configuration file, you must modify the preceding code by replacing both `easy_vision.DEEPLAB_SAMPLE_CONFIG_STEP1` and `easy_vision.DEEPLAB_SAMPLE_CONFIG_STEP2` with the path of the custom configuration file.

- **Set parameters**

  You can set the parameters that are used for model training and evaluation in Python code. Run the following Python code that contains related parameters to start model training and evaluation:

```
import easy_vision
param_config = """
  --model_type DeeplabV3
  --backbone  resnet_v1d_101
  --backbone_feature_stride 16
  --bn_trainable true
  --num_classes 21
  --num_epochs 1
  --model_dir experiments/pascal_voc/deeplab_stage1
  --train_data data/pascal_voc_seg_aug/voc_ev_train.tfrecord
  --test_data data/pascal_voc_seg_aug/voc_ev_val.tfrecord
  --num_test_example 2
  --train_batch_size 6
  --test_batch_size 1
  --image_crop_size 513
  --lr_type polynomial_decay
  --initial_learning_rate 0.007
  --power 0.9"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

  In the preceding code, the param_config structure contains the parameters that are used for model training and evaluation. The format of the param_config structure is the same as that of the ArgumentParser() object in Python. The following table describes the parameters in the param_config structure.

  > **Note** Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

  Parameters in the param_config structure

Parameter	Required	Description	Value type or sample value	Default value

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. To train an image segmentation model by using EasyVision, set this parameter to DeeplabV3.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: ○ resnet_v1_50 ○ resnet_v1_101 ○ resnet_v1a_18 ○ resnet_v1a_34 ○ resnet_v1d_50 ○ resnet_v1d_101 ○ xception_41 ○ xception_65 ○ xception_71	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	No	The number of categories, including background categories.	INT	N/A
backbone_feature_stride	No	The feature downsampling step size of the backbone network.	INT	16
bn_trainable	No	Specifies whether the batch normalization (BN) layer is trainable. If the value of the train_batch_size parameter is greater than 8, set this parameter to true.	BOOL	true
image_crop_size	No	The size of the image after cropping.	INT	513
optimizer	No	The type of the optimizer. Valid values: ○ momentum: stochastic gradient descent (SGD) with momentum ○ adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: ◦ exponential_decay: The learning rate is subject to exponential decay. ◦ polynomial_decay: The learning rate is subject to polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. ◦ manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate of each epoch as needed. ◦ cosine_decay The learning rate of each epoch is adjusted based on the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. If you set the lr_type parameter to cosine_decay, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	Floating point	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true

4.1.11.4.4. Instance segmentation

This topic describes how to use EasyVision that is provided by Machine Learning Platform for AI (PAI) to train an instance segmentation model. In this example, a Common Objects in Context (COCO) dataset is used to train a Mask R-CNN model.

Context

An instance segmentation model detects each distinct object in an image and predicts the movement of each object at the pixel level. The following figure shows an example of instance segmentation. EasyVision provides only Mask R-CNN models for you to implement instance segmentation.

Step 1: Prepare data

1. Download a dataset.

   EasyVision provides the COCO dataset that is converted to a TFRecord file. You can run the following command to download the COCO dataset to the *data* folder:

   ```
   ossutil  cp -r  oss://pai-vision-data-hz/data/coco_wmask/ data/coco_wmask
   ```

2. Run the following command to download the pretrained ResNet50 model to the *pretrained_models* folder:

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1d_50/ pretrained_models/resnet_v1d_50
   ```

Step 2: Train the model

You can set the parameters that are used for model training and evaluation in a configuration file to control the process of model training and evaluation. For more information about sample configuration files, see Instance segmentation. If you want to know the configuration details, submit a ticket to contact the customer service representatives of PAI. Run the following Python code that references a configuration file to start model training and evaluation:

```
import easy_vision
easy_vision.train_and_evaluate(easy_vision.MASK_RCNN_SAMPLE_CONFIG)
```

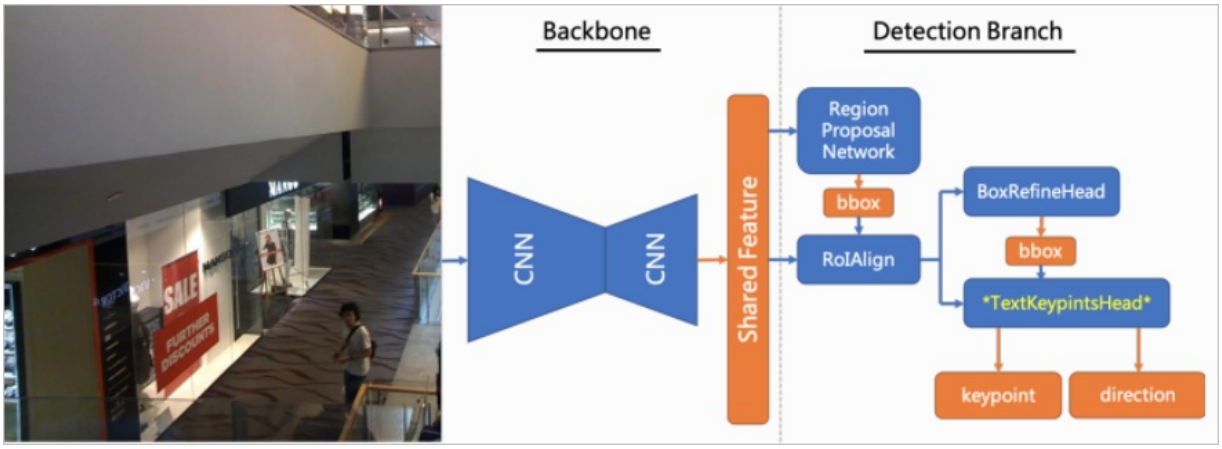
If you want to use a custom configuration file, you must modify the preceding code by replacing `easy_vision.MASK_RCNN_SAMPLE_CONFIG` with the path of the custom configuration file.

4.1.11.4.5. Text detection

This topic describes how to use EasyVision to train a text detection model. In this example, the ICDAR 2015 dataset is used and the Keypoint R-CNN model is trained.

Context

Text detection locates the text in complex text recognition scenarios. EasyVision supports the self-developed text detection model Keypoint R-CNN. Compared with the Faster R-CNN model that is used for common image detection, the Keypoint R-CNN model can predict the vertices and orientation of the text. This advantage facilitates the detection of malformed text and tilted text. The following figure shows the algorithm framework of the models for text detection.



Step 1: Prepare data

1. Download a dataset.

   EasyVision provides the ICDAR 2015 dataset that is converted to TFRecord files. You can download the dataset to the *data* folder by running the following command:

   ```
   ossutil cp -r oss://pai-vision-data-hz/data/icdar_detection_tfrecords/ data/icdar_detection_tfrecords
   ```

2. Download the ResNet50 pretrained model to the *pretrained_models* folder by running the following command:

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1_50/ pretrained_models/resnet_v1_50
   ```

Step 2: Train the model

EasyVision allows you to train a model by referencing a configuration file or setting parameters.

- **Reference a configuration file**

  You can set parameters related to training and evaluation in a configuration file and reference the file in the Python code. For more information about sample configuration files, see Text detection. If you want to know the configuration details, submit a ticket to contact the customer service representatives of Machine Learning Platform for AI (PAI). Run the following Python code that references a configuration file to start training and evaluation:

  ```
  import easy_vision
  easy_vision.train_and_evaluate(easy_vision.TEXT_KRCNN_SAMPLE_CONFIG_ICDARCH4)
  ```

  If you want to use a custom configuration file, replace `easy_vision.TEXT_KRCNN_SAMPLE_CONFIG_ICDARCH4` in the preceding code with the path of the custom configuration file.

- **Set parameters**

  You can set the parameters related to training and evaluation in the Python code. Run the following Python code that contains related parameters to start training and evaluation:

```
import easy_vision
param_config = """
  --model_type TextKRCNN
  --backbone  resnet_v1d_50
  --num_classes 1
  --num_steps 10
  --use_pretrained_model true
  --train_batch_size 1
  --test_batch_size 1
  --image_min_sizes 960
  --image_max_sizes 1440
  --initial_learning_rate 0.00001
  --optimizer adam
  --lr_type exponential_decay
  --decay_epochs 40
  --decay_factor 0.5
  --staircase true
  --train_data oss://pai-vision-data-hz/data/icdar_detection_tfrecords/icdar_training_*.tfrecord
  --test_data oss://pai-vision-data-hz/data/icdar_detection_tfrecords/icdar-ch4-test.tfrecord
  --model_dir oss://pai-vision-data-hz/test/icdar_ch4/text_krcnn_resnet50_fpn"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

In the preceding code, the param_config parameter contains the parameters that are used for training and evaluation. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following table describes the parameters.

Note Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameters in the param_config structure

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. Set the parameter to TextKRCNN for a text detection model.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: ○ resnet_v1_50 ○ resnet_v1_101	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	No	The number of categories. By default, the value is obtained by analyzing the dataset that is used for the training.	INT	-1

Parameter	Required	Description	Value type or sample value	Default value
anchor_scales	No	The size of the anchor box. The size of the anchor box is the same as that of the input image where the anchor box resides after the image is resized. You can set this parameter based on the size of the resized input image. Set this parameter to the size of the anchor box in the layer that has the highest resolution. The total number of layers is five. The size of the anchor box in a layer is twice as that in the previous layer. For example, if the size of the anchor box in the first layer is 32, the sizes of the anchor boxes in the next four layers are 64, 128, 256, and 512.	FLOAT list	24
anchor_ratios	No	The ratios of the width to the height of the anchor boxes.	FLOAT list	0.2 0.5 1 2 5
predict_text_direction	No	Specifies whether to predict the text orientation.	BOOL	false
text_direction_trainable	No	Specifies whether to train the model to predict the text orientation.	BOOL	false
text_direction_type	No	The type of the prediction of text orientation. Valid values: ◦ normal: greedy prediction. ◦ unified: The orientation of most text lines is determined as the text orientation. ◦ smart_unified: The orientation of most text lines excluding the lines of which the height is twice as the width is determined as the text orientation.	STRING	normal
aspect_ratio_min_jitter_coef	No	The minimum ratio of the width to the height at which images can be resized during the training. A value of 0 indicates that the ratios of the width to the height of images remain unchanged during the training.	FLOAT	0.8
aspect_ratio_max_jitter_coef	No	The maximum ratio of the width to the height at which images can be resized during the training. A value of 0 indicates that the ratios of the width to the height of images remain unchanged during the training.	FLOAT	1.2

Parameter	Required	Description	Value type or sample value	Default value
random_rotation_angle	No	The maximum angle to which images can be randomly rotated during the training, in the clockwise or anticlockwise direction. A value of 0 indicates that images are not randomly rotated during the training.	FLOAT	10
random_crop_min_area	No	The minimum ratio of the size of an image after it is randomly cropped to the size of the original image. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	0.1
random_crop_max_area	No	The maximum ratio of the size of an image after it is randomly cropped to the size of the original image. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	1.0
random_crop_min_aspect_ratio	No	The minimum ratio of the width to the height of images after they are randomly cropped during the training. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	0.2
random_crop_max_aspect_ratio	No	The maximum ratio of the width to the height of images after they are randomly cropped during the training. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	5
image_min_sizes	No	The length of the shorter side of images after they are resized. If you specify multiple lengths for the shorter sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the shorter sides of images, this length is used for both training and evaluation.	FLOAT list	800
image_max_sizes	No	The length of the longer side of images after they are resized. If you specify multiple lengths for the longer sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	1200

Parameter	Required	Description	Value type or sample value	Default value
random_distort_color	No	Specifies whether to randomly change the brightness, contrast, and saturation of images during the training.	BOOL	true
optimizer	No	The type of the optimizer. Valid values: ◦ momentum: stochastic gradient descent (SGD) with momentum ◦ adam	STRING	momentum
lr_type	No	The policy that is used to adjust the learning rate. Valid values: ◦ exponential_decay: the exponential decay. ◦ polynomial_decay: the polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. ◦ manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed. ◦ cosine_decay: The learning rate of each epoch is adjusted based on the cosine curve until the learning rate decreases to 0.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for the specified epochs. This parameter is required when you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The Object Storage Service (OSS) path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true

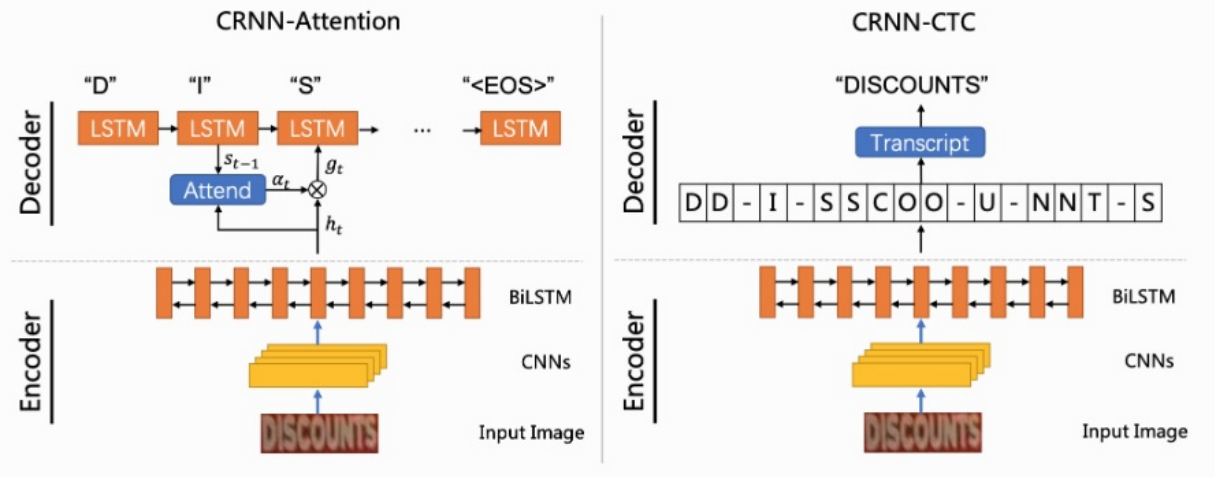
Parameter	Required	Description	Value type or sample value	Default value
num_epochs	Yes	The number of times the data is iterated for the training. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. A value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.1.11.4.6. Text recognition

This topic describes how to use EasyVision that is provided by Machine Learning Platform for AI (PAI) to train a text recognition model. In this example, a receipt dataset is used to train a CRNN-Attention model.

Context

EasyVision supports the following text recognition algorithms: CRNN-Attention, CRNN-CRCC, CNN-SpatialAttention, and TransformerOCR. The following figure shows the algorithm framework of text recognition models.



Step 1: Prepare data

1. Download a dataset.

   EasyVision provides the receipt dataset that is converted to a TFRecord file. You can run the following command to download the receipt dataset to the *data* folder:

   ```
   ssutil cp -r  oss://pai-vision-data-hz/data/recipt_text/recognition_tfrecords/ data/recipt_text/recognition_tfrecords
   ```

2. Run the following command to download the text recognition model that is provided by EasyVision to the *pretrained_models* folder. The model is pretrained by using data in Chinese and English.

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/general_crnn_attn_resnet15 pretrained_models/general_crnn_attn_resnet15
   ```

Step 2: Train the model

EasyVision allows you to train a model by referencing a configuration file or setting parameters.

- **Reference a configuration file**

  You can set the parameters that are used for model training and evaluation in a configuration file and reference the file in Python code. For more information about sample configuration files, see Text recognition. If you want to know the configuration details, submit a ticket to contact the customer service representatives of PAI. Run the following Python code that references a configuration file to start model training and evaluation:

  ```
  import easy_vision
  easy_vision.train_and_evaluate(easy_vision.TEXT_RECOG_CRNN_ATTN_CONFIG_RECIPT)
  ```

  If you want to use a custom configuration file, you must modify the preceding code by replacing `easy_vision.TEXT_RECOG_CRNN_ATTN_CONFIG_RECIPT` with the path of the custom configuration file.

- **Set parameters**

  You can set the parameters that are used for model training and evaluation in Python code. Run the following Python code that contains related parameters to start model training and evaluation:

```
import easy_vision
param_config = """
  --model_type TextRecognition
  --backbone text_resnet15
  --use_pretrained_model true
  --train_batch_size 32
  --test_batch_size 32
  --initial_learning_rate 0.0001
  --optimizer adam
  --lr_type exponential_decay
  --decay_epochs 10
  --decay_factor 0.7
  --staircase true
  --train_data data/recipt_text/recognition_tfrecords/train_*.tfrecord
  --test_data data/recipt_text/recognition_tfrecords/test.tfrecord
  --model_dir experiments/recipt_text/crnn_attn_resnet15_fixed_height"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

In the preceding code, the param_config structure contains the parameters that are used for model training and evaluation. The format of the param_config structure is the same as that of the ArgumentParser() object in Python. The following table describes the parameters in the param_config structure.

> **Note** Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameters in the param_config structure

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. To train a text recognition model, set this parameter to TextRecognition.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: ○ text_resnet15 ○ vgg_bai	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
image_resize_height	No	The height of images after they are resized.	INT	32
image_resize_width	No	The width of images after they are resized. Default value: -1, which indicates resizing based on a fixed ratio of width to height.	INT	-1
min_input_ratio	No	The minimum ratio of the width to the height of images. This parameter takes effect if the image_resize_width parameter is set to -1.	FLOAT	0.125

Parameter	Required	Description	Value type or sample value	Default value
max_input_ratio	No	The maximum ratio of the width to the height of images. This parameter takes effect if the image_resize_width parameter is set to -1.	FLOAT	38.0
num_buckets	No	The number of buckets into which images are classified. Images with similar ratios of width to height are classified into the same bucket. This parameter takes effect if the image_resize_width parameter is set to -1.	INT	10
random_distort_color	No	Specifies whether to randomly change the brightness, contrast, and saturation of images during the training.	BOOL	true
rgb_to_gray	No	Specifies whether to convert images to grayscale images.	BOOL	true
encoder_type	No	The type of the encoder. Valid values: ○ crnn: the hybrid Convolutional Neural Network (CNN)-Recurrent Neural Network (RNN) encoder. ○ cnn_line: the CNN encoder. ○ cnn_spatial: the encoder that uses spatial attention CNN.	STRING	crnn
encoder_num_layers	No	The number of RNN layers in the encoder. CNN layers are not counted.	INT	2
encoder_rnn_type	No	The type of RNN that is used by the encoder. Valid values: ○ bi: bidirectional RNN. ○ uni: unidirectional RNN.	STRING	uni
encoder_hidden_size	No	The number of neurons in the hidden layer of the encoder.	INT	512
encoder_cell_type	No	The type of RNN cells in the encoder. Valid values: ○ basic_lstm ○ gru ○ layer_norm_basic_lstm ○ nas	STRING	basic_lstm
decoder_type	No	The type of the decoder. Valid values: ○ attention ○ ctc	STRING	attention

Parameter	Required	Description	Value type or sample value	Default value
decoder_num_layers	No	The number of layers in the decoder.	INT	2
decoder_hidden_size	No	The number of neurons in the hidden layer of the decoder.	INT	512
decoder_cell_type	No	The type of RNN cells in the decoder. Valid values: ○ basic_lstm ○ gru ○ layer_norm_basic_lstm ○ nas	STRING	basic_lstm
embedding_size	No	The embedding size of the dictionary.	INT	64
beam_width	No	The beam width of the beam search.	INT	0
length_penalty_weight	No	The length penalty score of the beam search. This prevents shorter sentences from receiving higher scores.	FLOAT	0.0
attention_mechanism	No	The type of the attention mechanism of the decoder. Valid values: ○ luong ○ scaled_luong ○ bahdanau ○ normed_bahdanau	STRING	normed_bahdanau
optimizer	No	The type of the optimizer. Valid values: ○ momentum: stochastic gradient descent (SGD) with momentum ○ adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: ◦ exponential_decay: The learning rate is subject to exponential decay. ◦ polynomial_decay: The learning rate is subject to polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. ◦ manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate of each epoch as needed. ◦ cosine_decay The learning rate of each epoch is adjusted based on the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. If you set the lr_type parameter to cosine_decay, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for each specified epoch. This parameter is required if you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The Object Storage Service (OSS) path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true
num_epochs	Yes	The number of training iterations. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A

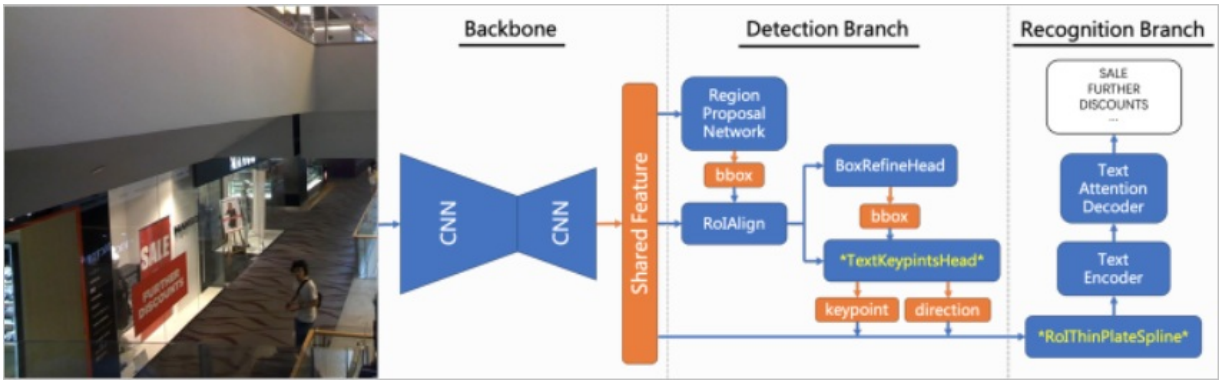
Parameter	Required	Description	Value type or sample value	Default value
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. The value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.1.11.4.7. End-to-end text recognition

This topic describes how to use EasyVision to train an end-to-end text recognition model. In this example, the receipt dataset is used and the TextEnd2End model is trained.

Context

The traditional optical character recognition (OCR) algorithm separates the text detection and text recognition steps and trains a task for each step. You need to write a large amount of code to process intermediate data that is generated between the two coupled steps. In this case, the recognition accuracy and speed of the OCR algorithm may be lowered. To resolve the preceding issue, EasyVision provides the end-to-end OCR algorithm. The end-to-end OCR algorithm simplifies the algorithm training and deployment, improves the recognition accuracy by about 2%, and increases the recognition speed by 170%. End-to-end text recognition models has greater advantages than the traditional detection and recognition algorithms. The following figure shows the algorithm framework of end-to-end text recognition models.



Step 1: Prepare data

1. Download a dataset.

   EasyVision provides the receipt dataset that is converted to TFRecord files. You can download the dataset to the *data* folder by running the following command:

   ```
   ossutil cp -r oss://pai-vision-data-hz/data/recipt_text/end2end_tfrecords/ data/recipt_text/end2end_tfrecords/
   ```

2. Download the TextEnd2End model provided by EasyVision to the *pretrained_models* folder by running the following command. The TextEnd2End model which is pretrained based on both Chinese and English data.

   ```
   ossutil cp -r oss://pai-vision-data-hz/pretrained_models/resnet_v1d_50/ pretrained_models/resnet_v1d_50
   ```

Step 2: Train the model

EasyVision allows you to train a model by referencing a configuration file or setting parameters.

- **Reference a configuration file**

  You can set parameters related to training and evaluation in a configuration file and reference the file in the Python code. For more information about sample configuration files, see End-to-End text recognition. If you want to know the configuration details, submit a ticket to contact the customer service representatives of Machine Learning Platform for AI (PAI). Run the following Python code that references a configuration file to start training and evaluation:

  ```
  import easy_vision
  easy_vision.train_and_evaluate(easy_vision.TEXT_END2END_SAMPLE_CONFIG_RECIPT)
  ```

  If you want to use a custom configuration file, replace `easy_vision.TEXT_END2END_SAMPLE_CONFIG_RECIPT` in the preceding code with the path of the custom configuration file.

- **Set parameters**

  You can set the parameters related to training and evaluation in the Python code. Run the following Python code that contains related parameters to start training and evaluation:

```
import easy_vision
param_config = """
  --model_type TextEnd2End
  --backbone  resnet_v1_50
  --num_classes 1
  --use_pretrained_model true
  --train_batch_size 1
  --test_batch_size 1
  --image_min_sizes 960
  --image_max_sizes 1440
  --initial_learning_rate 0.0001
  --optimizer adam
  --lr_type exponential_decay
  --decay_epochs 40
  --decay_factor 0.5
  --num_epochs 10
  --staircase true
  --predict_text_direction true
  --text_direction_trainable true
  --text_direction_type smart_unified
  --feature_gather_type fixed_height_pyramid
  --train_data data/recipt_text/end2end_tfrecords/train_*.tfrecord
  --test_data data/recipt_text/end2end_tfrecords/test.tfrecord
  --model_dir experiments/recipt_text/text_end2end_krcnn_resnet50_attn"""
easy_vision.train_and_evaluate_with_param_config(param_config)
```

In the preceding code, the param_config parameter contains the parameters that are used for training and evaluation. The format of the param_config parameter is the same as that of the ArgumentParser() object in Python. The following table describes the parameters.

> **Note** Do not enclose a parameter value of the STRING type in double quotation marks (") or single quotation marks (').

Parameters in the param_config structure

Parameter	Required	Description	Value type or sample value	Default value
model_type	Yes	The type of the model to train. Set this parameter to TextEnd2End when you train a model for end-to-end text recognition.	STRING	N/A
backbone	Yes	The name of the backbone network that is used by the model. Valid values: ○ resnet_v1_50 ○ resnet_v1_101	STRING	N/A
weight_decay	No	The value of L2 regularization.	FLOAT	1e-4
num_classes	No	The number of categories. By default, the value is obtained by analyzing the dataset that is used for the training.	21	-1

Parameter	Required	Description	Value type or sample value	Default value
anchor_scales	No	The size of the anchor box. The size of the anchor box is the same as that of the input image where the anchor box resides after the image is resized. Set this parameter to the size of the anchor box in the layer that has the highest resolution. The total number of layers is five. The size of the anchor box in a layer is twice as that in the previous layer. For example, if the size of the anchor box in the first layer is 32, the sizes of the anchor boxes in the next four layers are 64, 128, 256, and 512.	FLOAT list. Sample value: 32 (single scale).	24
anchor_ratios	No	The ratios of the width to the height of the anchor boxes.	FLOAT list	0.2 0.5 1 2 5
predict_text_direction	No	Specifies whether to predict the text orientation.	BOOL	false
text_direction_trainable	No	Specifies whether to train the model to predict the text orientation.	BOOL	false
text_direction_type	No	The type of the prediction of text orientation. Valid values: ◦ normal: greedy prediction. ◦ unified: The orientation of most text lines is determined as the text orientation. ◦ smart_unified: The orientation of most text lines excluding the lines of which the height is twice as the width is determined as the text orientation.	STRING	normal
feature_gather_type	No	The type of the extractor that is used to extract features of the text lines. Valid values: ◦ fixed_size: extracts features based on the specified width and height. ◦ fixed_height: extracts features based on the specified height and the specified ratio of the width to the height. ◦ fixed_height_pyramid: extracts features from multi-scale features based on the specified height and the specified ratio of the width to the height.	STRING	fixed_height

Parameter	Required	Description	Value type or sample value	Default value
feature_gather_aspect_ratio	No	The ratio of the width to the height of the text lines. If you set feature_gather_type to fixed_size, this parameter specifies the ratio of the specified height to width after the features are resized. If you set feature_gather_type to fixed_height, this parameter specifies the maximum ratio of the specified height to the custom width after the features are resized.	FLOAT	40
feature_gather_batch_size	No	The size of the current batch of the text lines that are used to train the model.	INT	160
recognition_norm_type	No	The type of the normalization that is used by the encoder and feature extractor. Valid values: ○ batch_norm ○ group_norm	STRING	group_norm
recognition_bn_trainable	No	Specifies whether the batch normalization value that is obtained by the encoder and feature extractor can be used for the training. This parameter takes effect only when norm_type is set to batch_norm.	BOOL	false
encoder_type	No	The type of the encoder. Valid values: ○ crnn: hybrid Convolutional Neural Network (CNN)-Recurrent Neural Network (RNN) encoder. ○ cnn_line: CNN encoder. ○ cnn_spatial: the encoder that uses spatial attention CNN.	STRING	crnn
encoder_cnn_name	No	The type of CNN that is used by the encoder. Valid values: ○ conv5_encoder ○ senet5_encoder	STRING	senet5_encoder
encoder_num_layers	No	The number of layers in the encoder, which refer to RNN layers. CNN layers are not counted.	INT	2
encoder_rnn_type	No	The type of RNN that is used by the encoder. Valid values: ○ bi: bidirectional RNN. ○ uni: unidirectional RNN.	STRING	uni

Parameter	Required	Description	Value type or sample value	Default value
encoder_hidden_size	No	The number of neurons in the hidden layer of the encoder.	INT	512
encoder_cell_type	No	The type of RNN cells in the encoder. Valid values: ○ basic_lstm ○ gru ○ layer_norm_basic_lstm ○ nas	STRING	basic_lstm
decoder_type	No	The type of the decoder. Valid values: ○ attention ○ ctc	STRING	attention
decoder_num_layers	No	The number of layers in the decoder.	INT	2
decoder_hidden_size	No	The number of neurons in the hidden layer of the decoder.	INT	512
decoder_cell_type	No	The type of RNN cells in the decoder. Valid values: ○ basic_lstm ○ gru ○ layer_norm_basic_lstm ○ nas	STRING	basic_lstm
embedding_size	No	The embedding size of the dictionary.	INT	64
beam_width	No	The beam width of the beam search.	INT	0
length_penalty_weight	No	The length penalty score of the beam search. This prevents shorter sentences from receiving higher scores.	FLOAT	0.0
attention_mechanism	No	The type of the attention mechanism of the decoder. Valid values: ○ luong ○ scaled_luong ○ bahdanau ○ normed_bahdanau	STRING	normed_bahdanau
aspect_ratio_min_jitter_coef	No	The minimum ratio of the width to the height at which images can be resized during the training. A value of 0 indicates that the ratios of the width to the height of images remain unchanged during the training.	FLOAT	0.8

Parameter	Required	Description	Value type or sample value	Default value
aspect_ratio_max_jitter_coef	No	The maximum ratio of the width to the height at which images can be resized during the training. A value of 0 indicates that the ratios of the width to the height of images remain unchanged during the training.	FLOAT	1.2
random_rotation_angle	No	The maximum angle to which images can be randomly rotated during the training, in the clockwise or anticlockwise direction. A value of 0 indicates that images are not randomly rotated during the training.	FLOAT	10
random_crop_min_area	No	The minimum ratio of the size of an image after it is randomly cropped to the size of the original image. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	0.1
random_crop_max_area	No	The maximum ratio of the size of an image after it is randomly cropped to the size of the original image. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	1.0
random_crop_min_aspect_ratio	No	The minimum ratio of the width to the height of images after they are randomly cropped during the training. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	0.2
random_crop_max_aspect_ratio	No	The maximum ratio of the width to the height of images after they are randomly cropped during the training. A value of 0 indicates that images are not randomly cropped during the training.	FLOAT	5
image_min_sizes	No	The length of the shorter side of images after they are resized. If you specify multiple lengths for the shorter sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the shorter sides of images, this length is used for both training and evaluation.	FLOAT list	800

Parameter	Required	Description	Value type or sample value	Default value
image_max_sizes	No	The length of the longer side of images after they are resized. If you specify multiple lengths for the longer sides of images in the value of this parameter, the last length but one is used to train the model, whereas the last one is used to evaluate the model. If you specify only one length for the longer sides of images, this length is used for both training and evaluation.	FLOAT list	1200
random_distort_color	No	Specifies whether to randomly change the brightness, contrast, and saturation of images during the training.	BOOL	true
optimizer	No	The type of the optimizer. Valid values: ◦ momentum: stochastic gradient descent (SGD) with momentum ◦ adam	STRING	momentum

Parameter	Required	Description	Value type or sample value	Default value
lr_type	No	The policy that is used to adjust the learning rate. Valid values: ◦ exponential_decay: the exponential decay. ◦ polynomial_decay: the polynomial decay. If you set the lr_type parameter to polynomial_decay, the num_steps parameter is automatically set to the total number of training iterations. The value of the end_learning_rate parameter is automatically set to one thousandth of the value of the initial_learning_rate parameter. ◦ manual_step: The learning rate of each epoch is manually adjusted. If you set the lr_type parameter to manual_step, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rate. You must also set the learning_rates parameter to specify the learning rate as needed. ◦ cosine_decay The learning rate of each epoch is adjusted based on the cosine curve. For more information, see SGDR: Stochastic Gradient Descent with Warm Restarts. If you set the lr_type parameter to cosine_decay, you must set the decay_epochs parameter to specify the epochs for which you want to adjust the learning rates.	STRING	exponential_decay
initial_learning_rate	No	The initial learning rate.	FLOAT	0.01

Parameter	Required	Description	Value type or sample value	Default value
decay_epochs	No	If you set the lr_type parameter to exponential_decay, the decay_epochs parameter is equivalent to the decay_steps parameter of tf.train.exponential.decay. In this case, the decay_epochs parameter specifies the epoch interval at which you want to adjust the learning rate. The system automatically converts the value of the decay_epochs parameter to the value of the decay_steps parameter based on the total number of training data entries. Typically, you can set the decay_epochs parameter to half of the total number of epochs. For example, if the total number of epochs is 20, you can set this parameter to 10. If you set the lr_type parameter to manual_step, the decay_epochs parameter specifies the epochs for which you want to adjust the learning rate. For example, a value of 16 18 indicates that you want to adjust the learning rate for the 16th and 18th epochs. Typically, if the total number of epochs is N, you can set the two values of the decay_epochs parameter to 8/10 × N and 9/10 × N.	INTEGER list. Sample value: 20 20 40 60.	20
decay_factor	No	The decay rate. This parameter is equivalent to the decay_factor parameter of tf.train.exponential.decay.	FLOAT	0.95
staircase	No	Specifies whether the learning rate changes based on the decay_epochs parameter. This parameter is equivalent to the staircase parameter of tf.train.exponential.decay.	BOOL	true
power	No	The power of the polynomial. This parameter is equivalent to the power parameter of tf.train.polynomial.decay.	FLOAT	0.9

Parameter	Required	Description	Value type or sample value	Default value
learning_rates	No	The learning rate that you want to set for the specified epochs. This parameter is required when you set the lr_type parameter to manual_step. If you want to adjust the learning rate for two epochs, specify two learning rates in the value. For example, if the decay_epoches parameter is set to 20 40, you must specify two learning rates in the learning_rates parameter, such as 0.001 0.0001. This indicates that the learning rate of the 20th epoch is adjusted to 0.001 and the learning rate of the 40th epoch is adjusted to 0.0001. We recommend that you adjust the learning rate to one tenth, one hundredth, and one thousandth of the initial learning rate in sequence.	FLOAT list	N/A
lr_warmup	No	Specifies whether to warm up the learning rate.	BOOL	false
lr_warm_up_epochs	No	The number of epochs for which you want to warm up the learning rate.	FLOAT	1
train_data	Yes	The Object Storage Service (OSS) path of the data that is used to train the model.	oss://path/to/train_*.tfrecord	N/A
test_data	Yes	The OSS path of the data that is evaluated during the training.	oss://path/to/test_*.tfrecord	N/A
train_batch_size	Yes	The size of the data that is used to train the model in the current batch.	INT. Sample value: 32.	N/A
test_batch_size	Yes	The size of the data that is evaluated in the current batch.	INT. Sample value: 32.	N/A
train_num_readers	No	The number of concurrent threads that are used to read the training data.	INT	4
model_dir	Yes	The OSS path of the model.	oss://path/to/model	N/A
pretrained_model	No	The OSS path of the pretrained model. If this parameter is specified, the actual model is finetuned based on the pretrained model.	oss://pai-vision-data-sh/pretrained_models/inception_v4.ckpt	""
use_pretrained_model	No	Specifies whether to use a pretrained model.	BOOL	true
num_epochs	Yes	The number of training iterations. A value of 1 indicates that all data is iterated once for the training.	INT. Sample value: 40.	N/A

Parameter	Required	Description	Value type or sample value	Default value
num_test_example	No	The number of data entries that are evaluated during the training. A value of -1 indicates that all training data is evaluated.	INT. Sample value: 2000.	-1
num_visualizations	No	The number of data entries that can be visualized during the evaluation.	INT	10
save_checkpoint_epochs	No	The epoch interval at which a checkpoint is saved. A value of 1 indicates that a checkpoint is saved each time an epoch is complete.	INT	1
save_summary_epochs	No	The epoch interval at which a summary is saved. The value of 0.01 indicates that a summary is saved each time 1% of the training data is iterated.	FLOAT	0.01
num_train_images	No	The total number of data entries that are used for the training. If you use custom TFRecord files to train the model, this parameter is required.	INT	0
label_map_path	No	The category mapping file. If you use custom TFRecord files to train the model, this parameter is required.	STRING	""

4.1.11.5. Examples of configuration files

4.1.11.5.1. Image classification

EasyVision that is provided by Machine Learning Platform for AI (PAI) allows you to set the training parameters in a configuration file to train a model. This topic provides examples of the configuration files for commonly used image classification models. You can use the complete configurations or modify specific parameters as required to train the image classification models.

Background information

The following models are involved in this topic:

- resnet_v1d_50
- mobilenet_v3
- efficientnet_b0
- darknet53

resnet_v1d_50

```
##-*- encoding:utf-8 -*-

4.1.11.5.3. Image semantic segmentation

EasyVision that is provided by Machine Learning Platform for AI (PAI) allows you to set the training parameters in a configuration file to train a model. This topic provides examples of the configuration files for commonly used image semantic segmentation models. You can use the complete configurations or modify specific parameters as required to train the image semantic segmentation models.

Background information

The following models are involved in this topic:

- deeplab_v3+_r101_stage1
- deeplab_v3+_r101_stage2

4.1.11.5.5. Text detection

EasyVision that is provided by Machine Learning Platform for AI (PAI) allows you to set the training parameters in a configuration file to train a model. This topic provides examples of the configuration files for the commonly used text detection model. You can use the complete configurations or modify specific parameters as required to train the text detection model.

4.1.11.5.7. End-to-End text recognition

EasyVision that is provided by Machine Learning Platform for AI (PAI) allows you to set the training parameters in a configuration file to train a model. This topic provides examples of the configuration files for the commonly used end-to-end text recognition model. You can use the complete configurations or modify specific parameters as required to train the end-to-end text recognition model.

4.1.11.5.8. SavedModel file evaluation

EasyVision that is provided by Machine Learning Platform for AI (PAI) allows you to set the evaluation parameters in a configuration file to evaluate an exported SavedModel file. This topic provides examples of the configuration files for SavedModel file evaluation. You can use the complete configurations or modify specific parameters as required to evaluate the SavedModel files that are exported from commonly used models.

Background information

The following models are involved in this topic:

- detector
- classifier
- multilabel_classifier
- text_detector
- text_recognizer
- text_spotter
- text_pipeline_predictor

detector

```
# -*- encoding:utf-8 -*-
# detector evaluation config
predictor_name: "Detector"
model_path: "data/test/inference/rfcn"
eval_data: {
  input_path: "data/voc0712_tfrecord/VOC2007_test.tfrecord"
  batch_size: 1
  shuffle: false
  prefetch_size: 32
  voc_decoder_config {
    label_map_path: "data/voc0712_tfrecord/pascal_label_map.pbtxt"
  }
  # do not need augmentation
  use_diff: true
  num_epochs: 1
}
eval_config: {
  num_examples: 10
  metrics_set: 'coco_detection_metrics'
  metrics_set: 'pascal_voc_detection_metrics'
  metrics_set: 'pascal_voc07_detection_metrics'
}
```

classifier

```
# -*- encoding:utf-8 -*-
# text pipeline predictor evaluation config
predictor_name: "Classifier"
model_path: "data/test/inference/cifar10_resnet50"
eval_data : {
  input_path: "data/cifar10/cifar10_test.tfrecord"
  batch_size: 100
  shuffle: false
  num_readers: 1
  drop_remainder: false
  classification_decoder_config{
    label_map_path: 'data/cifar10/labelmap.pbtxt'
  }
}
eval_config: {
  num_visualizations : 16
  visualization_export_dir: ''
  metrics_set: "classification_metrics"
}
```

multilabel_classifier

```
# -*- encoding:utf-8 -*-
# text pipeline predictor evaluation config
predictor_name: "MultiLabelClassifier"
model_path: "data/test/inference/objects365_resnet101"
eval_data : {
  input_path: "data/objects365_tfrecord/objects365_test*.tfrecord"
  batch_size: 16
  shuffle: false
  num_readers: 2
  classification_decoder_config {
    label_map_path: "data/objects365_tfrecord/objects365_label_map.pbtxt"
     is_multi_label: true
  }
}
eval_config: {
  metrics_set: "multi_label_classification_metrics"
  include_metrics_per_category: true
}
```

text_detector

```
# -*- encoding:utf-8 -*-
# text detector evaluation config
predictor_name: "TextDetector"
model_path: "data/test/inference/text_krcnn"
eval_data: {
  input_path: "data/icdar_detection_tfrecords/icdar-ch4-test.tfrecord"
  batch_size: 1
  shuffle: false
  prefetch_size: 32
  text_detection_decoder_config {
    label_map_path: "data/icdar_detection_tfrecords/label_map.pbtxt"
  }
  # do not need augmentation
  use_diff: true
  num_epochs: 1
}
eval_config: {
  metrics_set: "icdar_detection_metrics"
}
```

text_recognizer

```
# -*- encoding:utf-8 -*-
# text pipeline predictor evaluation config
predictor_name: "TextRecognizer"
model_path: "data/test/inference/crnn_attn"
eval_data: {
  input_path: "data/recipt_text/recognition_tfrecords/test.tfrecord"
  batch_size: 64
  shuffle: false
  text_recognition_decoder_config {
    char_dict_path: "data/recipt_text/recognition_tfrecords/char_dict"
    min_input_ratio: 0.125
    max_input_ratio: 100
  }
  # do not need augmentation
  num_epochs: 1
}
eval_config: {
  metrics_set: "text_recognition_metrics"
}
```

text_spotter

```
# -*- encoding:utf-8 -*-
# text pipeline predictor evaluation config
predictor_name: "TextSpotter"
model_path: "data/test/inference/text_end2end"
eval_data: {
  input_path: "data/recipt_text/end2end_tfrecords/test.tfrecord"
  batch_size: 1
  shuffle: false
  prefetch_size: 32
  text_end2end_decoder_config {
    char_dict_path: "data/recipt_text/end2end_tfrecords/char_dict"
    label_map_path: "data/recipt_text/end2end_tfrecords/label_map.pbtxt"
  }
  # do not need augmentation
  use_diff: true
  num_epochs: 1
}
eval_config: {
  num_visualizations : 16
  visualization_export_dir: ''
  metrics_set: "icdar_end2end_metrics"
}
```

text_pipeline_predictor

```
# -*- encoding:utf-8 -*-
# text pipeline predictor evaluation config
predictor_name: "TextPipelinePredictor"
model_path: "data/test/inference/text_pipeline"
eval_data: {
  input_path: "data/recipt_text/end2end_tfrecords/test.tfrecord"
  batch_size: 1
  shuffle: false
  prefetch_size: 32
  text_end2end_decoder_config {
    char_dict_path: "data/recipt_text/end2end_tfrecords/char_dict"
    label_map_path: "data/recipt_text/end2end_tfrecords/label_map.pbtxt"
  }
  # do not need augmentation
  use_diff: true
  num_epochs: 1
}
eval_config: {
  metrics_set: "icdar_end2end_metrics"
}
```

4.1.11.6. API

4.1.11.6.1. easy_vision.python.main

This topic describes major Python methods that are provided by EasyVision.

train_and_evaluate

```
easy_vision.python.main.train_and_evaluate(pipeline_config_path, continue_train=False)
```

- Feature: creates, trains, and evaluates a CV estimator.
- Parameters
  - `pipeline_config_path`: the path of the proto.CvEstimator configuration file.
  - `train_config`: the configuration file that is used for training. The configuration file contains the configurations about the model, data, and evaluation process.
  - `continue_train`: specifies whether to restart training from the point when last training stopped.
- No result is returned for this method. After you call this method, the system saves the trained model to the `train_config.model_dir` folder.

train_and_evaluate_with_param_config

```
easy_vision.python.main.train_and_evaluate_with_param_config(param_config_str, continue_train=False,
 data_prefix='')
```

- Feature: trains and evaluates a model by referencing a configuration file.
- Parameters
  - `param_config_str`: the string that can be converted to the configuration file used for model training.
  - `continue_train`: specifies whether to restart training from the point when last training stopped.
  - `data_prefix`: the prefix of the path where the data of the pretrained model are stored. Examples: OSS path: *oss://pai-vision-data/*. On-premises path: *local path/home/user/data*.
- No result is returned for this method. After you call this method, the system saves the trained model to the `train_config.model_dir` folder.

evaluate

```
easy_vision.python.main.evaluate(pipeline_config_path, eval_checkpoint_path='', eval_data_path=None,
eval_result_filename='eval_result.txt')
```

- Feature: evaluates the evaluation metrics in the path specified by the `pipeline_config_path` parameter. Evaluation results are displayed on a TensorBoard dashboard.
- Parameters
  - `pipeline_config_path`: the path of the `proto.CvEstimator` configuration file that contains the configurations about the model, evaluation metrics, and estimator.
  - `eval_checkpoint_path`: If you set this parameter, the model in the path specified by this parameter, instead of the model in the path specified by the `pipeline_config_path` parameter, is used for evaluation.
  - `eval_data_path`: the path of the evaluation metrics. By default, the evaluation metrics in the path specified by the `pipeline_config_path` parameter are evaluated. You can set this parameter to a path or a list of paths.
- A dictionary of evaluation results is returned for this method. You can configure evaluation metrics in the path specified by the `pipeline_config_path` parameter.
- The AssertionError code indicates that the path specified by the `pipeline_config_path` parameter does not exist.

predict

Test for evaluation for eval_data in pipeline_config_path.

```
easy_vision.python.main.predict(pipeline_config_path, test_checkpoint_path='', test_filelist=None)
```

- Feature: tests the evaluation metrics in the path specified by the `pipeline_config_path` parameter.
- Parameters
  - `pipeline_config_path`: the path of the `proto.CvEstimator` configuration file that contains the configurations about the model, evaluation metrics, and estimator.
  - `test_checkpoint_path`: If you set this parameter, the model in the path specified by this parameter, instead of the model in the path specified by the `pipeline_config_path` parameter, is used for testing.
- A list of test results is returned for this method. Each piece of test result indicates the prediction result for an image.
- The AssertionError code indicates that the path specified by the `pipeline_config_path` parameter does not exist, or the `train_config.model_dir` folder does not exist.

export

Export model defined in pipeline_config_path.

```
easy_vision.python.main.export(export_dir, pipeline_config_path, checkpoint_path='')
```

- Feature: exports the model in the path specified by the `pipeline_config_path` parameter.
- Parameters
  - `export_dir`: the path of the folder to which the model is exported.
  - `pipeline_config_path`: the path of the `proto.CvEstimator` configuration file that contains the configurations about the model, evaluation metrics, and estimator.
  - `checkpoint_path`: If you set this parameter, the model in the path specified by this parameter, instead of the model in the path specified by the `pipeline_config_path` parameter, is used for testing.
- The path of the folder to which the model is exported is returned for this method.
- The AssertionError code indicates that the path specified by the `pipeline_config_path` parameter does not exist.

predictor_evaluate

```
easy_vision.python.main.predictor_evaluate(config_path)
```

- Feature: evaluates a predictor.
- `config_path`: the path of the `proto.PredictorEval` configuration file.
- A dictionary of evaluation results is returned for this method.
- The AssertionError code indicates that the path specified by the `config_path` parameter does not exist.

4.1.11.6.2. easy_vision.python.data_main

This topic describes the data conversion methods provided by EasyVision.

create_dataset

```
easy_vision.python.data_main.create_dataset(input_path, config_path, output_prefix)
```

- Feature: converts the files in the path specified by the `input_path` parameter to TFRecord files.
- Parameters
  - `input_path`: the path of the files to be converted.
  - `config_path`: the path of the configuration file used for data conversion.
  - `output_prefix`: the prefix of the path of the output TFRecord files.
- The AssertionError code indicates that the path specified by the `config_path` parameter does not exist, or the value of the `config_path.proc_num` parameter is less than or equal to 0.

create_dataset_with_param_config

```
easy_vision.python.data_main.create_dataset_with_param_config(input_path, param_config_str, output_prefix, data_prefix='')
```

- Feature: converts the files in the path specified by the `input_path` parameter to TFRecord files by setting parameters.
- Parameters
  - `input_path`: the path of the files to be converted.
  - `param_config_str`: the string that can be converted to the configuration file used for data conversion.
  - `output_prefix`: the prefix of the path of the output TFRecord files.
  - `data_prefix`:data path prefix for data and pretrained-models, e.g., osspath oss://pai-vision-data/, local path /home/user/data.
  - `data_prefix`: the prefix of the path where data is stored. Examples: OSS path: *oss://pai-vision-data/*. On-premises path: *local path/home/user/data*.
- The AssertionError code indicates that the path specified by the `config_path` parameter does not exist, or the value of the `config_path.proc_num` parameter is less than or equal to 0.

4.1.11.6.3. easy_vision.python.inference

This topic describes the prediction classes provided by EasyVision.

predictor.Classifier

```
class easy_vision.python.inference.predictor.Classifier(model_path, profiling_file=None, verbose_result=False)
```

The base class of the `easy_vision.python.inference.predictor.Classifier` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.Classifier class.

Method	Description

Method	Description
`__init__(model_path, profiling_file=None, verbose_result=False)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file. • `verbose_result`: If you set this parameter to True, the prediction evaluator returns detailed results.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.Detector

```
class easy_vision.python.inference.predictor.Detector(model_path, profiling_file=None)
```

The base class of the `easy_vision.python.inference.predictor.Detector` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.Detector class.

Method	Description
`__init__(model_path, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: Default value: None.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.FeatureExtractor

```
class easy_vision.python.inference.predictor.FeatureExtractor(model_path, output_feature, profiling_file=None)
```

The base class of the `easy_vision.python.inference.predictor.FeatureExtractor` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.FeatureExtractor class.

Method	Description
`__init__(model_path, output_feature, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `output_feature`: the name of the output node.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.MultiLabelClassifier

```
class easy_vision.python.inference.predictor.MultiLabelClassifier(model_path, profiling_file=None, verbose_result=False)
```

The base class of the `easy_vision.python.inference.predictor.MultiLabelClassifier` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.MultiLabelClassifier class.

Method	Description
`__init__(model_path, profiling_file=None, verbose_result=False)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file. • `verbose_result`: If you set this parameter to True, the predictive evaluator returns detailed results.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.Predictor

```
class easy_vision.python.inference.predictor.Predictor(model_path, profiling_file=None, decode=True)
```

The base class of the `easy_vision.python.inference.predictor.Predictor` class is `easy_vision.python.inference.predictor.PredictorInterface`. The following table describes the methods contained in the easy_vision.python.inference.predictor.Predictor class.

Method	Description
`__init__(model_path, profiling_file=None, decode=True)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file. • `decode`: Default value: True.
`batch(images)`	• Feature: This method packages multiple red-green-blue (RGB) images. • Parameter: The `images` parameter specifies the information about images and image shapes. • Return value: a feed dictionary that contains one or more key-value pairs. The feed dictionary is an input format in TensorFlow.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`get_class_name(cls_id)`	• Feature: This method returns the name of the class whose ID is the same as the value of the `cls_id` parameter. • Parameter: The `cls_id` parameter specifies the class ID. The value of this parameter is of the INT32 type. • Return value: the class name that is of the STRING type.
`get_input_names`	Returns a list that contains the names of available input nodes in the model.
`get_output_names()`	Returns a list that contains the names of available output nodes in the model.

Method	Description

`predict(data_list, output_names=None, batch_size=1)`	• Parameters:
	  ◦ `data_list`: the input data in numPy arrays. The input data is of the UINT8 type.
	  ◦ `output_names`: If the parameter is not empty, specific output fields are returned.
	  ◦ `batch_size`: the size of the data in a batch that is used for prediction. A value of -1 indicates that the actual batch size is used.
	• Return value: a list of dictionaries. Each dictionary contains one or more key-value pairs. In each key-value pair, the key is the name of an output field, and the value is the value of the output field.

predictor.PredictorImpl

```
class easy_vision.python.inference.predictor.PredictorImpl(model_path, profiling_file=None, decode=True)
```

The base class of the `easy_vision.python.inference.predictor.PredictorImpl` class is `object`. The following table describes the methods contained in the easy_vision.python.inference.predictor.PredictorImpl class.

Method	Description
`__init__(model_path, profiling_file=None, decode=True)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file. • `decode`: Default value: True.

Method	Description

`predict(input_data_dict, output_names=None)`	• Parameters:
	  ◦ `input_data_dict`: a dictionary that contains all input data. The dictionary contains one or more key-value pairs. In each key-value pair, the key is the name of an input field, and the value is the value of the input field.
	  ◦ `output_names`: If the parameter is not empty, specific output fields are returned. If the parameter is empty, the specific output data is returned based on all the output information in the model signature.
	• Return value: a list of dictionaries. Each dictionary contains one or more key-value pairs. In each key-value pair, the key is the name of an output field, and the value is the value of the output field.

`search_pb(directory)`	• Feature: This method recursively searches for a PB file in the folders. If multiple PB files exist, an exception is thrown. • Return value: the folder that contains a PB file.

predictor.PredictorInterface

```
class easy_vision.python.inference.predictor.PredictorInterface(model_path, model_config=None)
```

The base class of the `easy_vision.python.inference.predictor.PredictorInterface` class is `object`. The following table describes the methods contained in the easy_vision.python.inference.predictor.PredictorInterface class.

Method	Description
`__init__(model_path, model_config=None)`	Initializes a session with Machine Learning Platform for AI (PAI)-TensorFlow and loads a TensorFlow model. You need to set the following parameters: • `model_path`: the path of the model that you want to initialize. • `model_config`: the configurations that you want to initialize for the model. The configurations are in a JSON string.
`check_signature(impl_cls)`	Checks whether the __init__ and predict methods are contained in the implementation classes that inherit this class.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.

Method	Description
`get_output_type()`	The type of the output data. If you want the output data to be returned as a dictionary, you can set the parameter to json. Then, the output data returned by the predictor is serialized to a JSON string. If the input data consists of images, the images are converted to binary images, and each binary image is written to Object Storage Service (OSS) as an object. The object name of each binary image is in the following format: output_dir/${key}/${input_filename}_${idx}.jpg. The system extracts a value from the image URL for the input_filename variable. The value of the key variable is the key in the output dictionary. If each image is an indexed element in a list, the system generates the value of the idx variable by referencing the index of the list element. If the input data is not an indexed list, the idx variable is empty. If the input data consists of videos, videos are converted to binary videos, and each binary video is written to OSS as an object. For example, {'image':'image','feature':'json'} indicates that each image in the output dictionary will be stored as an OSS object and the feature data in the output dictionary will be converted to the JSON format.

`predict(input_data, batch_size)`	• Feature: This method predicts a batch of sample data whose size is specified by the batch_size parameter in a session.
	• Parameters:
	  ◦ `input_data` : the input data in numPy arrays. Each array is a sample data entry to be predicted.
	  ◦ `batch_size` : the size of the data in a batch that is used for prediction. If you want to call the predict method and do not want to change the batch size during prediction, you can set the parameter to a fixed number and ignore the parameter in further configurations.
	• Return value: a list of dictionaries. Each dictionary is the prediction result of a sample data entry.
	
	For example, if the return value is {"output1":value1,"output2":value2}, the values can be of the INT, STRING, or FLOAT type in Python, or be numPy arrays in Python.

predictor.PredictorInterfaceV2

```
class easy_vision.python.inference.predictor.PredictorInterfaceV2(model_path, model_config=None)
```

The base class of the `easy_vision.python.inference.predictor.PredictorInterfaceV2` class is `easy_vision.python.inference.predictor.PredictorInterface`. The following table describes the methods contained in the easy_vision.python.inference.predictor.PredictorInterfaceV2 class.

Method	Description
`__init__(model_path, model_config=None)`	Initializes a session with PAI-TensorFlow and loads a TensorFlow model. You need to set the following parameters: • `model_path`: the path of the model that you want to initialize. • `model_config`: the configurations that you want to initialize for the model. The configurations are in a JSON string.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`get_output_type()`	The type of the output data. If you want the output data to be returned as a dictionary, you can set the parameter to json. Then, the output data returned by the predictor is serialized to a JSON string. If the input data consists of images, the images are converted to binary images, and each binary image is written to Object Storage Service (OSS) as an object. The object name of each binary image is in the following format: output_dir/${key}/${input_filename}_${idx}.jpg. The system extracts a value from the image URL for the input_filename variable. The value of the key variable is the key in the output dictionary. If each image is an indexed element in a list, the system generates the value of the idx variable by referencing the index of the list element. If the input data is not an indexed list, the idx variable is empty. If the input data consists of videos, videos are converted to binary videos, and each binary video is written to OSS as an object. For example, {'image':'image','feature':'json'}indicates that each image in the output dictionary will be stored as an OSS object and the feature data in the output dictionary will be converted to the JSON format.

Method	Description

`predict(input_data_dict_list, batch_size)`	• Feature: This method predicts a batch of sample data whose size is specified by the batch_size parameter in a session.
	• Parameters:
	  ◦ `input_data_dict_list`: the input data in dictionaries. Each dictionary is a sample data entry to be predicted.
	  ◦ `batch_size`: the size of the data in a batch that is used for prediction. If you want to call the predict method and do not want to change the batch size during prediction, you can set the parameter to a fixed number and ignore the parameter in further configurations.
	• Return value: a list of dictionaries. Each dictionary is the prediction result of a sample data entry.
	For example, if the return value is {"output1":value1,"output2":value2}, the values can be of the INT, STRING, or FLOAT type in Python, or be numPy arrays in Python.

predictor.PredictorV2

```
class easy_vision.python.inference.predictor.PredictorV2(model_path, profiling_file=None, decode=True)
```

The base class of the `easy_vision.python.inference.predictor.PredictorV2` class is `easy_vision.python.inference.predictor.PredictorInterfaceV2`. The following table describes the methods contained in the easy_vision.python.inference.predictor.PredictorV2 class.

Method	Description
`__init__(model_path, profiling_file=None, decode=True)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`batch(batch_data_dict_list)`	• Feature: This method packages multiple RGB images into a batch. • Parameter: The value of the `batch_data_dict_list` parameter is a list of dictionaries. • Return value: a feed dictionary. The feed dictionary is an input format in TensorFlow.

Method	Description
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`get_class_name(cls_id)`	• Feature: This method returns the name of the class whose ID is the same as the value of the `cls_id` parameter. • Parameter: The `cls_id` parameter specifies the class ID. The value of this parameter is of the INT32 type. • Return value: the class name that is of the STRING type.
`get_input_names()`	Returns a list that contains the names of available input nodes in the model.
`get_output_names()`	Returns a list that contains the names of available output nodes in the model.

`predict(input_data_dict_list, output_names=None, batch_size=1)`	• Feature: This method predicts a batch of sample data whose size is specified by the batch_size parameter in a session.
	• Parameters:
	  ○ `input_data_dict_list`: the input data in dictionaries. Each dictionary is a sample data entry to be predicted.
	  ○ `output_names`: If the parameter is not empty, specific output fields are returned.
	  ○ `batch_size`: the size of the data that is used for prediction in a batch. A value of -1 indicates that the batch size of the input data is used.
	• Return value: a list of dictionaries. Each dictionary is the prediction result of a sample data entry.

predictor.Segmentor

```
class easy_vision.python.inference.predictor.Segmentor(model_path, profiling_file=None)
```

The base class of the `easy_vision.python.inference.predictor.Segmentor` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.Segmentor class.

Method	Description

Method	Description
`__init__(model_path, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`get_output_type()`	The type of the output data. If you want the output data to be returned as a dictionary, you can set the parameter to json. Then, the output data returned by the predictor is serialized to a JSON string. If the input data consists of images, the images are converted to binary images, and each binary image is written to OSS as an object. The object name of each binary image is in the following format: output_dir/${key}/${input_filename}_${idx}.jpg. The system extracts a value from the image URL for the input_filename variable. The value of the key variable is the key in the output dictionary. If each image is an indexed element in a list, the system generates the value of the idx variable by referencing the index of the list element. If the input data is not an indexed list, the idx variable is empty. If the input data consists of videos, videos are converted to binary videos, and each binary video is written to OSS as an object. For example, {'image':'image','feature':'json'}indicates that each image in the output dictionary will be stored as an OSS object and the feature data in the output dictionary will be converted to the JSON format.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.TextDetector

```
class easy_vision.python.inference.predictor.TextDetector(model_path, profiling_file=None)
```

The base class of the `easy_vision.python.inference.predictor.TextDetector` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.TextDetector class.

Method	Description

Method	Description
`__init__(model_path, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.TextRecognizer

```
class easy_vision.python.inference.predictor.TextRecognizer(model_path, profiling_file=None)
```

The base class of the `easy_vision.python.inference.predictor.TextRecognizer` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.TextRecognizer class.

Method	Description
`__init__(model_path, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.TextSpotter

```
class easy_vision.python.inference.predictor.TextSpotter(model_path, profiling_file=None)
```

The base class of the `easy_vision.python.inference.predictor.TextSpotter` class is `easy_vision.python.inference.predictor.Predictor`. The following table describes the methods contained in the easy_vision.python.inference.predictor.TextSpotter class.

Method	Description
`__init__(model_path, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

predictor.batch_images

```
easy_vision.python.inference.predictor.batch_images(images, use_bgr)
```

text_pipeline_predictor.TextPipelinePredictor

```
class easy_vision.python.inference.text_pipeline_predictor.TextPipelinePredictor(model_path)
```

The base class of the `easy_vision.python.inference.text_pipeline_predictor.TextPipelinePredictor` class is `easy_vision.python.inference.predictor.PredictorInterface`. The following table describes the methods contained in the easy_vision.python.inference.text_pipeline_predictor.TextPipelinePredictor class.

Method	Description
`__init__(model_path)`	Initializes the text detector and recognizer. The `model_path` parameter specified the path of the detection model and the recognition model.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`crop_roi_image(img, coords)`	• `img`: the image object. • `coords`: a 4 × 2 numPy array. The value of coords parameter is in the format of [:, y,x].

Method	Description

`predict(image_list, batch_size=None)`	• Parameters:
	  ◦ `image_list`: the image data in numPy arrays. The image data is of the UINT8 type.
	  ◦ `batch_size`: You do not need to specify a value. This parameter is reserved to improve compatibility.
	• Return value:
	A list of dictionaries is returned. Each dictionary consists of key-value pairs. The following keys are returned:
	  ◦ detection_boxes: The value of the key is a numPy array of the FLOAT32 type. The shape of the numPy array is [Number of detected objects, 4].
	  ◦ detection_keypoints: The value of the key is a numPy array of the FLOAT32 type. The shape of the numPy array is [Number of detected objects, 8].
	  ◦ detection_classes: The value of the key is a numPy array of the FLOAT32 type. The shape of the numPy array is [Number of detected objects].
	  ◦ detection_class_names: The value of the key is a numPy array of class names.
	  ◦ detection_scores: The value of the key is a numPy array of the FLOAT32 type. The shape of the numPy array is [Number of detected objects].
	  ◦ detection_texts: The value of the key is a numPy array of the STRING type. The shape of the numPy array is [Number of detected objects].
	  ◦ detection_texts_scores:The value of the key is a numPy array of the FLOAT32 type. The shape of the numPy array is [Number of detected objects].

video_predictor.I3DClassifier

```
class easy_vision.python.inference.video_predictor.I3DClassifier(model_path, resize_height=256, resize_width=340, crop_size=224, input_modal='rgb', profiling_file=None)
```

The base class of the `easy_vision.python.inference.video_predictor.I3DClassifier` class is `easy_vision.python.inference.video_predictor.VideoPredictor`. The following table describes the methods contained in the easy_vision.python.inference.video_predictor.I3DClassifier class.

Method	Description

Method	Description
`__init__(model_path, resize_height=256, resize_width=340, crop_size=224, input_modal='rgb', profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of a model in the SavedModel format. The model can be an RGB model or a stream model. • `input_modal`: the input modal. A value of rgb indicates an RGB model. A value of flow indicates a stream model. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.
`predict_inner(data_dict_list, batch_size=4)`	This class is abstracted as a dual-stream classifier. You need to set the following parameters: • `data_dict_list`: the input data in numPy arrays. The input data is of the UINT8 type. • `batch_size`: the size of a batch.
`preprocess(data_dict)`	Preprocesses the three-dimensional (3D) data. This method assumes that the video frame data is cropped in the time dimension and resized in the space dimension. This method only crops images in the space dimension and normalizes images.

video_predictor.I3DTwoStreamClassifier

```
class easy_vision.python.inference.video_predictor.I3DTwoStreamClassifier(model_path, resize_height=256, resize_width=340, crop_size=224, profiling_file=None)
```

The base class of the `easy_vision.python.inference.video_predictor.I3DTwoStreamClassifier` class is `easy_vision.python.inference.predictor.PredictorInterfaceV2`. The following table describes the methods contained in the easy_vision.python.inference.video_predictor.I3DTwoStreamClassifier class.

Method	Description

Method	Description
`__init__(model_path, resize_height=256, resize_width=340, crop_size=224, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of both an RGB model and a stream model. The models are in the SavedModel format. • `resize_height`: the height after resizing. • `resize_width`: the width after resizing. • `crop_size`: the size after random cropping. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.

`predict(input_data_dict_list, batch_size=4)`	• Feature: This method predicts a batch of sample data whose size is specified by the batch_size parameter in a session.
	• Parameters:
	  ◦ `input_data_dict_list`: the input data in dictionaries. Each dictionary is a sample data entry to be predicted.
	  ◦ `batch_size`: the size of the data in a batch that is used for prediction. If you want to call the predict method and do not want to change the batch size during prediction, you can set the parameter to a fixed number and ignore the parameter in further configurations.
	• Return value: a list of dictionaries. Each dictionary is the prediction result of a sample data entry.
	For example, if the return value is {"output1":value1,"output2":value2}, the values can be of the INT, STRING, or FLOAT type in Python, or be numPy arrays in Python.

video_predictor.VideoClassifier

```
class easy_vision.python.inference.video_predictor.VideoClassifier(model_path, sample_duration=16, train_crop='corner', sample_size=112, output_feature=None, profiling_file=None)
```

The base class of the `easy_vision.python.inference.video_predictor.VideoClassifier` class is `easy_vision.python.inference.video_predictor.VideoPredictor`. The following table describes the methods contained in the easy_vision.python.inference.video_predictor.VideoClassifier class.

Method	Description
`__init__(model_path, sample_duration=16, train_crop='corner', sample_size=112, output_feature=None, profiling_file=None)`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `sample_duration`: the duration of the sample video. Default value: 16. • `train_crop`: the cropping method. Default value: corner. • `sample_size`: the size of an output frame. Default value: 112. • `output_feature`: the name of the extracted feature. Default value: None. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

video_predictor.VideoMultiLabelClassifier

```
class easy_vision.python.inference.video_predictor.VideoMultiLabelClassifier(model_path, sample_duration=16, train_crop='corner', sample_size=112, profiling_file=None)
```

The base class of the `easy_vision.python.inference.video_predictor.VideoMultiLabelClassifier` class is `easy_vision.python.inference.video_predictor.VideoPredictor`. The following table describes the methods contained in the easy_vision.python.inference.video_predictor.VideoMultiLabelClassifier class.

Method	Description

Method	Description
`__init__(model_path, sample_duration=16, train_crop='corner', sample_size=112, profiling_file=None)`	The initialization method for multi-label video classification. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `sample_duration`: the duration of the sample video. Default value: 16. • `train_crop`: the cropping method. Default value: corner. • `sample_size`: the size of an output frame. Default value: 112. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.
`predict(**kwargs)`	A method that is contained in the base class. This method is not implemented.

video_predictor.VideoPredictor

```
class easy_vision.python.inference.video_predictor.VideoPredictor(model_path, profiling_file=None, input_modal='rgb')
```

The base class of the `easy_vision.python.inference.video_predictor.VideoPredictor` class is `easy_vision.python.inference.predictor.PredictorV2`. The following table describes the methods contained in the easy_vision.python.inference.video_predictor.VideoPredictor class.

Method	Description

Method	Description
`__init__(model_path, profiling_file=None, input_modal='rgb')`	The initialization method. You need to set the following parameters: • `model_path`: the path of the model in the SavedModel format or the path of a Frozen Graph model in the PB format. • `profiling_file`: the output file that contains the prediction statistics. Default value: None. If you specify this parameter, the prediction function collects the statistics about the prediction time by using Timeline and returns the statistics in the JSON format in the output file. • `input_modal`: the input modal. A value of rgb indicates that video clips are used. If the preprocessed images are not exported, the data about video clips is a numPy array of the FLOAT32 type. The shape of the numPy array is [num_frame, h, w, c]. If the preprocessed images are exported, the data about video clips is a numPy array of the STRING type. The shape of the numPy array is [num_frame]. A value of flow indicates that video streams are used. If the preprocessed images are not exported, the data about video streams is a numPy array of the FLOAT32 type. The shape of the numPy array is [num_frame, h, w, c]. If the preprocessed images are exported, the data about video streams is a numPy array of the STRING type. The shape of the numPy array is [num_frame].
`batch(batch_data_dict_list)`	Packages multiple RGB images into a batch. The value of the `batch_data_dict_list` parameter is a list of dictionaries. This method returns a feed dictionary. The feed dictionary is an input format in TensorFlow.
`batch_clips(clips)`	Packages multiple clips. The value of the `clips` parameter is a list of numPy arrays. This method returns two numPy arrays. One numPy array contains a batch of data which is of the FLOAT type. The other numPy array contains the data about the original image shape and size. The data about the original image shape and size is of the INT32 type.
`create_class(name)`	Checks whether the class whose name is the same as the value of the name parameter is registered. If the class is registered, the class is returned. If the class is not registered, an exception is thrown.

4.1.12. Terms and acronyms

4.1.12.1. Terms

This topic describes the terms that are used in Apsara Stack Machine Learning Platform for AI.

experiment

A user-created data mining workflow.

project

The basic object in MaxCompute. A project is also known as a workspace. A project contains other objects, such as tables and instances.

component

The minimum operating unit that you can invoke and execute in Machine Learning Platform for AI. For example, you can use components to import and export data, process data, analyze data, train models, and make predictions.

CAP

Cloud Application Access Platform (CAP) is a unified access platform that is provided to integrate the basic data in various big data tools to share data and models. The runtime support platform involves concepts such as tenants, namespaces, resources, and messages. By connecting various big data tools to the runtime support platform, you can use consistent definitions of these concepts throughout the data platform. This way, you can share resources among the tools and shield the differences among underlying platforms. The runtime support platform connects to the underlying platforms so that you can deploy the upper-level tool platforms that run based on the runtime support platform to different platforms and environments without modifications.

Dmscloud

Dmscloud is a set of data mining, modeling, and prediction tools. It is developed based on MaxCompute. Dmscloud provides you with an all-in-one algorithm service that supports algorithm development, sharing, model training, deployment, and monitoring. Dmscloud allows you to manage experiments on the graphic user interface (GUI) or by running Machine Learning Platform for AI commands. Machine Learning Platform for AI provides features such as data preprocessing, machine learning algorithms, and model evaluation and prediction.

Machine Learning Platform for AI runs on MaxCompute. After you deploy algorithms in MaxCompute clusters, you can call the algorithms from the Machine Learning Platform for AI console. This decouples algorithm applications from computing engines.

Machine Learning Platform for AI provides you with bountiful algorithms and reliable technical support to help resolve issues in various business scenarios. In the data technology (DT) era, you can use Machine Learning Platform for AI to develop data-driven business.

JCS

Job Control System (JCS) is a task control engine that is used to schedule and control distributed tasks in Machine Learning Platform for AI. JCS supports directed acyclic graph (DAG) parsing and breakpoint reruns.

4.1.12.2. Acronyms

This topic describes the acronyms that are used in PAI User Guide.

MaxCompute

MaxCompute, formerly known as ODPS, is a data processing platform developed by Alibaba Cloud for large-scale data warehousing. MaxCompute can store and compute a large amount of structured data that does not require real-time processing. Therefore, MaxCompute provides support for various data warehouse solutions as well as big data analysis and modeling.

Relational Database Service (RDS)

ApsaraDB RDS is a stable, reliable, and scalable online database service on Alibaba Cloud. ApsaraDB RDS is also an out-of-box service that supports MySQL, SQL Server, PostgreSQL, and PPAS. ApsaraDB RDS is highly compatible with Oracle. ApsaraDB RDS provides various features, including online scale-out, backup, rollback, and performance monitoring and analysis.

Open Cache Service (OCS)

OCS is a memory-based cache service that allows a large number of requests to access a small amount of data with high speed.

Source and destination tables in MaxCompute

A table is a data storage object in MaxCompute. Similar to relational database tables, tables in MaxCompute have a two-dimensional logical structure. A source table is the input of an algorithm node, while a destination table is the output of an algorithm node.

5.DataHub

5.1. User Guide

5.1.1. What is DataHub?

DataHub collects, stores, and processes streaming data, allowing you to analyze streaming data and build applications based on the streaming data.

DataHub is a platform designed to process streaming data. You can publish and subscribe to streaming data in DataHub and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data.

DataHub collects, stores, and processes streaming data from mobile devices, applications, website services, and sensors. You can use your own applications or Apsara Stack Realtime Compute to process streaming data in DataHub, such as real-time website access logs, application logs, and events. The processing results such as alerts and statistics presented in graphs and tables are updated in real time.

Based on the Apsara system of Alibaba Cloud, DataHub features high availability, low latency, high scalability, and high throughput. DataHub is seamlessly integrated with Realtime Compute, allowing you to use SQL to analyze streaming data.

DataHub can also distribute streaming data to Apsara Stack services such as MaxCompute and Object Storage Service (OSS).

DataHub supports the following features:

- **Data queue**: DataHub automatically generates a cursor for each record in a shard, which can be considered as a logical data queue. The cursor is a unique sequence of numbers. You can improve the performance of a topic by increasing the number of shards in the topic.
- **Offset-based data consumption**: DataHub saves consumption offsets for applications. You can resume data consumption from a saved consumption offset when your application fails.
- **Data synchronization**: Data in DataHub can be automatically synchronized to other Apsara Stack services, including MaxCompute, OSS, AnalyticDB, ApsaraDB RDS for MySQL, Tablestore, and Elasticsearch.
- **Scalable topics**: DataHub allows you to scale in or out topics by splitting or merging shards.

5.1.2. Usage notes

Before you use DataHub, get familiar with the limits on specific features.

The following table describes the limits of DataHub.

Limits

Item	Limit	Description
Active shards per topic	(0,256]	Each topic can contain up to 256 active shards.
Shards	(0,512]	You can create up to 512 shards in each topic.
HTTP request body size	Up to 4 MB	The size of the HTTP request body cannot exceed 4 MB.
String size	Up to 1 MB	The size of a string cannot exceed 1 MB.

Item	Limit	Description
Merge and split operations on new shards	5s	You cannot merge a shard with another shard or split the shard within the 5s after the shard is created.
Queries per second (QPS)	Up to 5,000	The write QPS limit for each shard is 5,000. Multiple queries in one batch are considered as one query.
Throughput	Up to 5 MB/s	Each shard provides a throughput of up to 5 MB/s.
Projects	Up to 100	You can create up to 100 projects with each account.
Topics per project	Up to 1,000	You can create up to 1,000 topics in each project. Contact the administrator if you need to create more topics.
Time-to-live (TTL) of records	[1,7]	The TTL of each record in a topic ranges from one to seven days.

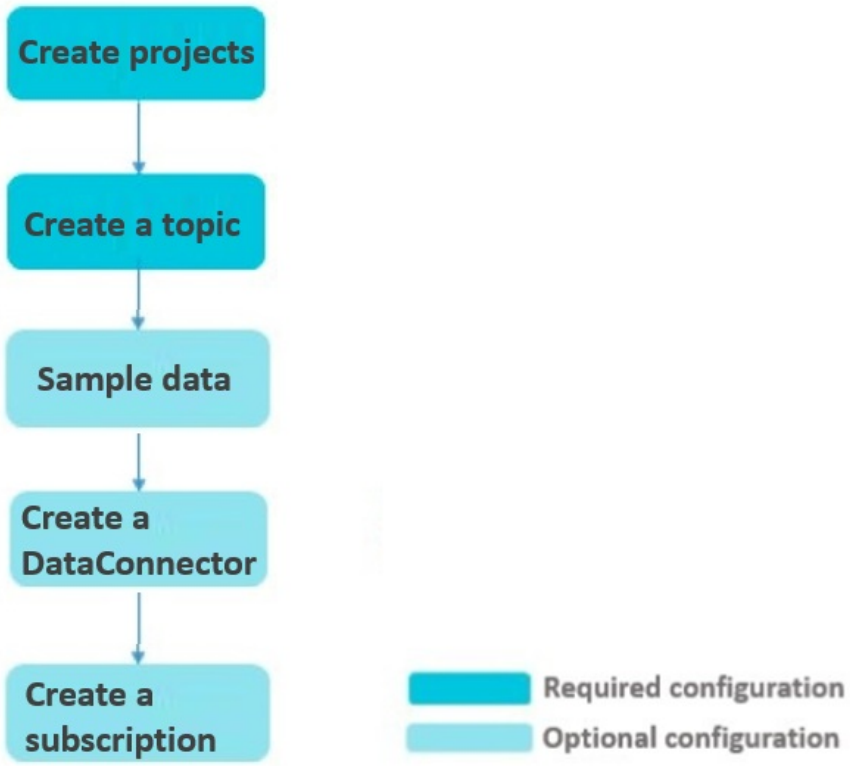
5.1.3. Quick Start

5.1.3.1. Overview

This topic describes the procedure of using DataHub.

Procedure shows the procedure of using DataHub.

Procedure



1. Create projects.

   A project is an organizational unit in DataHub and contains one or more topics. When you use DataHub, you must create a project first.

2. Create a topic.

   A topic is the smallest unit for data subscription and publication. You can use topics to distinguish different types of streaming data.

3. Optional. Sample data.

   DataHub supports data sampling. You can sample data of a specific shard.

4. Optional. Create a DataConnector.

   You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data.

5. Optional. Create a subscription.

   The subscription feature of DataHub supports saving consumption offsets on the server and allows applications to resume data consumption from saved consumption offsets. In addition, DataHub supports resetting offsets to ensure that data can be consumed at least once.

5.1.3.2. Log on to the DataHub console

This topic describes how to log on to the DataHub console. Google Chrome is used in this example.

Prerequisites

Before you log on to the DataHub console, make sure that the following requirements are met:

- You have obtained the URL of the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password from the operations administrator.

   > **Note** If you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. To ensure the security of your account, the password must be 8 to 20 characters in length and must contain at least two types of the following characters:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters: exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%)

3. Click **Login** to go to the Apsara Uni-manager Management Console.
4. In the top navigation bar, choose **Products > Big Data > DataHub** to go to the DataHub console. The **Overview** page appears.

5.1.3.3. Create a project

A project is an organizational unit in DataHub and contains one or more topics. When you use DataHub, you must create a project first. This topic describes how to create a project and bind a virtual private cloud (VPC) to the project in the DataHub console.

Prerequisites

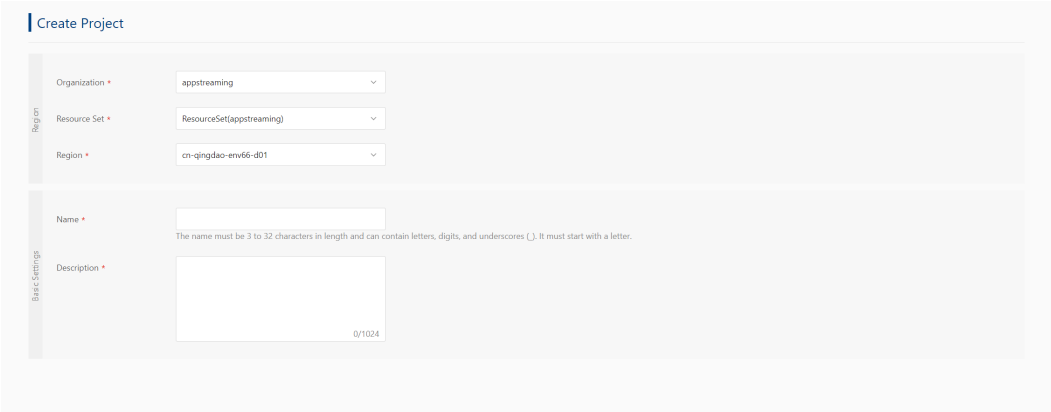
An Apsara Stack tenant account is created.

Considerations

- DataHub projects are independent of MaxCompute projects. Projects you created in MaxCompute cannot be used in DataHub.
- You can create up to 100 projects with each account.

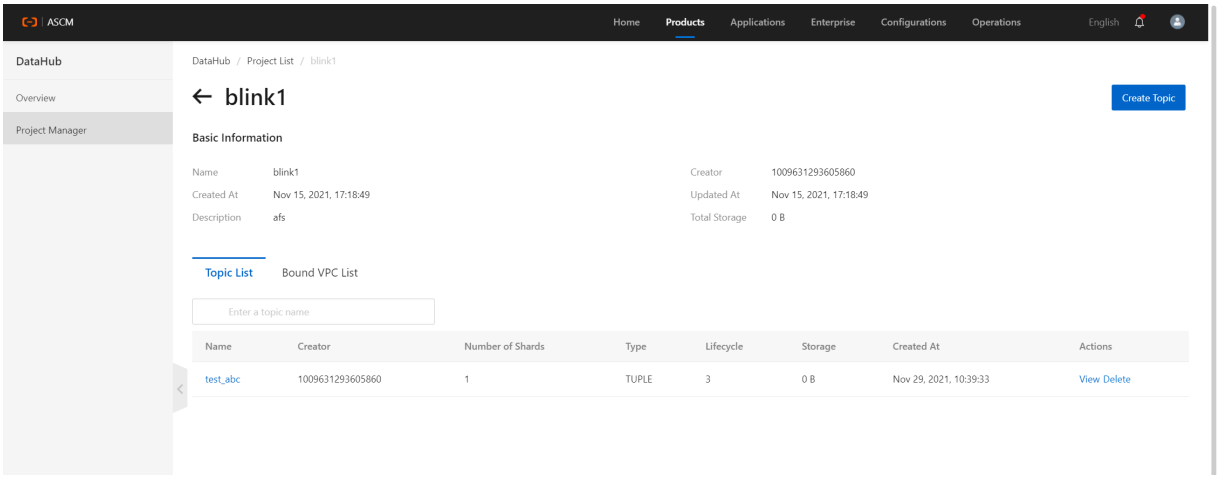
Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, click **Create Project**. On the Create Project page, set the parameters in the Region and Basic Settings sections and click **Submit**.



3. After the project is created, you can click **View** in the Actions column to view the details of the created

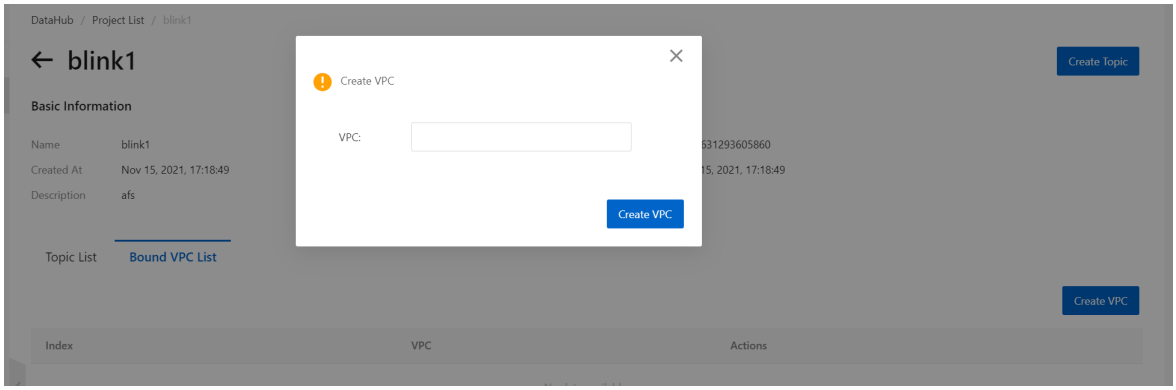
project.



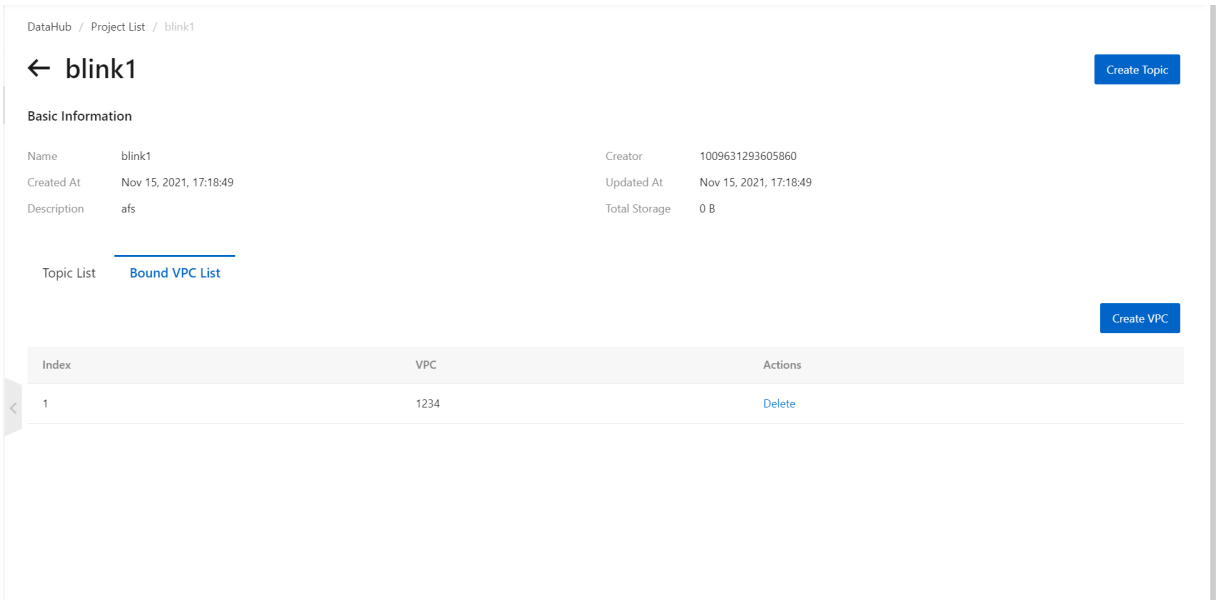
Bind a VPC to a DataHub project

You can bind a VPC to a DataHub project so that the DataHub project can be accessed only from IP addresses in this VPC. Perform the following operations to bind a VPC to a DataHub project:

1. On the project details page, click **Create VPC** on the **Bound VPC List** tab. In the dialog box that appears, enter the name of the VPC and click **Create VPC**.



2. To delete a VPC, click **Delete** in the Actions column.



5.1.3.4. Create a topic

A topic is the smallest unit for data subscription and publication. You can use topics to distinguish different types of streaming data. This topic describes how to create a topic in the DataHub console.

Prerequisites

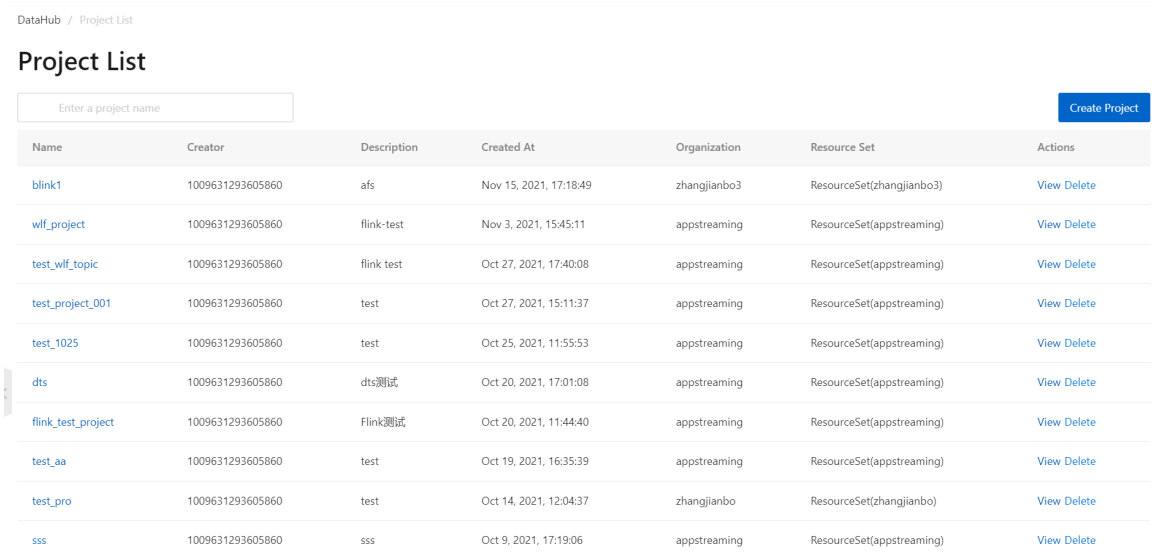
A project is created.

Considerations

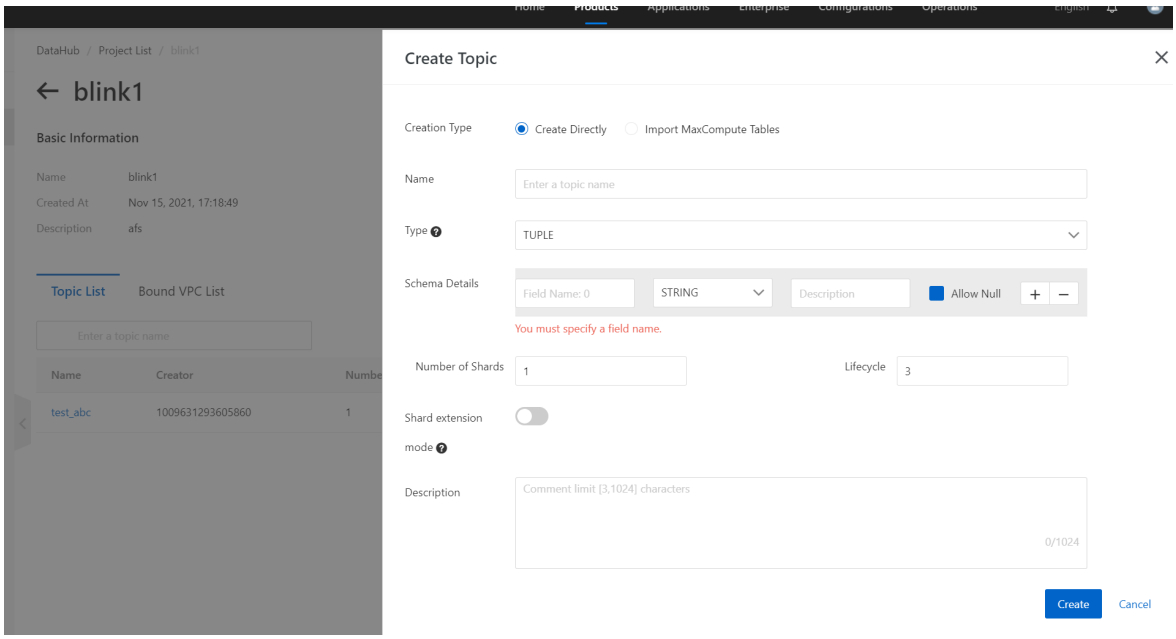
You can create up to 1,000 topics in each project. Contact the administrator if you need to create more topics.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the project for which you want to create a topic and click **View** in the Actions column.



3. On the project details page, click **Create Topic**.
4. In the Create Topic panel, set relevant parameters and click **Create**.



Note

- After a topic is created, you can click **View** in the Actions column to view the details of the created topic.
- DataHub allows you to directly create a topic or create a topic by importing a table schema from MaxCompute.

5.1.3.5. Sample data

DataHub supports data sampling. You can sample data of a specific shard. This topic describes how to sample data in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Background information

Before you sample data, you must specify the start time and the maximum number of records that you want to sample.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the Shard List tab of the topic details page, find the target shard and click **Sample** in the Operate column.
4. In the dialog box that appears, specify the start time and the maximum number of records that you want to sample and click **Sample**. DataHub samples the records that are written to the shard after the specified time and displays the sampled records in the table below Sample.

5.1.3.6. Create a DataConnector

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data. This topic describes how to create a DataConnector in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Background information

You can synchronize data from DataHub to MaxCompute, AnalyticDB, ApsaraDB RDS for MySQL, Tablestore, OSS, and Elasticsearch.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Connector**. In the Create connector dialog box, select the data warehouse to which data is synchronized.
4. In the Create connector dialog box, set relevant parameters and click **Create**.

5.1.3.7. Create a subscription

The subscription feature of DataHub supports saving consumption offsets on the server and allows applications to resume data consumption from saved consumption offsets. In addition, DataHub supports resetting offsets to ensure that data can be consumed at least once. This topic describes how to create a subscription in the DataHub console.

Prerequisites

A project and a topic are created and data is written to the topic.

Procedure

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Subscription**. In the Create subscription dialog box, set relevant parameters and click **Create**.

5.1.4. Access Control

5.1.4.1. Overview

DataHub allows you to improve data security by granting different permissions to Apsara Stack tenant accounts and RAM user accounts.

DataHub uses Resource Access Management (RAM) for access control. Only users that have been granted the required permissions can access the resources in your department. By default, users do not have permission to access resources in your department. This topic describes how access control for DataHub is achieved by using RAM.

> **Note** An Apsara Stack tenant account is owned by a department and requires no authorization. A RAM user account must be granted permissions by the tenant account.

5.1.4.2. DataHub resources in RAM

RAM users can access the following resources in DataHub: projects, topics, and subscriptions. Subscription is the action that you specify an application to read and process the records in topics of a specific project. DataHub supports the RAM authentication of each project, topic, and subscription. RAM authentication is not supported at the shard level.

In RAM, each resource type has an Alibaba Cloud Resource Name (ARN) format to describe the specific object of the resource type. For example, the ARN format of a project that resides in a specific region is *acs:dhs:$region:$accountid:projects/$projectName*. The *$region, $accountid, and $projectName* fields indicate the region that the project resides, the user ID, and the project name.

ARN format for different resource types

Resource type	ARN format
SingleProject	acs:dhs:$region:$accountid:projects/$projectName
AllProject	acs:dhs:$region:$accountid:projects/*
SingleTopic	acs:dhs:$region:$accountid:projects/$projectName/topics/$topicName
AllTopic	acs:dhs:$region:$accountid:projects/$projectName/topics/*
SingleSubscription	acs:dhs:$region:$accountid:projects/$projectName/topics/$topicName/subscriptions/$subId
AllSubscription	acs:dhs:$region:$accountid:projects/$projectName/topics/$topicName/subscriptions/*

5.1.4.3. API

DataHub provides application programming interfaces (APIs) for projects, topics, shards, subscriptions, and records. Before you can call the API operations, you must grant corresponding permissions to the RAM user by using RAM authorization policies.

The RAM authorization policy and resource type for each API operation is described as follows:

API operations for projects

API operations for projects

Operation name	RAM authorization policy	Resource type
CreateProject	dhs:CreateProject	AllProject
ListProject	dhs:ListProject	AllProject
DeleteProject	dhs:DeleteProject	SingleProject
GetProject	dhs:GetProject	SingleProject
UpdateProject	dhs: UpdateProject	SingleProject

API operations for topics

API operations for topics

Operation name	RAM authorization policy	Resource type
CreateTopic	dhs:CreateTopic	AllTopic
ListTopic	dhs:ListTopic	AllTopic
DeleteTopic	dhs:DeleteTopic	SingleTopic
GetTopic	dhs:GetTopic	SingleTopic
UpdateTopic	dhs: UpdateTopic	SingleTopic

API operations for subscriptions

API operations for subscriptions

Operation name	RAM authorization policy	Resource type
CreateSubscription	dhs:CreateSubscription	AllSubscription
ListSubscription	dhs:ListSubscription	AllSubscription
DeleteSubscription	dhs:DeleteSubscription	SingleSubscription
GetSubscription	dhs:GetSubscription	SingleSubscription
UpdateSubscription	dhs: UpdateSubscription	SingleSubscription
CommitOffset	dhs:CommitOffset	SingleSubscription
GetOffset	dhs:GetOffset	SingleSubscription

API operations for shards

API operations for shards

Operation name	RAM authorization policy	Resource type
ListShard	dhs:ListShard	SingleTopic
MergeShard	dhs:MergeShard	SingleTopic
SplitShard	dhs:SplitShard	SingleTopic

API operations for shards

API operations for shards

Operation name	RAM authorization policy	Resource type
PutRecords	dhs:PutRecords	SingleTopic
GetRecords	dhs:GetRecords	SingleTopic
GetCursor	dhs:GetRecords	SingleTopic

5.1.4.4. Conditions

This section describes conditions that can be applied to the RAM authorization policies for DataHub.

Conditions that can be applied to the RAM authorization policies for DataHub are as follows:

RAM authorization policy conditions for DataHub

Condition keyword	Description	Valid value
acs:SourceIp	The IP address range that can access the specified object.	Any valid IP address. Wildcard masks are supported.
acs:SecureTransport	Indicates whether HTTPS is used to access the specified object.	true/false
acs:MFAPresent	Indicates whether the specified object can be accessed by multiple clients.	true/false
acs:CurrentTime	The time that the specified object can be accessed.	This keyword must be described in ISO 8601 format.

5.1.4.5. Sample RAM authorization policy content

5.1.4.5.1. AliyunDataHubFullAccess

This section describes how to set the AliyunDataHubFullAccess policy content.

The authorization policy content can be set as follows:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": "dhs:*",
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

5.1.4.5.2. AliyunDataHubReadOnlyAccess

This section describes how to set the AliyunDataHubReadOnlyAccess policy content.

The authorization policy content can be set as follows:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": ["dhs:List*", "dhs:Get*"],
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

5.1.5. Data Acquisition

5.1.5.1. Overview

In addition to SDK and local file uploads, DataHub supports various data acquisition tools to help you quickly collect data to DataHub.

This section describes how to acquire data by using Fluentd, Logstash, and Oracle GoldenGate (OGG).

5.1.5.2. Fluentd

This topic describes how to install and use the DataHub plug-in for Fluentd.

Developed based on the open-source data collector Fluentd, the DataHub plug-in for Fluentd is easy to install and is used to write the collected data to DataHub.

Install the DataHub plug-in for Fluentd

- Install the plug-in by using RubyGems

  ```
  gem install fluent-plugin-datahub
  ```

  > **Notice** We recommend that you change the gem source to https://ruby.taobao.org/.

- Install the plug-in by using a local installation package

  The agent must be installed in Linux. Before you install the agent, install Ruby. For users who have not installed Fluentd, a full installation package for installing both Fluentd and DataHub plug-in is provided. For users who have installed Fluentd, an installation package of the DataHub plug-in is provided.

  - If you have not installed Fluentd, download the full installation package and run the following commands to install Fluentd with the DataHub plug-in:

    > **Notice** Fluentd 0.12.23 is provided in the full installation package.

    ```
    $ tar -xzvf fluentd-with-datahub-0.12.23.tar.gz
    $ cd fluentd-with-dataHub
    $ sudo sh install.sh
    ```

  - If you have installed Fluentd, download the installation package of the DataHub plug-in for Fluentd and run the following command to install the plug-in.

    ```
    $ sudo gem install --local fluent-plugin-dataHub-0.0.2.gem
    ```

Use cases

Case 1: Collect CSV files

This example shows how to write the incremental content of a Comma-Separated Values (CSV) file to DataHub in quasi-real time by using the DataHub plug-in for Fluentd. The following CSV file is used in this example:

```
0,qe614c760fuk8judu01tn5x055rpt1,true,100.1,14321111111
1,znv1py74o8ynn87k66o32ao4x875wi,true,100.1,14321111111
2,7nm0mtpgo1q0ubuljjjx9b000ybltl,true,100.1,14321111111
3,10t0n6pvonnan16279w848ukko5f6l,true,100.1,14321111111
4,0ub584kw88s6dczd0mta7itmta10jo,true,100.1,14321111111
5,1ltfpf0jt7fhvf0oy4lo8m3z62c940,true,100.1,14321111111
6,zpqsfxqy9379lmcehd7q8kftntrozb,true,100.1,14321111111
7,ce1ga9aln346xcj761c3iytshyzuxg,true,100.1,14321111111
8,k5j2id9a0ko90cykl40s6ojq6gruyi,true,100.1,14321111111
9,ns2zcx9bdip5y0aqd1tdicf7bkdmsm,true,100.1,14321111111
10,54rs9cm1xau2fk66pzyz62tf9tsse4,true,100.1,14321111111
```

Each line is a record to be written to DataHub. Columns are separated by commas (,). Save the CSV file as /temp/test.csv on the local computer. The following table shows the schema of the DataHub topic to which the CSV file is written.

DataHub topic schema

Field	Data type
id	BIGINT
name	STRING
gender	BOOLEAN
salary	DOUBLE
my_time	TIMESTAMP

After you edit the Fluentd configuration file based on the CSV file and topic schema, run the following command to start Fluentd to write the CSV file to DataHub:

```
${FLUENTD_HOME}/fluentd-with-dataHub/bin/fluentd -c fluentd_test.conf
```

Use the following Fluentd configuration file in this example:

```
<source>
  @type tail
  path /xxx/yyy (Specify the path of the CSV file.)
  tag test1
  format csv
  keys id,name,gender,salary,my_time
</source>
<match test1>
  @type dataHub
  access_id your_app_id
  access_key your_app_key
  endpoint http://ip:port
  project_name test_project
  topic_name fluentd_performance_test_1
  column_names ["id", "name", "gender", "salary", "my_time"]
  flush_interval 1s
  buffer_chunk_limit 3m
  buffer_queue_limit 128
  dirty_data_continue true
  dirty_data_file /xxx/yyy (Specify the path of the dirty record file.)
  retry_times 3
  put_data_batch_size 1000
</match>
```

Case 2: Collect Log4j logs

The following format of Log4j logs is used in this example:

```
11:48:43.439 [qtp1847995714-17] INFO  AuditInterceptor - [c2un5sh7cu52ek6am1ui1m5h] end /web/v1/proj
ect/tefe4mfurtix9kwwyrvfqd0m/node/0m0169kapshvgc3ujskwkk8g/health GET, 4061 ms
```

Use the following Fluentd configuration file in this example:

```
<source>
  @type tail
  path bayes.log
  tag test
  format /(? <request_time>\d\d:\d\d:\d\d.\d+)\s+\[(? <thread_id>[\w\-]+)\]\s+(? <log_level>\w+)\s+(
? <class>\w+)\s+-\s+\[(? <request_id>\w+)\]\s+(? <detail>.+)/
</source>
<match test>
  @type dataHub
  access_id your_access_id
  access_key your_access_key
  endpoint http://ip:port
  project_name test_project
  topic_name dataHub_fluentd_out_1
  column_names ["thread_id", "log_level", "class"]
</match>
```

Parameter description

Input configuration

Parameter	Description

Parameter	Description
tag test1	The tag, which is mapped to the destination information by using the specified regular expression.
format csv	The format of the file from which data is collected.
keys id,name,gender,salary,my_time	The columns to be collected from the CSV file. The column names must be the same as those in the schema of the destination DataHub topic.

Output configuration

Parameter	Description
shard_id 0	The ID of the shard to which all records are written. By default, all records are written to the shard by polling. The default ID is 0.
shard_keys ["id"]	The column used as the shard key. Hashed shard key values are used as indexes for writing data.
flush_interval 1	The interval between data flushes. The default value is 60s.
buffer_chunk_limit 3m	The maximum size of a chunk. Unit: k or m, which indicates KB or MB. We recommend you set the maximum size to 3 MB.
buffer_queue_limit 128	The maximum length of the chunk queue. Both the buffer_chunk_limit and buffer_queue_limit parameters determine the size of the buffer. The default value is 128 MB.
put_data_batch_size 1000	The number of records to be written to DataHub at a time. In this example, 1,000 records are written to DataHub each time.
retry_times 3	The number of retries for writing data to DataHub. Default value: 3.
retry_interval 3	The retry interval at which data is written. Unit: seconds. Default value: 3.
dirty_data_continue true	Specifies whether to ignore dirty records. The value true indicates that the plug-in retries the operation for a specified number of times before it writes the dirty records to the dirty record file.
dirty_data_file /xxx/yyy	The directory where the dirty record file is stored.
column_names ["id"]	The name of the columns to be written to DataHub.

5.1.5.3. Logstash

This topic describes how to install and use Logstash to import data to DataHub and export data from DataHub.

Logstash is a distributed log collection framework. It is often used with Elasticsearch and Kibana, known as the ELK Stack, for log data analysis. To support a wider variety of data inputs, DataHub offers Output and Input plug-ins for data transfer with Logstash. By using Logstash, you can access more than 30 types of data sources in the Logstash open source community, such as files, Syslog logs, Redis logs, Log4j logs, Apache logs, and NGINX logs. Logstash also supports filter plug-ins for customizing the fields to be transferred. This topic demonstrates how to use Logstash with DataHub.

Install Logstash and DataHub plug-ins

Java Runtime Environment (JRE) 7 or later is required to run Logstash. If the JRE version does not meet the requirement, several features of Logstash are unavailable. You can install Logstash and DataHub plug-ins with one click by downloading and decompressing the software package or install Logstash and DataHub plug-ins separately.

- Install Logstash and DataHub plug-ins with one click: Download the software package.

  Run the following commands to decompress the package and go to the software directory:

  ```
  $ tar -xzvf logstash-with-datahub-2.3.0.tar.gz
  $ cd logstash-with-datahub-2.3.0
  ```

- Install Logstash and DataHub plug-ins separately
  - Install Logstash. For more information, see the documentation on the official website of Logstash.
  - Install the DataHub Output plug-in for Logstash. You can use this plug-in to import data to DataHub.
  - Install the DataHub Input plug-in for Logstash. You can use this plug-in to export data from DataHub.

Use cases

Case 1: Collect Log4j logs

This example shows how to collect unstructured Log4j logs and derive a structure out of the logs by using Logstash. The following format of Log4j logs is used in this example:

```
20:04:30.359 [qtp1453606810-20] INFO  AuditInterceptor - [13pn9kdr5tl84stzkmaa8vmg] end /web/v1/proj
ect/fhp4clxfbu0w3ym2n7ee6ynh/statistics? executionName=bayes_poc_test GET, 187 ms
```

In this example, you can derive a structure out of the logs and transfer the data to DataHub. The following table shows the schema of the DataHub topic to which the Log4j logs are written.

DataHub topic schema

Field	Data type
request_time	STRING
thread_id	STRING
log_level	STRING
class_name	STRING
request_id	STRING
detail	STRING

Use the following configuration of the Logstash task in this example:

```
input {
    file {
        path => "${APP_HOME}/log/bayes.log"
        start_position => "beginning"
    }
}
filter{
    grok {
        match => {
           "message" => "(? <request_time>\d\d:\d\d:\d\d\.\d+)\s+\[(? <thread_id>[\w\-]+)\]\s+(? <lo
g_level>\w+)\s+(? <class_name>\w+)\s+\-\s+\[(? <request_id>\w+)\]\s+(? <detail>.+)"
        }
    }
}
output {
    datahub {
        access_id => "Your accessId"
        access_key => "Your accessKey"
        endpoint => "Endpoint"
        project_name => "project"
        topic_name => "topic"
        #shard_id => "0"
        #shard_keys => ["thread_id"]
        dirty_data_continue => true
        dirty_data_file => "/Users/ph0ly/trash/dirty.data"
        dirty_data_file_max_size => 1000
    }
}
```

Case 2: Collect CSV files

This example shows how to use Logstash to collect CSV files. The following CSV file is used in this example:

```
1111,1.23456789012E9,true,14321111111000000,string_dataxxx0,
2222,2.23456789012E9,false,14321111111000000,string_dataxxx1
```

The following table shows the schema of the DataHub topic to which the CSV file is written.

DataHub topic schema

Field	Data type
col1	BIGINT
col2	DOUBLE
col3	BOOLEAN
col4	TIMESTAMP
col5	STRING

Use the following configuration of the Logstash task in this example:

```
input {
    file {
        path => "${APP_HOME}/data.csv"
        start_position => "beginning"
    }
}
filter{
    csv {
        columns => ['col1', 'col2', 'col3', 'col4', 'col5']
    }
}
output {
    datahub {
        access_id => "Your accessId"
        access_key => "Your accessKey"
        endpoint => "Endpoint"
        project_name => "project"
        topic_name => "topic"
        #shard_id => "0"
        #shard_keys => ["thread_id"]
        dirty_data_continue => true
        dirty_data_file => "/Users/ph0ly/trash/dirty.data"
        dirty_data_file_max_size => 1000
    }
}
```

Case 3: Consume data from DataHub

Use the following configuration of the Logstash task in this example:

```
input {
    datahub {
        access_id => "Your accessId"
        access_key => "Your accessKey"
        endpoint => "Endpoint"
        project_name => "test_project"
        topic_name => "test_topic"
        interval=> 5
        #cursor => {
        #    "0"=>"20000000000000000000000003110091"
        #    "2"=>"20000000000000000000000003110091"
        #    "1"=>"20000000000000000000000003110091"
        #    "4"=>"20000000000000000000000003110091"
        #    "3"=>"20000000000000000000000003110000"
        #}
        shard_ids => []
        pos_file => "/home/admin/logstash/logstash-2.3.0/pos_file"
    }
}
output {
    file {
        path => "/home/admin/logstash/logstash-2.3.0/output"
    }
}
```

Start Logstash

Run the following command to start Logstash:

```
$LOGSTASH_HOME/bin/logstash -f <The preceding configuration file> -b 256
```

Note -f is followed by the path of the configuration file. -b is followed by the number of records transferred to DataHub at a time. Default value: 125.

Parameters

The following table describes the parameters of the DataHub Output plug-in.

Parameters of the DataHub Output plug-in

Parameter	Description
access_id	Required. The AccessKey ID of your Apsara Stack tenant account.
access_key	Required. The AccessKey secret of your Apsara Stack tenant account.
endpoint	Required. The endpoint used to access DataHub.
project_name	Required. The name of the DataHub project.
topic_name	Required. The name of the DataHub topic.
retry_times	Optional. The maximum number of retries. The value -1 indicates unlimited retries. The value 0 indicates no retries. A value greater than 0 indicates the specified number of retries. Default value: -1.
retry_interval	Optional. The interval between retries. Unit: seconds. Default value: 5.
shard_keys	Optional. The key of the shard. The hash of the key value is used to map the ID of the shard to which the records are written. If the shard_keys and shard_id parameters are not specified, the system polls the shards to decide which shard the records are written to.
shard_id	Optional. The ID of the shard where records are written. If the shard_keys and shard_id parameters are not specified, the system polls the shards to decide which shard the records are written to.
dirty_data_continue	Optional. Specifies whether to ignore dirty records. The value true indicates that dirty records are to be ignored. Default value: false. If you set the value to true, you must specify the dirty_data_file parameter.
dirty_data_file	Optional. The name of the dirty record file. The dirty record file is divided into .part 1 and .part 2. The most recent records are stored in .part 2.
dirty_data_file_max_size	Optional. The maximum size of the dirty record file. This value is for reference only.

The following table describes the parameters of the DataHub Input plug-in.

Parameters of the DataHub Input plug-in

Parameter	Description
access_id	Required. The AccessKey ID of your Apsara Stack tenant account.
access_key	Required. The AccessKey secret of your Apsara Stack tenant account.
endpoint	Required. The endpoint used to access DataHub.

Parameter	Description
project_name	Required. The name of the DataHub project.
topic_name	Required. The name of the DataHub topic.
retry_times	Optional. The maximum number of retries. The value -1 indicates unlimited retries. The value 0 indicates no retries. A value greater than 0 indicates the specified number of retries. Default value: -1.
retry_interval	Optional. The interval between retries. Unit: seconds. Default value: 5.
shard_ids	Optional. The shards in which records are to be consumed. If this parameter is not specified, records in all the shards are consumed.
cursor	Optional. The sequence number of the record from which the consumption begins. The consumption starts from the earliest record by default.
pos_file	Required. The checkpoint file, which is used to reset the consumption offset.

5.1.5.4. Oracle GoldenGate

This topic describes how to install and use Oracle GoldenGate (OGG).

OGG is a tool for log-based structured data replication across heterogeneous environments. It is used for data backup between primary and secondary Oracle databases. It is also used to synchronize data from Oracle databases to other databases such as IBM Db2 and MySQL databases. OGG must be deployed in the source and destination databases. It is composed of the following components: Manager, Extract, data pump, Collector, and Replicat.

- Manager is the control process of OGG. A Manager process must be running on the source and destination databases. It is responsible for starting, stopping, and monitoring other processes.
- Extract is a process that captures data from the source database or transaction logs. You can configure the Extract process for initial data loads and incremental data synchronization. For initial data loads, Extract captures a set of data directly from their source objects. To keep source data synchronized to the destination database, Extract captures incremental DML and DDL operations after the initial data loading has taken place. This topic describes incremental data synchronization.
- A data pump is a secondary Extract group within the source OGG configuration. In a typical configuration with a data pump, the primary Extract group writes to a trail on the source database. The data pump reads the trail and sends the DML or DDL operations over the network to a remote trail on the destination database.
- Collector is a process on the destination database, which receives data from the source database and generates trail files.
- Replicat is a process that reads the trail on the destination database, reconstructs the DML or DDL operations, and then applies them to the destination database.

The DataHub agent for OGG offers the Replicat feature that applies the updated data to DataHub by analyzing the trail. The data in DataHub is processed in real time by using Realtime Compute and can be archived into MaxCompute.

The following example shows how to synchronize incremental data from an Oracle database to DataHub and process the data in DataHub.

Install OGG

Prerequisites:

- You have installed the Oracle database client.
- You have obtained the OGG installation package for the source database. We recommend that you use OGG

V12.1.2.1.

- You have obtained the OGG Adapters installation package for the destination database. We recommend that you use OGG Application Adapters 12.1.2.1.
- You have installed Java 7.

Follow these steps to install OGG:

1. Install OGG for the source database.
   i. Extract the OGG installation package for the source database and the following directories appear:

```
drwxr-xr-x install
drwxrwxr-x response
-rwxr-xr-x runInstaller
drwxr-xr-x stage
```

   ii. Install dependencies in response/oggcore.rsp. The OGG response file template is as follows:

```
oracle.install.responseFileVersion=/oracle/install/rspfmt_ogginstall_response_schema
#The installation option, which must reflect the installed Oracle version. Specify ORA11g fo
r installing OGG for Oracle Database 11g.
INSTALL_OPTION=ORA11g
#The location in which OGG is installed.
SOFTWARE_LOCATION=/home/oracle/u01/ggate
#Indicates whether to start the Manager after installation.
START_MANAGER=false
#The port number of the Manager process.
MANAGER_PORT=7839
#The location of the Oracle database.
DATABASE_LOCATION=/home/oracle/u01/app/oracle/product/11.2.0/dbhome_1
#The location that stores the inventory files. This parameter is not required to be configur
ed.
INVENTORY_LOCATION=
#The UNIX group of the inventory directory. In this example, OGG is installed by using the o
gg_test Oracle account. You can also create a dedicated account for OGG as necessary.
UNIX_GROUP_NAME=oinstall
```

   iii. Run the following command to install OGG:

```
runInstaller -silent -responseFile {YOUR_OGG_INSTALL_FILE_PATH}/response/oggcore.rsp
```

> **Note**
>
> In this example, OGG is installed in */home/oracle/u01/ggate* and the installation logs are stored in */home/oracle/u01/ggate/cfgtoollogs/oui*. The OGG installation is complete when the following message appears in the silentInstall{time}.log file:
>
> ```
> The installation of Oracle GoldenGate Core was successful.
> ```

   iv. Run the following command and enter `CREATE SUBDIRS` as required to create OGG directories:

```
/home/oracle/u01/ggate/ggsci
```

2. Perform Oracle configurations in the source database.

   Navigate to *sqlplus: sqlplus / as sysdba* as the database administrator and complete the following configurations:

```
#Create a tablespace.
create tablespace ATMV datafile '/home/oracle/u01/app/oracle/oradata/uprr/ATMV.dbf' size 100m au
toextend on next 50m maxsize unlimited;
 #Create a user named ogg_test. The password is also set to ogg_test.
create user ogg_test identified by ogg_test default tablespace ATMV;
 #Grant required privileges to ogg_test.
grant connect,resource,dba to ogg_test;
 #Check whether supplemental logging is enabled for the database.
Select SUPPLEMENTAL_LOG_DATA_MIN, SUPPLEMENTAL_LOG_DATA_PK, SUPPLEMENTAL_LOG_DATA_UI, SUPPLEMENT
AL_LOG_DATA_FK, SUPPLEMENTAL_LOG_DATA_ALL from v$database;
 #If the result is NO, enable supplemental logging.
alter database add supplemental log data;
alter database add supplemental log data (primary key, unique,foreign key) columns;
 #Enable rollback.
alter database drop supplemental log data (primary key, unique,foreign key) columns;
alter database drop supplemental log data;
 #Enable all column logging at the database level. Note: Even when all column logging is enabled
, only primary key columns are logged for a delete operation.
ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (ALL) COLUMNS;
 #Enable the forced logging mode.
alter database force logging;
 #Run the marker_setup.sql script.
@marker_setup.sql
 #Run the ddl_setup.sql script.
@ddl_setup.sql
 #Run the role_setup.sql script.
@role_setup.sql
 #Grant the GGS_GGSUSER_ROLE to ogg_test.
grant GGS_GGSUSER_ROLE to ogg_test;
 #Run the ddl_enable.sql script to enable the DDL trigger.
@ddl_enable.sql
 #Run the ddl_pin script to improve the performance of the DDL trigger.
@ddl_pin ogg_test
 #Run the sequence.sql script.
@sequence.sql
#
alter table sys.seq$ add supplemental log data (primary key) columns;
```

3. Configure the Manager process on the source database.

   Start the Oracle GoldenGate Software Command Interface (GGSCI) and perform the following steps:

   i. Run the following command to configure the Manager process:

   ```
   edit params mgr
   PORT 7839
   DYNAMICPORTLIST  7840-7849
   USERID ogg_test, PASSWORD ogg_test
   PURGEOLDEXTRACTS ./dirdat/*, USECHECKPOINTS, MINKEEPDAYS 7
   LAGREPORTHOURS 1
   LAGINFOMINUTES 30
   LAGCRITICALMINUTES 45
   PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
   PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
   ```

   ii. Run the following command to start the Manager process. The logs are stored in ggate/dirrpt.

   ```
   start mgr
   ```

iii. Run the following command to check whether the Manager process is running:

```
info mgr
```

iv. Run the following command to view the Manager parameter file:

```
view params mgr
```

4. Configure the Extract process on the source database.

   Start the GGSCI and perform the following steps:

   i. Run the following command to configure the Extract process. In the following example, the group name of the process is extract.

```
edit params extractEXTRACT extract
SETENV (NLS_LANG="AMERICAN_AMERICA.AL32UTF8")
DBOPTIONS   ALLOWUNUSEDCOLUMN
USERID ogg_test, PASSWORD ogg_test
REPORTCOUNT EVERY 1 MINUTES, RATE
NUMFILES 5000
DISCARDFILE ./dirrpt/ext_test.dsc, APPEND, MEGABYTES 100
DISCARDROLLOVER AT 2:00
WARNLONGTRANS 2h, CHECKINTERVAL 3m
EXTTRAIL ./dirdat/st, MEGABYTES 200
DYNAMICRESOLUTION
TRANLOGOPTIONS CONVERTUCS2CLOBS
TRANLOGOPTIONS RAWDEVICEOFFSET 0
DDL &
INCLUDE MAPPED OBJTYPE 'table' &
INCLUDE MAPPED OBJTYPE 'index' &
INCLUDE MAPPED OBJTYPE 'SEQUENCE' &
EXCLUDE OPTYPE COMMENT
DDLOPTIONS  NOCROSSRENAME  REPORT
TABLE     OGG_TEST. *;
SEQUENCE  OGG_TEST. *;
GETUPDATEBEFORES
```

   ii. Run the following command to add an Extract process. Replace extract in the following command with your actual group name.

```
add ext extract,tranlog, begin now
```

   iii. Run the following command to delete an Extract process. In the following example, the process name is DP_TEST.

```
delete ext DP_TEST
```

   iv. Run the following command to create a trail, associate the trail with the Extract group named extract, and set the maximum file size in the trail to 200 megabytes:

```
add exttrail ./dirdat/st,ext extract, megabytes 200
```

   v. Run the following command to start the Extract process. The logs are stored in ggate/dirrpt.

```
start extract extract
```

> **Note** After the Extract process configuration is complete, you can view the changes to the database in the files stored in the *ggate/dirdat* directory.

5. Create a DEFGEN parameter file.

i. Start the GGSCI in the source database. In GGSCI, run the following command to create a DEFGEN parameter file and copy the file to the dirdef directory in the destination database:

```
edit params defgen
DEFSFILE ./dirdef/ogg_test.def
USERID ogg_test, PASSWORD ogg_test
table OGG_TEST. *;
```

ii. Run the following command from the shell to create a DEFGEN parameter file named ogg_test.def:

```
./defgen paramfile ./dirprm/defgen.prm
```

6. Install and configure OGG in the destination database.

i. Extract the OGG installation package to the destination database.

ii. Copy the dirdef/ogg_test.def file in the source database to dirdef of the destination database.

iii. Start the GGSCI and run the following command to create the default directories of OGG:

```
create subdirs
```

iv. Run the following command to configure the Manager process:

```
edit params mgr
PORT 7839
DYNAMICPORTLIST  7840-7849
PURGEOLDEXTRACTS ./dirdat/*, USECHECKPOINTS, MINKEEPDAYS 7
LAGREPORTHOURS 1
LAGINFOMINUTES 30
LAGCRITICALMINUTES 45
PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 7
```

v. Run the following command to start the Manager process:

```
start mgr
```

7. Configure a data pump in the source database.

Start the GGSCI and perform the following steps:

i. Run the following command to configure a data pump:

```
edit params pump
EXTRACT pump
RMTHOST xx.xx.xx.xx, MGRPORT 7839, COMPRESS
PASSTHRU
NUMFILES 5000
RMTTRAIL ./dirdat/st
DYNAMICRESOLUTION
TABLE      OGG_TEST. *;
SEQUENCE   OGG_TEST. *;
```

ii. Run the following command to create a data-pump Extract process. The process reads from the specified trail.

```
add ext pump,exttrailsource ./dirdat/st
```

iii. Run the following command to create a trail and set the maximum file size in the trail to 200 megabytes:

```
add rmttrail ./dirdat/st,ext pump,megabytes 200
```

iv. Run the following command to start the data pump:

```
start pump
```

> **Note** After the data pump is started, you can view the trail files in the dirdat directory of the destination database.

8. Install and configure the DataHub agent for OGG.

i. Run the following command to configure the *JAVA_HOME and LD_LIBRARY_PATH* environment variables and specify the configurations in the ~/.bash_profile:

```
export JAVA_HOME=/xxx/xxx/jrexx
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:$JAVA_HOME/lib/amd64:$JAVA_HOME/lib/amd64/server
```

ii. After the environment variables are configured, restart the Manager process in the destination database.

iii. Download the DataHub agent for OGG and extract the installation package.

iv. Modify the javaue.properties and log4j.properties files in the conf sub-directory of the installation directory and replace {YOUR_HOME} with the target path of the extracted files:

```
gg.handlerlist=ggdatahub
gg.handler.ggdatahub.type=com.aliyun.odps.ogg.handler.datahub.DatahubHandler
gg.handler.ggdatahub.configureFileName={YOUR_HOME}/datahub-ogg-plugin/conf/configure.xml
goldengate.userexit.nochkpt=false
goldengate.userexit.timestamp=utc
gg.classpath={YOUR_HOME}/datahub-ogg-plugin/lib/*
gg.log.level=debug
jvm.bootoptions=-Xmx512m -Dlog4j.configuration=file:{YOUR_HOME}/datahub-ogg-plugin/conf/log4
j.properties -Djava.class.path=ggjava/ggjava.jar
```

v. Modify the configure.xml file in the conf sub-directory of the installation directory as follows:

```
<? xml version="1.0" encoding="UTF-8"? >
<configue>
    <defaultOracleConfigure>
        <! --(Required) The Oracle database system identifier (SID).-->
        <sid>100</sid>
        <! --The schema of the Oracle table, which can be overwritten by oracleSchema in the
column mappings. At least one of them must be specified.-->
        <schema>ogg_test</schema>
    </defaultOracleConfigure>
    <defalutDatahubConfigure>
        <! --(Required) The endpoint of DataHub.-->
        <endPoint>YOUR_DATAHUB_ENDPOINT</endPoint>
        <! --The DataHub project, which can be overwritten by datahubProject in the column m
appings. At least one of them must be specified.-->
        <project>YOUR_DATAHUB_PROJECT</project>

            <! --(Required) The DataHub topic name.-->
            <datahubTopic>t_person</datahubTopic>
            <ctypeColumn></ctypeColumn>
            <ctimeColumn></ctimeColumn>
            <cidColumn></cidColumn>
            <columnMapping>
                <! --
                src: (Required) The column names in the Oracle table.
                dest: (Required) The column names in the DataHub topic.
                destOld: (Optional) The DataHub topic column that records the data before it
is updated.
                isShardColumn: (Optional) Indicates whether the shard ID is generated based
on the hash key value, which can be overwritten by shardId. Default value: false.
                isDateFormat: Indicates whether the timestamp is converted into a string bas
ed on dateFormat. Default value: true. If you set the value to false, the data type in the s
ource database must be long.
                dateFormat: The format that the timestamp is converted into. If this paramet
```

```
er is left blank, the default format is used.
                -->
                <column src="id" dest="id" isShardColumn="true"  isDateFormat="false" dateFo
rmat="yyyy-MM-dd HH:mm:ss"/>
                <column src="name" dest="name" isShardColumn="true"/>
                <column src="age" dest="age"/>
                <column src="address" dest="address"/>
                <column src="comments" dest="comments"/>
                <column src="sex" dest="sex"/>
                <column src="temp" dest="temp" destOld="temp1"/>
            </columnMapping>
            <! --(Optional) The ID of the shard prioritized to be written into.-->
            <shardId>1</shardId>
        </mapping>
    </mappings>
</configue>
```

vi. Run the following command in GGSCI to start the DataHub writer:

```
edit params dhwriter
extract dhwriter
getEnv (JAVA_HOME)
getEnv (LD_LIBRARY_PATH)
getEnv (PATH)
CUSEREXIT ./libggjava_ue.so CUSEREXIT PASSTHRU INCLUDEUPDATEBEFORES, PARAMS "{YOUR_HOME}/dat
ahub-ogg-plugin/conf/javaue.properties"
sourcedefs ./dirdef/ogg_test.def
table OGG_TEST. *;
```

vii. Run the following command to add a DataHub writer:

```
add extract dhwriter, exttrailsource ./dirdat/st
```

viii. Run the following command to start the writer:

```
start dhwriter
```

Use case

For example, you have an Oracle table that stores order information. The table has three columns. The column names are oid, pid, and num, which indicate order ID, product ID, and product quantity. You can synchronize incremental data to DataHub by using the DataHub agent for OGG. The steps are as follows:

> **Note** Before performing incremental data synchronization, you must synchronize existing data from the source table to MaxCompute by using DataX.

1. Create a topic in DataHub. The schema of the topic is as follows:

   ```
   string record_id, string optype, string readtime, bigint oid_before, bigint oid_after, bigint pi
   d_before, bigint pid_after, bigint num_before, bigint num_after
   ```

2. Make sure that you have completed the deployment of the DataHub agent for OGG. Then configure the column mappings as follows:

```
<ctypeColumn>optype</ctypeColumn>
            <ctimeColumn>readtime</ctimeColumn>
            <cidColumn>record_id</cidColumn>
            <columnMapping>
                <column src="oid" dest="oid_after" destOld="oid_before" isShardColumn="true"/>
                <column src="pid" dest="pid_after" destOld="pid_before"/>
                <column src="num" dest="num_after" destOld="num_before"/>
            </columnMapping>
```

> **Note** The optype parameter indicates the type of the data update. Valid values of the optype parameter are **I**, **D**, and **U**, which represent an **insert**, **delete**, and **update** operation, respectively. The readtime parameter indicates the time of the data update.

3. When the agent can run properly, data updates are synchronized from the source table to DataHub.

5.1.6. Data synchronization

5.1.6.1. Overview

You can synchronize real-time data from DataHub to other data warehouses by using DataConnectors so that you can analyze and process historical data.

The following topics describe how to synchronize data from DataHub to MaxCompute.

5.1.6.2. Synchronize data to MaxCompute

5.1.6.2.1. Create a DataConnector

This topic describes how to create a DataConnector to synchronize data from DataHub to MaxCompute.

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Connector**. In the Create connector dialog box, select the data warehouse to which data is synchronized.
4. In the Create connector dialog box, set relevant parameters and click **Create**.

Note

The following table describes the parameters of the DataConnector for synchronizing data from DataHub to MaxCompute.

Parameter	Description
Project Name	The name of the MaxCompute project to which data in the topic is synchronized.
Table Name	The name of the MaxCompute table to which data in the topic is synchronized.
AccessID and AccessKey	The AccessKey pair used to access MaxCompute. The AccessKey pair must belong to a RAM user that has CreateInstance, Desc, and Alter permissions on the MaxCompute table.
Partition Mode	The method used to create partitions. Valid values: SYSTEM_TIME, EVENT_TIME, USER_DEFINE, and META_TIME. If you select SYSTEM_TIME, partitions are created based on the recording time. If you select EVENT_TIME, partitions are created based on the value of the event_time field. When you create the topic, you must define a field named event_time for the topic and set its data type to TIMESTAMP. The value of the event_time field must be accurate to microseconds. If you select USER_DEFINE, partitions are created based on the user-defined partition key.
Partition Config	The format of the time based on which partitions are created. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME.
Time Range	The interval of creating partitions. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME. The minimum value is 15 minutes.
Timezone	The time zone of the time based on which partitions are created. This parameter takes effect only when you set the Partition Mode parameter to SYSTEM_TIME, EVENT_TIME, or META_TIME.
Start Time	The time when data synchronization starts.

5.1.6.2.2. View data synchronization details

This section describes how to view data synchronization details after a DataConnector is created.

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, find the target topic and click **View** in the Operate column.
4. On the topic details page, click the **Connector** tab. On the Connector tab, find the target DataConnector and click **View** in the Operate column.

Notice You can restart or stop a DataConnector. Exercise caution when you perform the operations.

5.1.7. Metric statistics

This topic describes how to view the metric statistics of a topic in DataHub.

In the DataHub console, you can view the metric statistics of topics in quasi-real-time, such as QPS and throughput. The following metrics are available:

- Read and write QPS
- Read and write records per second (RPS)
- Read and write throughput, measured in KB per second
- Read and write latency, measured in microseconds per request

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click **View** in the Operate column.
3. On the project details page, find the target topic and click **View** in the Operate column.
4. On the topic details page, click the **Metric Statistics** tab.

You can view the metric statistics for a specified time range.

5.1.8. Data subscription

5.1.8.1. Overview

Resumable consumption is required in scenarios where you consume data in DataHub topics and want to resume the consumption from the time when your application fails. If you need to resume consumption, you must save the current consumption offset and make sure that the service for saving consumption offsets supports high availability. This increases the complexity of developing applications. The subscription feature of DataHub supports saving consumption offsets to the server to solve the preceding problem. You only need to enable this feature and add a few lines of code to your application to obtain a consumption offset maintenance service with high availability.

In addition, the subscription feature allows you to reset consumption offsets. This ensures that the data can be consumed at least once. For example, if an error occurs when your application processes the data consumed in a specific time period and you need to consume the data again, you can reset the consumption offset without restarting the application. Your application automatically consumes data from the specified consumption offset.

5.1.8.2. Create a subscription

You can create subscriptions only in the DataHub console. Make sure that your account is authorized to subscribe to topics of the specified project.

Perform the following steps to create a subscription:

1. Log on to the DataHub console.
2. In the left-side navigation pane, click **Project Manager**. On the Project List page, find the target project and click View in the Operate column. On the project details page, find the target topic and click **View** in the Operate column.
3. On the topic details page, click **Subscription**. In the Create subscription dialog box, set relevant parameters and click **Create**.
4. After the subscription is created, click the **Subscription List** tab on the topic details page to view the subscriptions of the topic.

> **Note** You can click **Reset** or **Delete** in the Operate column of a subscription.
>
> - **Reset**: resets the consumption offset of the subscription to the required time. Specify the time in the *mm-dd-yyyy HH:MM:SS* format.
> - **Delete**: permanently deletes the subscription, including all consumption offsets that are saved for the subscription.

5.1.8.3. Use case

The subscription feature allows you to save consumption offsets. You can use the read and write capabilities of DataHub with the capability of saving consumption offsets in scenarios where you must save consumption offsets after data is read.

The following sample code is used for reference only.

```
// The following sample code consumes data from a saved consumption offset and submit consumption of
fsets during consumption.
public void offset_consumption(int maxRetry) {
    String endpoint = "<YourEndPoint>";
    String accessId = "<YourAccessId>";
    String accessKey = "<YourAccessKey>";
    String projectName = "<YourProjectName>";
    String topicName = "<YourTopicName>";
    String subId = "<YourSubId>";
    String shardId = "0";
    List<String> shardIds = Arrays.asList(shardId);
    // Create a DataHub client.
    DatahubClient datahubClient = DatahubClientBuilder.newBuilder()
            .setDatahubConfig(
                    new DatahubConfig(endpoint,
                            // Specify whether to enable binary data transmission. The server of V2.
12 or later supports binary data transmission.
                            new AliyunAccount(accessId, accessKey), true))
            .build();
    RecordSchema schema = datahubClient.getTopic(projectName, topicName).getRecordSchema();
    OpenSubscriptionSessionResult openSubscriptionSessionResult = datahubClient.openSubscriptionSess
ion(projectName, topicName, subId, shardIds);
    SubscriptionOffset subscriptionOffset = openSubscriptionSessionResult.getOffsets().get(shardId);
    // 1. Obtain the cursor of the record at the current consumption offset. If the record expired o
r the record is not consumed, obtain the cursor of the first record within the TTL of the topic.
    String cursor = "";
    // If the sequence number is smaller than 0, the record is not consumed.
    if (subscriptionOffset.getSequence() < 0) {
        // Obtain the cursor of the first record within the TTL of the topic.
        cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).getCurs
or();
    } else {
        // Obtain the cursor of the next record.
        long nextSequence = subscriptionOffset.getSequence() + 1;
        try {
            // If the SeekOutOfRange error is returned after you obtain the cursor based on the sequ
ence number, the record expired.
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SEQUENCE, n
extSequence).getCursor();
        } catch (SeekOutOfRangeException e) {
            // Obtain the cursor of the first record within the TTL of the topic.
            cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLDEST).get
Cursor();
        }
    }
    // 2. Read records and save consumption offsets. In this example, you read tuple records and sav
e consumption offsets each time 1,000 records are read.
    long recordCount = 0L;
    // Read 1,000 records each time.
    int fetchNum = 1000;
    int retryNum = 0;
```

```
    int commitNum = 1000;
    while (retryNum < maxRetry) {
        try {
            GetRecordsResult getRecordsResult = datahubClient.getRecords(projectName, topicName, sha
rdId, schema, cursor, fetchNum);
            if (getRecordsResult.getRecordCount() <= 0) {
                // If no records can be read, pause the thread for 1s and continue to read records.
                System.out.println("no data, sleep 1 second");
                Thread.sleep(1000);
                continue;
            }
            for (RecordEntry recordEntry : getRecordsResult.getRecords()) {
                // Consume data.
                TupleRecordData data = (TupleRecordData) recordEntry.getRecordData();
                System.out.println("field1:" + data.getField("field1") + "\t"
                        + "field2:" + data.getField("field2"));
                // Save the consumption offset after the data is consumed.
                recordCount++;
                subscriptionOffset.setSequence(recordEntry.getSequence());
                subscriptionOffset.setTimestamp(recordEntry.getSystemTime());
                // commit offset every 1000 records
                if (recordCount % commitNum == 0) {
                    // Submit the consumption offset.
                    Map<String, SubscriptionOffset> offsetMap = new HashMap<>();
                    offsetMap.put(shardId, subscriptionOffset);
                    datahubClient.commitSubscriptionOffset(projectName, topicName, subId, offsetMap)
;
                    System.out.println("commit offset successful");
                }
            }
            cursor = getRecordsResult.getNextCursor();
        } catch (SubscriptionOfflineException | SubscriptionSessionInvalidException e) {
            // The subscription session is exited. The Offline exception indicates that the subscrip
tion is offline. The SessionChange exception indicates that the subscription is consumed by other cl
ients.
            e.printStackTrace();
            throw e;
        } catch (SubscriptionOffsetResetException e) {
            // The consumption offset is reset. You must obtain the version information of the consu
mption offset again.
            SubscriptionOffset offset = datahubClient.getSubscriptionOffset(projectName, topicName,
subId, shardIds).getOffsets().get(shardId);
            subscriptionOffset.setVersionId(offset.getVersionId());
            // After the consumption offset is reset, you must obtain the cursor of the record at th
e consumption offset again. The method for obtaining the cursor depends on the method of resetting t
he consumption offset.
            // If both the sequence number and timestamp are specified to reset the consumption offs
et, you can obtain the cursor based on the sequence number or the timestamp.
            // If only the sequence number is specified to reset the consumption offset, you can obt
ain the cursor only based on the sequence number.
            // If only the timestamp is specified to reset the consumption offset, you can obtain th
e cursor only based on the timestamp.
            // Generally, preferentially obtain the cursor based on the sequence number. If the curs
or failed to be obtained based on the sequence number or the timestamp, obtain the cursor of the ear
liest record.
            cursor = null;
            if (cursor == null) {
                try {
                    long nextSequence = offset.getSequence() + 1;
```

```
                    cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SEQ
UENCE, nextSequence).getCursor();
                    System.out.println("get cursor successful");
                } catch (DatahubClientException exception) {
                    System.out.println("get cursor by SEQUENCE failed, try to get cursor by SYSTEM_T
IME");
                }
            }
            if (cursor == null) {
                try {
                    cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.SYS
TEM_TIME, offset.getTimestamp()).getCursor();
                    System.out.println("get cursor successful");
                } catch (DatahubClientException exception) {
                    System.out.println("get cursor by SYSTEM_TIME failed, try to get cursor by OLDES
T");
                }
            }
            if (cursor == null) {
                try {
                    cursor = datahubClient.getCursor(projectName, topicName, shardId, CursorType.OLD
EST).getCursor();
                    System.out.println("get cursor successful");
                } catch (DatahubClientException exception) {
                    System.out.println("get cursor by OLDEST failed");
                    System.out.println("get cursor failed!!") ;
                    throw e;
                }
            }
        } catch (LimitExceededException e) {
            // limit exceed, retry
            e.printStackTrace();
            retryNum++;
        } catch (DatahubClientException e) {
            // other error, retry
            e.printStackTrace();
            retryNum++;
        } catch (Exception e) {
            e.printStackTrace();
            System.exit(-1);
        }
    }
}
```

Note

- When you start the application for the first time, your application consumes data from the earliest record. During the running of the application, you can refresh the Subscription List tab in the console.
- If you reset the consumption offset by clicking Reset in the console during the consumption, your application automatically detects the change of the consumption offset and consumes data from the specified consumption offset. When the application catches OffsetResetedException, the application calls the getSubscriptionOffset method to query the latest consumption offset from the server. Then, the application can consume data from the latest consumption offset.
- Note that a shard in a subscription cannot be consumed by multiple threads or processes at the same time. Otherwise, the consumption offset submitted by a thread is overwritten by that submitted by another thread and the server cannot determine to which thread the saved consumption offset belongs. In this case, the server throws OffsetSessionChangedException. We recommend that you exit the subscription session to check whether data is repeatedly consumed if this exception is caught.

5.1.9. Collaborative consumption

5.1.9.1. Note

DataHub-client-library encapsulates the Java SDK and integrates the consumer for collaborative consumption and the producer for distributing data evenly among shards.

5.1.9.2. Overview

Offset-based data consumption

The offset-based data consumption feature allows you to save consumption offsets to the server. A consumption offset consists of the sequence number of a record and the timestamp when the record is written to DataHub.

You can create a subscription for a topic and submit the consumption offset to the server after specific data is consumed. When you application starts the next time, the application can obtain the consumption offset from the server and consume data from the next record. The consumption offsets must be saved on the server so that your application can consume data from a submitted consumption offset after shards are reallocated. This is a prerequisite for collaborative consumption.

You do not need to manually submit consumption offsets in the consumer. You only need to specify the interval of submitting consumption offsets in the configurations of the consumer. The system considers that the previous records are consumed when it reads records. If the interval of submitting consumption offsets is exceeded, the system submits a consumption offset again. If the consumption offset fails to be submitted and your application is interrupted, the consumption offset may fail to be submitted in time. In this case, your application may repeatedly consume specific data.

Collaborative consumption

The collaborative consumption feature automatically allocates shards when multiple consumers consume a topic at the same time. This feature simplifies the data processing of clients.

Note Manual shard allocation is difficult because multiple consumers may reside on different machines. If multiple consumers that subscribe to the same topic are in the same consumer group, a shard can be allocated to only one consumer in the consumer group.

Example:

Assume that A, B, and C are three consumer instances and the topic has 10 shards.

1. When the consumer instance A is started at first, 10 shards are allocated to it.
2. When the other two consumer instances are started, the shards are reallocated in the following way: four to A, three to B, and three to C.
3. When one of the shards consumed by the consumer instance A is split into two and the two shards are released after consumption, the shards are reallocated in the following way: four to A, four to B, and three to C.
4. When the consumer instance C is stopped, the shards are reallocated in the following way: six to A and five to B.

Heartbeat

You must use the heartbeat feature to notify the server of the status of consumer instances. If the server has not received heartbeats from a consumer instance after the specified interval, the server considers that the consumer instance is stopped. When the status of a consumer instance changes, the server reallocates shards. The server returns the new allocation plan in heartbeat requests. Therefore, the client takes time to detect reallocation of shards.

5.1.9.3. Maven dependencies and JDK

Maven dependencies

```
<dependency>
      <groupId>com.aliyun.datahub</groupId>
      <artifactId>datahub-client-library</artifactId>
      <version>1.0.6-public</version>
</dependency>
```

JDK

```
jdk: >= 1.7
```

5.1.9.4. Use case

The following sample code is for reference only.

Initialize the producer

```
String endpoint = "http://dh-cn-hangzhou.aliyuncs.com";
String accessId = "<YourAccessKeyId>";
String accessKey = "<YourAccessKeySecret>";
String projectName = "<YourProjectName>";
String topicName = "<YourTopicName>";
ProducerConfig config = new ProducerConfig(endpoint, accessId, accessKey);
Producer producer = new Producer(projectName, topicName, config);
```

Write data to DataHub

```
RecordSchema schema = new RecordSchema();
schema.addField(new Field("field1", FieldType.STRING));
schema.addField(new Field("field2", FieldType.BIGINT));
List<RecordEntry> recordEntries = new ArrayList<>();
for (int cnt = 0; cnt < 10; ++cnt) {
    RecordEntry entry = new RecordEntry();
    entry.addAttribute("key1", "value1");
    entry.addAttribute("key2", "value2");
    TupleRecordData data = new TupleRecordData(schema);
    data.setField("field1", "testValue");
    data.setField("field2", 1);
    entry.setRecordData(data);
    recordEntries.add(entry);
}
int maxRetry = 3;
while (true) {
    try {
        producer.send(records, maxRetry);
        break;
    } catch (MalformedRecordException e) {
        // malformed RecordEntry
    } catch (InvalidParameterException e) {
        // invalid param
    } catch (ResourceNotFoundException e) {
        // project, topic or shard not found, sometimes caused by split/merge shard
    } catch (DatahubClientException e) {
        // network or other exceptions exceeded retry limit
    }
}
// close before exit
producer.close();
```

Initialize the consumer

```
String endpoint = "http://dh-cn-hangzhou.aliyuncs.com";
String accessId = "<YourAccessKeyId>";
String accessKey = "<YourAccessKeySecret>";
String projectName = "<YourProjectName>";
String topicName = "<YourTopicName>";
String SubId = "<YourSubscriptionId>";
// 1. If you need to use the collaborative consumption feature, specify the subscription ID.
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, config);
// 2. If you need to use the offset-based data consumption feature instead of the collaborative cons
umption feature, specify the subscription ID and the shards to be read by the consumer.
List<String> assignment = Arrays.asList("0", "1", "2");
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, assignment, config);
// 3. If you do not need to use the collaborative consumption feature nor the offset-based data cons
umption feature, specify the subscription ID, the shards to be read by the consumer, and the consump
tion offset.
Map<String, Offset> offsetMap = new HashMap<>();
// If both the sequence number and timestamp are specified but the sequence number is invalid, obtai
n the cursor based on the timestamp.
offsetMap.put("0", new Offset(100, 1548573440756L));
// If only the sequence number is specified, obtain the cursor based on the sequence number.
offsetMap.put("1", new Offset().setSequence(1));
// If only the timestamp is specified, obtain the cursor based on the timestamp.
offsetMap.put("2", new Offset().setTimestamp(1548573440756L));
ConsumerConfig config = new ConsumerConfig(endpoint, accessId, accessKey);
Consumer consumer = new Consumer(projectName, topicName, SubId, offsetMap, config);
```

Read data from DataHub

```
int maxRetry = 3;
boolean stop = false;
while (! stop) {
    try {
        while (true) {
            RecordEntry record = consumer.read(maxRetry);
            if (record ! = null) {
                TupleRecordData data = (TupleRecordData) record.getRecordData();
                System.out.println("field1:" + data.getField(0) + ", field2:" + data.getField("field
2"));
            }
        }
    } catch (SubscriptionSessionInvalidException | SubscriptionOffsetResetException e) {
        // subscription exception, will not recover
        // print some log or just use a new consumer
        consumer.close();
        consumer = new Consumer(TEST_PROJECT, TEST_TOPIC, TEST_SUB_ID, config);
    } catch (ResourceNotFoundException | InvalidParameterException e) {
        // - project, topic, shard, subscription not found
        // - seek out of range
        // - sometimes shard operation cause ResourceNotFoundException
        // should make sure if resource exists, print some log or just exit
    } catch (DatahubClientException e) {
        // - network or other exception exceed retry limit
        // can just sleep and retry
    }
}
// close before exit
consumer.close();
```

5.1.9.5. Usage notes

A consumer or producer cannot access DataHub by using multiple threads. If you need to use multiple threads, specify a different consumer or producer for each thread.
