 - After TTL is set, data expiration is difficult to predict if you specify a data timestamp (when writing data) that is significantly different from the actual time. For example, if the specified data timestamp is too small, the data may expire and be deleted as soon as it is written. If the specified timestamp is too large, the data may not expire when expected. Therefore, when using TTL, ensure that you set a reasonable timestamp during data writing.
- MaxVersions: the maximum number of versions retained by each attribute column.
 - The latest API version of Table Store supports data models with multiple versions. For more information, see the **Data model concepts** section in Product Introduction. MaxVersions is used to specify the maximum number of data versions saved by each attribute column. The server deletes a few earlier versions to ensure that the number of versions does not exceed the MaxVersions value.
- MaxTimeDeviation: This parameter specifies the maximum deviation allowed between the specified version and the current system time (measured in seconds) when you write data for a version.
 - Table Store supports multiple versions. The system automatically generates a new version number when new data is written. The version number is a timestamp corresponding to the write time (measured in milliseconds). The TTL function uses this timestamp to determine whether data has expired. You can also specify the timestamp of the data. If the value of the timestamp is too small and its deviation from the current time exceeds the TTL of the table, the data expires immediately

after being written. To prevent the problem, you can set `MaxTimeDeviation` for the table. `MaxTimeDeviation` limits the permissible deviation between the data write timestamp and the current system time. The unit of this value is second. You can specify `MaxTimeDeviation` when creating a table and modify this value by using the `UpdateTable` API.

ReservedThroughput

This parameter is used to configure the reserved read/write throughput of a table, which affects billing. When the reserved read/write throughput is greater than 0, you are charged based on the reserved volume and duration. The traffic that exceeds the reserved volume is billed on a Pay-As-You-Go basis. The reserved read/write throughput is 0 by default and all traffic is billed on a Pay-As-You-Go basis. If you want to set the reserved read/write throughput to a value greater than 0, read the Table Store billing documentation to avoid unexpected fees.

For container instances, the reserved read/write throughput can only be set to 0. These instances do not allow you to reserve throughput.

Examples

```
private static void createTable(SyncClient client) {
    TableMeta tableMeta = new TableMeta(TABLE_NAME);
    tableMeta.addPrimaryKeyColumn(new PrimaryKeySchema(PRIMARY_KEY_NAME,
        PrimaryKeyType.STRING));
    // The data validity period, in seconds. -1 indicates that the data does not expire. To
    // set the validity period to one year, set timeToLive to 365 x 24 x 3600.
    int timeToLive = -1;
    // The maximum number of versions to save. If it is set to 3, each column saves only
    // the three latest versions.
    int maxVersions = 3;
    TableOptions tableOptions = new TableOptions(timeToLive, maxVersions);
    CreateTableRequestEx request = new CreateTableRequestEx(tableMeta, tableOptions
    );
    // Set the reserved read/write throughput value.
    request.setReservedThroughput(new ReservedThroughput(new CapacityUnit(100,
    200)));
    client.createTable(request);
}
```

ListTable

You can use the `ListTable` API to obtain the names of all tables created in the current instance.

Examples

The following code provides an example of how to obtain the names of all tables in an instance:

```
private static void listTable(SyncClient client) {
    ListTableResponse response = client.listTable();
    System.out.println("The list of tables is as follows:");
    for (String tableName : response.getTableNames()) {
        System.out.println(tableName);
    }
}
```

UpdateTable

You can use the UpdateTable API to update ReservedThroughput and TableOptions of a table.

For ReservedThroughput and TableOptions, see CreateTable at the beginning of this article. The interval between attempts to change ReservedThroughput is a minimum of one minute.

Examples

The following code provides an example of how to update TTL and MaxVersions of a table:

```
private static void updateTable(SyncClient client) {
    int timeToLive = -1;
    int maxVersions = 5; //Update the MaxVersions value to 5.
    TableOptions tableOptions = new TableOptions(timeToLive, maxVersions);
    UpdateTableRequest request = new UpdateTableRequest(TABLE_NAME);
    request.setTableOptionsForUpdate(tableOptions);
    client.updateTable(request);
}
```

DescribeTable

You can use the DescribeTable API to query TableMeta, TableOptions, and ReservedThroughputDetails of a table. TableMeta and TableOptions have already been described in the **CreateTable** section. ReservedThroughputDetails contains the reserved throughput values, as well as the last time the values were increased or decreased.

Examples

The following code provides an example of how to obtain the descriptive information of a table:

```
private static void describeTable(SyncClient client) {
    DescribeTableRequest request = new DescribeTableRequest(TABLE_NAME);
    DescribeTableResponse response = client.describeTable(request);
    TableMeta tableMeta = response.getTableMeta();
    System.out.println("Table name:" + tableMeta.getTableName());
    System.out.println("Table primary key:");
    for (PrimaryKeySchema primaryKeySchema : tableMeta.getPrimaryKeyList()) {
        System.out.println(primaryKeySchema);
    }
}
```

```

TableOptions tableOptions = response.getTableOptions();
System.out.println("Table TTL:" + tableOptions.getTimeToLive());
System.out.println("Table MaxVersions:" + tableOptions.getMaxVersions());
ReservedThroughputDetails reservedThroughputDetails = response.getReservedThroughputDetails();
System.out.println("Table reserved read throughput:"
    + reservedThroughputDetails.getCapacityUnit().getReadCapacityUnit());
System.out.println("Table reserved write throughput:"
    + reservedThroughputDetails.getCapacityUnit().getWriteCapacityUnit());
}

```

DeleteTable

You can use the DeleteTable API to delete a specified table from an instance.

Examples

The following code provides an example of how to delete a table:

```

private static void deleteTable(SyncClient client) {
    DeleteTableRequest request = new DeleteTableRequest(TABLE_NAME);
    client.deleteTable(request);
}

```

2.5.2.1.2.10 Error handling

Method

The Table Store Java SDK adopts the **Exception** method to handle errors. If the operation succeeds, the called API does not throw an exception. If the operation fails, an exception is thrown.

Note:

Batch operation APIs such as BatchGetRow and BatchWriteRow are used to check for exceptions. Batch operation APIs are called only when the status check of each row is successful.

Exception

The Table Store Java SDK has two types of exceptions: ClientException and OTSException. Both are inherited from RuntimeException.

- ClientException: indicates an internal SDK exception, such as an incorrect parameter value.

- **OTSEException**: indicates a server error arising from the resolution of a server error message. **OTSEException** has the following components:
 - **getStatusCode()**: an HTTP status code, such as 200 or 404.
 - **getErrorCode()**: an error type string returned by Table Store.
 - **getRequestId()**: the UUID that uniquely identifies a request. If a problem persists, submit the request ID to Table Store technical support personnel to obtain help.

2.5.2.2 Python SDK

2.5.2.2.1 Quick start

This topic describes how to obtain and use the Table Store Python SDK.

Environment preparation

You must have a RAM user and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Python SDK. For more information about how to obtain and view your AccessKey pair in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).

Install the Python SDK

Use one of the following methods to install the Python SDK:

- Method 1: Use pip.

The command to install the Python SDK is as follows:

```
sudo pip install tablestore
```

- Method 2: Use GitHub.

Make sure that you have installed [git](#), and then run the following command:

```
git clone https://github.com/aliyun/aliyun-tablestore-python-sdk.git
sudo python setup.py install
```

- Method 3: Use source code.

1. Download the [SDK package](#).
2. Decompress the SDK package, and then run the following command:

```
sudo python setup.py install
```

Use the Python SDK

To call the Alibaba Cloud Python SDK, perform the following steps:

1. Create a client instance. When creating the client instance, you must obtain the Region ID, AccessKey ID, and AccessKey Secret.
2. Create an API request and set its parameters.
3. Initiate the request and handle its response or exception.

2.5.2.2.2 Use the SDK

2.5.2.2.2.1 Preface

Overview

This document describes how to install and use Python SDK V2.1.0 for Table Store (formerly known as OTS). This document assumes that you have activated Table Store, and you have created an AccessKey pair (AccessKey ID and AccessKey Secret).

Perform the following operations to obtain the AccessKey ID and AccessKey Secret: Log on to Apsara Stack Management Console. In the upper-right corner of the webpage, click the inverted triangle icon and select **Personal Information** from the drop-down list.

Download the SDK

- [SDK package](#)
- [GitHub](#)

Compatibility

For SDKs V2.x.x: compatible.

Version

Latest version: 2.1.0.

Change description

Connection pool parameters are adjusted to support access and certificate authentication over HTTPS.

2.5.2.2.2.2 Installation

Environment preparation

Applicable to Python 2 and Python 3.

Installation methods

- Method 1: Install the Python SDK by using pip.

The command to install the Python SDK is as follows:

```
sudo pip install tablestore
```

- Method 2: Install the Python SDK by using GitHub.

Make sure you have installed [git](#), and then run the following command:

```
git clone https://github.com/aliyun/aliyun-tablestore-python-sdk.git
sudo python setup.py install
```

- Method 3: Install the Python SDK by using source code.

1. Download the [SDK package](#).
2. Decompress the SDK package, and then run the following command:

```
sudo python setup.py install
```

Verify the SDK

Enter python on the command line and press Enter to check the SDK version in the Python environment.

```
>>> import tablestore
>>> tablestore.__version__
'4.3.7'
```

Uninstall the SDK

Uninstall the Python SDK by using pip.

```
sudo pip uninstall tablestore
```

2.5.2.2.3 Initialization

TableStoreClient is the client for Table Store. It provides callers with a series of methods to perform operations on tables, a single row, or multiple rows.

Determine an endpoint

An endpoint is the domain name for the Table Store service in each region. It can be in the formats listed in the following table.

Endpoint type	Description
Region address	The address of the region where a Table Store instance is located, such as https://instance.regionid.ots.example.com .

Region address of Table Store

To query the endpoint where your Table Store instance is located, perform the following steps:

1. Log on to the Table Store console.
2. Click the instance name to go to the Instance Details page. Locate Access URL. You can view the endpoint of the instance.

Configure an AccessKey pair

To access Alibaba Cloud Table Store, you must have a valid AccessKey pair (AccessKey ID and AccessKey Secret) for signature authentication.

1. Register an Apsara Stack tenant account on the Alibaba Cloud website.
2. Log on to Apsara Stack Management Console to apply for an AccessKey pair.

After you obtain the AccessKey pair (AccessKey ID and AccessKey Secret), you must initialize a Table Store client instance as follows:

API

```
```python
"""
Initialize the OTSClient instance.
end_point indicates the endpoint of the Table Store service (such as https://instance.
regionid.ots.example.com:80), which must start with https://.
accessid indicates the access ID used to access Table Store. You can visit the official
website or contact an administrator to obtain an access ID.
accesskey indicates the AccessKey pair used to access Table Store. You can visit the
official website or contact an administrator to obtain an AccessKey pair.
instance_name indicates the name of the instance to be accessed. You can create an
instance in the Table Store console or contact an administrator to obtain the name of an
existing instance.
encoding indicates the encoding method of the request parameter string. It is UTF-8 by
default.
socket_timeout indicates the timeout period for each socket connection in the
connection pool. It can be an integer or float number (measured in seconds). The default
value is 50.
max_connection indicates the maximum number of connections in a connection pool.
The default value is 50.
logger_name is used to display the DEBUG log in the request or display the ERROR log
when an error occurs.
retry_policy defines the retry policy. The default retry policy is DefaultRetryPolicy. You
can inherit a RetryPolicy class to implement your own retry policy. For more information,
see the code in DefaultRetryPolicy.
"""
class OTSClient(object):
 def __init__(self, end_point, accessid, accesskey, instance_name, **kwargs):
```

Examples

```
```python
```

```
ots_client = OTSClient('your_instance_endpoint', 'your_user_id', 'your_user_key', 'your_instance_name', logger_name = 'table_store.log')
```

HTTPS

- HTTPS is supported in V2.0.8 and later.
- OpenSSL V0.9.8j or later is required. We recommend that you use OpenSSL V1.0.2d.
- The Python V2.0.8 release pack contains a certifi package that can be installed and used. To update the root certificate, download the latest root certificate from Root Certificate.

2.5.2.2.4 Single-row operations

The Table Store SDK provides the following APIs for single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can use the PutRow API to insert data into a specified row.

API

```
"""
Description: This operation writes a single row of data. The number of capacity units
(CUs) consumed by the operation is returned.
table_name indicates the name of the table.
condition is an instance of the ots2.metadata.Condition class. It indicates the
conditions to be checked before an operation is executed. If the conditions are met, the
operation is executed.
This function only supports row existence checks. Check conditions include: 'IGNORE',
'EXPECT_EXIST', and 'EXPECT_NOT_EXIST'.
primary_key indicates the primary key of the dict type.
attribute_columns indicates the attribute columns of the dict type.
Response: the number of CUs consumed by this operation.
consumed is an instance of the ots2.metadata.CapacityUnit class. It indicates the
number of CUs consumed.
"""
def put_row(self, table_name, condition, primary_key, attribute_columns):
```

Examples

The following code provides an example of how to insert a row of data:

```
# The primary key column values of the data to be inserted: pk0(1) and pk1(101)
# The attribute columns: col0(100), col1(200), and col2('hangzhou')
primary_key = {'pk0':1, 'pk1':101}
attribute_columns = {'col0':100, 'col1':200, 'col2':'hangzhou'}
# The condition for data insertion: Data is inserted only when the specified row does
not exist.
condition = Condition('EXPECT_NOT_EXIST')
try:
    ots_client.put_row('SampleTable', condition, primary_key, attribute_columns)
    # If task execution succeeds, no exception is thrown.
    print "put row succeeded"
except Exception:
    # If task execution fails, an exception is thrown.
```

```
print "put row failed."
```

**Note:**

- RowExistenceExpectation.IGNORE indicates that new data is inserted regardless of whether the specified row exists. If the row exists, the existing data is overwritten.
- RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
- RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.
- To view more detailed code, see [PutRow@GitHub](#).

GetRow

You can use the GetRow API to read a single row of data based on a specified primary key.

API

```
"""
Description: This operation reads a single row of data.
table_name indicates the name of the table.
primary_key indicates the primary key of the dict type.
columns_to_get is an optional parameter that lists the names of the columns to be
read. If you do not set this parameter to a specific value, all columns are read.
Response: the number of CUs consumed by this operation, as well as the primary
key columns and attribute columns.
consumed is an instance of the ots2.metadata.CapacityUnit class. It indicates the
number of CUs consumed by this operation.
primary_key_columns indicates the primary key columns of the dict type. Example: {'
pk0':value0, 'pk1':value1}.
attribute_columns indicates the attribute columns of the dict type. Example: {'col0':
value0, 'col1':value1}.
"""
```

Examples

The following code provides an example of how to read a row of data:

```
# Construct the primary key column for the row to be queried.
primary_key = {'pk0':1, 'pk1':101}
# Only query columns col0 and col1.
columns_to_get = ['col0', 'col1']
# Call the get_row API to query data.
try:
    consumed, primary_key_columns, attribute_columns = ots_client.get_row('
SampleTable', primary_key, columns_to_get)
    # If task execution succeeds, no exception is thrown and data is displayed.
    print 'get row succeeded'
    print 'col0: %s' % attribute_columns.get('col0')
    print 'col1: %s' % attribute_columns.get('col1')
except Exception:
    # If task execution fails, an exception is thrown.
```

```
print "get row failed."
```

**Note:**

- If you query a row of data, the system returns the data in all columns of the row. You can use the `columns_to_get` parameter to read the data in specified columns. For example, the system only returns the data in `col0` and `col1` if `col0` and `col1` are inserted into `columns_to_get`.
- To view more detailed code, see [GetRow@GitHub](#).

UpdateRow

You can use the `UpdateRow` API to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values of the specified columns are added, modified, or deleted based on the request content.

API

```
"""
Description: This operation updates a single row of data.
table_name indicates the name of the table.
condition is an instance of the ots2.metadata.Condition class. It indicates the
conditions to be checked before an operation is executed. If the conditions are met, the
operation is executed.
This function only supports row existence checks. Check conditions include: 'IGNORE',
'EXPECT_EXIST', and 'EXPECT_NOT_EXIST'.
primary_key indicates the primary key of the dict type.
update_of_attribute_columns indicates the attribute columns of the dict type. This
can include put and delete operations. In this case, put is of the dict type and indicates
the attribute columns to be written.
Delete is of the list type and indicates the names of the attribute columns to be
deleted. This is shown in the following example.
Response: the number of CUs consumed by this operation.
consumed is an instance of the ots2.metadata.CapacityUnit class. It indicates the
number of CUs consumed by this operation.
"""

def update_row(self, table_name, condition, primary_key, update_of_attribute_
columns):
```

Examples

The following code provides an example of how to update a row of data.

```
# Construct the primary key column, with unique values for each row of data.
primary_key = {'pk0':1, 'pk1':101}
# Update the values of columns col0 and col2, and delete column col1.
update_of_attribute_columns = {'put' : {'col0':100, 'col2':'chengdu'}, 'delete' : ['col1'],
}
# The update operation is executed only when the row exists.
condition = Condition('EXPECT_EXIST')
try:
    # Call the update_row API to update a row.
    ots_client.update_row('myTable', condition, primary_key, update_of_attribute_
columns)
```

```
# If task execution succeeds, no exception is thrown.
print "update row succeeded"
except Exception:
    # If task execution fails, an exception is thrown.
    print "update row failed"
```

**Note:**

To view more detailed code, see [UpdateRow@GitHub](#).

DeleteRow

API

```
"""
Description: This operation deletes a single row of data.
table_name indicates the name of the table.
condition is an instance of the ots2.metadata.Condition class. It indicates the
conditions to be checked before an operation is executed. If the conditions are met, the
operation is executed.
This function only supports row existence checks. Check conditions include: 'IGNORE',
'EXPECT_EXIST', and 'EXPECT_NOT_EXIST'.
primary_key indicates the primary key of the dict type.
Response: the number of CUs consumed by this operation.
consumed is an instance of the ots2.metadata.CapacityUnit class. It indicates the
number of CUs consumed by this operation.
"""
def delete_row(self, table_name, condition, primary_key):
```

Examples

The following code provides an example of how to delete a row of data:

```
# Construct the primary key column values of the row you want to delete.
primary_key = {'pk0':1, 'pk1':101}
# The delete operation is executed regardless of whether the row exists.
condition = Condition('IGNORE')
try:
    ots_client.delete_row('SampleTable', condition, primary_key)
    # If task execution succeeds, no exception is thrown.
    print "delete row succeeded"
except Exception:
    # If task execution fails, an exception is thrown.
    print "delete row failed"
```

**Note:**

To view more detailed code, see [DeleteRow@GitHub](#).

2.5.2.2.5 Table-level operations

The Table Store SDK provides the following APIs for table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can use the CreateTable API to create a table based on the specified table structure information.

When creating a table in Table Store, you must specify the primary keys of the table. A primary key contains one to four primary key columns. Each primary key column has a name and a type.

API

```

"""
Description: This operation creates a table based on the specified table information.
table_meta is an instance of the ots.metadata.TableMeta class. It contains the table
name and primary key schema.
For more information, see the documentation for the TableMeta class. After a table is
created, it takes one minute to load the partitions.
Then, you can perform operations on the table.
reserved_throughput is an instance of the ots.metadata.ReservedThroughput class.
It indicates the reserved read/write throughput.
Response: None.
"""
def create_table(self, table_meta, reserved_throughput):

```

Note:

After a table is created in Table Store, it takes several seconds to load the table. We recommend that you do not perform any operations during this period.

Examples

The following code provides an example of how to create a table with two primary key columns and a reserved read/write throughput of (0,0):

```

# Create a schema for the primary key columns, including the quantity, names, and
types of primary keys.
# The first primary key column (partition column) is named pk0 and requires an integer
value.
# The second primary key column is named pk1 and requires a string value.
schema_of_primary_key = [('pk0', 'INTEGER'), ('pk1', 'STRING')]
# Create a tableMeta class based on the table name and primary key columns.
table_meta = TableMeta('SampleTable', schema_of_primary_key)
# Set the reserved read throughput and reserved write throughput both to 0.
reserved_throughput = ReservedThroughput(CapacityUnit(0, 0))
# Call the create_table API of the client. If task execution succeeds, no exception is
thrown. If task execution fails, an exception is thrown.
try:
    ots_client.create_table(table_meta, reserved_throughput)
    print "create table succeeded"

```

```
# Handle exceptions.
except Exception:
    print "create table failed."
```

**Note:**

To view more detailed code, see [CreateTable@GitHub](#).

ListTable

You can use the ListTable API to obtain the names of all tables created in the current instance.

API

```
"""
Description: This operation lists all table names.
Response: the table name list.
table_list indicates the table name list of the tuple type. Example: ('MyTable1', '
MyTable2').
"""
def list_table(self):
```

Examples

The following code provides an example of how to obtain the names of all tables in an instance:

```
try:
    list_response = ots_client.list_table()
    print 'table list:'
    for table_name in list_response:
        print table_name
    print "list table succeeded"
except Exception:
    print "list table failed."
```

**Note:**

To view more detailed code, see [ListTable@GitHub](#).

UpdateTable

You can use the UpdateTable API to update the reserved read/write throughput settings of the specified table.

API

```
"""
Description: This operation updates table attributes. This function can only modify
the reserved read/write throughput.
table_name indicates the name of the table.
reserved_throughput is an instance of the ots2.metadata.ReservedThroughput class
. It indicates the reserved read/write throughput.
```

```

Response: the last time when the reserved throughput was raised or lowered for this
table and the number of times it was lowered today.
update_table_response is an instance of the ots2.metadata.UpdateTableResponse
class. It indicates the update results.
"""
def update_table(self, table_name, reserved_throughput):

```

Examples

The following code provides an example of how to update the read CU to 1 and the write CU of a table to 2:

```

# Update the reserved read throughput to 1 and the reserved write throughput to 2.
reserved_throughput = ReservedThroughput(CapacityUnit(1, 2))
try:
    # Call the API to update the reserved read/write throughput of the table.
    ots_client.update_table('SampleTable', reserved_throughput)
    # If task execution succeeds, no exception is thrown.
    print "update table succeeded"
except Exception:
    # If task execution fails, an exception is thrown and an error message is displayed.
    print "update table failed"
}

```

Note:

To view more detailed code, see [UpdateTable@GitHub](#).

DescribeTable

You can use the DescribeTable API to query the structure information and the reserved read/write throughput settings of the specified table.

API

```

"""
Description: This operation obtains the table description.
table_name indicates the name of the table.
Response: the table description.
describe_table_response is an instance of the ots2.metadata.DescribeTableResponse
class. It indicates the table description.
"""
def describe_table(self, table_name):

```

Examples

The following code provides an example of how to obtain the descriptive information of a table:

```

try:
    describe_response = ots_client.describe_table('myTable')
    # If task execution succeeds, no exception is thrown and the following table
    information is displayed.
    print "describe table succeeded."
    print 'read cu: %s' % describe_response.reserved_throughput_details.capacity_unit.
read

```

```

    print 'write cu: %s' % update_response.reserved_throughput_details.capacity_unit.
write
except Exception:
    # If task execution fails, an exception is thrown and handled.
    print "describe table failed."

```

**Note:**

To view more detailed code, see [DescribeTable@GitHub](#).

DeleteTable

You can use the DeleteTable API to delete a specified table from an instance.

API

```

"""
    Description: This operation deletes the table that corresponds to the specified table
name.
    table_name indicates the name of the table.
    Response: None.
"""
def delete_table(self, table_name):

```

Examples

The following code provides an example of how to delete a table:

```

try:
    # Call the API to delete the table named SampleTable.
    ots_client.delete_table('SampleTable')
    # If task execution succeeds, no exception is thrown.
    print "delete table succeeded"
    # If task execution fails, an exception is thrown and handled.
except Exception:
    print "delete table failed"

```

**Note:**

To view more detailed code, see [DeleteTable@GitHub](#).

2.5.2.2.2.6 Multiple-row operations

The Table Store SDK provides the following APIs for multiple-row operations: BatchGetRow, BatchWriteRow, and GetRange.

BatchGetRow

You can use the BatchGetRow API to simultaneously read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the request response time and increase the data read rate.

API

```

"""
    Description: This operation simultaneously reads data from multiple rows.
    batch_list indicates a condition list that contains the rows to be obtained. The syntax
    is as follows:
    [
        (table_name0, [row0_primary_key, row1_primary_key, ...], [column_name0,
        column_name1, ...]),
        (table_name1, [row0_primary_key, row1_primary_key, ...], [column_name0,
        column_name1, ...])
        ...
    ]
    Where, row0_primary_key and row1_primary_key are the primary keys of the dict
    type.
    Response: the results for the corresponding rows.
    response_rows_list indicates a list of returned results. The results are displayed in the
    same order as they are requested. The syntax is as follows:
    [
        [row_data_item0, row_data_item1, ...], # for table_name0
        [row_data_item0, row_data_item1, ...], # for table_name1
        ...
    ]
    Where, row_data_item0 and row_data_item1 are instances of the ots2.metadata.
    RowDataItem class.
"""
def batch_get_row(self, batch_list):

```

Examples

The following code provides an example of how to simultaneously read three rows of data:

```

# Read data from the following three rows:
row1_primary_key = {'pk0':1, 'pk1':101}
row2_primary_key = {'pk0':2, 'pk1':202}
row3_primary_key = {'pk0':3, 'pk1':303}
# Only return the following columns:
columns_to_get = ['col0', 'col1']
# Construct batch_list to define the rows obtained in the BatchRowGet operation.
batch_list = [('SampleTable', [row1_primary_key, row2_primary_key, row3_primary_key
], columns_to_get)]
try:
    batch_get_response = ots_client.batch_get_row(batch_list)
    # If task execution succeeds, no exception is thrown and each row is retrieved in
    batch_get_response. Otherwise, the execution fails.
    # For the logic used to determine the success or failure of each row retrieval, see the
    batch_write_row example.
    print "batch get row succeeded"
except Exception:
    # If task execution fails, an exception is thrown.

```

```
print "batch get row failed."
```

**Note:**

To view more detailed code, see [BatchGetRow@GitHub](#).

BatchWriteRow

You can use the BatchWriteRow API to simultaneously insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

API

```
"""
Description: This operation simultaneously modifies data from multiple rows.
batch_list indicates a condition list that contains the rows to be obtained. The syntax
is as follows:
```

```
[
  {
    'table_name':table_name0,
    'put':[put_row_item, ...],
    'update':[update_row_item, ...],
    'delete':[delete_row_item, ..]
  },
  {
    'table_name':table_name1,
    'put':[put_row_item, ...],
    'update':[update_row_item, ...],
    'delete':[delete_row_item, ..]
  },
  ...
]
```

Where, put_row_item is an instance of the ots2.metadata.PutRowItem class.

update_row_item is an instance of the ots2.metadata.UpdateRowItem class.

delete_row_item is an instance of the ots2.metadata.DeleteRowItem class.

Response: the modification results for the corresponding rows.

response_rows_list indicates a list of returned results. The results are displayed in the same order as they are requested. The syntax is as follows:

```
[
  {
    # for table_name0
    'put':[put_row_resp, ...],
    'update':[update_row_resp, ...],
    'delete':[delete_row_resp, ..]
  },
  {
    # for table_name1
    'put':[put_row_resp, ...],
    'update':[update_row_resp, ...],
    'delete':[delete_row_resp, ..]
  },
  ...
]
```

Where, put_row_resp, update_row_resp, and delete_row_resp are instances of the ots2.metadata.BatchWriteRowResponseItem class.

```
"""
```

```
def batch_write_row(self, batch_list):
```

Examples

The following code provides an example of how to simultaneously write multiple rows of data.

```
# Insert a new row, and set the primary key column values to 2 and 202.
primary_key = {'pk0':2, 'pk1':202}
attribute_columns = {'col0':11, 'col1':22, 'col2':'hangzhou'}
condition = Condition('EXPECT_NOT_EXIST')
put_row_item = PutRowItem(condition, primary_key, attribute_columns)
# Update a row, and set the primary key column values to 3 and 303. A column will be
inserted and then deleted regardless of whether the row exists.
primary_key = {'pk0':3, 'pk1':303}
condition = Condition('IGNORE')
update_of_attribute_columns = {
    'put': {'name':'Zhang San', 'address':'XX China'},
    'delete': ['mobile', 'age'],
}
update_row_item = UpdateRowItem(condition, primary_key, update_of_attribute_
columns)
# Delete a row whose primary key column values are 4 and 404.
primary_key = {'pk0':4, 'pk1':404}
condition = Condition('IGNORE')
delete_row_item = DeleteRowItem(condition, primary_key)
# Construct the rows of data to be operated on in table1.
table_item1 = {'table_name':'table1', 'put':[put_row_item], 'update':[update_row_item
], 'delete':[delete_row_item]}
# Construct the rows of data to be operated on in table2.
table_item2 = {'table_name':'table2', 'put':[put_row_item], 'update':[update_row_item
], 'delete':[delete_row_item]}
batch_list = [table_item1, table_item2]
# Each row operation is independent, and their success or failure must be individually
determined. Failed sub-operations are retried.
retry_count = 0
operation_list = ['put', 'update', 'delete']
try:
    while retry_count < 3:
        # Call the batch_write_row API to write data to table1 and table2.
        batch_write_response = ots_client.batch_write_row(batch_list)
        failed_batch_list = []

                else:
                    operation_item.append(item)
            return
        table_item = {'table_name':table_name, operation:[item]}
        batch_list.append(table_item)

```

**Note:**

To view more detailed code, see [BatchWriteRow@GitHub](#).

GetRange

You can use the GetRange API to read data within the specified primary key range.

API

```

"""
Description: This operation reads data from multiple rows in the specified range.
table_name indicates the name of the table.
direction indicates the direction a range is read in and can be set to a string of
FORWARD or BACKWARD.
inclusive_start_primary_key indicates the primary key to start from (included in the
read range).
exclusive_end_primary_key indicates the primary key to end with (excluded from the
read range).
columns_to_get is an optional parameter that lists the names of specific columns to
read. If you do not set this parameter, all columns are read.
limit is an optional parameter that indicates the maximum number of rows to read. If
you do not set this parameter, there is no limit.
Response: the results that meet the conditions.
consumed is an instance of the ots2.metadata.CapacityUnit class. It indicates the
number of CUs consumed by this operation.
next_start_primary_key indicates the primary key column value from which you want
to start the next get_range operation. It is of dict type.
row_list lists the row data returned by this operation. The syntax is [(primary_ke
y_columns, attribute_columns), ...].
"""
def get_range(self, table_name, direction,
              inclusive_start_primary_key,
              exclusive_end_primary_key,
              columns_to_get=None, limit=None):

```

Examples

The following code provides an example of how to read data within the specified range:

```

# Query interval: [(1, INF_MIN), (4, INF_MAX)). The starting primary key is included
while the ending primary key is excluded.
# Set the start primary key, which is included in the result.

```

```

inclusive_start_primary_key = {'pk0':1, 'pk1':INF_MIN}
# Set the ending primary key, which is excluded from the result.
exclusive_end_primary_key = {'pk0':4, 'pk1':INF_MAX}
# Set which columns to return.
columns_to_get = ['col0', 'col2']
try:
    # Call the get_range API to read in the forward direction for 100 columns.
    consumed, next_start_primary_key, row_list = ots_client.get_range('SampleTable', '
FORWARD',
    inclusive_start_primary_key, exclusive_end_primary_key, columns_to_get, 100
)
    # If task execution succeeds, no exception is thrown.
    print "get range succeeded"
    # Display data from all rows.
    for row in row_list:
        attribute_columns = row[1]
        print 'col0: %s' % attribute_columns.get('col0')
        print 'col1: %s' % attribute_columns.get('col1')
    # Display the number of CUs consumed by this operation.
    print 'consumed CapacityUnit: %s' % consumed.read
    # If this operation fails to obtain all data, repeat the steps to read the response items
    and display the next primary key to start reading from.
    print 'next begin key: %s' % next_start_primary_key
except Exception:
    # If task execution fails, an exception is thrown.
    print 'get range failed.'

```

**Note:**

To view more detailed code, see [GetRange@GitHub](#).

2.5.2.2.2.7 Error handling

Method

The Table Store Python SDK adopts the **Exception** method to handle errors. If the operation succeeds, the called API does not throw an exception. If the operation fails, an exception is thrown.

**Note:**

Batch operation APIs such as `batch_get_row` and `batch_write_row` are called only when the status check of each row is successful.

Exception

The Table Store Python SDK has two types of exceptions: `OTSClientError` and `OTSServiceError`. Both are inherited from `Exception`.

- `OTSClientError`: indicates an internal SDK exception, such as an incorrect parameter value or a failure to parse the results returned by the server.

- OTSServiceError: indicates a server error arising from the resolution of a server error message. OTSServiceError has the following components:
 - get_http_status: an HTTP status code, such as 200 or 404.
 - get_error_code: an error type string returned by Table Store.
 - get_error_message: an error message string returned by Table Store.
 - get_request_id: the UUID that uniquely identifies a request. If a problem persists, submit the request ID to Table Store technical support personnel to obtain help.

Retry

- The system retries an operation when an error occurs in the SDK. The default policy sets the maximum retry attempts to 3, and a maximum retry interval of 2,000 ms. For more information about how the system retries the operation on throttling errors and read-related internal server errors, see [ots2/retry.py](#).
- You can also use an inherited RetryPolicy class to implement your own retry policy. When constructing an OTSClient object, you can use this class as an input parameter.

2.5.2.3 C++ SDK

2.5.2.3.1 Quick start

This topic describes how to obtain and use the Table Store C++ SDK.

Environment preparation

You must have a RAM user and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the C++ SDK. For more information about how to obtain and view your AccessKey pair in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).

Install the C++ SDK

For more information about how to install the C++ SDK, see [Installation](#).

Use the C++ SDK

To call the C++ SDK, perform the following steps:

1. Create an instance.
2. Create an API request and set its parameters.
3. Initiate the request and handle its response or exception.

2.5.2.3.2 Use the SDK

2.5.2.3.2.1 Preface

This document describes how to install and use C++ SDK V4.0.0 and later for Table Store (formerly known as OTS).

If you have not activated Table Store or want to learn more about Table Store, visit the [Table Store product homepage](#).

If you have not created an AccessKey ID and AccessKey Secret, see [Obtain an AccessKey pair](#).

Download URL: [GitHub](#)

2.5.2.3.2.2 Installation

Due to the unique characteristics of C++, we recommend that you use the backup method described in this topic to compile and copy build/release/src/tablestore/core/impl/buildinfo.cpp. Then, copy the C++ SDK source code and buildinfo.cpp to your own code library and use your selected compiler.

Compilation parameters

When compiling client-side code, you must set some compiler parameters.

The GCC compiler parameters are described as follows.

Parameter	Required	Description
--std=gnu++03	Required	Supports C++98 TR1 language with GCC extension (that is, typedef).
-pthread	Required	Required parameter for multithreaded programming . This parameter is required for both compiling and linking.

Parameter	Required	Description
-fwrapv	Required	Rotates upon integer overflow. Specifically, this parameter yields 0 in the case of an unsigned integer overflow and the smallest negative number in the case of a signed integer overflow. The client checks overflow based on this behavior.
-O2	Recommended	Optimization grade. Typically, we do not recommend that you use a higher optimization grade.
-fsanitize=address and -fvar-tracking-assignments	Recommended	GCC versions later than V4.9 support libasan, a lightweight detector that can quickly detect errors in memory usage. If you need Table Store developers to locate errors, provide these two compilation parameters so that the errors can be reproduced. You must also provide the first parameter when linking.  Note: libasan and valgrind are incompatible.

Environment dependency and pre-compiled packages

This example uses the Debian 8 system to demonstrate how to generate pre-compiled packages.

1. Go to the docker/debian8/Dockerfile directory and select dockerfile to export the environment dependency of the client on the system. This method automatically guarantees consistency between the code and the environment.

```
RUN apt-get install -y scons g++ libboost-all-dev protobuf-compiler libprotobuf-dev
uuid-dev libssl-dev
```

RUN apt-get install -y ca-certificates # for HTTPS support

The SDK has the following dependencies:

- **scons & gcc**: a compiler system.
- **boost**
- **uuid**
- **protobuf**: a serialization library.
- **openssl**: a signature generation toolkit used to enable HTTPS connections.
- **ca-certificates**: a package that is only used to handle SSL certificates for HTTPS URLs.

If you only use the HTTP URL of Table Store, you can choose not to install this library.

We recommend that you use HTTPS URLs to improve security.

2. You can compile the client after installing these packages. Download the source code of the client and run the **scons** command in the source code directory.

```
$ git clone https://github.com/aliyun/aliyun-tablestore-cpp-sdk.git
$ cd aliyun-tablestore-cpp-sdk
$ scons -j4
```

After these steps are completed, a TAR package is compiled. Typically, you can find the package name in the final output of **scons**. For example, the package name in the Debian8 system can be found in the following path: `build/release/pkg/aliyun-tablestore-cpp98-sdk-4.4.1-debian8.9-x86_64.tar.gz`.

- The package name includes the following elements:
 - C++ version (C++98)
 - SDK version (4.4.1)
 - OS version (Debian 8.9)
 - OS architecture (x86_64)
- The content of the package includes:

```
$ tar -tf build/release/pkg/aliyun-tablestore-cpp98-sdk-4.4.1-debian8.9-x86_64.tar.gz
version.ini
lib/libtablestore_core.so
lib/libtablestore_core_static.a
lib/libtablestore_util.so
lib/libtablestore_util_static.a
include/tablestore/util/arithmetic.hpp
include/tablestore/util/assert.hpp
include/tablestore/util/foreach.hpp
include/tablestore/util/iterator.hpp
include/tablestore/util/logger.hpp
include/tablestore/util/logging.hpp
include/tablestore/util/mempiece.hpp
include/tablestore/util/mempool.hpp
```

```

include/tablestore/util/metaprogramming.hpp
include/tablestore/util/move.hpp
include/tablestore/util/optional.hpp
include/tablestore/util/prettyprint.hpp
include/tablestore/util/random.hpp
include/tablestore/util/result.hpp
include/tablestore/util/security.hpp
include/tablestore/util/seq_gen.hpp
include/tablestore/util/threading.hpp
include/tablestore/util/timestamp.hpp
include/tablestore/util/try.hpp
include/tablestore/util/assert.hpp
include/tablestore/util/iterator.hpp
include/tablestore/util/logging.hpp
include/tablestore/util/mempiece.hpp
include/tablestore/util/move.hpp
include/tablestore/util/prettyprint.hpp
include/tablestore/core/client.hpp
include/tablestore/core/error.hpp
include/tablestore/core/range_iterator.hpp
include/tablestore/core/retry.hpp
include/tablestore/core/types.hpp

```

The package includes the following elements:

- Version file: version.ini
- Library files: all files in lib/. libtablestore_core_static.a depends on libtablestore_util_static.a. The dependency relationship is similar in the dynamic library.
- Header files: all files in include/.

2.5.2.3.2.3 Initialization

The Table Store client provides a series of methods to perform operations on tables, single rows, and multiple rows.

Determine an endpoint

An endpoint is the domain name for Table Store in each region. It can be in the formats listed in the following table.

Example	Description
http://sun.cn-hangzhou.ots.aliyuncs.com	Public network access to the sun instance in China (Hangzhou) over HTTP.
https://sun.cn-hangzhou.ots.aliyuncs.com	Public network access to the sun instance in China (Hangzhou) over HTTPS.

Note:

- Table Store supports public and private network access.

- You can log on to the [Table Store console](#). Go to the instance details page and locate the instance URL, which is the endpoint of the instance.

Configure an AccessKey pair

To access Apsara Stack Table Store, you must have a valid AccessKey pair (AccessKey ID and AccessKey Secret) for signature authentication. The following methods are supported:

- Use the AccessKey ID and AccessKey Secret.
- Use an STS token for temporary access. The procedure is as follows:
 1. The application server uses RAM or STS to obtain and send you a temporary AccessKey ID, AccessKey Secret, and token.
 2. You can use the received AccessKey ID, AccessKey Secret, and token to access Table Store.

Create a client

When using Table Store SDKs, you must create a client and then call the client API to access Table Store. The client API has the same functions as the RESTful API provided by Table Store.

- Client types

The Table Store C++ SDK offers two client types: SyncClient and AsyncClient. SyncClient is designed for synchronous operations and AsyncClient is designed for asynchronous operations.

- Synchronous operations: After a synchronous operation is called, the service request succeeds. You can call synchronous operations to learn about the various functions of Table Store.
- Asynchronous operations: Compared with synchronous operations, asynchronous operations provide greater flexibility. If you have high performance requirements, you can choose between the use of asynchronous operations and multithreading as needed.

Note:

Both SyncClient and AsyncClient are thread-safe and can internally manage threads and connection resources. You do not need to create a client for each thread or request. Instead, create a global client.

- Synchronous operations
 - Create a client by using a Table Store endpoint

```
Endpoint ep("YourEndpoint", "YourInstance");
Credential cr("AccessKeyId", "AccessKeySecret");
ClientOptions opts;
SyncClient* client = NULL;
Optional<OTSError> res = SyncClient::create(client, ep, cr, opts);
```

**Note:**

For security reasons, we recommend that you do not use the AccessKey pair of your Apsara Stack tenant account. You can use a temporary STS token or the AccessKey pair of an authorized RAM user. If you choose to use a temporary STS token, the Credential object in the preceding code must be changed to: Credential cr ("AccessKeyId", "AccessKeySecret", "SecurityToken");.

The parameters included in ClientOptions are described as follows. You can customize the parameters or use their default values.

Parameter	Description
mMaxConnections	The maximum number of connections and also the maximum number of concurrent requests. A persistent connection is maintained between the SDK and the Table Store service. Each new request is sent by a randomly selected idle connection.
mConnectTimeout	The connection timeout period. Taking the DNS resolution time into account, we recommend that you set the connection timeout period to a minimum of 10 seconds.
mRequestTimeout	The request timeout period.
mRetryStrategy	The retry policy. The retry policy retries failed idempotent requests within 10 seconds by default. You can define your own retry policy.
mLogger	The logger. The logger exports logs to standard errors by default. We recommend that you define your own logger.

Parameter	Description
mActors	The thread pool. The thread pool is used to run your callback. The number of threads is 10 by default.

- Create a client from AsyncClient

```
AsyncClient& async = ... ;
SyncClient* sync = SyncClient::create(async);
```

- Asynchronous operations

For more information about how to create and use an asynchronous operation client, see [Asynchronous operations](#).

Multithreading

Multithreading is supported. We recommend that you use the same client object to perform multithreading tasks.

2.5.2.3.2.4 Single-row operations

Table Store provides the following single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

Note:

The following examples are based on synchronous operations. For more information about how to use asynchronous table-level operations, see [Asynchronous operations](#).

PutRow

You can call this operation to insert a row of data. If this row already exists, it is overwritten (all columns of the row and column values of all versions are deleted).

Example

```
PutRowRequest req;
{
    RowPutChange& chg = req.mutableRowChange();
    chg.mutableTable() = "YourTable";
    {
        // set primary key of the row to put
        PrimaryKey& pkey = chg.mutablePrimaryKey();
        pkey.append() = PrimaryKeyColumn(
            "pkey",
            PrimaryKeyValue::toStr("pkey-value"));
    }
    {
        // set attributes of the row to put
        IVector<Attribute>& attrs = chg.mutableAttributes();
        attrs.append() = Attribute(
```

```

        "attr",
        AttributeValue::toInteger(123));
    }
}
PutRowResponse resp;
Optional<OTSError> res = client.putRow(resp, req);

```

GetRow

You can call this operation to read a row of data.

If you specify the table name and the primary key of a row, the two possible read results are as follows:

- If this row exists, the `GetRowResponse` object returns all the primary key columns and attribute columns for the row.
- If this row does not exist, the `GetRowResponse` object does not report errors or include this row in the response.

Example

```

GetRowRequest req;
{
    PointQueryCriterion& query = req.mutableQueryCriterion();
    query.mutableTable() = "YourTable";
    {
        PrimaryKey& pkey = query.mutablePrimaryKey();
        pkey.append() = PrimaryKeyColumn(
            "pkey",
            PrimaryKeyValue::toStr("some_key")); // Assume that the table has only one
        primary key column that is of the string type.
    }
    query.mutableMaxVersions().reset(1);
}
GetRowResponse resp;
Optional<OTSError> res = client.getRow(resp, req);

```

UpdateRow

You can call this operation to update a single row of data. If no row exists, a new row is added.

The update operations apply to the following four scenarios:

- Write a column value without specifying the version number. The Table Store service automatically generates a version number to ensure that the version number is incremented.
- Write a column value with a specific version number. The existing column value is overwritten. However, if the column does not have a column value corresponding to the specified version, the data is inserted.

- Delete the column values of the specified version.
- Delete the column values of all versions for the entire column.

Example

```
UpdateRowRequest req;
{
  RowUpdateChange& chg = req.mutableRowChange();
  chg.mutableTable() = "YourTable";
  {
    // set primary key of the row to put
    PrimaryKey& pkey = chg.mutablePrimaryKey();
    pkey.append() = PrimaryKeyColumn(
      "pkey",
      PrimaryKeyValue::toStr("pkey"));
  }
  {
    // insert a value without specifying version
    RowUpdateChange::Update& up = chg.mutableUpdates().append();
    up.mutableType() = RowUpdateChange::Update::kPut;
    up.mutableAttrName() = "attr0";
    up.mutableAttrValue().reset(AttributeValue::toStr("new value without specifying
version"));
  }
  {
    // insert a value with version
    RowUpdateChange::Update& up = chg.mutableUpdates().append();
    up.mutableType() = RowUpdateChange::Update::kPut;
    up.mutableAttrName() = "attr1";
    up.mutableAttrValue().reset(AttributeValue::toStr("new value with version"));
    up.mutableTimestamp().reset(UtcTime::now());
  }
  {
    // delete a value with specific version
    RowUpdateChange::Update& up = chg.mutableUpdates().append();
    up.mutableType() = RowUpdateChange::Update::kDelete;
    up.mutableAttrName() = "attr2";
    up.mutableTimestamp().reset(UtcTime::now());
  }
  {
    // delete all values of a attribute column
    RowUpdateChange::Update& up = chg.mutableUpdates().append();
    up.mutableType() = RowUpdateChange::Update::kDeleteAll;
    up.mutableAttrName() = "attr3";
  }
}
UpdateRowResponse resp;
Optional<OTSError> res = client.updateRow(resp, req);
```

DeleteRow

You can call this operation to delete a row of data. No errors are reported regardless of whether the specified row exists.

Example

```
DeleteRowRequest req;
{
  RowDeleteChange& chg = req.mutableRowChange();
```

```

chg.mutableTable() = "YourTable";
{
    // set primary key of the row to delete
    PrimaryKey& pkey = chg.mutablePrimaryKey();
    pkey.append() = PrimaryKeyColumn(
        "pkey",
        PrimaryKeyValue::toInteger(1));
}
}
DeleteRowResponse resp;
Optional<OTSError> res = client.deleteRow(resp, req);

```

2.5.2.3.2.5 Multiple-row operations

Table Store provides the following multiple-row operations: BatchGetRow, BatchWriteRow, and GetRange.

Note:

The following examples are based on synchronous operations. For more information about how to use asynchronous table-level operations, see [Asynchronous operations](#).

BatchGetRow

You can call this operation to simultaneously read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently. Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the response time for requests and increase the data read rate.

Two possible errors may occur when you use BatchGetRow:

- Errors affecting the entire BatchGetRow operation, such as a network error. These errors are stored in the response of batchGetRow().
- No errors affecting the entire BatchGetRow operation, but a few individual-row related errors. These errors are stored in the results of the corresponding rows.

Example

```

BatchGetRowRequest req;
{
    MultiPointQueryCriterion& criterion = req.mutableCriteria().append();
    IVector<MultiPointQueryCriterion::RowKey>& rowkeys = criterion.mutableRowKeys();
    {
        MultiPointQueryCriterion::RowKey& exist = rowkeys.append();
        exist.mutableGet().append() = PrimaryKeyColumn(
            "pkey",
            PrimaryKeyValue::toStr("some key"));
        exist.mutableUserData() = &userDataForSomeKey;
    }
}

```

```

    }
    {
        MultiPointQueryCriterion::RowKey& exist = rowkeys.append();
        exist.mutableGet().append() = PrimaryKeyColumn(
            "pkey",
            PrimaryKeyValue::toStr("another key"));
        exist.mutableUserData() = &userDataForAnotherKey;
    }
    criterion.mutableTable() = "YourTable";
    criterion.mutableMaxVersions().reset(1);
}
BatchGetRowResponse resp;
Optional<OTSError> res = client.batchGetRow(resp, req);

```

**Note:**

For the complete code for BatchGetRow, see [batchGetRow@GitHub](#).

BatchWriteRow

You can use call this operation to simultaneously insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

Two possible errors may occur when you use BatchWriteRow:

- Errors affecting the entire BatchWriteRow operation, such as a network timeout. These errors are stored in the response of batchWriteRow().
- Errors in individual rows, such as an invalid primary key value. These errors are stored in each row of BatchWriteRowResponse.

Example

```

static const char kPutRow[] = "PutRow";
static const char kUpdateRow[] = "UpdateRow";
static const char kDeleteRow[] = "DeleteRow";
BatchWriteRowRequest req;
{
    // put row
    BatchWriteRowRequest::Put& put = req.mutablePuts().append();
    put.mutableUserData() = kPutRow;
    put.mutableGet().mutableTable() = kTableName;
    PrimaryKey& pkey = put.mutableGet().mutablePrimaryKey();
    pkey.append() = PrimaryKeyColumn(
        "pkey",
        PrimaryKeyValue::toStr("row to put"));
}
{
    // update row
    BatchWriteRowRequest::Update& update = req.mutableUpdates().append();
    update.mutableUserData() = kUpdateRow;
    update.mutableGet().mutableTable() = kTableName;
}

```

```

PrimaryKey& pkey = update.mutableGet().mutablePrimaryKey();
pkey.append() = PrimaryKeyColumn(
    "pkey",
    PrimaryKeyValue::toStr("row to update"));
RowUpdateChange::Update& attr = update.mutableGet().mutableUpdates().append();
attr.mutableType() = RowUpdateChange::Update::kPut;
attr.mutableAttrName() = "attr0";
attr.mutableAttrValue().reset(AttributeValue::toStr("some value"));
}
{
    // delete row
    BatchWriteRowRequest::Delete& del = req.mutableDeletes().append();
    del.mutableUserData() = kDeleteRow;
    del.mutableGet().mutableTable() = kTableName;
    PrimaryKey& pkey = del.mutableGet().mutablePrimaryKey();
    pkey.append() = PrimaryKeyColumn(
        "pkey",
        PrimaryKeyValue::toStr("row to delete"));
}
BatchWriteRowResponse resp;
Optional<OTSError> res = client.batchWriteRow(resp, req);

```

**Note:**

For the complete code for BatchWriteRow, see [batchWriteRow@GitHub](#).

GetRange

You can call this operation to read data within the specified primary key range.

We recommend that you use `Rangelterator`. To construct `Rangelterator`, you must provide the following elements:

- [AsyncClient](#)
- `RangeQueryCriterion` is similar to `PointQueryCriterion`, but `RangeQueryCriterion` also requires you to perform the following operations:
 - Set the starting point (inclusive) and end point (exclusive) of the range. In addition to the normal primary key value, you can also use two special values: "negative infinity" (strictly smaller than all normal primary key column values) and "positive infinity" (strictly greater than all primary key column values).
 - Set the query direction to FORWARD (values going from small to large) or BACKWARD (values going from large to small). Data is read in the forward direction by default. When data is read in the forward direction, the starting point must be smaller than the end point. When data is read in the backward direction, the starting point must be greater than the end point.

The `Rangelterator` object is an iterator that provides three operations:

- `moveNext()` moves the `Rangelterator` object to the next row. You must call `moveNext()` to obtain the value of a newly constructed `Rangelterator` object. If reading data fails, `moveNext()` displays the error in the response.
- `valid()` shows whether the `Rangelterator` object has reached the end point of the range.
- If `valid()` is true, the row object can be read by using `get()`. You can remove the row object content returned by `get()` to avoid memory replication. After the content is removed, `get()` returns the removed content.

Example

```
RangeQueryCriterion query;
query.mutableTable() = "YourTable";
query.mutableMaxVersions().reset(1);
{
    PrimaryKey& start = query.mutableInclusiveStart();
    start.append() = PrimaryKeyColumn(
        "pkey",
        PrimaryKeyValue::toInfMin());
}
{
    PrimaryKey& end = query.mutableExclusiveEnd();
    end.append() = PrimaryKeyColumn(
        "pkey",
        PrimaryKeyValue::toInfMax());
}
auto_ptr<AsyncClient> aclient(AsyncClient::create(client));
Rangelterator iter(*aclient, query);
for(;;) {
    Optional<OTSError> err = iter.moveNext();
    if (err.present()) {
        // do something with err
        abort();
    }
    if (! iter.valid()) {
        break;
    }
    Row& row = iter.get();
    // do something with row
}
```

Note:

For the complete code for `GetRange`, see [GetRange@GitHub](#).

Read specified columns

Table Store supports infinite row width. However, in most scenarios, you only require to read specified columns. `QueryCriterion` (`PointQueryCriterion`, `MultiPointQueryCriterion`, and `RangeQueryCriterion`) provides the `mutableColumnsToGet()` method to specify columns that must be read. These columns can be attribute columns or primary key columns. If the value is null, the entire row is read.

If a specified column does not exist in the row being read, the column is not included in the response. Table Store does not provide placeholders.

In `GetRange`, if all specified columns are attribute columns, and all these columns are missing from a row in the range, this row is not included in the result. If you want to read the row, you can add the primary key column to the specified columns.

Read specified versions

Each attribute column can contain multiple versions. Each version number (timestamp) corresponds to a column value. When reading attribute columns, you can define the number of versions (`mutableMaxVersions()`) and the range of versions (`mutableTimeRange()`) to read.

You must specify at least one of the following parameters: `MaxVersions` or `TimeRange`.

- If you only specify the number of versions, the specified amount of data in all versions is returned in descending order.
- If you only specify the range of versions, all data within this range is returned.
- If you specify both the number of versions and the range of versions, the specified amount of data within the version range is returned in descending order.

Conditional writes

In conditional writing, certain conditions must be checked and met before rows are written. Table Store guarantees the atomicity of conditional checks and writes.

Table Store supports row existence conditions and column value conditions:

- Row existence conditions can be divided into the following types:
 - Ignore: This is the default value. Data is written regardless of whether a row exists.
 - ExpectExist: Data is written only when a row exists.
 - ExpectNotExist: Data is written only when a row does not exist.
- The column value condition is equivalent to [Filter](#).

2.5.2.3.2.6 Primary key column auto-increment

The C++ SDK supports the auto-increment of primary key columns. If you set a primary key column as an auto-increment column, you can leave the value of this column empty when you write a row of data. This is because Table Store automatically generates this value. This generated value is unique on the partition key and adheres to a strict incremental order. For more information, see [Primary key column auto-increment](#).

Create a table

Note:

An auto-increment primary key column must be an integer and `PrimaryKeyColumnSchema::AutoIncrement` must be set.

```

CreateTableRequest req;
{
    // Immutable configurations of the table.
    TableMeta& meta = req.mutableMeta();
    meta.mutableTableName() = kTableName;
    Schema& schema = meta.mutableSchema();
    {
        PrimaryKeyColumnSchema& pkColSchema = schema.append();
        pkColSchema.mutableName() = "ShardKey";
        pkColSchema.mutableType() = kPKT_String;
    }
    {
        PrimaryKeyColumnSchema& pkColSchema = schema.append();
        pkColSchema.mutableName() = "AutoIncrKey";
        pkColSchema.mutableType() = kPKT_Integer;
        pkColSchema.mutableOption().reset(PrimaryKeyColumnSchema::AutoIncrement);
    }
}
CreateTableResponse resp;
Optional<OTSError> res = client.createTable(resp, req);

```

Write data

The value of an auto-increment primary key column is filled by the Table Store service. Therefore, the primary key column must be filled with a special placeholder when you write data. `PrimaryKeyValue::toAutoIncrement()` can be used to obtain this placeholder object. To read this row of data, you can set the [returned value to include the primary key](#). The Table Store service replaces the placeholder for the auto-increment primary key column in the primary key with the actual column values before returning them. You can record this primary key for subsequent use.

This example is based on a single row-based overwrite task. The method is similar for writing data with other APIs.

```

PutRowRequest req;
{
    RowPutChange& chg = req.mutableRowChange();
    chg.mutableTable() = kTableName;
    chg.mutableReturnType() = RowChange::kRT_PrimaryKey;
    PrimaryKey& pkey = chg.mutablePrimaryKey();
    pkey.append() = PrimaryKeyColumn(
        "ShardKey",
        PrimaryKeyValue::toStr("shard0"));
    pkey.append() = PrimaryKeyColumn(
        "AutoIncrKey",
        PrimaryKeyValue::toAutoIncrement());
}

```

}

2.5.2.3.2.7 Table-level operations

The SDK provides the following table-level operations: CreateTable, ListTable, UpdateTable, DescribeTable, and DeleteTable.

Note:

The following examples are based on synchronous operations. For more information about how to use asynchronous table-level operations, see [Asynchronous operations](#).

CreateTable

You must specify the name and primary key of the table you want to create. A primary key contains one to four primary key columns. Each primary key column has a name and a type .

In Table Store tables, you can set auto-increment of primary key columns. For more information, see [Primary key column auto-increment](#).

- Example

In this example, the table name is `simple_create_delete_table`. The primary key has only one primary key column. The column is named `pkey` and is an integer (`kPKT_Integer`).

```
CreateTableRequest req;
{
    // immutable configurations of the table
    TableMeta& meta = req.mutableMeta();
    meta.mutableTableName() = "simple_create_delete_table";
    {
        // with exactly one integer primary key column
        Schema& schema = meta.mutableSchema();
        PrimaryKeyColumnSchema& pkColSchema = schema.append();
        pkColSchema.mutableName() = "pkey";
        pkColSchema.mutableType() = kPKT_Integer;
    }
}
CreateTableResponse resp;
Optional<OTSError> res = client.createTable(resp, req);
```

For the complete code for CreateTable, see [createTable@GitHub](#).

- Variable parameters

You can configure several variable parameters for a data table. You can configure variable parameters when creating tables, or use [UpdateTable](#) to modify variable parameters.

The following table lists the variable parameters.

Variable parameter	Name	Default value
mutableTimeToLive()	time to live	-1 (Data never expires.)
mutableMaxVersions()	Max versions	1
mutableMaxTimeDeviation() ()	Max version offset	86400 (in seconds, which indicates one day)
mutableReservedThroughput() ghput()	Reserved read/write throughput	0 (All read/write operations are billed on a pay-as-you-go basis.)

The following code provides an example of how to set the reserved read/write throughput when a table is created:

```
CreateTableRequest req;
{
    // immutable configurations of the table
    TableMeta& meta = req.mutableMeta();
    meta.mutableTableName() = "create_table_with_reserved_throughput";
    {
        // with exactly one integer primary key column
        Schema& schema = meta.mutableSchema();
        PrimaryKeyColumnSchema& pkColSchema = schema.append();
        pkColSchema.mutableName() = "pkey";
        pkColSchema.mutableType() = kPKT_Integer;
    }
}
{
    TableOptions& opts = req.mutableOptions();
    {
        // 0 reserved read capacity-unit, 1 reserved write capacity-unit
        CapacityUnit cu(0, 1);
        opts.mutableReservedThroughput().reset(util::move(cu));
    }
}
CreateTableResponse resp;
Optional<OTSError> res = client.createTable(resp, req);
```

ListTable

You can call this operation to query the names of all tables created in the current instance.

SyncClient::listTable() is used to list all tables in the instance.

```
SyncClient* client = ... ;
```

```
ListTableRequest req;
ListTableResponse resp;
Optional<OTSError> res = client->listTable(resp, req);
```

Query the names of all tables in the instance. Example:

```
const IVector<string>& xs = resp.tables();
for(int64_t i = 0; i < xs.size(); ++i) {
    cout << xs[i] << endl;
}
```

For the complete code for ListTable, see [listTable@GitHub](#).

UpdateTable

You can call this operation to update the [variable parameters](#) listed in this topic.

Update the reserved throughput. Example:

```
UpdateTableRequest req;
req.mutableTable() = "YourTable";
UpdateTableResponse resp;
{
    TableOptions& opts = req.mutableOptions();
    {
        // 0 reserved read capacity-unit, 1 reserved write capacity-unit
        CapacityUnit cu(0, 1);
        opts.mutableReservedThroughput().reset(util::move(cu));
    }
}
Optional<OTSError> res = client.updateTable(resp, req);
```

For the complete code for UpdateTable, see [updateTable@GitHub](#).

DescribeTable

You can call the **describeTable()** operation to query the following table information.

Item	Description
Table status	• kTS_Active: Read and write operations can be performed on the table. • kTS_Inactive: Read or write operations cannot be performed on the table, but table data is retained. This status typically occurs during primary-secondary table switching. • kTS_Loading: The table is being created . Read or write operations cannot be performed on the table. • kTS_Unloading: The table is being deleted. Read or write operations cannot be performed on the table. • kTS_Updating: The variable table parameters are being updated. Read or write operations cannot be performed on the table.
Table meta	See CreateTable .
Variable table parameter	For more information, see the Variable parameters section in this topic.
Split points between partitions	A Table Store table is split horizontally into several partitions. Split points can be obtained by using this operation.  Note: Based on the load, Table Store tables can be automatically split and merged in the back end. The split points retrieved by this operation indicate previous partitioning status, but may not match the current situation.

Example:

```
DescribeTableRequest req;
req.mutableTable() = "YourTable";
DescribeTableResponse resp;
Optional<OTSError> res = client.describeTable(resp, req);
```

For the complete code for DescribeTable, see [describeTable@GitHub](#).

DeleteTable

You can call this operation to delete a specified table from an instance. You only need to specify the table name.

```
DeleteTableRequest req;  
req.mutableTable() = "YourTable";  
DeleteTableResponse resp;  
Optional<OTSError> res = client.deleteTable(resp, req);
```

For the complete code for DeleteTable, see [deleteTable@GitHub](#).

2.5.2.3.2.8 Filter

Table Store can filter the read results on the server side to limit the amount of data transmitted over the network.

In the tree structure of a filter, the internal node is a logical operator (CompositeColumnCondition) and its leaf nodes are comparison operators (SingleColumnCondition).

- CompositeColumnCondition supports AND, OR, and NOT operators. Two or more sub-nodes can be mounted on AND and OR. Only one node can be mounted on NOT.
- SingleColumnCondition supports all six comparison conditions (EQUAL TO, NOT EQUAL TO, GREATER THAN, SMALLER THAN, GREATER THAN OR EQUAL TO, and SMALLER THAN OR EQUAL TO).
- Each SingleColumnCondition object supports comparing a column (which can be a primary key column) with a constant. Comparing two columns or two constants is not supported.
- The latestVersionOnly parameter of SingleColumnCondition controls how multiple versions of a column value are involved in the comparison. The default value is true.
 - If this parameter is set to true, only the latest version of the column value within the specified range of versions is compared. (The latest version is only involved in the comparison. If the filter accepts this row, other versions of the column value are still returned.)
 - If the parameter is set to false, when any column value meets the conditions, the node considers it true.
- The passIfMissing parameter of SingleColumnCondition controls what values the node must consider if the column value is missing. The default value is false.

The filter acts on the results filtered based on other conditions. Therefore, if a column in the filter is not specified in the specified column read operation, or if no column value exists within the range of versions, the filter considers this column to be missing.

Examples

The following code provides an example of how to filter all rows in a table that meet this condition: The primary key column pkey is greater than 1 and the attribute column attr is equal to A.

```
RangeQueryCriterion query;
query.mutableTable() = kTableName;
query.mutableMaxVersions().reset(1);
{
  PrimaryKey& start = query.mutableInclusiveStart();
  start.append() = PrimaryKeyColumn(
    "pkey",
    PrimaryKeyValue::toInfMin());
}
{
  PrimaryKey& end = query.mutableExclusiveEnd();
  end.append() = PrimaryKeyColumn(
    "pkey",
    PrimaryKeyValue::toInfMax());
}
{
  // Set the filter.
  shared_ptr<ColumnCondition> pkeyCond(
    new SingleColumnCondition(
      "pkey",
      SingleColumnCondition::kLarger,
      AttributeValue::toInteger(1)));
  shared_ptr<ColumnCondition> attrCond(
    new SingleColumnCondition(
      "attr",
      SingleColumnCondition::kEqual,
      AttributeValue::toStr("A")));
  shared_ptr<CompositeColumnCondition> top(new CompositeColumnCondition());
  top->mutableOp() = CompositeColumnCondition::kAnd;
  top->mutableChildren().append() = pkeyCond;
  top->mutableChildren().append() = attrCond;
  query.mutableFilter() = top;
}
```

2.5.2.3.2.9 Asynchronous operations

Create a client

- Create a client by using a Table Store endpoint

```
Endpoint ep("YourEndpoint", "YourInstance");
Credential cr("AccessKeyId", "AccessKeySecret");
ClientOptions opts;
AsyncClient* client = NULL;
```

```
Optional<OTSError> res = AsyncClient::create(client, ep, cr, opts);
```

**Note:**

For security reasons, we recommend that you do not use the AccessKey pair of your Apsara Stack tenant account. You can use a temporary STS token or the AccessKey pair of an authorized RAM user. If you choose to use a temporary STS token, the Credential object in the preceding code must be changed to: `Credential cr("AccessKeyId", "AccessKeySecret", "SecurityToken");`.

For more information about the parameters, see the "Synchronous operations" section in [Initialization](#).

- Create a client from SyncClient

```
SyncClient& sync = ... ;
AsyncClient* async = AsyncClient::create(sync);
```

Table-level operations

This example uses a table-level operation to demonstrate how to use an asynchronous operation.

- Preparations

Two functions must be ready:

- Request object

The function signature of `listTable` is as follows:

```
void listTable(
    ListTableRequest&,
    const std::tr1::function<void(
        ListTableRequest&, util::Optional<OTSError>&, ListTableResponse&>&>);
```

The first parameter is a mutable reference. (In contrast, an immutable reference is used in a synchronous operation.) After `listTable()` returns a value (but the `listTable` operation is not completed), the passed-in `ListTableRequest` object may be changed or destructed, which may cause errors that are difficult to locate. To avoid such issues,

asynchronous clients transfer (not copy) the content of the passed-in request object to internal storage. After you call `listTable()`, passed-in objects may be changed.

- Callback function

The callback function does not return any values. It accepts the following three parameters:

- Request object. This is the request object that is passed in when you call `listTable()`. After callback, the asynchronous client no longer needs the request object and returns it to your callback function in the form of a mutable reference. This allows you to transfer the content of the request object.
- Error object wrapped in `Optional`. If no errors exist, the `present()` method of this object returns **false**.
- Response object. Similar to a request object, a response object is also returned to the callback function in the form of a mutable reference. If an error exists, the response object is a valid object (one that can be destructured). However, the content of the response object is undefined.

Note:

- The asynchronous client makes sure that each callback request is called once.
- The callback function can be called before `listTable()` is returned.

- Example

```
void listTableCallback(
    ListTableRequest&,
    Optional<OTSError>& err,
    ListTableResponse& resp)
{
    if (err.present()) {
        // Handle the error.
    } else {
        const IVector<string>& xs = resp.tables();
        for(int64_t i = 0; i < xs.size(); ++i) {
            cout << xs[i] << endl;
        }
    }
}

void listTable(AsyncClient& client)
{
    ListTableRequest req;
    client.listTable(req, listTableCallback);
}
```

}

2.5.2.3.2.10 Logs

The client provides a logger by default. If your application has its own logger, we recommend that you use it to facilitate log management.

A logger has the following four elements, as defined in `tablestore/util/logger.hpp`.

- **Logger API**

Logger is used to assemble the content of a log into a Record object that is forwarded to and written out by Sinker. The client also organizes Logger into a tree structure, the root of which is the logger you have defined in ClientOptions. The request logic and the networking logic use different sub-loggers derived from this root logger.

```
class Logger
{
public:
    enum LogLevel
    {
        kDebug,
        kInfo,
        kError,
    };
    virtual ~Logger() {}
    virtual LogLevel level() const =0;
    virtual void record(LogLevel, const std::string&) =0;
    virtual Logger* spawn(const std::string& key) =0;
    virtual Logger* spawn(const std::string& key, LogLevel) =0;
};
```

- `level()` returns the log grade accepted by Logger. Logs of lower grades are not transferred to Sinker.
- `record()` accepts a log and its grade, which are then used to form a Record object that is sent to the corresponding Sinker of Logger.
- `spawn()`: derives a sub-logger.

- **Record API**

Logger uses the Record object to transfer the content of a log to Sinker.

The Record API does not provide a method. Logger and Sinker determine which methods are provided by the Record class.

- **Sinker API**

Sinker writes out Record objects.

```
class Sinker
{
public:
```

```
virtual ~Sink() {}
virtual void sink(Record*) =0;
virtual void flush() =0;
};
```

- `sink()` writes out a Record. The Record can only be written to a cache.
- `flush()` clears the cache to make sure that every log is stored.
- SinkCenter singleton object

SinkCenter stores all Sink objects and associates them with specific keys.

```
class SinkCenter
{
public:
    virtual ~SinkCenter() {}
    static std::tr1::shared_ptr<SinkCenter> singleton();
    virtual Sink* registerSink(const std::string& key, Sink*) =0;
    virtual void flushAll() =0;
};
```

- `singleton()` obtains SinkCenter singleton objects.
- `registerSink()` registers a Sink in the SinkCenter.
- `flushAll()` clears all Sinks in the SinkCenter.

2.5.2.3.2.11 Error handling

The Table Store C++ SDK handles errors by using a method that returns values. All APIs that can generate errors return `Optional<OTSError>` objects.

- `Optional<T>` is a template class defined in `tablestore/util/optional.hpp`. Visualize a box that can store a maximum of one `T` object. Inside the box are two scenarios that can be used to judge whether an error has occurred:
 - If a `T` object exists, it can be taken out and used. In this case, `Optional<T>::present()` returns true, indicating that an error has occurred.
 - If no `T` object exists, `Optional<T>::present()` returns false, indicating that no errors occurred.

- The `OTSError` object indicates a specific error. It has five fields:
 - `httpStatus` and `errorCode`: an HTTP status code and an error code. In addition to the [Error codes](#), the following errors occur only on the client.

HTTP status code	Error code	Description
6	<code>OTSCouldntResolveHost</code>	Unable to resolve the domain name. The instance access address is incorrect or the network is disconnected.
7	<code>OTSCouldntConnect</code>	Unable to connect to the service. Configuration error in local host files.
28	<code>OTSRequestTimeout</code>	Request timeout.
35	<code>OTSSslHandshakeFail</code>	HTTPS handshake failure . Local certificate not installed.
55	<code>OTSWriteRequestFail</code>	Network delivery failure. Network interruption.
56	<code>OTSCorruptedResponse</code>	Incomplete response.
89	<code>OTSNoAvailableConnection</code>	No available connection . This typically occurs when clients are newly constructed or when concurrent requests exceed the total number of network connections.

- `message`: error details.
- `requestId`: The server assigns a number to each request sent to the server. If a response is returned, the response object contains a request ID. If the service determines that a request has errors, the error object contains the request ID. If errors occur before the request is sent, or if they occur on the network link, the error object does not contain the request ID.
- `traceId`: Each API invocation is assigned a trace ID by the client. Different API invocations are assigned different trace IDs. If the same API invocation is tried repeatedly, the trace ID remains the same but the request ID may vary.

2.5.2.3.2.12 Retry

Common retry policies

The SDK provides the following common retry policies:

- Default retry policy

The SDK automatically triggers retries when errors occur. The maximum retry interval is 10 seconds.

- Counter-based retry policy

Retry at user-defined intervals. If the retry policy is secure, the maximum number of retry attempts cannot exceed the user-defined number.

- No retry

Custom retry policies

You can modify `RetryStrategy` to customize your retry policy.

```
class RetryStrategy
{
public:
    virtual ~RetryStrategy() {}
    virtual RetryStrategy* clone() const =0;
    virtual int64_t retries() const throw() =0;
    virtual bool shouldRetry(Action, const OTSError&) const =0;
    virtual util::Duration nextPause() =0;
};
```

- `Clone ()`: clones a new object. The new object must be of the same type and have the same internal status (including the number of retries) as the original object.
- `retries()`: indicates the number of completed retries.
- `shouldRetry()`: specifies operations and errors to determine whether a retry is required.

Table Store provides two utility functions for easier operations:

- The first retrievable function divides errors into three categories.
 - Harmless retries, such as `OTSTableNotReady`.
 - Malicious or irrelevant retries, such as parameter errors.
 - Retries that cannot be determined based on errors alone, such as `OTSRequest Timeout`.
- The second retrievable function determines whether a retry attempt can be performed based on the idempotence principles of an operation in combination with operations

and errors. DEPENDS errors of a read operation and RETRABLE errors are judged to be retrievable.

```
enum RetryCategory
{
    UNRETRIABLE,
    RETRIABLE,
    DEPENDS,
};
static RetryCategory retrievable(const OTSError&);
static bool retrievable(Action, const OTSError&);
```

- `nextPause()`: indicates the interval between retry attempts.

2.5.2.4 Go SDK

2.5.2.4.1 Quick start

The Go SDK allows you to access Table Store without performing complex programming operations. This topic describes how to obtain and use the Go SDK.

Environment preparation

You must have a RAM user and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Go SDK. For more information about how to obtain and view your AccessKey pair in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).

Install the Go SDK

The command to install the Go SDK is as follows:

```
go get github.com/aliyun/aliyun-tablestore-go-sdk
```

Use the Go SDK

To call the Go SDK, perform the following steps:

1. Create an instance.
2. Create an API request and set its parameters.
3. Initiate the request and handle its response or exception.

2.5.2.4.2 Use the SDK

2.5.2.4.2.1 Preface

Overview

This document describes how to install and use Go SDK V4.0.0 and later for Table Store.

Perform the following operations to obtain the AccessKey ID and AccessKey Secret: Log on to Apsara Stack Management Console. In the upper-right corner of the webpage, click the inverted triangle icon and select **Personal Information** from the drop-down list.

Download the SDK

- [SDK package](#) (includes JAR files, source code, and samples).
- For more information about the installation method, see [Installation](#).

Version

Latest version: 4.0.0

2.5.2.4.2.2 Installation

Environment preparation

Applicable to Go 1.4 and later.

Installation methods

The command to install the Go SDK is as follows:

```
go get github.com/aliyun/aliyun-tablestore-go-sdk
```

2.5.2.4.2.3 Initialization

TableStoreClient is the client for Table Store. It provides callers with a series of methods to perform operations on tables, a single row, or multiple rows.

Determine an endpoint

An endpoint is the domain name for the Table Store service in each region. It can be in the formats listed in the following table.

Table 2-315: Endpoint types

Endpoint type	Description
Region address	The address of the region where a Table Store instance is located, such as <code>https://instance.region.ots.example.com</code> .

To query the endpoint where your Table Store instance is located, perform the following steps:

1. Log on to the Table Store console.

2. Click the instance name to go to the **Instance Details** page.

Locate **Access URL**. You can view the endpoint of the instance.

Configure an AccessKey pair

To access Table Store, you must have a valid AccessKey pair (AccessKey ID and AccessKey Secret) for signature authentication.

After you obtain the AccessKey ID and AccessKey Secret, you must initialize a Table Store client instance.

Use the endpoint of Table Store to create a client:

- API

```
// Initialize the TableStoreClient instance.
// end_point indicates the endpoint of the Table Store service (such as 'https://
instance.region.ots.example.com:80'), which must start with https://.
// accessid indicates the access ID used to access Table Store. You can visit the
official website or contact an administrator to obtain an access ID.
// accesskey indicates the AccessKey pair used to access Table Store. You can visit
the official website or contact an administrator to obtain an AccessKey pair.
// instance_name indicates the name of the instance to be accessed. You can create
an instance in the Table Store console or contact an administrator to obtain the name
of an existing instance.
func NewClient(endPoint, instanceName, accessKeyId, accessKeySecret string, options
... ClientOption) *TableStoreClient
```

- Examples

```
client = NewClient("your_instance_endpoint", "your_instance_name", "your_user_id",
"your_user_key")
```

2.5.2.4.2.4 Table-level operations

The Table Store SDK provides the following APIs for table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can use the CreateTable API to create a table based on the specified table structure information.

When creating a table in Table Store, you must specify the primary keys of the table. A primary key contains one to four primary key columns. Each primary key column has a name and a type.

API

```
// Description: This operation creates a table based on the specified table information.
// request is the instance of the CreateTableRequest class, which contains tableMeta,
TableOption, and ReservedThroughput.
```

```
// For more information, see the documentation for the TableMeta class. After a table is
// created, it takes one minute to load the partitions.
// Then, you can perform table-level operations.
// Response: CreateTableResponse.
CreateTable(request *CreateTableRequest) (*CreateTableResponse, error)
```

**Note:**

After a table is created in Table Store, it takes several seconds to load the table. We recommend that you do not perform any operations during this period.

Examples

The following code provides an example of how to create a table with two primary key columns and a reserved read/write throughput of (0,0):

```
//Create a schema for the primary key columns, including the quantity, names, and
//types of primary keys.
//The first primary key column (partition column) is named pk0 and requires an
//integer value.
//The second primary key column is named pk1 and requires an integer value.
tableMeta := new(tablestore.TableMeta)
tableMeta.TableName = tableName
tableMeta.AddPrimaryKeyColumn("pk0", tablestore.PrimaryKeyType_INTEGER)
tableMeta.AddPrimaryKeyColumn("pk1", tablestore.PrimaryKeyType_STRING)
tableOption := new(tablestore.TableOption)
tableOption.TimeToAlive = -1
tableOption.MaxVersion = 3
reservedThroughput := new(tablestore.ReservedThroughput)
reservedThroughput.Readcap = 0
reservedThroughput.Writecap = 0
createtableRequest.TableMeta = tableMeta
createtableRequest.TableOption = tableOption
createtableRequest.ReservedThroughput = reservedThroughput
response, err = client.CreateTable(createtableRequest)
if (err != nil) {
    fmt.Println("Failed to create table with error:", err)
} else {
    fmt.Println("Create table finished")
}
```

ListTable

You can use the ListTable API to obtain the names of all tables created in the current instance.

API

```
// List all tables. If the operation succeeds, names of all tables are returned.
ListTable() (*ListTableResponse, error)
```

Examples

The following code provides an example of how to obtain the names of all tables in an instance:

```
tables, err := client.ListTable()
if err != nil {
    fmt.Println("Failed to list table")
} else {
    fmt.Println("List table result is")
    for _, table := range (tables.TableNames) {
        fmt.Println("TableName: ", table)
    }
}
```

UpdateTable

You can use the UpdateTable API to update the reserved read/write throughput settings of the specified table.

API

```
// Update TableOptions and ReservedThroughput of a table.
UpdateTable(request *UpdateTableRequest) (*UpdateTableResponse, error)
```

Examples

The following code provides an example of how to set the maximum number of versions for a table to 5:

```
updateTableReq := new(tablestore.UpdateTableRequest)
updateTableReq.TableName = tableName
updateTableReq.TableOption = new(tablestore.TableOption)
updateTableReq.TableOption.TimeToAlive = -1
updateTableReq.TableOption.MaxVersion = 5
_, err := client.UpdateTable(updateTableReq)
if (err != nil) {
    fmt.Println("failed to update table with error:", err)
} else {
    fmt.Println("update finished")
}
```

DescribeTable

You can use the DescribeTable API to query the structure information and the reserved read/write throughput settings of the specified table.

API

```
// Query the description of a table by using the table name.
DescribeTable(request *DescribeTableRequest) (*DescribeTableResponse, error)
```

Examples

```
describeTableReq := new(tablestore.DescribeTableRequest)
describeTableReq.TableName = tableName
```

```

describ, err := client.DescribeTable(describeTableReq)
if err != nil {
    fmt.Println("failed to update table with error:", err)
} else {
    fmt.Println("DescribeTableSample finished. Table meta:", describ.TableOption.
MaxVersion, describ.TableOption.TimeToAlive)
}

```

DeleteTable

You can use the DeleteTable API to delete a specified table from an instance.

API

```
DeleteTable(request DeleteTableRequest) (DeleteTableResponse, error)
```

Examples

The following code provides an example of how to delete a table:

```

deleteReq := new(tablestore.DeleteTableRequest)
deleteReq.TableName = tableName
_, err := client.DeleteTable(deleteReq)
if (err != nil) {
    fmt.Println("Failed to delete table with error:", err)
} else {
    fmt.Println("Delete table finished")
}

```

2.5.2.4.2.5 Single-row operations

The Table Store SDK provides the following APIs for single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can use the PutRow API to insert data into a specified row.

API

```

// @param PutRowRequest  Encapsulate the parameters required to perform the
PutRow operation.
// @return PutRowResponse
PutRow(request *PutRowRequest) (*PutRowResponse, error)

```

Examples

```

putRowRequest := new(tablestore.PutRowRequest)
putRowChange := new(tablestore.PutRowChange)
putRowChange.TableName = tableName
putPk := new(tablestore.PrimaryKey)
putPk.AddPrimaryKeyColumn("pk1", "pk1value1")
putPk.AddPrimaryKeyColumn("pk2", int64(2))
putPk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
putRowChange.PrimaryKey = putPk
putRowChange.AddColumn("col1", "col1data1")
putRowChange.AddColumn("col2", int64(3))

```

```
putRowChange.AddColumn("col3", []byte("test"))
putRowChange.SetCondition(tablestore.RowExistenceExpectation_IGNORE)
putRowRequest.PutRowChange = putRowChange
_, err := client.PutRow(putRowRequest)
if err != nil {
    fmt.Println("putrow failed with error:", err)
} else {
    fmt.Println("putrow finished")
}
```

- RowExistenceExpectation.IGNORE indicates that new data is inserted regardless of whether the specified row exists. If the row exists, the existing data is overwritten.
- RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
- RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.

GetRow

You can use the GetRow API to read a single row of data based on a specified primary key.

API

```
//Return a row of data from a table.
//
// @param GetRowRequest      Encapsulate the parameters required to perform the
GetRow operation.
// @return GetRowResponse    The content of the response to the GetRow operation
.
GetRow(request *GetRowRequest) (*GetRowResponse, error)
```

Examples

The following code provides an example of how to read a row of data:

```
getRowRequest := new(tablestore.GetRowRequest)
criteria := new(tablestore.SingleRowQueryCriteria);
putPk := new(tablestore.PrimaryKey)
putPk.AddPrimaryKeyColumn("pk1", "pk1value1")
putPk.AddPrimaryKeyColumn("pk2", int64(2))
putPk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
criteria.PrimaryKey = putPk
getRowRequest.SingleRowQueryCriteria = criteria
getRowRequest.SingleRowQueryCriteria.TableName = tableName
getRowRequest.SingleRowQueryCriteria.MaxVersion = 1
getResp, err := client.GetRow(getRowRequest)
if err != nil {
    fmt.Println("getrow failed with error:", err)
} else {
    fmt.Println("get row col0 result is ",getResp.Columns[0]. ColumnName, getResp.
Columns[0]. Value,)
```

```
}
```

UpdateRow

You can use the UpdateRow API to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values of the specified columns are added, modified, or deleted based on the request content.

API

```
// Update a row of data in a table.
// @param UpdateRowRequest  Encapsulate the parameters required to perform the
UpdateRow operation.
// @return UpdateRowResponse The content of the response to the UpdateRow
operation.
UpdateRow(request *UpdateRowRequest) (*UpdateRowResponse, error)
```

Examples

The following code provides an example of how to update a row of data:

```
updateRowRequest := new(tablestore.UpdateRowRequest)
updateRowChange := new(tablestore.UpdateRowChange)
updateRowChange.TableName = tableName
updatePk := new(tablestore.PrimaryKey)
updatePk.AddPrimaryKeyColumn("pk1", "pk1value1")
updatePk.AddPrimaryKeyColumn("pk2", int64(2))
updatePk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
updateRowChange.PrimaryKey = updatePk
updateRowChange.DeleteColumn("col1")
updateRowChange.PutColumn("col2", int64(77))
updateRowChange.PutColumn("col4", "newcol3")
updateRowChange.SetCondition(tablestore.RowExistenceExpectation_EXPECT_EXIST)
updateRowRequest.UpdateRowChange = updateRowChange
_, err := client.UpdateRow(updateRowRequest)
if err != nil {
    fmt.Println("update failed with error:", err)
} else {
    fmt.Println("update row finished")
}
```

DeleteRow

API

```
// Delete a row of data from a table.
// @param DeleteRowRequest  Encapsulate the parameters required to perform
the DeleteRow operation.
// @return DeleteRowResponse The content of the response to the DeleteRow
operation.
DeleteRow(request *DeleteRowRequest) (*DeleteRowResponse, error)
```

Examples

The following code provides an example of how to delete a row of data:

```
deleteRowReq := new(tablestore.DeleteRowRequest)
```

```

deleteRowReq.DeleteRowChange = new(tablestore.DeleteRowChange)
deleteRowReq.DeleteRowChange.TableName = tableName
deletePk := new(tablestore.PrimaryKey)
deletePk.AddPrimaryKeyColumn("pk1", "pk1value1")
deletePk.AddPrimaryKeyColumn("pk2", int64(2))
deletePk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
deleteRowReq.DeleteRowChange.PrimaryKey = deletePk
deleteRowReq.DeleteRowChange.SetCondition(tablestore.RowExistenceExpectation_EXPECT_EXIST)
clCondition1 := tablestore.NewSingleColumnCondition("col2", tablestore.CT_EQUAL, int64(3))
deleteRowReq.DeleteRowChange.SetColumnCondition(clCondition1)
_, err := client.DeleteRow(deleteRowReq)
if err != nil {
    fmt.Println("delete failed with error:", err)
} else {
    fmt.Println("delete row finished")
}

```

2.5.2.4.2.6 Multiple-row operations

The Table Store SDK provides the following APIs for multiple-row operations: BatchGetRow, BatchWriteRow, GetRange, and GetByIterator.

BatchGetRow

You can use the BatchGetRow API to simultaneously read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the request response time and increase the data read rate.

API

```

//Return multiple rows of data in a table.
//
// @param BatchGetRowRequest      Encapsulate the parameters required to
perform the BatchGetRow operation.
// @return BatchGetRowResponse    The content of the response to the BatchGetRow
operation.
BatchGetRow(request *BatchGetRowRequest) (*BatchGetRowResponse, error)

```

Examples

The following code provides an example of how to simultaneously read 10 rows of data:

```

batchGetReq := &tablestore.BatchGetRowRequest{}
mqCriteria := &tablestore.MultiRowQueryCriteria{}
for i := 0; i < 10; i++ {
    pkToGet := new(tablestore.PrimaryKey)
    pkToGet.AddPrimaryKeyColumn("pk1", "pk1value1")
    pkToGet.AddPrimaryKeyColumn("pk2", int64(i))
}

```

```

pkToGet.AddPrimaryKeyColumn("pk3", []byte("pk3"))
mqCriteria.AddRow(pkToGet)
mqCriteria.MaxVersion = 1
}
mqCriteria.TableName = tableName
batchGetReq.MultiRowQueryCriteria = append(batchGetReq.MultiRowQueryCriteria,
mqCriteria)
batchGetResponse, err := client.BatchGetRow(batchGetReq)
if err != nil {
    fmt.Println("batchget failed with error:", err)
} else {
    fmt.Println("batchget finished")
}

```

**Note:**

You can use conditional statements to simultaneously read multiple rows of data.

BatchWriteRow

You can use the BatchWriteRow API to simultaneously insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

API

```

// Add, delete, or modify multiple rows of data in multiple tables.
//
// @param BatchWriteRowRequest      Encapsulate the parameters required to
perform the BatchWriteRow operation.
// @return BatchWriteRowResponse    The content of the response to the BatchWrite
Row operation.
BatchWriteRow(request *BatchWriteRowRequest) (*BatchWriteRowResponse,error)

```

Examples

The following code provides an example of how to simultaneously write 100 rows of data:

```

batchWriteReq := &tablestore.BatchWriteRowRequest{}
for i := 0; i < 100; i++ {
    putRowChange := new(tablestore.PutRowChange)
    putRowChange.TableName = tableName
    putPk := new(tablestore.PrimaryKey)
    putPk.AddPrimaryKeyColumn("pk1", "pk1value1")
    putPk.AddPrimaryKeyColumn("pk2", int64(i))
    putPk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
    putRowChange.PrimaryKey = putPk
    putRowChange.AddColumn("col1", "fixvalue")
    putRowChange.SetCondition(tablestore.RowExistenceExpectation_IGNORE)
    batchWriteReq.AddRowChange(putRowChange)
}
response, err := client.BatchWriteRow(batchWriteReq)
if err != nil {
    fmt.Println("batch request failed with:", response)
}

```

```
} else {
    fmt.Println("batch write row finished")
}
```

**Note:**

You can use conditional statements to simultaneously write multiple rows of data.

GetRange

You can use the GetRange API to read data within the specified primary key range.

API

```
// Read multiple rows of data within the specified range in a table.
//
// @param GetRangeRequest      Encapsulate the parameters required to perform
the GetRange operation.
// @return GetRangeResponse    The content of the response to the GetRange
operation.
GetRange(request *GetRangeRequest) (*GetRangeResponse,error)
```

Examples

The following code provides an example of how to read data within the specified range:

```
getRangeRequest := &tablestore.GetRangeRequest{
    rangeRowQueryCriteria := &tablestore.RangeRowQueryCriteria{
        rangeRowQueryCriteria.TableName = tableName
        startPK := new(tablestore.PrimaryKey)
        startPK.AddPrimaryKeyColumnWithMinValue("pk1")
        startPK.AddPrimaryKeyColumnWithMinValue("pk2")
        startPK.AddPrimaryKeyColumnWithMinValue("pk3")
        endPK := new(tablestore.PrimaryKey)
        endPK.AddPrimaryKeyColumnWithMaxValue("pk1")
        endPK.AddPrimaryKeyColumnWithMaxValue("pk2")
        endPK.AddPrimaryKeyColumnWithMaxValue("pk3")
        rangeRowQueryCriteria.StartPrimaryKey = startPK
        rangeRowQueryCriteria.EndPrimaryKey = endPK
        rangeRowQueryCriteria.Direction = tablestore.FORWARD
        rangeRowQueryCriteria.MaxVersion = 1
        rangeRowQueryCriteria.Limit = 10
    }
    getRangeRequest.RangeRowQueryCriteria = rangeRowQueryCriteria
    getRangeResp, err := client.GetRange(getRangeRequest)
    fmt.Println("get range result is ", getRangeResp)
    for ; ; {
        if err != nil {
            fmt.Println("get range failed with error:", err)
        }
        if (len(getRangeResp.Rows) > 0) {
            for _, row := range getRangeResp.Rows {
                fmt.Println("range get row with key", row.PrimaryKey.PrimaryKeys[0].Value, row.
                PrimaryKey.PrimaryKeys[1].Value, row.PrimaryKey.PrimaryKeys[2].Value)
            }
            if getRangeResp.NextStartPrimaryKey == nil {
                break
            } else {

```

```

        fmt.Println("next pk is :", getRangeResp.NextStartPrimaryKey.PrimaryKeys[
0]. Value, getRangeResp.NextStartPrimaryKey.PrimaryKeys[1]. Value, getRangeResp.
NextStartPrimaryKey.PrimaryKeys[2]. Value)
        getRangeRequest.RangeRowQueryCriteria.StartPrimaryKey = getRangeResp.
NextStartPrimaryKey
        getRangeResp, err = client.GetRange(getRangeRequest)
    }
    } else {
        break
    }
    }
    fmt.Println("continue to query rows")
}
fmt.Println("putrow finished")

```

**Note:**

- You can use conditional statements to read data within the specified range.
- Note that the data may be read in pages when you perform the GetRange operation.

2.5.2.5 NodeJS SDK

2.5.2.5.1 Quick start

The NodeJS SDK allows you to access Table Store without performing complex programming operations. This topic describes how to obtain and use the NodeJS SDK.

Environment preparation

- You must have a RAM user and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the NodeJS SDK. For more information about how to obtain and view your AccessKey pair in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- The NodeJS SDK is applicable to Node.js V4.0 and later.

Install the NodeJS SDK

npm

The command to install the NodeJS SDK is as follows:

```
npm install tablestore
```

**Note:**

If you encounter any network problems when using npm, you can use cnpm, which is the npm image provided by Taobao.

Use the NodeJS SDK

To call the NodeJS SDK, perform the following steps:

1. Create and initialize an instance.

2. Create an API request and set its parameters.
3. Initiate the request and handle its response or exception.

2.5.2.5.2 Use the SDK

2.5.2.5.2.1 Preface

Overview

This document describes how to install and use the NodeJS SDK that is applicable to Node.js V4.0 and later. Perform the following operations to obtain the AccessKey ID and AccessKey Secret: Log on to Apsara Stack Management Console. In the upper-right corner of the webpage, click the inverted triangle icon and select **Personal Information** from the drop-down list.

Download the SDK

- [SDK](#)
- [GitHub](#)

Version

Latest version: 4.0.0

2.5.2.5.2.2 Installation

Prerequisites

Applicable to Node.js V4.0 and later.

Installation methods

npm

The command to install the NodeJS SDK is as follows:

```
npm install tablestore
```

**Note:**

If you encounter any network problems when using npm, you can use cnpm, which is the npm image provided by Taobao.

Sample programs

The Table Store NodeJS SDK provides a diverse collection of sample programs. You can use either of the following methods to locate the sample programs:

- Download and decompress the Table Store NodeJS SDK package, and find the sample programs in the examples folder.
- Access the GitHub project for Table Store NodeJS SDK.

2.5.2.5.2.3 Initialization

TableStore.Client is the client for Table Store. It provides callers with a series of methods to perform operations on tables, a single row, or multiple rows.

Determine an endpoint

An endpoint is the domain name for the Table Store service in each region. It can be in the formats listed in the following table.

Table 2-316: Endpoint types

Endpoint type	Description
Region address	The address of the region where a Table Store instance is located, such as <code>https://instance.region.ots.example.com</code> .

To query the endpoint where your Table Store instance is located, perform the following steps:

1. Log on to the Table Store console.
2. Click the instance name to go to the **Instance Details** page.

Locate **Access URL**. You can view the endpoint of the instance.

Configure an AccessKey pair

To access Apsara Stack Table Store, you must have a valid AccessKey pair (AccessKey ID and AccessKey Secret) for signature authentication.

After you obtain the AccessKey ID and AccessKey Secret, you must initialize a Table Store client instance.

Use the endpoint of Table Store to create a client:

```
var client = new TableStore.Client({
  accessKeyId: '<your access key id>',
  secretAccessKey: '<your access key secret>',
  endpoint: '<your endpoint>',
  instancename: '<your instance name>',
  maxRetries:20, //The default number of retry attempts is 20. You can ignore this parameter.
```

```
});
```

2.5.2.5.2.4 Table-level operations

The Table Store SDK provides the following APIs for table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DeleteTable.

CreateTable

You can use the CreateTable API to create a table based on the specified table structure information.

When creating a table in Table Store, you must specify the primary keys of the table. A primary key contains one to four primary key columns. Each primary key column has a name and a type.

API

```
/**
 * Create a table based on the specified table structure information.
 */
createTable(params, callback)
```

Note:

After a table is created in Table Store, it takes several seconds to load the table. We recommend that you do not perform any operations during this period.

Examples

The following code provides an example of how to create a table with two primary key columns and a reserved read/write throughput of (0,0):

```
var client = require('./client');
var params = {
  tableMeta: {
    tableName: 'sampleTable',
    primaryKey: [
      {
        name: 'gid',
        type: 'INTEGER'
      },
      {
        name: 'uid',
        type: 'INTEGER'
      }
    ]
  },
  reservedThroughput: {
    capacityUnit: {
      read: 0,
      write: 0
    }
  }
},
```

```

tableOptions: {
  timeToLive: -1, // The data validity period in seconds. -1 indicates that the data does
not expire. To set the validity period to one year, set timeToLive to 365 x 24 x 3600.
  maxVersions: 1 // The maximum number of versions retained for each attribute column
. If it is set to 1, only the latest version is retained for each column.
}
};
client.createTable(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});

```

ListTable

You can use the ListTable API to obtain the names of all tables created in the current instance.

API

```

/**
 * Obtain the names of all tables created in the current instance.
 */
listTable(params, callback)

```

Examples

The following code provides an example of how to obtain the names of all tables in an instance:

```

var client = require('./client');
client.listTable({}, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});

```

UpdateTable

You can use the UpdateTable API to update the maximum number of versions and the reserved read/write throughput settings of the specified table.

API

```

/**
 * Update the reserved read/write throughput settings of the specified table.
 */
updateTable(params, callback)

```

Examples

The following code provides an example of how to set the maximum number of versions for a table to 5:

```
var client = require('./client');
var params = {
  tableName: 'sampleTable',
  tableOptions: {
    maxVersions: 5,
  }
};
client.updateTable(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

DescribeTable

You can use the DescribeTable API to query the structure information and the reserved read /write throughput settings of the specified table.

API

```
/**
 * Query the structure information and the reserved read/write throughput settings of
 * the specified table.
 */
describeTable(params, callback)
```

Examples

```
var client = require('./client');
var params = {
  tableName: 'sampleTable'
};
client.describeTable(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

DeleteTable

You can use the DeleteTable API to delete a specified table from an instance.

API

```
/**
 * Delete the specified table from an instance.
 */
```

```
deleteTable(params, callback)
```

Examples

The following code provides an example of how to delete a table:

```
var client = require('./client');
var params = {
  tableName: 'sampleTable'
};
client.deleteTable(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

2.5.2.5.2.5 Long type

Data types

Table Store supports five data types. The following table describes the relationship between Table Store data types and NodeJS SDK data types.

Table 2-317: Data types

Data type	NodeJS SDK	Description
String	string	The basic data type in JavaScript.
Integer	int64	The type of data encapsulated by NodeJS SDK.
Double	number	The basic data type in JavaScript.
Boolean	boolean	The basic data type in JavaScript.
Binary	Buffer	The buffer object of NodeJS.

int64 type

The integer data in Table Store is a 64-bit signed integer, which does not have a corresponding data type in JavaScript. Therefore, a data type that can represent a 64-bit signed integer is required for NodeJS.

You can perform the following conversions:

```
var numberA = TableStore.Long.fromNumber(1000);
var numberB = TableStore.Long.fromString('2000');
```

```
var num = numberA.toNumber();
num = numberA.toString();
var str = numberB.toNumber();
str = numberB.toString();
```

2.5.2.5.2.6 Multiple-row operations

The Table Store SDK provides the following APIs for multiple-row operations: BatchGetRow, BatchWriteRow, GetRange, and GetByIterator.

BatchGetRow

You can use the BatchGetRow API to simultaneously read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the request response time and increase the data read rate.

API

```
/**
 * Simultaneously read several rows of data from one or more tables.
 */
batchGetRow(params, callback)
```

Examples

The following code provides an example of how to simultaneously read multiple tables and multiple rows of data, and retry the operation if an error occurs in a single row:

```
var client = require('./client');
var TableStore = require('../index.js');
var Long = TableStore.Long;
var params = {
  tables: [{
    tableName: 'sampleTable',
    primaryKey: [
      [{ 'gid': Long.fromNumber(20013) }, { 'uid': Long.fromNumber(20013) }],
      [{ 'gid': Long.fromNumber(20015) }, { 'uid': Long.fromNumber(20015) }],
    ],
    startColumn: "col2",
    endColumn: "col4"
  },
  {
    tableName: 'notExistTable',
    primaryKey: [
      [{ 'gid': Long.fromNumber(10001) }, { 'uid': Long.fromNumber(10001) }],
    ]
  }
],
};
```

```

var maxRetryTimes = 3;
var retryCount = 0;
function batchGetRow(params) {
  client.batchGetRow(params, function (err, data) {
    if (err) {
      console.log('error:', err);
      return;
    }
    var isSuccess = true;
    var retryRequest = { tables: [] };
    for (var i = 0; i < data.tables.length; i++) {
      var faildRequest = { tableName: data.tables[i][0].tableName, primaryKey: [] };
      for (var j = 0; j < data.tables[i].length; j++) {
        if (! data.tables[i][j].isOk && null != data.tables[i][j].primaryKey) {
          isSuccess = false;
          var pks = [];
          for (var k in data.tables[i][j].primaryKey) {
            var name = data.tables[i][j].primaryKey[k].name;
            var value = data.tables[i][j].primaryKey[k].value;
            var kp = {};
            kp[name] = value;
            pks.push(kp);
          }
          faildRequest.primaryKey.push(pks);
        } else {
          // get success data
        }
      }
      if (faildRequest.primaryKey.length > 0) {
        retryRequest.tables.push(faildRequest);
      }
    }
    if (! isSuccess && retryCount++ < maxRetryTimes) {
      batchGetRow(retryRequest);
    }
    console.log('success:', data);
  });
}
batchGetRow(params, maxRetryTimes);

```

**Note:**

You can use conditional statements to simultaneously read multiple rows of data.

BatchWriteRow

You can use the BatchWriteRow API to simultaneously insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

API

```

/**
 * Simultaneously modify multiple rows of data.
 */

```

```
batchWriteRow(params, callback)
```

Examples

The following code provides an example of how to simultaneously write multiple rows of data:

```
var client = require('./client');
var TableStore = require('../index.js');
var Long = TableStore.Long;
var params = {
  tables: [{
    tableName: 'sampleTable',
    rows: [{
      type: 'PUT',
      condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE
, null),
      primaryKey: [{ 'gid': Long.fromNumber(8) }, { 'uid': Long.fromNumber(80) }],
      attributeColumns: [{ 'attrCol1': 'test1' }, { 'attrCol2': 'test2' }],
      returnContent: { returnType: TableStore.ReturnType.Primarykey }
    }],
  }],
};
client.batchWriteRow(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

Note:

You can use conditional statements to simultaneously write multiple rows of data.

GetRange

You can use the GetRange API to read data within the specified primary key range.

API

```
/**
 * Read data within the specified primary key range.
 */
getRange(params, callback)
```

Examples

The following code provides an example of how to read data within the specified range:

```
var Long = TableStore.Long;
var client = require('./client');
var params = {
  tableName: "sampleTable",
  direction: TableStore.Direction.FORWARD,
  inclusiveStartPrimaryKey: [{ "gid": TableStore.INF_MIN }, { "uid": TableStore.INF_MIN }],
  exclusiveEndPrimaryKey: [{ "gid": TableStore.INF_MAX }, { "uid": TableStore.INF_MAX }],
```

```

    limit: 50
  };
  client.getRange(params, function (err, data) {
    if (err) {
      console.log('error:', err);
      return;
    }
    //If the value of data.next_start_primary_key is not null, continue the read operation.
    if (data.next_start_primary_key) {
    }
    console.log('success:', data);
  });

```

**Note:**

- You can use conditional statements to read data within the specified range.
- Note that the data may be read in pages when you perform the GetRange operation.

2.5.2.5.2.7 Single-row operations

The Table Store SDK provides the following APIs for single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can use the PutRow API to insert data into a specified row.

API

```

/**
 * Insert data into a specified row. If the row does not exist, a new row is added. If the
 * row exists, the existing data is overwritten.
 */
putRow(params, callback)

```

Examples

```

var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var currentTimeStamp = Date.now();
var params = {
  tableName: "sampleTable",
  condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE, null
),
  primaryKey: [{ 'gid': Long.fromNumber(20013) }, { 'uid': Long.fromNumber(20013) }],
  attributeColumns: [
    { 'col1': 'Table Store' },
    { 'col2': '2', 'timestamp': currentTimeStamp },
    { 'col3': 3.1 },
    { 'col4': -0.32 },
    { 'col5': Long.fromNumber(123456789) }
  ],
  returnContent: { returnType: TableStore.ReturnType.PrimaryKey }
};
client.putRow(params, function (err, data) {
  if (err) {

```

```

    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});

```

- RowExistenceExpectation.IGNORE indicates that new data is inserted regardless of whether the specified row exists. If the row exists, the existing data is overwritten.
- RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
- RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.

GetRow

You can use the GetRow API to read a single row of data based on a specified primary key.

API

```

/**
 * Read a single row of data based on a specified primary key.
 */
getRow(params, callback)

```

Examples

The following code provides an example of how to read a row of data:

```

var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var params = {
  tableName: "sampleTable",
  primaryKey: [{ 'gid': Long.fromNumber(20004) }, { 'uid': Long.fromNumber(20004) }],
  maxVersions: 2
};
var condition = new TableStore.CompositeCondition(TableStore.LogicalOperator.AND);
condition.addSubCondition(new TableStore.SingleColumnCondition('name', 'john',
TableStore.ComparatorType.EQUAL));
condition.addSubCondition(new TableStore.SingleColumnCondition('addr', 'china',
TableStore.ComparatorType.EQUAL));
params.columnFilter = condition;
client.getRow(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});

```

```
});
```

UpdateRow

You can use the UpdateRow API to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values of the specified columns are added, modified, or deleted based on the request content.

API

```
/**
 * Update the data of the specified row. If the row does not exist, a new row is added. If
 the row exists, the values of the specified columns are added, modified, or deleted based
 on the request content.
 */
updateRow(params, callback)
```

Examples

The following code provides an example of how to update a row of data:

```
var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var params = {
  tableName: "sampleTable",
  condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE, null
),
  primaryKey: [{ 'gid': Long.fromNumber(9) }, { 'uid': Long.fromNumber(90) }],
  updateOfAttributeColumns: [
    { 'PUT': [{ 'col4': Long.fromNumber(4) }, { 'col5': '5' }, { 'col6': Long.fromNumber(6) } ] },
    { 'DELETE': [{ 'col1': Long.fromNumber(1496826473186) } ] },
    { 'DELETE_ALL': ['col2'] }
  ]
};
client.updateRow(params,
  function (err, data) {
    if (err) {
      console.log('error:', err);
      return;
    }
    console.log('success:', data);
  });
```

DeleteRow

API

```
/**
 * Delete a row of data.
 */
deleteRow(params, callback)
```

Examples

The following code provides an example of how to delete a row of data:

```
var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var params = {
  tableName: "sampleTable",
  condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE, null
),
  primaryKey: [{ 'gid': Long.fromNumber(8) }, { 'uid': Long.fromNumber(80) }]
};
client.deleteRow(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

2.5.2.5.2.8 Error handling

Method

The Table Store NodeJS SDK uses the **Exception** method to handle errors. If the operation succeeds, the called API does not throw an exception. If the operation fails, an exception is thrown.

Note:

Batch operation APIs such as BatchGetRow and BatchWriteRow are called only when the status check of each row is successful.

Exception

In the Table Store NodeJS SDK, all errors are handled in a unified manner, and are returned to the err parameter of the callback method. Therefore, you must check whether the err parameter has a value before obtaining the returned data. If an error is reported on the Table Store server, the request ID is returned, specifying the UUID that uniquely identifies the request. If a problem persists, submit the request ID to Table Store technical support personnel to obtain help.

Retry

The system automatically retries an operation when an error occurs in the SDK. The default policy sets the maximum retry attempts to 20, and a maximum retry interval of 3,000 ms. For more information about how the system retries the operation on throttling errors and read-related internal server errors, see `tablestore/lib/retry.js`.

2.5.2.6 .NET SDK

2.5.2.6.1 Quick start

The .NET SDK allows you to access Table Store without performing complex programming operations. This topic describes how to obtain and use the .NET SDK.

Environment preparation

- You must have a RAM user and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the .NET SDK. For more information about how to obtain and view your AccessKey pair in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- The .NET SDK is applicable to .NET Framework 4.0 and later.

Install the .NET SDK

To call the SDK of a service, you must install the SDK core library and the SDK of the service. For example, to call the Table Store SDK, you need to obtain and install the SDK core library and the SDK of Table Store. Use either of the following methods to install the .NET SDK:

- Add DLL references
 1. Download the [SDK installation package](#). The Aliyun.TableStore.dll file is in the bin directory.
 2. In Visual Studio, go to **Solution Explorer** and locate your project. Right-click the project name and choose **Reference > Add Reference** from the shortcut menu.
 3. In the Add Reference dialog box that appears, click **Browse**, and find the directory that contains the SDK package.
 4. Select the Aliyun.TableStore.dll file in the bin directory and click **OK**.
- Add a project reference
 1. If you want to use the source code to install the SDK package downloaded from GitHub, right-click **Solution** and choose **Add > Existing Project** from the shortcut menu.
 2. In the dialog box that appears, select the aliyun-tablestore-sdk.csproj file, and click **Open**.
 3. Right-click **Your Project**, and choose **Reference > Add Reference** from the shortcut menu. In the dialog box that appears, select the **Project** tab, click the aliyun-tablestore-sdk project, and click **OK**.

Use the .NET SDK

To call the .NET SDK, perform the following steps:

1. Create and initialize an instance.
2. Create an API request and set its parameters.
3. Initiate the request and handle its response or exception.

2.5.2.6.2 Use the SDK

2.5.2.6.2.1 Preface

Overview

This document describes how to install and use C# SDK V3.0.0 for Table Store. This document assumes that you have activated Table Store, and you have created an AccessKey pair (AccessKey ID and AccessKey Secret). Perform the following operations to obtain the AccessKey ID and AccessKey Secret: Log on to Apsara Stack Management Console. In the upper-right corner of the webpage, click the inverted triangle icon and select **Personal Information** from the drop-down list.

Download the SDK

- [SDK package](#)
- [GitHub](#)

Compatibility

For SDKs V2.x.x:

- A few APIs are incompatible. The following APIs are deleted: `Condition.IGNORE`, `Condition.EXPECT_EXIST`, and `Condition.EXPECT_NOT_EXIST`.
- The DLL file name `Aliyun.dll` is changed to `Aliyun.TableStore.dll`.

Version

Latest version: 3.0.0

Change description

- Filters are added.
- The warnings generated during the compilation process are cleared.
- The unnecessary dependent packages are cleared.
- The unnecessary code is cleared.
- The code for template invocation is simplified.
- The check for invalid parameters is added.
- The user-configured parameters are trimmed.

- The UserAgent header is added.
- The DLL file name Aliyun.dll is changed to Aliyun.TableStore.dll.
- The open-source code is released to GitHub.

2.5.2.6.2.2 Installation

Version dependency

Windows

- Applicable to .NET 4.0 and later.
- Applicable to Visual Studio 2010 and later.

Install the .NET SDK through DLL references

1. Download and decompress the [SDK installation package](#). The Aliyun.TableStore.dll file is in the bin directory.
2. In Visual Studio, go to **Solution Explorer** and locate your project. Right-click the project name and choose **Reference > Add Reference** from the shortcut menu.
3. Click **Browse** in the Add Reference dialog box and find the SDK folder.
4. Select the Aliyun.TableStore.dll file in the bin directory and click **OK**.

Install the .NET SDK by introducing a project

1. If you want to install the SDK package (downloaded from GitHub) by using the source code, right-click **Solution** and choose **Add > Existing Project** from the shortcut menu.
2. Click **Browse** in the dialog box that appears, select the aliyun-tablestore-sdk.csproj file, and click **Open**.
3. Right-click **Your Project** and choose **Reference > Add Reference** from the shortcut menu. In the Add Reference dialog box that appears, click the **Project** tab, select the aliyuntablestore-sdk project, and click **OK**.

2.5.2.6.2.3 Initialization

TableStoreClient is the client for Table Store. It provides callers with a series of methods to perform operations on tables, a single row, or multiple rows.

Determine an endpoint

An endpoint is the domain name for the Table Store service in each region. It can be in the formats listed in the following table.

Endpoint type	Description
Region address	The address of the region where a Table Store instance is located, such as <code>https://instance.regionid.ots.example.com</code> .

Region address of Table Store

To query the endpoint where your Table Store instance is located, perform the following steps:

1. Log on to the Table Store console.
2. Go to the Instance Details page and locate the instance URL, which is the endpoint of the instance.

Configure an AccessKey pair

To access Apsara Stack Table Store, you must have a valid AccessKey pair (AccessKey ID and AccessKey Secret) for signature authentication.

After you obtain the AccessKey ID and AccessKey Secret, you must initialize a Table Store client instance.

Use the endpoint of Table Store to create a client as follows:

API

```

/// <summary>
/// OTSClient constructor.
/// </summary>
/// <param name="endPoint">Endpoint of the Table Store service (such as https://
instance.regionid.ots.example.com:80). It must start with https://. </param>
/// <param name="accessKeyId">AccessKey ID of Table Store. It must be applied for on
the Alibaba Cloud website. </param>
/// <param name="accessKeySecret">AccessKey Secret of Table Store. It must be applied
for on the Alibaba Cloud website. </param>
/// <param name="instanceName">Name of your Table Store instance. It is created in
the Table Store console. </param>
public OTSClient(string endPoint, string accessKeyId, string accessKeySecret, string
instanceName);
/// <summary>
/// Create an OTSClient instance through the OTSClientConfig instance.
/// </summary>
/// <param name="config">OTSClientConfig instance</param>
public OTSClient(OTSClientConfig config);

```

Examples

```

// Construct an OTSClientConfig object.
var config = new OTSClientConfig(Endpoint, AccessKeyId, AccessKeySecret, InstanceName);
// Disable log output. (This function is enabled by default.)
config.OTSDebugLogHandler = null;
config.OTSErrorLogHandler = null;

```

```
// Create an OTSClient object through OTSClientConfig.
var otsClient = new OTSClient(config);
// Use OTSClient to insert or query data.
```

**Note:**

- You can set the ConnectionLimit parameter in the OTSClientConfig object. The default value of ConnectionLimit is 300.
- Logging behavior is customizable and is controlled by OTSDebugLogHandler and OTSErrorLogHandler in OTSClientConfig.
- The retry logic is customizable and is controlled by RetryPolicy in OTSClientConfig. A default retry policy is provided.

Multithreading

- Multithreading is supported.
- We recommend that you use the same OTSClient object to perform multithreading tasks.

2.5.2.6.2.4 Table-level operations

The Table Store SDK provides the following APIs for table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can use the CreateTable API to create a table based on the specified table structure information.

When creating a table in Table Store, you must specify the primary keys of the table. A primary key contains one to four primary key columns. Each primary key column has a name and a type.

API

```
/// <summary>
/// Create a table based on table information (including the table name, primary key
schema, and reserved read/write throughput).
/// </summary>
/// <param name="request">Request parameter</param>
/// <returns>Information returned by CreateTable. The result is null.
/// </returns>
public CreateTableResponse CreateTable(CreateTableRequest request);
/// <summary>
/// Asynchronous mode of CreateTable.
/// </summary>
public Task<CreateTableResponse> CreateTableAsync(CreateTableRequest request);
```

**Note:**

After you create a table in Table Store, it takes several seconds to fully load the table. We recommend that you do not perform any operations during this period.

Examples

The following code provides an example of how to create a table with two primary key columns and a reserved read/write throughput of (0,0).

```
//Create a schema for the primary key columns, which includes the quantity, names,
//and types of primary keys.
//The first primary key column (partition column) is named pk0 and requires an
//integer value.
//The second primary key column is named pk1 and requires a string value.
var primaryKeySchema = new PrimaryKeySchema();
primaryKeySchema.Add("pk0", ColumnValueType.Integer);
primaryKeySchema.Add("pk1", ColumnValueType.String);
//Create a tableMeta class based on the table name and primary key columns.
var tableMeta = new TableMeta("SampleTable", primaryKeySchema);
// Set the reserved read throughput and reserved write throughput both to 0.
var reservedThroughput = new CapacityUnit(0, 0);
try
{
    // Construct the CreateTableRequest object.
    var request = new CreateTableRequest(tableMeta, reservedThroughput);
    // Call the CreateTable API of the client. If the table is created, no exception is
    // thrown. If the table fails to be created, an exception is thrown.
    otsClient.CreateTable(request);
    Console.WriteLine("Create table succeeded.");
}
// Handle exceptions.
catch (Exception ex)
{
    Console.WriteLine("Create table failed, exception:{0}", ex.Message);
}
```

Note:

To view the detailed code, see [CreateTable@GitHub](#).

ListTable

You can use the ListTable API to obtain the names of all tables created in the current instance.

API

```
/// <summary>
/// Obtain the names of all tables created in the current instance.
/// </summary>
/// <param name="request">Request parameter</param>
/// <returns>Information returned by ListTable that contains the table name list.</
returns> </returns>
public ListTableResponse ListTable(ListTableRequest request);
/// <summary>
/// Asynchronous mode of ListTable.
/// </summary>
```

```
public Task<ListTableResponse> ListTableAsync(ListTableRequest request);
```

Examples

The following code provides an example of how to obtain the names of all tables in an instance:

```
var request = new ListTableRequest();
try
{
    var response = otsClient.ListTable(request);
    foreach (var tableName in response.TableNames)
    {
        Console.WriteLine("Table name:{0}", tableName);
    }
    Console.WriteLine("List table succeeded.");
}
catch (Exception ex)
{
    Console.WriteLine("List table failed, exception:{0}", ex.Message);
}
```

UpdateTable

You can use the UpdateTable API to update the reserved read/write throughput settings of a specified table.

API

```
/// <summary>
/// Update the reserved read/write throughput settings of the specified table. New
settings take effect within one minute of a successful update.
/// </summary>
/// <param name="request">Request parameter, including the table name and
reserved read/write throughput.</param>
/// <returns>Contains information such as the updated reserved read/write
throughput.</returns>
public UpdateTableResponse UpdateTable(UpdateTableRequest request);
/// <summary>
/// Asynchronous mode of UpdateTable.
/// </summary>
public Task<UpdateTableResponse> UpdateTableAsync(UpdateTableRequest request
);
```

Examples

The following code provides an example of how to update the read CU to 1 and the write CU of a table to 2:

```
// Update the reserved read throughput to 1 and the reserved write throughput to 2.
var reservedThroughput = new CapacityUnit(1, 2);
// Construct the UpdateTableRequest object.
var request = new UpdateTableRequest("SampleTable", reservedThroughput);
try
{
    // Call the API to update the reserved read/write throughput of the table.
    otsClient.UpdateTable(request);
}
```

```
// If task execution succeeds, no exception is thrown.
Console.WriteLine("Update table succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Update table failed, exception:{0}", ex.Message);
}
```

**Note:**

To view the detailed code, see [UpdateTable@GitHub](#).

DescribeTable

You can use the DescribeTable API to query the structure information and reserved read/write throughput settings of a specified table.

API

```
/// <summary>
/// Query the structure information and reserved read/write throughput settings of
the specified table.
/// </summary>
/// <param name="request">Request parameter, including the table name.</param>
/// <returns>Contains the structure information and reserved read/write throughput
settings of the specified table.</returns> </returns>
public DescribeTableResponse DescribeTable(DescribeTableRequest request);
/// <summary>
/// Asynchronous mode of DescribeTable.
/// </summary>
public Task<DescribeTableResponse> DescribeTableAsync(DescribeTableRequest
request);
```

Examples

The following code provides an example of how to obtain the descriptive information of a table:

```
try
{
    var request = new DescribeTableRequest("SampleTable");
    var response = otsClient.DescribeTable(request);
    // Display the descriptive information of the specified table.
    Console.WriteLine("Describe table succeeded.");
    Console.WriteLine("LastIncreaseTime: {0}", response.ReservedThroughputDetails.
LastIncreaseTime);
    Console.WriteLine("LastDecreaseTime: {0}", response.ReservedThroughputDetails.
LastDecreaseTime);
    Console.WriteLine("NumberOfDecreaseToday: {0}", response.ReservedTh
roughputDetails.LastIncreaseTime);
    Console.WriteLine("ReadCapacity: {0}", response.ReservedThroughputDetails.
CapacityUnit.Read);
    Console.WriteLine("WriteCapacity: {0}", response.ReservedThroughputDetails.
CapacityUnit.Write);
}
catch (Exception ex)
{
}
```

```
// If task execution fails, an exception is thrown and an error message is displayed.
Console.WriteLine("Describe table failed, exception:{0}", ex.Message);
}
```

**Note:**

To view the detailed code, see [DescribeTable@GitHub](#).

DeleteTable

You can use the DeleteTable API to delete a specified table from an instance.

API

```
/// <summary>
/// Delete the table with the specified table name.
/// </summary>
/// <param name="request">Request parameter, including the table name.</param>
/// <returns>Information returned by DeleteTable. The result is null.
/// </returns>
public DeleteTableResponse DeleteTable(DeleteTableRequest request);
/// <summary>
/// Asynchronous mode of DeleteTable.
/// </summary>
public Task<DeleteTableResponse> DeleteTableAsync(DeleteTableRequest request);
```

Examples

The following code provides an example of how to delete a table:

```
var request = new DeleteTableRequest("SampleTable");
try
{
    otsClient.DeleteTable(request);
    Console.WriteLine("Delete table succeeded.");
}
catch (Exception ex)
{
    Console.WriteLine("Delete table failed, exception:{0}", ex.Message);
}
```

**Note:**

To view the detailed code, see [DeleteTable@GitHub](#).

2.5.2.6.2.5 Single-row operations

The Table Store SDK provides the following APIs for single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can use the PutRow API to insert data into a specified row.

API

```

/// <summary>
/// Write a row of data based on the specified table name, primary keys, and
attributes. The number of CUs consumed by the operation is returned.
/// </summary>
/// <param name="request">Data insertion request</param>
/// <returns>The number of CUs consumed by the operation</returns>
public PutRowResponse PutRow(PutRowRequest request);
/// <summary>
/// Asynchronous mode of PutRow.
/// </summary>
public Task<PutRowResponse> PutRowAsync(PutRowRequest request);

```

Example 1

The following code provides an example of how to insert a row of data:

```

// Define the primary keys of the row. These primary keys must be consistent with the
primary keys defined in TableMeta during table creation.
var primaryKey = new PrimaryKey();
primaryKey.Add("pk0", new ColumnValue(0));
primaryKey.Add("pk1", new ColumnValue("abc"));
// Define the attribute columns of the row.
var attribute = new AttributeColumns();
attribute.Add("col0", new ColumnValue(0));
attribute.Add("col1", new ColumnValue("a"));
attribute.Add("col2", new ColumnValue(true));
try
{
    // Construct the request object for data insertion. RowExistenceExpectation.
    IGNORE indicates that data is inserted regardless of whether the specified row exists.
    var request = new PutRowRequest("SampleTable", new Condition(RowExistence
ceExpectation.IGNORE),
        primaryKey, attribute);
    // Call the PutRow API to insert data.
    otsClient.PutRow(request);
    // If task execution succeeds, no exception is thrown.
    Console.WriteLine("Put row succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Put row failed, exception:{0}", ex.Message);
}

```

**Note:**

- Condition.IGNORE, Condition.EXPECT_EXIST, and Condition.EXPECT_NOT_EXIST are deprecated in V3.0.0 and later. Use new Condition (RowExistenceExpectation.IGNORE), new Condition (RowExistenceExpectation.EXPECT_EXIST), and new Condition (RowExistenceExpectation.EXPECT_NOT_EXIST) instead.
- RowExistenceExpectation.IGNORE indicates that new data is inserted regardless of whether the specified row exists. If the row exists, the existing data is overwritten.

- RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
- RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.
- In addition to row conditions, the Condition parameter also supports column conditions in V2.2.0 and later.
- To view the detailed code, see [PutRow@GitHub](#).

Example 2

The following code provides an example of how to insert a row of data based on specified conditions.

Assume that data is inserted only when a specified row exists and the value of col1 is greater than 24.

```
// Define the primary keys of the row. These primary keys must be consistent with the
// primary keys defined in TableMeta during table creation.
var primaryKey = new PrimaryKey();
primaryKey.Add("pk0", new ColumnValue(0));
primaryKey.Add("pk1", new ColumnValue("abc"));
// Define the attribute columns of the row.
AttributeColumns attribute = new AttributeColumns();
attribute.Add("col0", new ColumnValue(0));
attribute.Add("col1", new ColumnValue("a"));
attribute.Add("col2", new ColumnValue(true));
var request = new PutRowRequest(tableName, new Condition(RowExistenceExpectation.EXPECT_EXIST),
    primaryKey, attribute);
// When the value of col0 is greater than 24, rerun PutRow to overwrite the existing
// value.
try
{
    request.Condition.ColumnCondition = new RelationalCondition("col0",
        RelationalCondition.CompareOperator.GREATER_THAN,
        new ColumnValue(24));
    otsClient.PutRow(request);
    Console.WriteLine("Put row succeeded.");
}
catch (Exception ex)
{
    Console.WriteLine("Put row failed. error:{0}", ex.Message);
}
```

Note:

- You can set a single condition or a combination of conditions. For example, you can set two conditions for data insertion such as col1 > 5 and pk2 < 'xyz'.
- Attribute columns and primary key columns can be used to set conditions.

- When the column specified in a condition does not exist in a row, `PassIfMissing` in `RelationCondition` determines the next action. The default value is `true`.
- To view the detailed code, see [ConditionPutRow@GitHub](#).

Example 3

The following code provides an example of how to asynchronously insert a row of data:

```
try
{
    var putRowTaskList = new List<Task<PutRowResponse>>();
    for (int i = 0; i < 100; i++)
    {
        // Define the primary keys of the row. These primary keys must be consistent
        with the primary keys defined in TableMeta during table creation.
        var primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(i));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        // Define the attribute columns of the row.
        var attribute = new AttributeColumns();
        attribute.Add("col0", new ColumnValue(i));
        attribute.Add("col1", new ColumnValue("a"));
        attribute.Add("col2", new ColumnValue(true));
        var request = new PutRowRequest(TableName, new Condition(RowExistenceExpectation.IGNORE),
            primaryKey, attribute);
        putRowTaskList.Add(TabeStoreClient.PutRowAsync(request));
    }
    // Wait until each asynchronous invocation returns results and displays the
    consumed CUs.
    foreach (var task in putRowTaskList)
    {
        task.Wait();
        Console.WriteLine("consumed read:{0}, write:{1}", task.Result.ConsumedCapacityUnit.Read,
            task.Result.ConsumedCapacityUnit.Write);
    }
    // Data is inserted if no exception is thrown.
    Console.WriteLine("Put row async succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Put row async failed. exception:{0}", ex.Message);
}
```

Note:

- Each asynchronous invocation starts a thread. A timeout error may occur if too many asynchronous invocations are started consecutively and each invocation consumes an extended period of time.
- To view the detailed code, see [PutRowAsync@GitHub](#).

GetRow

You can use the GetRow API to read a single row of data based on a specified primary key.

API

```

/// <summary>
/// Read a single row of data based on a specified primary key.
/// </summary>
/// <param name="request">Data query request</param>
/// <returns>Response of GetRow</returns>
public GetRowResponse GetRow(GetRowRequest request);
/// <summary>
/// Asynchronous mode of GetRow.
/// </summary>
public Task<GetRowResponse> GetRowAsync(GetRowRequest request);

```

Example 1

The following code provides an example of how to read a row of data:

```

// Define the primary keys of the row. These primary keys must be consistent with the
// primary keys defined in TableMeta during table creation.
PrimaryKey primaryKey = new PrimaryKey();
primaryKey.Add("pk0", new ColumnValue(0));
primaryKey.Add("pk1", new ColumnValue("abc"));
try
{
    // Construct a query request object. The entire row is read if no column is specified
    var request = new GetRowRequest(TableName, primaryKey);
    // Call the GetRow API to query data.
    var response = otsClient.GetRow(request);
    // Generate the data of the row. The generated data is not shown here. For more
    // information, see the GitHub link.
    // If task execution succeeds, no exception is thrown.
    Console.WriteLine("Get row succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Update table failed, exception:{0}", ex.Message);
}

```

Note:

- If you query a row of data, the system returns the data in all columns of the row. You can use the columnsToGet parameter to read data from specified columns. For example, if col0 and col1 are inserted into columnsToGet, the system returns only the data in col0 and col1.
- Conditional filtering is supported. For example, you can configure the system to return results only when the value of col0 is greater than 24.

- When the `columnsToGet` and `Condition` parameters are both used, the system returns results based on `columnsToGet`, and then filters the returned columns by the `Condition` parameter.
- When the specified column does not exist, `PassIfMissing` determines the next action.
- To view the detailed code, see [GetRow@GitHub](#).

Example 2

The following code provides an example of how to use the filter feature to read a row of data.

In the example, data is queried. Only data in `col0` and `col1` is returned. The data in `col0` is filtered based on the condition of `col0=24`.

```
// Define the primary keys of the row. These primary keys must be consistent with the
// primary keys defined in TableMeta during table creation.
PrimaryKey primaryKey = new PrimaryKey();
primaryKey.Add("pk0", new ColumnValue(0));
primaryKey.Add("pk1", new ColumnValue("abc"));
var rowQueryCriteria = new SingleRowQueryCriteria("SampleTable");
rowQueryCriteria.RowPrimaryKey = primaryKey;
// Condition 1: The value of col0 is 5.
var filter1 = new RelationalCondition("col0",
    RelationalCondition.CompareOperator.EQUAL,
    new ColumnValue(5));
// Condition 2: The value of col1 is not ff.
var filter2 = new RelationalCondition("col1", RelationalCondition.CompareOperator.
NOT_EQUAL, new ColumnValue("ff"));
// Construct a combination of Condition 1 and Condition 2 with the OR relationship.
var filter = new CompositeCondition(CompositeCondition.LogicOperator.OR);
filter.AddCondition(filter1);
filter.AddCondition(filter2);
rowQueryCriteria.Filter = filter;
// Configure the rows you want to query with the condition [col0, col1], and then
// filter the queried data based on the previously specified conditions.
rowQueryCriteria.AddColumnsToGet("col0");
rowQueryCriteria.AddColumnsToGet("col1");
// Construct GetRowRequest.
var request = new GetRowRequest(rowQueryCriteria);
try
{
    // Query data.
    var response = otsClient.GetRow(request);
    // Generate data or perform the related logical operation (omitted).
    // If task execution succeeds, no exception is thrown.
    Console.WriteLine("Get row with filter succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Get row with filter failed, exception:{0}", ex.Message);
}
```

Note:

To view the detailed code, see [GetRowWithFilter@GitHub](#).

UpdateRow

You can use the UpdateRow API to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values of the specified columns are added, modified, or deleted based on the request content.

API

```
/// <summary>
/// Update the data of the specified row. If the row does not exist, a new row is
added. If the row exists, the values of the specified columns are added, modified, or
deleted based on the request content.
/// </summary>
/// <param name="request">Request instance</param>
public UpdateRowResponse UpdateRow(UpdateRowRequest request);
/// <summary>
/// Asynchronous mode of UpdateRow.
/// </summary>
/// <param name="request"></param>
/// <returns></returns>
public Task<UpdateRowResponse> UpdateRowAsync(UpdateRowRequest request);
```

Examples

The following code provides an example of how to update the data of a specified row:

```
// Define the primary keys of the row. These primary keys must be consistent with the
primary keys defined in TableMeta during table creation.
PrimaryKey primaryKey = new PrimaryKey();
primaryKey.Add("pk0", new ColumnValue(0));
primaryKey.Add("pk1", new ColumnValue("abc"));
// Define the attribute columns of the row.
UpdateOfAttribute attribute = new UpdateOfAttribute();
attribute.AddAttributeColumnToPut("col0", new ColumnValue(0));
attribute.AddAttributeColumnToPut("col1", new ColumnValue("b")); // Change the
original value a to b.
attribute.AddAttributeColumnToPut("col2", new ColumnValue(true));
try
{
    // Construct the request object for row updating. RowExistenceExpectation.IGNORE
indicates that data is updated regardless of whether the specified row exists.
    var request = new UpdateRowRequest(TableName, new Condition(RowExisten
ceExpectation.IGNORE),
        primaryKey, attribute);
    // Call the UpdateRow API to run the following line of code:
    otsClient.UpdateRow(request);
    // If task execution succeeds, no exception is thrown.
    Console.WriteLine("Update row succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Update row failed, exception:{0}", ex.Message);
}
```

}

**Note:**

- You can use conditional statements to update rows.
- To view the detailed code, see [UpdateRow@GitHub](#).

DeleteRow

API

```

/// <summary>
/// Delete a row of data based on the specified table name and primary keys.
/// </summary>
/// <param name="request">Request instance</param>
/// <returns>Response instance</returns>
public DeleteRowResponse DeleteRow(DeleteRowRequest request);
/// <summary>
/// Asynchronous mode of DeleteRow.
/// </summary>
public Task<DeleteRowResponse> DeleteRowAsync(DeleteRowRequest request);

```

Examples

The following code provides an example of how to delete a row of data:

```

// The values of the primary key columns of the row to be deleted are 0 and "abc".
var primaryKey = new PrimaryKey();
primaryKey.Add("pk0", new ColumnValue(0));
primaryKey.Add("pk1", new ColumnValue("abc"));
try
{
    // Construct a request. Condition.EXPECT_EXIST indicates that the row is deleted
    only when it exists.
    var deleteRowRequest = new DeleteRowRequest("SampleTable", Condition.
    EXPECT_EXIST, primaryKey);
    // Call the DeleteRow API to delete the row.
    otsClient.DeleteRow(deleteRowRequest);
    // If task execution succeeds, no exception is thrown.
    Console.WriteLine("Delete table succeeded.");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Delete table failed, exception:{0}", ex.Message);
}

```

**Note:**

- You can use conditional statements to delete rows.
- To view the detailed code, see [DeleteRow@GitHub](#).

2.5.2.6.2.6 Multiple-row operations

The Table Store SDK provides the following APIs for multiple-row operations: BatchGetRow, BatchWriteRow, GetRange, and GetRangeIterator.

BatchGetRow

You can use the BatchGetRow API to simultaneously read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the request response time and increase the data read rate.

API

```

    /// <summary>
    /// <para>Simultaneously read several rows of data from one or more tables. </para>
    >
    /// <para>The BatchGetRow operation is a set of multiple GetRow operations. The
    execution, returning of results, and CU consumption of each individual operation are
    carried out independently. </para>
    /// Compared with the execution of a large number of GetRow operations, the use of
    BatchGetRow can reduce the request response time and increase the data read rate.
    /// </summary>
    /// <param name="request">Request instance</param>
    /// <returns>Response instance</returns>
    public BatchGetRowResponse BatchGetRow(BatchGetRowRequest request);
    /// <summary>
    /// Asynchronous mode of BatchGetRow.
    /// </summary>
    public Task<BatchGetRowResponse> BatchGetRowAsync(BatchGetRowRequest
    request);

```

Examples

The following code provides an example of how to simultaneously read 10 rows of data:

```

    // Construct a batch-read request object, including the primary key values of the 10
    rows.
    List<PrimaryKey> primaryKeys = new List<PrimaryKey>();
    for (int i = 0; i < 10; i++)
    {
        PrimaryKey primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(i));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        primaryKeys.Add(primaryKey);
    }
    try
    {
        BatchGetRowRequest request = new BatchGetRowRequest();
        request.Add(TableName, primaryKeys);
        // Call BatchGetRow to read 10 rows of data.
    }

```

```

var response = otsClient.BatchGetRow(request);
var tableRows = response.RowDataGroupByTable;
var rows = tableRows[TableName];
// Enter the input data for the rows. The input data is not shown here. For more
information, see the GitHub link.
// BatchGetRow may partially fail. Therefore, you must check the status of each
row. For more information, see the GitHub link.
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Batch get row failed, exception:{0}", ex.Message);
}

```

**Note:**

- You can use conditional statements to filter the results returned by a BatchGetRow operation.
- To view the detailed code, see [BatchGetRow@GitHub](#).

BatchWriteRow

You can use the BatchWriteRow API to insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

API

```

/// <summary>
/// <para>You can use the BatchWriteRow API to insert, modify, or delete several
rows of data in one or more tables. </para>
/// <para>The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and
DeleteRow operations. The execution, returning of results, and CU consumption of each
individual operation are carried out independently. </para>
/// <para>Compared with the execution of a large number of write operations, the
use of BatchWriteRow can reduce the request response time and increase the data write
rate. </para>
/// </summary>
/// <param name="request">Request instance</param>
/// <returns>Response instance</returns>
public BatchWriteRowResponse BatchWriteRow(BatchWriteRowRequest request);
/// <summary>
/// Asynchronous mode of BatchWriteRow.
/// </summary>
/// <param name="request"></param>
/// <returns></returns>
public Task<BatchWriteRowResponse> BatchWriteRowAsync(BatchWriteRowRequest
request);

```

Examples

The following code provides an example of how to simultaneously import 100 rows of data:

```
// Construct a batch-import request object, including the primary key values of the
100 rows.
var request = new BatchWriteRowRequest();
var rowChanges = new RowChanges();
for (int i = 0; i < 100; i++)
{
    PrimaryKey primaryKey = new PrimaryKey();
    primaryKey.Add("pk0", new ColumnValue(i));
    primaryKey.Add("pk1", new ColumnValue("abc"));
    // Define the attribute columns of the 100 rows.
    UpdateOfAttribute attribute = new UpdateOfAttribute();
    attribute.AddAttributeColumnToPut("col0", new ColumnValue(0));
    attribute.AddAttributeColumnToPut("col1", new ColumnValue("a"));
    attribute.AddAttributeColumnToPut("col2", new ColumnValue(true));
    rowChanges.AddUpdate(new Condition(RowExistenceExpectation.IGNORE),
primaryKey, attribute);
}
request.Add(TableName, rowChanges);
try
{
    // Call the BatchWriteRow API.
    var response = otsClient.BatchWriteRow(request);
    var tableRows = response.TableResponses;
    var rows = tableRows[TableName];
    // BatchWriteRow may partially fail. Therefore, you must check the status of each
row. For more information, see the GitHub link.
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Batch put row failed, exception:{0}", ex.Message);
}
```

Note:

- You can use conditional statements to filter the results returned by a BatchWriteRow operation.
- To view the detailed code, see [BatchWriteRow@GitHub](#).

GetRange

You can use the GetRange API to read data within the specified primary key range.

API

```
/// <summary>
/// Obtain data from multiple rows within a specified range.
/// </summary>
/// <param name="request">Request instance</param>
/// <returns>Response instance</returns>
public GetRangeResponse GetRange(GetRangeRequest request);
/// <summary>
/// Asynchronous mode of GetRange.
/// </summary>
/// <param name="request"></param>
/// <returns></returns>
```

```
public Task<GetRangeResponse> GetRangeAsync(GetRangeRequest request);
```

Examples

The following code provides an example of how to read data within the specified range:

```
// Read all rows in the range from (0, INF_MIN) to (100, INF_MAX).
var inclusiveStartPrimaryKey = new PrimaryKey();
inclusiveStartPrimaryKey.Add("pk0", new ColumnValue(0));
inclusiveStartPrimaryKey.Add("pk1", ColumnValue.INF_MIN);
var exclusiveEndPrimaryKey = new PrimaryKey();
exclusiveEndPrimaryKey.Add("pk0", new ColumnValue(100));
exclusiveEndPrimaryKey.Add("pk1", ColumnValue.INF_MAX);
try
{
    // Construct a read request object in the specified range.
    var request = new GetRangeRequest(TableName, GetRangeDirection.Forward,
        inclusiveStartPrimaryKey, exclusiveEndPrimaryKey);
    var response = otsClient.GetRange(request);
    // Continue the read operation if only partial data is returned.
    var rows = response.RowDataList;
    var nextStartPrimaryKey = response.NextPrimaryKey;
    while (nextStartPrimaryKey != null)
    {
        request = new GetRangeRequest(TableName, GetRangeDirection.Forward,
            nextStartPrimaryKey, exclusiveEndPrimaryKey);
        response = otsClient.GetRange(request);
        nextStartPrimaryKey = response.NextPrimaryKey;
        foreach (RowDataFromGetRange row in response.RowDataList)
        {
            rows.Add(row);
        }
    }
    // Generate the data of the rows. The generated data is not shown here. For more
    information, see the GitHub link.
    // If task execution succeeds, no exception is thrown.
    Console.WriteLine("Get range succeeded");
}
catch (Exception ex)
{
    // If task execution fails, an exception is thrown and an error message is displayed.
    Console.WriteLine("Get range failed, exception:{0}", ex.Message);
}
```

Note:

- You can use conditional statements to filter the read data returned from the specified range.
- To view the detailed code, see [GetRange@GitHub](#).

GetRangeIterator

You can use the GetRangeIterator API to obtain an iterator within the specified range.

API

```
/// <summary>
```

```

    /// Obtain data from multiple rows within the specified range. Return the iterator
    used to process each row of data.
    /// </summary>
    /// <param name="request"><see cref="GetIteratorRequest"/></param>
    /// <returns>Return the <see cref="RowDataFromGetRange"/> iterator. </returns>
    public IEnumerable<RowDataFromGetRange> GetRangeIterator(GetIteratorRequest
    request);

```

Examples

The following code provides an example of how to obtain an iterator:

```

// Read all rows in the range from (0, "a") to (1000, "xyz").
PrimaryKey inclusiveStartPrimaryKey = new PrimaryKey();
inclusiveStartPrimaryKey.Add("pk0", new ColumnValue(0));
inclusiveStartPrimaryKey.Add("pk1", new ColumnValue("a"));
PrimaryKey exclusiveEndPrimaryKey = new PrimaryKey();
exclusiveEndPrimaryKey.Add("pk0", new ColumnValue(1000));
exclusiveEndPrimaryKey.Add("pk1", new ColumnValue("xyz"));
// Construct a CapacityUnit to record the number of CUs consumed by iteration.
var cu = new CapacityUnit(0, 0);
try
{
    // Construct a GetIteratorRequest. Filter conditions are supported.
    var request = new GetIteratorRequest(TableName, GetRangeDirection.Forward,
    inclusiveStartPrimaryKey,
        exclusiveEndPrimaryKey, cu);
    var iterator = otsClient.GetRangeIterator(request);
    // Iterator that reads data in a traversal method.
    foreach (var row in iterator)
    {
        // Processing logic.
    }
    Console.WriteLine("Iterate row succeeded");
}
catch (Exception ex)
{
    Console.WriteLine("Iterate row failed, exception:{0}", ex.Message);
}

```

Note:

- You can use conditional statements to filter the data read through an iterator.
- To view the detailed code, see [GetRangeIterator@GitHub](#).

2.5.2.6.2.7 Error handling

Method

The Table Store .NET SDK adopts the **Exception** method to handle errors. If an operation succeeds, the called API does not throw an exception. If the operation fails, an exception is thrown.

Note:

Batch operation APIs such as BatchGetRow and BatchWriteRow are called only when the status check of each row is successful.

Error

The Table Store .NET SDK has two types of exceptions: OTSClientException and OTSServerException. Both are inherited from Exception.

- OTSClientException: indicates an internal SDK exception, such as an incorrect parameter value or a failure to parse the results returned by the server.
- OTSServerException: indicates a server error arising from the resolution of a server error message. OTSServerException has the following components:
 - HttpStatusCode: an HTTP status code, such as 200 or 404.
 - ErrorCode: an error type string returned by Table Store.
 - ErrorMessage: an error message string returned by Table Store.
 - RequestId: the UUID that uniquely identifies a request. If a problem persists, submit the request ID to Table Store technical support personnel to obtain help.

Retry

- The system retries an operation when an error occurs in the SDK. The operation is retried three times at a maximum interval of two seconds by default. For more information, see the Aliyun.OTS.Retry.DefaultRetryPolicy class.
- You can modify RetryPolicy in OTSClientConfig to customize a retry policy.

2.5.2.7 Obtain an AccessKey pair

You can obtain the AccessKey pair on the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.6 Network Attached Storage (NAS)

2.6.1 List of operations by function

Table 2-318: APIs lists the APIs provided by NAS.

Table 2-318: APIs

Number	Category	API	Description
1	Region	DescribeRegions	Returns all region IDs .
2	NAS	CreateFileSystem	Creates a NAS instance.
3	NAS	DeleteFileSystem	Deletes an existing NAS instance.
4	NAS	DescribeFileSystems	Returns the description of a NAS instance.
5	NAS	ModifyFileSystem	Modifies the information of a NAS instance.
6	Mount point	CreateMountTarget	Create a mount point .
7	Mount point	DeleteMountTarget	Deletes an existing mount point.

Number	Category	API	Description
8	Mount point	DescribeMountTargets	Returns the description of a mount point.
9	Mount point	ModifyMountTarget	Modifies the attributes of a mount point.
10	Permission group	CreateAccessGroup	Creates a permission group.
11	Permission group	DeleteAccessGroup	Deletes an existing permission group.
12	Permission group	DescribeAccessGroups	Returns the description of a permission group.
13	Permission group	ModifyAccessGroup	Modifies the attributes of a permission group.
14	Permission group	CreateAccessRule	Creates a permission rule.
15	Permission group	DeleteAccessRule	Deletes an existing permission rule.
16	Permission group	DescribeAccessRules	Returns the description of a permission rule.
17	Permission group	ModifyAccessRule	Modifies the attributes of a permission rule.

2.6.2 Make API requests

2.6.2.1 Common parameters

Common request parameters

Common request parameters are available to all APIs.

Table 2-319: Common request parameters

Name	Type	Required	Description
Format	String	No	The type of response. Valid values: JSON and XML . Default value: JSON .
Version	String	Yes	The API version, which is represented as a date in the format of YYYY-MM-DD. The current API version is 2017-06-26 .
AccessKeyId	String	Yes	The AccessKey ID that is used to access services. For more information, see Obtain an AccessKey pair .
Signature	String	Yes	The string that represents signature.
SignatureMethod	String	Yes	The type of signature. Valid value: HMAC-SHA1 .
Timestamp	String	Yes	The time when you send the request. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC. For example, 2017-05-26T12:00:00Z.
SignatureVersion	String	Yes	The version of the signature algorithm. The current version is 1.0 .
SecurityToken	String	No	If Security Token Service (STS) credentials are required , you must specify this parameter.
SignatureNonce	String	No	A unique random number . This parameter is used to prevent replay attacks. You must use different random numbers for different requests.

Sample request

```
GET https://nas.regionid.example.com/?Action=<Action>
&Format=xml
&Version=2017-06-26
&AccessKeyId=key-test
&Signature=Pc5***%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&Timestamp=2012-06-01T12:00:00Z
...
```

Common response parameters

Whenever you send an API request, a GUID that is included in the **RequestId** parameter will be returned to you regardless of whether the request is successful.

Table 2-320: Common response parameters

Name	Type	Description
RequestId	Integer	The GUID generated by Alibaba Cloud for the request.

Sample response

XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<An API name+Response>
  <!--Returned RequestId-->
  <RequestId> 6D9F62C5-BF52-447C-AA34-C77F7AFCCC12</RequestId>
  <!--Response parameters-->
</An API name+Response>
```

JSON format

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /* Response parameters*/
}
```

2.6.2.2 Structure of a request

Endpoints

The format of a NAS API endpoint is as follows: [Obtain an endpoint](#)

Protocols

You can send API requests by using HTTP or HTTPS. We recommend that you use HTTPS to ensure high security.

Request methods

You can send requests by using the HTTP GET method. With this method, you must specify request parameters in the request URL.

Request parameters

You must specify the required operation for the Action parameter of each request, such as DescribeRegions. Each operation must include common request parameters and other request parameters that are specific to an operation.

Character encoding

Requests or responses are all encoded by UTF-8.

2.6.3 Region

2.6.3.1 DescribeRegions

Description

Return all region IDs.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to DescribeRegions.
PageSize	Integer	FALSE	The number of regions that are displayed on each page. Default value: 10 .
PageNumber	Integer	FALSE	The page number of the list, which starts from 1.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of returned region information records
PageSize	Integer	The number of regions that are displayed on each page
PageNumber	Integer	The page number of the list
Regions	RegionType	The region description

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=DescribeRegions
&PageSize=2
&PageNumber=1
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeRegionsResponse>
  <PageNumber>1</PageNumber>
  <TotalCount>4</TotalCount>
  <PageSize>2</PageSize>
  <RequestId>A70BEE5D-76D3-49FB-B58F-1F398211A5C3</RequestId>
  <Regions>
    <Region>
      <RegionId>cn-hangzhou</RegionId>
      <LocalName>China (Hangzhou)</LocalName>
    </Region>
    <Region>
      <RegionId>cn-shanghai</RegionId>
      <LocalName>China (Shanghai)</LocalName>
    </Region>
  </Regions>
</DescribeRegionsResponse>
```

- JSON format

```
{
  "TotalCount": 4,
  "PageSize": 2,
  "RequestId": "A70BEE5D-76D3-49FB-B58F-1F398211A5C3",
  "PageNumber": 1,
  "Regions": {
    "Region": [
      {
        "RegionId": "cn-hangzhou",
        "LocalName": "China (Hangzhou)"
      },
      {
        "RegionId": "cn-shanghai",
        "LocalName": "China (Shanghai)"
      }
    ]
  }
}
```

```
{
  "RegionId": "cn-shanghai",
  "LocalName": "China (Shanghai)"
}
```

2.6.4 NAS instance

2.6.4.1 CreateFileSystem

Description

You can call this operation to create a file system.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this value to <code>CreateFileSystem</code> .
StorageType	String	Yes	The type of the file system. Valid values : Performance and Capacity.
ProtocolType	String	Yes	The type of protocol used by the file system.
Description	String	No	The description of the file system. Space () characters are not allowed.

Name	Type	Required	Description
VolumeSize	Long	No	The size of the file system to be created.  Note: If you do not specify a value for this parameter, the default size of a Performance-type file system is 10 PB and the default size of a Capacity-type file system is 1 PB.

Response parameters

Name	Type	Description
FileSystemId	String	The new file system ID.

Examples

Sample request

```
GET https://nas.regionid.example.com/?Action=CreateFileSystem
&StorageType=Performance
&ProtocolType=NFS
&Description=balabala
&<Common request parameters>
...
```

Sample response

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateFileSystemResponse>
  <FileSystemId>1ca404a666</FileSystemId>
  <RequestId>98696EF0-1607-4E9D-B01D-F20930B68845</RequestId>
</CreateFileSystemResponse>
```

- JSON format

```
{
  "RequestId": "98696EF0-1607-4E9D-B01D-F20930B68845",
  "FileSystemId": "1ca404a666"
```

```
}
```

2.6.4.2 DeleteFileSystem

Description

You can call this operation to delete an existing NAS instance.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to DeleteFileSystem.
FileSystemId	String	TRUE	The ID of the NAS instance to be deleted.

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=DeleteFileSystem
&FileSystemId=1ca404a348
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteFileSystemResponse>
  <RequestId>9E15E394-38A6-457A-A62A-D9797C9A0262</RequestId>
</DeleteFileSystemResponse>
```

- JSON format

```
{
  "RequestId": "9E15E394-38A6-457A-A62A-D9797C9A0262"
```

```
}
```

2.6.4.3 DescribeFileSystems

Description

You can call this operation to retrieve a list of file systems and the details of each file system

.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this value to <code>DescribeFileSystems</code> .
FileSystemId	String	No	The file system ID.
PageSize	Integer	No	The number of file systems that are displayed on each page. Default value: 10 .
PageNumber	Integer	No	The number of a page. The number starts at 1.

Response parameters

Name	Type	Description
TotalCount	Integer	The total number of file systems.
PageSize	Integer	The number of file systems that are displayed on each page.
PageNumber	Integer	The number of a page.
FileSystems	FileSystemType	The file system description.
VolumeSize	Long	The size of the file system to be created. Unit: GB

Examples

Sample request

```
GET https://nas.regionid.example.com/?Action=DescribeFileSystems
&FileSystemId=109c042666
&<Common request parameters>
...
```

Sample response

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeFileSystemsResponse>
  <PageNumber>1</PageNumber>
  <TotalCount>1</TotalCount>
  <PageSize>1</PageSize>
  <RequestId>035B3A3A-E514-4B41-B906-5D906CFBD65F</RequestId>
  <FileSystems>
    <FileSystem>
      <FileSystemId>109c042666</FileSystemId>
      <ProtocolType>NFS</ProtocolType>
      <VolumeSize>10240</VolumeSize>
      <RegionId>cn-hangzhou</RegionId>
      <CreateTime>2017-05-27T15:43:06CST</CreateTime>
      <Destription/>
      <MountTargets>
        <MountTarget>
          <MountTargetDomain>109c042666-wjb85.regionid.nas.example.com</
MountTargetDomain>
        </MountTarget>
      </MountTargets>
      <StorageType>Performance</StorageType>
      <MeteredSize>1611661312</MeteredSize>
    </FileSystem>
  </FileSystems>
</DescribeFileSystemsResponse>
```

- JSON format

```
{
  "FileSystems": {
    "FileSystem": [
      {
        "StorageType": "Performance",
        "ProtocolType": "NFS",
        "CreateTime": "2017-05-27T15:43:06CST",
        "VolumeSize": "10240",
        "Destription": "",
        "MountTargets": {
          "MountTarget": {
            {
              "MountTargetDomain": "109c042666-wjb85.regionid.nas.example.com"
            }
          }
        },
        "FileSystemId": "109c042666",
        "RegionId": "cn-hangzhou",
        "MeteredSize": 1611661312
      }
    ]
  }
}
```

```
]
},
"TotalCount": 1,
"PageSize": 1,
"RequestId": "035B3A3A-E514-4B41-B906-5D906CFBD65F",
"PageNumber": 1
}
```

2.6.4.4 ModifyFileSystem

Description

You can call this operation to modify the NAS instance information.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to <code>ModifyFileSystem</code> .
FileSystemId	String	TRUE	The NAS instance ID.
Description	String	FALSE	The description. Space characters are not allowed.

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=ModifyFileSystem
&FileSystemId=1ca404a666
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyFileSystemResponse>
  <RequestId>5BC5CB97-9F28-42FE-84A4-0CD0DF4211C8</RequestId>
</ModifyFileSystemResponse>
```

- JSON format

```
{
  "RequestId": "5BC5CB97-9F28-42FE-84A4-0CD0DF4211C8"
```

```
}
```

2.6.5 Mount point

2.6.5.1 CreateMountTarget

Description

You can call this operation to create a mount point.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to <code>CreateMountTarget</code> .
FileSystemId	String	TRUE	The NAS instance ID.
AccessGroupName	String	TRUE	The permission group name.
NetworkType	String	TRUE	The network type. Valid values: VPC and Classic.
VpcId	String	FALSE	The VPC ID.
VSwitchId	String	FALSE	The VSwitch ID.

Response parameters

Parameter	Type	Description
MountTargetDomain	String	The domain name of the mount point

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=CreateMountTarget
&FileSystemId=174494b666
&AccessGroupName=classic-test
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateMountTargetResponse>
  <RequestId>70EACC9C-D07A-4A34-ADA4-77506C42B023</RequestId>
  <MountTargetDomain>174494b666-xog95.regionid.nas.example.com</MountTargetDomain>
</CreateMountTargetResponse>
```

- JSON format

```
{
  "RequestId": "70EACC9C-D07A-4A34-ADA4-77506C42B023",
  "MountTargetDomain": "174494b666-xog95.regionid.nas.example.com"
}
```

2.6.5.2 DeleteMountTarget

Description

You can call this operation to delete an existing mount point.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to DeleteMountTarget.
FileSystemId	String	TRUE	The NAS instance ID.
MountTargetDomain	String	TRUE	The domain name of the mount point.

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=DeleteMountTarget
&FileSystemId=174494b666
&MountTargetDomain=174494b666-xog95.regionid.nas.example.com
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
```

```
<DeleteMountTargetResponse>
  <RequestId>5BC5CB97-9F28-42FE-84A4-0CD0DF4211C8</RequestId>
</DeleteMountTargetResponse>
```

- JSON format

```
{
  "RequestId": "5BC5CB97-9F28-42FE-84A4-0CD0DF4211C8"
}
```

2.6.5.3 DescribeMountTargets

Description

You can call this operation to retrieve a list of mount points and the details of each mount point.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this value to <code>DescribeMountTargets</code> .
FileSystemId	String	Yes	The file system ID.
MountTargetDomain	String	No	The name of the mount point.
PageSize	Integer	No	The number of mount points that are displayed on each page. Default value: 10 .
PageNumber	Integer	No	The number of a page. The number starts at 1.

Response parameters

Name	Type	Description
TotalCount	Integer	The total number of mount points.
PageSize	Integer	The number of mount points that are displayed on each page.

Name	Type	Description
PageNumber	Integer	The number of a page.
MountTargets	MountTargetType	A list of mount points and the details of each mount point.

Examples

Sample request

```
GET https://nas.regionid.example.com/?Action=DescribeMountTargets
&FileSystemId=1ca404a666
&<Common request parameters>
...
```

Sample response

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<? xml version="1.0" encoding="UTF-8"? >
<DescribeMountTargetsResponse>
  <PageNumber>1</PageNumber>
  <TotalCount>1</TotalCount>
  <PageSize>1</PageSize>
  <RequestId>3BAB90FD-B4A0-48DA-9F09-2B963510A0EF</RequestId>
  <MountTargets>
    <MountTarget>
      <Status>Active</Status>
      <NetworkType>Vpc</NetworkType>
      <VswId>vsw-2zevmwkwyztjuoffg****</VswId>
      <VpcId>vpc-2zesj9afh3y518k9o****</VpcId>
      <MountTargetDomain>1ca404a666-XXXXX.regionid.nas.example.com</
MountTargetDomain>
      <AccessGroup>DEFAULT_VPC_GROUP_NAME</AccessGroup>
    </MountTarget>
  </MountTargets>
</DescribeMountTargetsResponse>
```

- JSON format

```
{
  "TotalCount": 1,
  "PageSize": 1,
  "RequestId": "3BAB90FD-B4A0-48DA-9F09-2B963510A0EF",
  "PageNumber": 1,
  "MountTargets": {
    "MountTarget": [
      {
        "Status": "Active",
        "VswId": "vsw-2zevmwkwyztjuoffg****",
        "VpcId": "vpc-2zesj9afh3y518k9o****",
        "MountTargetDomain": "1ca404a666-.regionid.nas.example.com",
        "NetworkType": "Vpc",
        "AccessGroup": "DEFAULT_VPC_GROUP_NAME"
      }
    ]
  }
}
```

```
}  
}
```

2.6.5.4 ModifyMountTarget

Description

You can call this operation to modify the information of a mount point.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to <code>ModifyMountTarget</code> .
FileSystemId	String	TRUE	The NAS instance ID.
MountTargetDomain	String	TRUE	The domain name of the mount point.
AccessGroupName	String	FALSE	The permission group name.
Status	String	FALSE	The status. Valid values: Active and Inactive .

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=ModifyMountTarget  
&FileSystemId=1ca404a666  
&MountTargetDomain=1ca404a666  
&Status=Inactive  
&<Common request parameters>  
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<ModifyMountTargetResponse>  
  <RequestId>FF387D95-34C4-4879-B65A-99D1FA1B65CD</RequestId>
```

```
</ModifyMountTargetResponse>
```

- JSON format

```
{
  "RequestId": "FF387D95-34C4-4879-B65A-99D1FA1B65CD"
}
```

2.6.6 Permission group

2.6.6.1 CreateAccessGroup

Description

You can call this operation to create a permission group.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to <code>CreateAccessGroup</code> .
AccessGroupName	String	TRUE	The permission group name.
AccessGroupType	String	TRUE	The permission group type. Valid values: VPC and Classic .
Description	String	FALSE	The permission group description. It is the same as the permission group name by default.

Response parameters

Parameter	Type	Description
AccessGroupName	String	The permission group name

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=CreatAccessGroup
&AccessGroupName=classic-test
&AccessGroupType=Classic
```

```
&Description=classic test access group  
&<Common request parameters>  
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<CreateAccessGroupResponse>  
  <RequestId>55C5FFD6-BF99-41BD-9C66-FFF39189F4F8</RequestId>  
  <AccessGroupName>classic-test</AccessGroupName>  
</CreateAccessGroupResponse>
```

- JSON format

```
{  
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",  
  "AccessGroupName ": "classic-test"  
}
```

2.6.6.2 CreateAccessRule

Description

You can call this operation to create a permission rule.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to CreateAccessRule.
AccessGroupName	String	TRUE	The permission group name.
SourceCidrIp	String	TRUE	The IP address or address segment.
RWAccessType	String	FALSE	The access permission type. Valid values: - RDWR (default) - RDONLY

Parameter	Type	Required	Description
UserAccessType	String	FALSE	The user permission type. Valid values: - no_squash (default) - root_squash - all_squash
Priority	Integer	FALSE	The priority. Valid values: 1 to 100. Default value: 1 .

Response parameters

Parameter	Type	Description
AccessRuleId	String	The rule serial number

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=CreatAccessRule
&AccessGroupName=classic-test
&SourceCidrIp=10.0.0.1/32
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateAccessRuleResponse>
  <AccessRuleId>1</AccessRuleId>
  <RequestId>A323836B-5BC6-45A6-8048-60675C23EE2A</RequestId>
</CreateAccessRuleResponse>
```

- JSON format

```
{
  "RequestId": "A323836B-5BC6-45A6-8048-60675C23EE2A",
  "AccessRuleId": "1"
```

```
}
```

2.6.6.3 DeleteAccessGroup

Description

You can call this operation to delete an existing permission group.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to <code>DeleteAccessGroup</code> .
AccessGroupName	String	TRUE	The permission group name.

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=DeleteAccessGroup
&AccessGroupName=classic-test
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteAccessGroupResponse>
  <RequestId>5BC5CB97-9F28-42FE-84A4-0CD0DF4211C8</RequestId>
</DeleteAccessGroupResponse>
```

- JSON format

```
{
  "RequestId": "9E15E394-38A6-457A-A62A-D9797C9A0262"
}
```

2.6.6.4 DeleteAccessRule

Description

You can call this operation to delete an existing permission rule.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to DeleteAccessRule.
AccessGroupName	String	TRUE	The permission group name.
AccessRuleId	String	TRUE	The rule serial number.

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=CreatAccessRule
&AccessGroupName=classic-test
&AccessRuleId=1
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteAccessRuleResponse>
  <RequestId>5B4511A7-C99E-4071-AA8C-32E2529DA963</RequestId>
</DeleteAccessRuleResponse>
```

- JSON format

```
{
  "RequestId": "5B4511A7-C99E-4071-AA8C-32E2529DA963",
}
```

2.6.6.5 DescribeAccessGroups

Description

You can call this operation to return the description of a permission group.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to DescribeAccessGroups.
AccessGroupName	String	FALSE	The permission group name.
PageSize	Integer	FALSE	The number of permission groups that are displayed on each page. Default value: 10 .
PageNumber	Integer	FALSE	The page number of the list, which starts from 1.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of permission groups
PageSize	Integer	The number of permission groups that are displayed on each page
PageNumber	Integer	The page number of the list
AccessGroups	String	The permission group description

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=DescribeAccessGroups
    &<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
```

```
<DescribeAccessGroupsResponse>
  <PageNumber>1</PageNumber>
  <TotalCount>2</TotalCount>
  <PageSize>2</PageSize>
  <RequestId>3E569F4A-F743-490B-AC01-A8088F5C17A1</RequestId>
  <AccessGroups>
    <AccessGroup>
      <Description>DEFAULT ACCESS GROUP NAME</Description>
      <RuleCount>1</RuleCount>
      <AccessGroupType>Vpc</AccessGroupType>
      <AccessGroupName>DEFAULT_VPC_GROUP_NAME</AccessGroupName>
      <MountTargetCount>8</MountTargetCount>
    </AccessGroup>
    <AccessGroup>
      <Description>This is a classic test access group~</Description>
      <RuleCount>0</RuleCount>
      <AccessGroupType>Classic</AccessGroupType>
      <AccessGroupName>classic-test</AccessGroupName>
      <MountTargetCount>0</MountTargetCount>
    </AccessGroup>
  </AccessGroups>
</DescribeAccessGroupsResponse>
```

- JSON format

```
{
  "AccessGroups": {
    "AccessGroup": [
      {
        "RuleCount": 1,
        "AccessGroupType": "Vpc",
        "Description": "DEFAULT ACCESS GROUP NAME",
        "AccessGroupName": "DEFAULT_VPC_GROUP_NAME",
        "MountTargetCount": 8
      },
      {
        "RuleCount": 0,
        "AccessGroupType": "Classic",
        "Description": "This is a classic test access group~",
        "AccessGroupName": "classic-test",
        "MountTargetCount": 0
      }
    ]
  },
  "TotalCount": 2,
  "PageSize": 2,
  "RequestId": "2514F97E-FFF0-4A1F-BF04-729CEAC64B6F",
  "PageNumber": 1
}
```

2.6.6.6 DescribeAccessRules

Description

You can call this operation to retrieve a list of permission group rules and the details of each rule.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this value to DescribeAccessRules.
AccessGroupName	String	Yes	The name of the permission group.
AccessRuleId	String	No	The rule ID.
PageSize	Integer	No	The number of rules that are displayed on each page. Default value: 10 .
PageNumber	Integer	No	The number of a page. The number starts at 1.

Response parameters

Name	Type	Description
TotalCount	Integer	The total number of rules.
PageSize	Integer	The number of rules that are displayed on each page.
PageNumber	Integer	The number of a page.
AccessRules	AccessRules	The description of a rule.

Examples

Sample request

```
GET https://nas.regionid.example.com/?Action=DescribeAccessRules
&AccessGroupName=classic-test
&<Common request parameters>
...
```

Sample response

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeAccessRulesResponse>
  <AccessRules>
    <AccessRule>
      <SourceCidrIp>10.0.XX.XX/32</SourceCidrIp>
```

```
<AccessRuleId>1</AccessRuleId>
<RWAccess>RDWR</RWAccess>
<UserAccess>no_squash</UserAccess>
<Priority>1</Priority>
</AccessRule>
</AccessRules>
<PageNumber>1</PageNumber>
<TotalCount>1</TotalCount>
<PageSize>1</PageSize>
<RequestId>86D89E82-4297-4343-8E1E-A2495B35CC70</RequestId>
</DescribeAccessRulesResponse>
```

- JSON format

```
{
  "TotalCount": 1,
  "PageSize": 1,
  "RequestId": "86D89E82-4297-4343-8E1E-A2495B35CC70",
  "PageNumber": 1,
  "AccessRules": {
    "AccessRule": [
      {
        "RWAccess": "RDWR",
        "UserAccess": "no_squash",
        "Priority": 1,
        "SourceCidrIp": "10.0.XX.XX/32",
        "AccessRuleId": "1"
      }
    ]
  }
}
```

2.6.6.7 ModifyAccessGroup

Description

You can call this operation to modify a permission group.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to ModifyAccessGroup.
AccessGroupName	String	TRUE	The permission group name.
Description	String	FALSE	The permission group description.

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=ModifyAccessGroup
&AccessGroupName=classic-test
&Description=classic-test
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyAccessGroupResponse>
  <RequestId>ED2AE737-9D50-4CA4-B0DA-31BD610C2363</RequestId>
</ModifyAccessGroupResponse>
```

- JSON format

```
{
  "RequestId": "ED2AE737-9D50-4CA4-B0DA-31BD610C2363"
}
```

2.6.6.8 ModifyAccessRule

Description

You can call this operation to delete a permission rule.

Request parameters

Parameter	Type	Required	Description
Action	String	TRUE	The operation that you want to perform. Set the value to <code>ModifyAccessRule</code> .
AccessGroupName	String	TRUE	The permission group name.
AccessRuleId	String	TRUE	The rule serial number.
SourceCidrIp	String	FALSE	The IP address or address segment.
RWAccessType	String	FALSE	The access permission type.
UserAccessType	String	FALSE	The user permission type.

Parameter	Type	Required	Description
Priority	Integer	FALSE	The priority. Valid values: 1 to 100. Default value: 1 .

Response parameters

None

Examples

Sample requests

```
GET https://nas.regionid.example.com/?Action=ModifyAccessRule
&AccessGroupName=classic-test
&AccessRuleId=1
&SourceCidrIp=192.168.0.1
&RWAccessType=RDWR
&UserAccessType=all_squash
&<Common request parameters>
...
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyAccessRuleResponse>
  <RequestId>6299428C-3861-435D-AE54-9B330A0007C8</RequestId>
</ModifyAccessRuleResponse>
```

- JSON format

```
{
  "RequestId": "6299428C-3861-435D-AE54-9B330A0007C8",
}
```

2.6.7 Appendix: Error codes

An error code consists of four components, as listed in [Table 2-321: Error codes](#).

Table 2-321: Error codes

Component	Description
HttpCode	The HTTP response code that complies with HTTP syntax
Code	The error code
Message	The error message
Advice	The recommended solution

Error codes

HTTP status code	Code	Message	Advice
500	InternalServerError	A system internal error occurred.	Please try again later .
503	ServiceUnavailable	This service is unavailable right now.	Please try again later .
504	ServiceTimeout	Service request timed out.	Please try again later .
503	SubRam.CheckFailed	The sub user ram check has failed due to some internal error.	Please try again later .
503	VpcRam.CheckFailed	The Vpc ram check has failed due to some internal error.	Please try again later .
503	VpcSubRam.CheckFailed	The Vpc sub user ram check has failed due to some internal error.	Please try again later .
400	MissingParameter.callerUid	Request parameter missing: callerUid is not specified.	Add the callerUid request parameter.
400	MissingParameter.RegionId	Request parameter missing: RegionId of the domain name is not specified.	Add the RegionId field to the domain name.
400	MissingParameter.VSwitchId	Request parameter missing: VSwitchId is not specified.	Add the VSwitchId request parameter.
400	MissingParameter.VpcId	Request parameter missing: VpcId is not specified.	Add the VpcId request parameter.
400	InvalidParameter.StorageType	Invalid request parameter: StorageType is invalid.	Set StorageType to Performance or Capacity .

HTTP status code	Code	Message	Advice
400	InvalidParameter. ProtocolType	Invalid request parameter: ProtocolType is invalid.	Set ProtocolType to NFS .
400	InvalidParameter. Description	Invalid request parameter: Description contains invalid characters.	Set Description to a string that contains English letters and special characters such as at signs (@) , number signs (#) , dollar signs (\$) , underscores (_) , plus signs (+) , and hyphens (-) .
404	InvalidFileSystem. NotFound	The specified NAS instance does not exist.	The specified NAS instance does not exist or has been deleted.
403	InvalidFileSystem. AlreadyExisted	The specified NAS instance already exists.	Call DescribeFileSystems and specify the NAS instance ID to view the instance information.
404	InvalidMountTarget. NotFound	The specified mount point does not exist.	The specified mount point does not exist or has been deleted.
404	InvalidAccessGroup. NotFound	The specified permission group does not exist.	The specified permission group does not exist or has been deleted.
403	InvalidAccessGroup. AlreadyExisted	The specified permission group already exists.	Call DescribeMountTargets and specify the permission group to view its information.

HTTP status code	Code	Message	Advice
403	InvalidAccessGroup. AlreadyAttached	The specified permission group has been bound to a mount point.	Unbind the permission group from the mount point before deleting the permission group.
404	InvalidAccessRule. NotFound	The specified permission rule does not exist.	The specified permission rule does not exist or has been deleted.
404	InvalidLocatin. NotFound	The specified location does not exist.	The requested location does not exist or is not providing services.
404	InvalidRegionId. NotFound	The specified region does not exist.	The requested region does not exist or is not providing services.
404	InvalidAZone. NotFound	The specified zone does not exist.	The requested zone does not exist or is not providing services.
404	InvalidVpc.NotFound	The specified VPC does not exist.	Create a VPC first.
404	InvalidVip.NotFound	The specified VIP does not exist.	Make sure that there are available IP addresses in your VPC.
404	InvalidLBid.NotFound	The specified LBid does not exist.	Please try again later .
404	InvalidVpcTunnelId. NotFound	The specified VPC tunnelId does not exist.	Check the VPC information first.
404	InvalidVpc. CreationFailed	The specified vpc instance creation failed.	Make sure that the VPC information is correct and there is an available IP address for the VPC, and then try again.

HTTP status code	Code	Message	Advice
403	OperationDenied.DefaultAccessGroupCannotDelete	Operation not allowed: The default permission group cannot be deleted.	You can only edit custom permission groups.
403	OperationDenied.DefaultAccessGroupCannotModify	Operation not allowed: The default permission group cannot be modified.	You can only edit custom permission groups.
403	OperationDenied.NetworkTypeNotMatched	Operation not allowed: The mount point network type does not match the AccessGroupType.	Make sure that the NetworkType of the mount point and the AccessGroupType of the permission group are consistent.
403	OperationDenied.MountTargetNotEmpty	Operation not allowed: The specified NAS instance already has a mount point. Delete the existing mount point first.	Delete the existing mount points first.
403	OperationDenied.FileSystemCountsExceeded	The number of NAS instances has already reached the upper limit (a user can create a maximum of 10 NAS instances).	To raise the limit, contact technical support.
403	OperationDenied.MountTargetCountsExceeded	The number of mount points has already reached the upper limit (a maximum of two mount points can be created for each NAS instance).	To raise the limit, contact technical support.
403	OperationDenied.AccessGroupCountsExceeded	The number of permission groups has already reached the upper limit.	To raise the limit, contact technical support.

HTTP status code	Code	Message	Advice
403	OperationDenied .AccessRule CountsExceeded	The number of permission rules has already reached the upper limit.	To raise the limit, contact technical support.
403	Forbidden.InvalidUserType	No permission: The user type is invalid.	Sorry, this API does not support your account type.
403	Forbidden.Ram	User not authorized to operate on the specified resource, or this API doesn't support RAM.	Access RAM to grant required NAS permissions.
403	NotQualified	No public beta qualification yet	Please initiate an application for a trial of the related features. If your application fails to be approved, contact the technical support.

Error response examples

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<Error>
  <RequestId>B71B4C68-6C6B-4D4B-AD70-8951BD7D188E</RequestId>
  <HostId>nas.regionid.example.com</HostId>
  <Code>InvalidFileSystem.NotFound</Code>
  <Message>The specified NAS instance does not exist.</Message>
</Error>
```

- JSON format

```
{
  "RequestId": "B71B4C68-6C6B-4D4B-AD70-8951BD7D188E",
  "HostId": "nas.regionid.example.com",
  "Code": "InvalidFileSystem.NotFound",
  "Message": "The specified NAS instance does not exist."
}
```

2.6.8 Obtain an endpoint

You can obtain the product endpoint in Apsara Stack Operations.

Procedure

1. Log on to Apsara Stack Operations.

For how to log on to Apsara Stack Operations, see **Operations of basic platforms > Apsara Stack Operations > Log on to Apsara Stack Operations** in Operations Guide .

2. Click **Products** in the left-side navigation pane.

3. Choose **Apsara Infrastructure Management Framework** in the product list to go to the Apsara Infrastructure Management Framework page.

4. Choose **Operations > Machine Operations**. The **Machine Operations** page appears.

5. Select a machine and then click **Terminal** to log on to the machine.

Machine Operations

Search Allows fuzzy or batch search. Separate multiple machines with commas or space. ☐ Exact Match

Hostname	IP	Cluster	Project	IDC	Room	Rack	Warranty	Status	Actions
vm010012016112		tianji-A-3788	tianji	amtest72				GOOD	Terminal Machine Operation
a50e05101.cloud.e06.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E06		GOOD	Terminal Machine Operation
a50e07101.cloud.e08.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E08		GOOD	Terminal Machine Operation
a50e00001.cloud.e09.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E09		GOOD	Terminal Machine Operation
vm010012016020		tianji-A-3788	tianji	amtest72				GOOD	Terminal Machine Operation
a50f11014.cloud.f11.amtest72		tianji-A-3788	tianji	amtest72	A5-6	F11		GOOD	Terminal Machine Operation
a50e09106.cloud.e10.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E10		GOOD	Terminal Machine Operation

6. Run the command `curl -l "http://127.0.0.1:7070/api/v3/column/c.sr.service_registration,c.sr.id?c.sr.service_registration"` to obtain JSON data.

```

vm010036041107
02.cloud.h14.amtest85,101h11209.cloud.h13.amtest85,101h11212.cloud.h13.amtest85,\"db-redis_ip_list\":\

},

```

- Based on the ID (nas-yaochi) and key value (nas.openapi.endpoint) of a NAS file system, you can locate the endpoint of the NAS file system.

```

    "c.sr.id": "nas-yaochi",
    "c.sr.service_registration": "{ \"nas.controller.ips\": \"10.11.24.11\", \"nas.openapi.endpoint\": \"nas.cn-qingdao-env12-d01.env12.shuguang.com\", \"nas.yaochi.db.host\": \"nasyaochi.mysql.minirds.env12.ops.shuguang.com\", \"nas.yaochi.db.name\": \"nas_yaochi\", \"nas.yaochi.db.password\": \"51cbeLqskoyhoyH1\", \"nas.yaochi.db.port\": \"3152\", \"nas.yaochi.db.user\": \"nasyaochi\", \"nas.yaochi.domain\": \"nas-inner.cn-qingdao-env12-d01.env12.ops.shuguang.com\", \"nas.yaochi.ips\": \"10.11.24.11\" }"
  },

```

2.6.9 Obtain an AccessKey pair

You can obtain the AccessKey pair on the Apsara Stack console.

Obtain an AccessKey pair of a department

You can obtain an AccessKey pair of a department as follows:

- Log on to the Apsara Stack console as an administrator.
- In the top navigation bar, click the  icon, and then choose **User Center** >

Department Management.

- Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

You can obtain an AccessKey pair of a personal account as follows:

- Log on to the Apsara Stack console as an administrator.
- In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

- Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.7 Apsara File Storage for HDFS

2.7.1 API reference

2.7.1.1 List of operations by function

This topic introduces the Apsara File Storage for HDFS operations that you can call.

**Note:**

This API reference is intended for HDFS API version 2018-02-28.

No.	Category	Operation	Description
1	Regions	ListRegions	Queries all region IDs.
2	Region	GetRegion	Queries the configuration information in a specified region.
3	File system	CreateFileSystem	Creates a file system instance.
4	File system	DeleteFileSystem	Deletes an existing file system instance.
5	File system	ModifyFileSystem	Modifies the attributes of a file system.
6	File system	GetFileSystem	Queries the detailed information about a file system instance.
7	File system	ListFileSystems	Queries the detailed information about multiple file system instances.
8	Permission	CreateAccessGroup	Creates a permission group.
9	Permission	DeleteAccessGroup	Deletes a permission group.
10	Permission	ModifyAccessGroup	Modifies the attributes of a permission group.

No.	Category	Operation	Description
11	Permission	GetAccessGroup	Queries detailed information about a permission group.
12	Permission	ListAccessGroups	Queries detailed information about permission groups in batches.
13	Permission	CreateAccessRule	Creates a permission rule.
14	Permission	DeleteAccessRule	Deletes a permission rule.
15	Permission	ModifyAccessRule	Modifies attributes about a rule.
16	Permission	GetAccessRule	Queries detailed information about a permission rule.
17	Permission	ListAccessRules	Queries detailed information about permission rules in batches.
18	Mount point	CreateMountPoint	Creates a mount point.
19	Mount point	DeleteMountPoint	Deletes a mount point.
20	Mount point	ModifyMountPoint	Modifies the attributes of a mount point.
21	Mount point	GetMountPoint	Queries detailed information about a mount point.
22	Mount point	ListMountPoints	Queries detailed information about mount points in batches.

2.7.1.2 Make API requests

2.7.1.2.1 Common parameters

This topic describes the common request parameters and response parameters of Apsara File Storage for HDFS.

Common request parameters

Common request parameters must be included in the request of each API.

Table 2-322: Common request parameters

Parameter	Type	Required	Description
Format	String	No	The type of the returned value. Valid values: JSON and XML . Default value: JSON .
Version	String	Yes	The API version, in the format of YYYY-MM-DD . The current version is 2018-02-28 .
AccessKeyId	String	Yes	The AccessKey ID provided to you by Alibaba Cloud.
Signature	String	Yes	The signature string.
SignatureMethod	String	Yes	The signature method. Set this parameter to HMAC-SHA1 .
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC. For example, 2017-05-26T12:00:00Z.
SignatureVersion	String	Yes	The signature algorithm version. The current version is 1.0 .

Parameter	Type	Required	Description
SecurityToken	String	No	The security token. This parameter is required when STS credentials are used.
SignatureNonce	String	No	A unique random number . This parameter is used to prevent replay attacks . You must use a different random number for each request.

Sample requests

```
GET https://dfs.regionid.example.com/?Action=<Action>
&Format=xml
&Version=2018-02-28
&AccessKeyId=key-test
&Signature=Pc5WB8gokVn0xfeu%2FZV%2BiNM1dg****
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&Timestamp=2012-06-01T12:00:00Z
...
```

Common response parameters

The system returns a unique identifier (**RequestId**) for each API request, regardless of whether the API operation was called successfully.

Table 2-323: Common response parameters

Parameter	Type	Description
RequestId	Integer	The unique ID of the request.

Sample responses

XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<Operation name+Response>
  <!--Returned request tag-->
  <RequestId> 6D9F62C5-BF52-447C-AA34-C77F7AFCCC12</RequestId>
  <!--Returned results-->
</Operation name+Response>
```

JSON format

```
{
```

```
"RequestId": "4C467B38-3910-447D-87BC-AC049166F216",  
/* Response data */  
}
```

2.7.1.2 Request structure

This topic describes the endpoints, protocols, methods, parameters, and encoding methods involved in the request structure.

Endpoints

For information about how to query the endpoints of Apsara File Storage for HDFS APIs, see [Obtain an endpoint](#).

Protocols

You can send API requests over HTTP or HTTPS. For security considerations, we recommend that you use HTTPS.

Methods

You can call an API operation by sending an HTTP GET request. If you use this method, the request parameters must be included in the request URL.

Request parameters

For each request, you must specify the Action parameter (such as ListRegions), common request parameters, and API-specific parameters.

Encoding

Requests and responses are encoded using UTF-8.

2.7.1.3 Regions

2.7.1.3.1 ListRegions

You can call this operation to query the IDs of all regions that support Apsara File Storage for HDFS deployment.

Request parameters

Parameter	Type	Required	Description
StartOffset	Integer	FALSE	The start position. Default value: 1 .

Parameter	Type	Required	Description
Limit	Integer	FALSE	The maximum number of entries to return. Default value: 10 .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of entries returned. Maximum value: the value of the Limit parameter.
Regions	Array(Region)	The list of region IDs.
Region.Index	Integer	The serial number of the region.
Region.RegionId	String	The ID of the zone.
Region.RegionName	String	The name of the region.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ListRegions
&StartOffset=10
&Limit=10
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "Regions": {
    {
      "Index": 3,
      "RegionId": "cn-shanghai",
      "RegionName": "China (Hangzhou)"
    }
  },
  "TotalCount": 1,
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.3.2 GetRegion

You can call this operation to query the configuration information of each zone in a region, namely the storage medium types that the user can purchase and the supported access interfaces. Configurations may vary with zones.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AvailableZones	Array(AvailableZone)	The list of zones.
AvailableZone.ZoneId	String	The ID of the zone.
AvailableZone.Options	Array(Option)	The list of configurations.
AvailableZone.Option.ProtocolType	String	The interface protocol type. Set this parameter to HDFS . This value indicates Hadoop FileSystem.
AvailableZone.Option.StorageType	String	The type of the storage medium. Set this parameter to STANDARD .

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=GetRegion
&InputRegionId=cn-hangzhou
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "AvailableZones": [
    {
      "Options": [
        {
```

```
{
  "ProtocolType": "HDFS",
  "StorageType": "STANDARD"
},
{
  "ZoneId": "cn-hangzhou-b"
},
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.4 File systems

2.7.1.4.1 CreateFileSystem

You can call this operation to create a file system instance.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
ZoneId	String	TRUE	The ID of the zone.
ProtocolType	String	TRUE	The interface protocol type. Set this parameter to HDFS .
StorageType	String	TRUE	The type of the storage medium. Set this parameter to STANDARD .
Description	String	FALSE	The custom description. Maximum length: 100 bytes.
FileSystemName	String	TRUE	The name of the file system instance. This parameter cannot be an empty string . Specify a globally unique value to avoid confusion. Maximum length: 100 bytes.

Parameter	Type	Required	Description
SpaceCapacity	Long	TRUE	The estimated capacity of the file system instance. Unit: GB. When the amount of stored data reaches this value, write requests fail, but stored data is not affected.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
FileSystemId	String	The ID of the file system instance.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=CreateFileSystem
&InputRegionId=cn-hangzhou
&ZoneId=cn-hangzhou-b
&ProtocolType=HDFS
&StorageType=STANDARD
&Description=This is the first Apsara File Storage for HDFS instance of my company.
&FileSystemName=MyFirstDFS
&SpaceCapacity=1024
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "FileSystemId": "037cb4****",
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.4.2 DeleteFileSystem

You can call this operation to delete an existing file system instance. The file system instance to be deleted must have no mount points. If the file system instance to be deleted has a mount point, deletion fails.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=DeleteFileSystem
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.4.3 ModifyFileSystem

You can call this operation to modify the attributes of a file system, such as name, description, and estimated capacity.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.
FileSystemName	String	FALSE	The name of the file system. This parameter cannot be an empty string . Specify a globally unique value to avoid confusion. Maximum length: 100 bytes.
SpaceCapacity	Long	FALSE	The estimated capacity of the file system instance. Unit : GB.
Description	String	FALSE	The custom description. Maximum length: 100 bytes.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ModifyFileSystem
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
```

```
&FileSystemName=MyFirstDFS
&SpaceCapacity=1024
&Description=This is the first Apsara File Storage for HDFS instance of my company.
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.4.4 GetFileSystem

You can call this operation to query the detailed information about a file system instance.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
FileSystem	Struct	The detailed information about the file system.
FileSystem.RegionId	String	The ID of the region.
FileSystem.ZoneId	String	The ID of the zone.
FileSystem.FileSystemName	String	The name of the file system instance.
FileSystem.Description	String	The description of the file system instance.
FileSystem.ProtocolType	String	The interface protocol type.
FileSystem.StorageType	String	The type of the storage medium.

Parameter	Type	Description
FileSystem.SpaceCapacity	Long	The estimated capacity of the file system instance. Unit : GB.
FileSystem.MountPointCount	Long	The number of mount points.
FileSystem.FileSystemId	String	The ID of the file system instance.
FileSystem.CreateTime	String	The time at which the file system was created.
FileSystem.UsedSpaceSize	Float	The space in use. Unit: GB.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=GetFileSystem
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",
  "FileSystem": {
    "SpaceCapacity": 1024,
    "Description": "This is the first Apsara File Storage for HDFS instance of my company",
    "ProtocolType": "HDFS",
    "UsedSpaceSize": 100.0,
    "RegionId": "cn-hangzhou",
    "FileSystemId": "037cb4****",
    "ZoneId": "cn-hangzhou-b",
    "StorageType": "STANDARD",
    "FileSystemName": "MyFirstDFS",
    "CreateTime": "2018-01-18 12:50:00",
    "MountPointCount": 2
  }
}
```

```
}
```

2.7.1.4.5 ListFileSystems

You can call this operation to query the detailed information about multiple file system instances.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
StartOffset	Integer	FALSE	The start position. Default value: 1 .
Limit	Integer	FALSE	The maximum number of entries to return. Default value: 10 .
OrderBy	String	FALSE	The sorting field. Valid values: CreateTime , FileSystemName , SpaceCapacity , and UsedSpaceSize . Default value: CreateTime .
OrderType	String	FALSE	The ordering mode. ASC indicates ascending order and DESC indicates descending order. Default value: ASC .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of entries returned. Maximum value: the value of the Limit parameter.
FileSystems	Array(Filesystem)	The list of detailed information about file systems.
FileSystem.RegionId	String	The ID of the region.
FileSystem.ZoneId	String	The ID of the zone.
FileSystem.FileSystemName	String	The name of the file system instance.

Parameter	Type	Description
FileSystem.Description	String	The description of the file system instance.
FileSystem.ProtocolType	String	The interface protocol type.
FileSystem.StorageType	String	The type of the storage medium.
FileSystem.SpaceCapacity	Long	The estimated capacity of the file system instance. Unit : GB.
FileSystem.MountPointCount	Long	The number of mount points.
FileSystem.FileSystemId	String	The ID of the file system instance.
FileSystem.CreateTime	String	The time at which the file system instance was created .
FileSystem.UsedSpaceSize	Float	The space in use. Unit: GB.

Examples

Sample requests

```
GET https://dfs.cn-hangzhou.aliyuncs.com/?Action=ListFileSystems
&InputRegionId=cn-hangzhou
&StartOffset=10
&Limit=10
&OrderBy=CreateTime
&OrderType=ASC
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "TotalCount": 1,
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",
  "FileSystems": [
    {
      "SpaceCapacity": 1024,
      "Description": "This is the first Apsara File Storage for HDFS instance of my company.",
      "ProtocolType": "HDFS",
      "UsedSpaceSize": 100.0,
      "RegionId": "cn-hangzhou",
      "FileSystemId": "037cb4****",
      "ZoneId": "cn-hangzhou-b",
      "StorageType": "STANDARD",
      "FileSystemName": "MyFirstDFS",

```

```
"CreateTime": "2018-01-18 12:50:00",
"MountPointCount": 2
}
]
```

2.7.1.5 Permissions

2.7.1.5.1 CreateAccessGroup

You can call this operation to create a permission group.

**Note:**

Each permission group can contain multiple permission rules. A permission group is a list of IP addresses that are allowed to access the file system. When mounting a file system instance, you must specify a permission group to define the IP address range allowed to access the file system instance.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupName	String	TRUE	The name of the permission group. Maximum length: 100 bytes.
NetworkType	String	TRUE	The type of the permission group. Set this parameter to VPC .
Description	String	FALSE	The description of the permission group. Maximum length: 100 bytes.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AccessGroupId	String	The ID of the permission group.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=CreateAccessGroup
&InputRegionId=cn-hangzhou
&AccessGroupName=my-online-cluster-policy
&NetworkType=VPC
&Description=Special policy for online cluster segments
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",
  "AccessGroupId": "c5ffd6-bf99****"
}
```

2.7.1.5.2 DeleteAccessGroup

You can call this operation to delete an existing permission group.

Note:

A permission group can be deleted only when it is not associated with any mount points. All rules in the permission group are deleted along with the permission group.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=DeleteAccessGroup
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf99****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.5.3 ModifyAccessGroup

You can call this operation to modify the attributes of a permission group.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.
AccessGroupName	String	FALSE	The new permission group name. Maximum length: 100 bytes.
Description	String	FALSE	The new permission group description. Maximum length: 100 bytes.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ModifyAccessGroup
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf99****
&AccessGroupName=my-online-cluster-policy
&Description=Special policy for online cluster segments
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.5.4 GetAccessGroup

You can call this operation to query information about a permission group.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AccessGroup	Struct	The detailed information about the permission group.
AccessGroup.RegionId	String	The ID of the zone.
AccessGroup.AccessGroupName	String	The name of the permission group.
AccessGroup.NetworkType	String	The type of the permission group.
AccessGroup.Description	String	The description of the permission group.
AccessGroup.AccessGroupId	String	The ID of the permission group.
AccessGroup.CreateTime	String	The time the permission group was created.
AccessGroup.RuleCount	Integer	The number of rules in the permission group.
AccessGroup.MountPointCount	Integer	The number of mount entries associated with the permission group.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=GetAccessGroup
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf99****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "AccessGroup": {
    "Description": "Special permission group for the test cluster",
    "RegionId": "cn-shanghai",
    "AccessGroupName": "test-cluster-policy",
    "RuleCount": 3,
    "NetworkType": "VPC",
    "CreateTime": "2018-01-05 12:30:15",
    "AccessGroupId": "c5ffd6-bf99****",
    "MountPointCount": 1
  },
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.5.5 ListAccessGroups

You can call this operation to query the detailed information about multiple permission groups.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
StartOffset	Integer	FALSE	The position from which to start listing permission groups. Default value: 1 .
Limit	Integer	FALSE	The maximum number of entries to return. Default value: 10 .
OrderBy	String	FALSE	The field by which to sort permission groups. Valid values: AccessGroupName and CreateTime . Default value: CreateTime .
OrderType	String	FALSE	The ordering mode. Valid values: ASC and DESC . Default value: ASC .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of entries returned. Maximum value: the value of the Limit parameter.
AccessGroups	Array(AccessGroup)	The list of detailed information about permission groups.
AccessGroup.RegionId	String	The ID of the zone.
AccessGroup.AccessGroupName	String	The name of the permission group.
AccessGroup.NetworkType	String	The type of the permission group.
AccessGroup.Description	String	The description of the permission group.
AccessGroup.AccessGroupId	String	The ID of the permission group.
AccessGroup.CreateTime	String	The time the permission group was created.
AccessGroup.RuleCount	Integer	The number of rules in the permission group.
AccessGroup.MountPointCount	Integer	The number of mount entries associated with the permission group.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ListAccessGroups
&InputRegionId=cn-hangzhou
&StartOffset=10
&Limit=10
&OrderBy=CreateTime
&OrderType=ASC
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "TotalCount": 1,
  "AccessGroups": [
    {
      "Description": "Special permission group for the test cluster",
      "RegionId": "cn-shanghai",
      "AccessGroupName": "test-cluster-policy",
      "RuleCount": 3,
      "NetworkType": "VPC",
      "CreateTime": "2018-01-05 12:30:15",
      "AccessGroupId": "c5ffd6-bf99****",
      "MountPointCount": 1
    }
  ],
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.5.6 CreateAccessRule

You can call this operation to create a permission rule.

**Note:**

Priority indicates the matching sequence of the rules in a permission group. The smaller the **Priority** value, the higher the priority is.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.
NetworkSegment	String	TRUE	The IP address or address range. For example, 192.168.1.220 indicates an IP address, and 10.10.3.0/24 indicates an IP address range from 10.10.3.0 to 10.10.3.255.

Parameter	Type	Required	Description
RWAccessType	String	TRUE	The access type. RDWR indicates read/write permissions, and RDONLY indicates read-only. Set this parameter to RDWR .
Priority	Integer	TRUE	The priority of the rule. The smaller the value, the higher the priority is. The rules are matched in the ascending order of the Priority value until a match is found. Valid values: 0 to 100.
Description	String	FALSE	The description of the rule. Maximum value: 100 bytes.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AccessRuleId	String	The ID of the rule.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=CreateAccessRule
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf9941bd
&NetworkSegment=10.10.3.0/24
&RWAccessType=RDWR
&Priority=2
"Description": "network segment of the server to which logs are uploaded",
&<Common request parameters>
```

Sample responses

- JSON format

```
{
```

```
"RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",  
"AccessRuleId": "a0ws0****"  
}
```

2.7.1.5.7 DeleteAccessRule

You can call this operation to delete a permission rule.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.
AccessRuleId	String	TRUE	The ID of the rule.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=DeleteAccessRule  
&InputRegionId=cn-hangzhou  
&AccessGroupId=c5ffd6-bf99****  
&AccessRuleId=a0ws0****  
&<Common request parameters>
```

Sample responses

- JSON format

```
{  
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"  
}
```

}

2.7.1.5.8 ModifyAccessRule

You can call this operation to modify attributes about a rule.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupID	String	TRUE	The ID of the permission group.
AccessRuleId	String	TRUE	The ID of the rule.
RWAccessType	String	FALSE	The access type. RDWR indicates read/write permissions, and RDONLY indicates read-only. Set this parameter to RDWR .
Priority	Integer	FALSE	The priority of the rule. The smaller the value, the higher the priority is. The rules are matched in the ascending order of the Priority value until a match is found. Valid values: 0 to 100.
Description	String	FALSE	The description of the rule. Maximum value: 100 bytes.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ModifyAccessRule
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf99****
&AccessRuleId=a0ws0****
&RWAccessType=RDWR
&Priority=2
"Description": "network segment of the server to which logs are uploaded",
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.5.9 GetAccessRule

You can query this operation to query detailed information about a rule.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.
AccessRuleId	String	TRUE	The ID of the rule.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AccessRule	Struct	The detailed information about the rule.
AccessRule.AccessRuleId	String	The ID of the rule.
AccessRule.AccessGroupId	String	The ID of the permission group.
AccessRule.RegionId	String	The ID of the zone.

Parameter	Type	Description
AccessRule.NetworkSegment	String	The IP address or address range. For example, 192.168.1.220 indicates an IP address , and 10.10.3.0/24 indicates an IP address range from 10.10.3.0 to 10.10.3.255.
AccessRule.Description	String	The description of the rule.
AccessRule.Priority	Integer	The priority of the rule. The smaller the value, the higher the priority is. The rules are matched in the ascending order of the Priority value until a match is found.
AccessRule.RWAccessType	String	The access type. RDWR indicates read/write permissions, and RDONLY indicates read-only. Set this parameter to RDWR .
AccessRule.CreateTime	String	The time the rule was created.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=GetAccessRule
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf99****
&AccessRuleId=a0ws0****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",
  "AccessRule": {
    "NetworkSegment": "10.10.3.0/24",
    "Description": "Network segment of the server to which logs are uploaded",
    "RWAccessType": "RDWR",
    "RegionId": "cn-shanghai",
    "AccessRuleId": "a0ws0****",
    "Priority": 2,
    "CreateTime": "2018-01-05 12:30:15",
    "AccessGroupId": "c5ffd6-bf99****"
  }
}
```

}

2.7.1.5.10 ListAccessRules

You can call this operation to query the detailed information about multiple rules.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
AccessGroupId	String	TRUE	The ID of the permission group.
StartOffset	Integer	FALSE	The position from which to start listing access rules. Default value: 1 .
Limit	Integer	FALSE	The maximum number of entries to return. Default value: 10 .
OrderBy	String	FALSE	The field by which to sort access rules. Valid values: Priority and CreateTime . Default value: Priority .
OrderType	String	FALSE	The ordering mode. Valid values: ASC and DESC . Default value: ASC .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of entries returned. Maximum value: the value of the Limit parameter.
AccessRules	Array(AccessRule)	The list of detailed information about rules.

Parameter	Type	Description
AccessRule.AccessRuleId	String	The ID of the rule.
AccessRule.AccessGroupId	String	The ID of the permission group.
AccessRule.RegionId	String	The ID of the zone.
AccessRule.NetworkSegment	String	The IP address or address range. For example, 192.168.1.220 indicates an IP address , and 10.10.3.0/24 indicates an IP address range from 10.10.3.0 to 10.10.3.255.
AccessRule.Description	String	The description of the rule.
AccessRule.Priority	Integer	The priority of the rule. The smaller the value, the higher the priority is. The rules are matched in the ascending order of the Priority value until a match is found.
AccessRule.RWAccessType	String	The access type. RDWR indicates read/write permissions, and RDONLY indicates read-only. Set this parameter to RDWR .
AccessRule.CreateTime	String	The time the rule was created.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ListAccessRules
&InputRegionId=cn-hangzhou
&AccessGroupId=c5ffd6-bf99****
&StartOffset=10
&Limit=10
&OrderBy=CreateTime
&OrderType=ASC
&<Common request parameters>
```

Sample responses

- JSON format

```
{
```

```

"TotalCount": 1,
"AccessRules": [
  {
    "NetworkSegment": "10.10.3.0/24",
    "Description": "Network segment of the server to which logs are uploaded",
    "RWAccessType": "RDWR",
    "RegionId": "cn-shanghai",
    "AccessRuleId": "a0ws0****",
    "Priority": 2,
    "CreateTime": "2018-01-05 12:30:15",
    "AccessGroupId": "c5ffd6-bf99****"
  }
],
"RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}

```

2.7.1.6 Mount points

2.7.1.6.1 CreateMountPoint

You can call this operation to create a mount point. You can attach a file system instance to a VPC and allow the IP addresses defined in the specified permission rules to access the file system instance.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.
AccessGroupId	String	TRUE	The ID of the permission group.
NetworkType	String	TRUE	The network type of the mount point. Set this parameter to VPC .
VpcId	String	TRUE	The ID of the VPC.
VSwitchId	String	TRUE	The ID of the VSwitch.
Description	String	FALSE	The description of the mount point. Maximum length: 100 bytes.

Response parameters

Parameter	Type	Description
MountPointId	String	The ID of the mount point.
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=CreateMountPoint
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&AccessGroupId=c5ffd6-bf99****
&NetworkType=VPC
&VpcId=vpc-bp1lferqlollad1e****
&VSwitchId=vsw-bp11990m3zf3hp867****
&Description=Attach the online file system instance to the VSwitch in the VPC log cluster
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "MountPointId": "037cb49e1d-c****",
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.6.2 DeleteMountPoint

You can call this operation to delete a mount point.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.
MountPointId	String	TRUE	The ID of the mount point.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=DeleteMountPoint
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&MountPointId=037cb49e1d-c****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.6.3 ModifyMountPoint

You can call this operation to enable or disable a mount point, or modify the description of a mount point.

Description

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.
MountPointId	String	TRUE	The ID of the mount point.
AccessGroupId	String	FALSE	The ID of the permission group.
Description	String	FALSE	The description of the mount point. Maximum length: 100 bytes.

Parameter	Type	Required	Description
Status	String	FALSE	The status of the mount point. Inactive indicates that the mount point is disabled. Active indicates that the mount point is enabled.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ModifyMountPoint
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&MountPointId=037cb49e1d-c****
&AccessGroupId=c5ffd6-bf99****
&Description=Attach the online file system instance to the VSwitch in the VPC log cluster
&Status=Inactive
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.6.4 GetMountPoint

You can call this operation to query detailed information about a mount point.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.

Parameter	Type	Required	Description
FileSystemId	String	TRUE	The ID of the specified file system instance.
MountPointId	String	TRUE	The ID of the mount point.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
MountPoint	Struct	The detailed information about a mount point.
MountPoint.RegionId	String	The ID of the zone.
MountPoint.FileSystemId	String	The ID of the specified file system instance.
MountPoint.NetworkType	String	The network type of the mount point. Set this parameter to VPC .
MountPoint.VpcId	String	The ID of the VPC.
MountPoint.VSwitchId	String	The ID of the VSwitch.
MountPoint.AccessGroupId	String	The ID of the permission group.
MountPoint.Description	String	The description of the mount point.
MountPoint.Status	String	The status of the mount point. Inactive indicates that the mount point is disabled. Active indicates that the mount point is enabled.
MountPoint.MountPointId	String	The ID of the mount point.
MountPoint.MountPointDomain	String	The domain name of the mount point. Users within the mounted VPC network segment can use this domain name to access Apsara File Storage for HDFS.

Parameter	Type	Description
MountPoint.CreateTime	String	The time the mount point was created.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=GetMountPoint
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&MountPointId=037cb49e1d-c****
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "MountPoint": {
    "Status": "Inactive",
    "VpcId": "vpc-bp1lfyerqlollad1ee6k7",
    "Description": "Attach the online file system instance to the VSwitch in the VPC log cluster",
    "RegionId": "cn-shanghai",
    "CreateTime": "2018-01-05 12:30:15",
    "FileSystemId": "037cb4****",
    "VSwitchId": "vsw-bp11990m3zf3hp867****",
    "MountPointDomain": "037cb49e1d-cpu65.cn-hangzhou.dfs.aliyuncs.com",
    "MountPointId": "037cb49e1d-c****",
    "NetworkType": "VPC",
    "AccessGroupId": "c5ffd6-bf99****"
  },
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8"
}
```

2.7.1.6.5 ListMountPoints

You can call this operation to query the detailed information about multiple mount points.

Request parameters

Parameter	Type	Required	Description
InputRegionId	String	TRUE	The ID of the specified region.
FileSystemId	String	TRUE	The ID of the specified file system instance.

Parameter	Type	Required	Description
StartOffset	Integer	FALSE	The position from which to start listing mount points. Default value: 1 .
Limit	Integer	FALSE	The maximum number of entries to return. Default value: 10 .
OrderBy	String	FALSE	The field by which to sort mount points. Set this parameter to CreateTime . Default value: CreateTime .
OrderType	String	FALSE	The ordering mode. Valid values: ASC and DESC . Default value: ASC .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of entries returned. Maximum value: the value of the Limit parameter.
MountPoints	Array(MountPoint)	The list of detailed information about mount points entries.
MountPoint.RegionId	String	The ID of the zone.
MountPoint.FileSystemId	String	The ID of the specified file system instance.
MountPoint.NetworkType	String	The network type of the mount point. Set this parameter to VPC .
MountPoint.VpcId	String	The ID of the VPC.
MountPoint.VSwitchId	String	The ID of the VSwitch.

Parameter	Type	Description
MountPoint.AccessGroupId	String	The ID of the permission group.
MountPoint.Description	String	The description of the mount point.
MountPoint.Status	String	The status of the mount point. Inactive indicates that the mount point is disabled. Active indicates that the mount point is enabled.
MountPoint.MountPointId	String	The ID of the mount point.
MountPoint.MountPointDomain	String	The domain name of the mount point. Users within the mounted VPC network segment can use this domain name to access Apsara File Storage for HDFS.
MountPoint.CreateTime	String	The time the mount point was created.

Examples

Sample requests

```
GET https://dfs.regionid.example.com/?Action=ListMountPoints
&InputRegionId=cn-hangzhou
&FileSystemId=037cb4****
&StartOffset=10
&Limit=10
&OrderBy=CreateTime
&OrderType=ASC
&<Common request parameters>
```

Sample responses

- JSON format

```
{
  "TotalCount": 1,
  "RequestId": "55C5FFD6-BF99-41BD-9C66-FFF39189F4F8",
  "MountPoints": [
    {
      "Status": "Inactive",
      "VpcId": "vpc-bp1lfyerqlollad1e****",
      "Description": "Attach the online file system instance to the VSwitch in the VPC log cluster",
      "RegionId": "cn-shanghai",
      "CreateTime": "2018-01-05 12:30:15",
```

```
"FileSystemId": "037cb4****",
"VSwitchId": "vsw-bp11990m3zf3hp867****",
"MountPointDomain": "037cb49e1d-cpu65.cn-hangzhou.dfs.aliyuncs.com",
"MountPointId": "037cb49e1d-c****",
"NetworkType": "VPC",
"AccessGroupId": "c5ffd6-bf99****"
}
]
```

2.7.1.7 Appendix: Error codes

An error code consists of three components, as described in [Table 2-324: Error codes](#).

Table 2-324: Error codes

Component	Description
HTTP status code	The HTTP response code that complies with HTTP syntax.
Code	The error code.
Message	The error message.

Error codes

HTTP status code	Error code	Error message	Description
500	InternalServerError	An internal error occurred, please try again later.	The error message returned because an unknown internal error has occurred. Try again later.
503	ServiceUnavailable	The service is unavailable, please try again later.	The error message returned because the service is unavailable. Try again later.

HTTP status code	Error code	Error message	Description
401	NoPermission	The user is not authorized to operate on the specified resource, please check the permission of the user.	The error message returned because the user is not authorized to operate this resource. Check the permissions of the user.
501	NotFoundAction	Cannot find this action, please check whether the action is valid.	The error message returned because this operation was not found. Check whether the operation is valid.
400	InvalidRequest	Invalid request , please check request parameters.	The error message returned because the request is invalid. Check whether the request parameters are correct.
400	InvalidUserStatus	Invalid user, please check the user status.	The error message returned because the user status is not valid. Check the user status.

HTTP status code	Error code	Error message	Description
400	InvalidFileSystemName	Invalid filesystem name , please check whether it is unique.	The error message returned because the file system instance name is invalid. Check whether the name is unique.
400	InvalidFileSystemId	Invalid filesystem id, please check it.	The error message returned because the file system instance ID is invalid. Check whether the instance ID is valid.
400	InvalidMountPointId	Invalid mountpoint id, please check it.	The error message returned because the mount point ID is invalid. Check whether the mount point ID is valid.

HTTP status code	Error code	Error message	Description
403	FileSystemCountExceedLimit	The filesystem number has exceed the limit , please check the number of the owned filesystems.	The error message returned because the number of file system instances exceeds the limit. Check the number of file system instances that you own.
403	FileSystemHasMountPoint	The filesystem has mount points, please delete them first .	The error message returned because there are still mount points in the file system instance. Delete the mount points first.
403	MountPointCountExceedLimit	The mount point number has exceeded the limit, please check the number of the owned mount points. mount points.	The error message returned because the number of mount points exceeds the limit. Check the number of mount points that you own.

HTTP status code	Error code	Error message	Description
410	ResourceAlreadyDelete	The resource has already been deleted, please refresh.	The error message returned because the resource has been deleted . Refresh the page.
400	InvalidSpaceCapacity	The value of SpaceCapacity is invalid, please check the input.	The error message returned because the SpaceCapacity value is invalid . Check whether the specified value is valid.
403	ResourceNotEnough	The storage resource is not enough, please contact the system administrator.	The error message returned because there are insufficient storage resources . Contact the system administrator.
403	ActionNotComplete	The preceding action is still running, please wait a moment.	The error message returned because the previous operation is still in progress. Wait until it is complete and try again.

HTTP status code	Error code	Error message	Description
403	RegionNotSupport	The specified region is not support.	The error message returned because the specified region does not support the operation.
400	MissingParameter	The parameter %s is required.	The error message returned because the %s parameter is not specified . Specify this parameter.
403	ResourceLimitExceed	The %s resource has exceeded the limit.	The error message returned because the %s resource has exceeded its limit.
403	DependencyFound	The %s resource is being depended, please remove it first.	The error message returned because the %s resource is in use. Remove it first.
400	InvalidParameter	Invalid parameter, name: %s value : %s	The error message returned because the %s parameter and %s value are invalid.

HTTP status code	Error code	Error message	Description
404	ResourceNotExist	Resource %s does not exist, id: %s	The error message returned because the %s resource with %s as its ID does not exist.
409	ResourceNameConflict	The name of resource %s conflicts with others.	The error message returned because the %s resource name conflicts with another resource name.
409	ResourceAlreadyCreate	Resource %s has already been created, id: %s	The error message returned because the resource of the %s type with %s as its ID has already been created.

2.7.2 SDK reference

2.7.2.1 Overview

Apsara File Storage for HDFS SDKs consist of the file system SDK and the management Java SDK.

- The file system SDK provides a Hadoop-compatible file system through the implementation of [Hadoop FileSystem](#) interfaces. It is a JAR file named alicloud dfs-1.0.0.jar.

With this SDK, Apache Hadoop computing and analysis applications such as MapReduce , Hive, and Spark can use Apsara File Storage for HDFS as the default file system for better features and performance over the original HDFS.

- You can use the management Java SDK to call the management APIs of Apsara File Storage for HDFS to implement the corresponding functions available in the Apsara Stack console. The management Java SDK is a JAR file named aliyun-java-sdk-dfs-1.0.jar.

2.7.2.2 File system SDK

This topic uses `hadoop-mapreduce-examples` to describe how to use the file system SDK. MapReduce runs in the pseudo-distributed mode. For more information about the pseudo-distributed mode of MapReduce, see [Pseudo-Distributed Operation](#).

2.1 Check the environment

1. Run the `java -version` command to view the JDK version.

If the JDK version is earlier than 1.8, install the latest JDK.

2. After the JDK is installed, set the environment variables as follows: (Assume that the installation path is `/opt/install/java`.)

```
JAVA_HOME=/opt/install/java
```

```
PATH=/opt/install/java/bin:$PATH
```

2.2 Download the file system SDK

You can click [here](#) to download the JAR package of the file system SDK: `alicloud.dfs-1.0.0.jar`.

2.3 Configure Hadoop

1. Download the Hadoop 2.7.2 release package.
2. Run the `tar -zxvf hadoop-2.7.2.tar.gz` command to decompress the downloaded package.
3. Run the `export HADOOP_HOME=yourWorkingDir/hadoop-2.7.2` command to set the environment variables.
4. Run the `cd hadoop-2.7.2` command to access the hadoop directory.
5. Modify the `etc/hadoop/hadoop-env.sh` file. Add **JAVA_HOME** set in Section "2.1 Check the environment."

```
# set to the root of your Java installation
```

```
export JAVA_HOME=youJAVADir
```

6. Modify the `etc/hadoop/core-site.xml` file and synchronize the `core-site.xml` file to all nodes that are dependent on **hadoop-common**. The following code shows the content to be modified in the `core-site.xml` file:

```
<property>
  <name>fs.defaultFS</name>
  <value>dfs://DfsInstanceID.RegionID.alidfs.aliyun.com:10290</value>
</property>
<property>
  <name>fs.dfs.impl</name>
  <value>com.alibaba.dfs.DistributedFileSystem</value>
</property>
<property>
  <name>fs.AbstractFileSystem.dfs.impl</name>
  <value>com.alibaba.dfs.DFS</value>
</property>
<property>
  <name>alidfs.usergroupservice.impl</name>
  <value>com.alibaba.dfs.security.LinuxUserGroupService.class</value>
</property>
```

Note:

- Replace RegionID and DfsInstanceID with the actual region ID and Apsara File Storage for HDFS instance ID.
- You must synchronize the content from `core-site.xml` to all nodes dependent on **hadoop-common**.

2.4 Deploy dependencies

Copy the `alicloud.dfs-1.0.0.jar` package obtained in the preceding step to CLASSPATH of the Hadoop ecosystem component. We recommend that you deploy the package to the directory where `hadoop-common-X.YZ.jar` resides and copy this package to all Hadoop nodes. The directory of the MapReduce component is `$HADOOP_HOME/share/hadoop/hdfs`.

2.5 Verify installation

2.5.1 Prepare data

1. Run the following command to create a directory:

```
$HADOOP_HOME/bin/hadoop fs -mkdir inputDir
```

2. Run the following command to upload the `a.txt` file to the directory:

```
touch a.txt
$HADOOP_HOME/bin/hadoop fs -put a.txt inputDir/
```

2.5.2 Run sample code

Run the following sample code in \$HADOOP_HOME:

- wordcount:

```
bin/hadoop jar ./share/hadoop/mapreduce/hadoop-mapreduce-examples-2.7.2.jar
wordcount inputDir outputDir
```

- grep:

```
bin/hadoop jar ./share/hadoop/mapreduce/hadoop-mapreduce-examples-2.7.2.jar
grep inputDir/ outputDirGrep/ "the"
```

2.7.2.3 Management Java SDK

2.7.2.3.1 Java SDK

2.7.2.3.1.1 Quick start

This topic describes how to obtain and call the management Java SDK of Apsara File Storage for HDFS.

Preparation

- To use the management Java SDK of Apsara File Storage for HDFS, you need a RAM user and an AccessKey pair which consists of an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- For more information about how to obtain the endpoint of Apsara File Storage for HDFS, see [Obtain an endpoint](#).
- The management Java SDK of Apsara File Storage for HDFS requires JDK V1.6 or later.

Installation

If you use Apache Maven to manage Java projects, you need only to import the JAR file to pom.xml of the project.

To use the SDK, you must install both the SDK core library and the Java SDK of Apsara File Storage for HDFS.

The version of SDK core library is 3.7.1. The version of the Java SDK of Apsara File Storage for HDFS for Java is 1.0.

```
<dependencies>
```

```

<dependency>
  <groupId>com.aliyun</groupId>
  <artifactId>aliyun-java-sdk-core</artifactId>
  <version>3.7.1</version>
  <scope>system</scope>
  <systemPath>${project.basedir}/lib/aliyun-java-sdk-core-3.7.1.jar</systemPath>
</dependency>
<dependency>
  <groupId>com.aliyun</groupId>
  <artifactId>aliyun-java-dfs</artifactId>
  <version>1.0</version>
  <scope>system</scope>
  <systemPath>${project.basedir}/lib/aliyun-java-sdk-dfs-1.0.jar</systemPath>
</dependency>
</dependencies>

```

Usage

The following code provides an example of how to use the management Java SDK of Apsara File Storage for HDFS:

1. Create a DefaultAcsClient instance and initialize it.
2. Create an API request and specify its parameters.
3. Initiate a request and process the responses or exceptions.

```

package com.aliyuncs.dfs.test;
import com.alibaba.fastjson.JSONObject;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.cms.model.v20180228.CreateFileSystemRequest;
import com.aliyuncs.cms.model.v20180228.CreateFileSystemResponse;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.http.FormatType;
import com.aliyuncs.profile.DefaultProfile;
import com.aliyuncs.profile.IClientProfile;
public class CreateFileSystemDemo {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize it.
        IClientProfile profile = DefaultProfile.getProfile(
            "cn-hangzhou", // The region name.
            "<your-access-key-id>", // The AccessKey ID of the RAM user.
            "<your-access-key-secret>"); // The AccessKey Secret of the RAM user.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and specify its parameters.
        CreateFileSystemRequest request = new CreateFileSystemRequest();
        request.setZoneId("cn-hangzhou-b");
        request.setInputRegionId("cn-hangzhou");
        request.setDescription("My first dfs file system instance");
        request.setFileSystemName("My_AliCloud_DFS");
        request.setProtocolType("HDFS");
        request.setStorageType("STANDARD");
        request.setSpaceCapacity("20"); // in GB
        request.setAcceptFormat(FormatType.JSON);
        // Initiate the request and handle the responses or exceptions.
        try {
            CreateFileSystemResponse response = client.getAcsResponse(request);
            System.out.println(response.getRequestId());
            System.out.println(response.getFileSystemId());
        }
    }
}

```

```
    } catch (ServerException e) {  
        e.printStackTrace();  
    } catch (ClientException e) {  
        e.printStackTrace();  
    }  
    }  
}
```

2.7.2.3.1.2 Use the Java SDK

2.7.2.3.1.2.1 Install the management Java SDK

This topic describes how to install and call the management Java SDK of Apsara File Storage for HDFS.

The management Java SDK of Apsara File Storage for HDFS supports JDK V1.6 and later. You can install the latest JDK version by importing the JAR file.

You can click [here](#) to download the JAR package of the management Java SDK: `aliyun-java-sdk-dfs-1.0.jar`.

You can import the JAR package to install the management Java SDK, regardless of whether Eclipse or IntelliJ is used as the integrated development environment (IDE).

The installation method is as follows:

- Use Eclipse

Perform the following steps to install the management Java SDK of Apsara File Storage for HDFS in Eclipse:

1. Copy the `aliyun-java-sdk-dfs-1.0.jar` file to your project folder.
2. In Eclipse, open your project, right-click the project, and choose **Properties** from the shortcut menu.
3. In the dialog box that appears, choose **Java Build Path > Libraries > Add JARs** to add the downloaded JAR files.
4. Click **Apply and Close**.

- Use IntelliJ

Perform the following steps to install the management Java SDK of Apsara File Storage for HDFS in IntelliJ:

1. Copy the `aliyun-java-sdk-dfs-1.0.jar` file to your project folder.
2. Open your project in IntelliJ. In the menu bar, choose **File > Project Structure**.
3. Click **Apply** and then click **OK**.

2.7.2.3.1.2.2 Configure authentication credentials

When you use the management Java SDK to access Apsara File Storage for HDFS, you need to provide an authorized account for authentication.

The Java SDK supports the use of AccessKey pairs for authentication. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use an AccessKey pair as the credential, you must configure it as a credential when client is being initialized.

Notice:

Do not disclose any code containing your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your authorized account may be compromised.

```
IClientProfile profile = DefaultProfile.getProfile(
    "cn-hangzhou", // The region name.
    "<your-access-key-id>", // The AccessKey ID of the RAM user.
    "<your-access-key-secret>"); // The AccessKey Secret of the RAM user.
```

2.7.2.3.1.2.3 Initiate a call

This topic describes how to use the management Java SDK of Apsara File Storage for HDFS to initiate a request.

Procedure

1. Create an AcsClient instance.

```
IAcsClient client = new DefaultAcsClient(profile);
```

2. Create a request.

The request name is in the format of `${apiName}Request`, where **`${apiName}`** indicates the API name, such as `CreateFileSystem`.

When SDKs of multiple services are introduced, different requests may have the same name. Differentiate the requests based on the package.

```
CreateFileSystemRequest request = new CreateFileSystemRequest();
request.setZoneId("cn-hangzhou-b");
request.setInputRegionId("cn-hangzhou");
request.setDescription("My first dfs file system instance");
request.setFileSystemName("My_AliCloud_DFS");
request.setProtocolType("HDFS");
request.setStorageType("STANDARD");
request.setSpaceCapacity("20"); // in GB
request.setAcceptFormat(FormatType.JSON);
```

3. Initiate a call and handle the response.

```
try {
    CreateFileSystemResponse response = client.getAcsResponse(request);
    System.out.println(response.getRequestId());
}
```

```

        System.out.println(response.getFileSystemId());
    } catch (ServerException e) {
        e.printStackTrace();
    } catch (ClientException e) {
        e.printStackTrace();
    }
}

```

All returned fields are deserialized into the response. You can call `response.getXXX()` to obtain the response fields.

```
FileSystemId := response.getFileSystemId()
```

If an exception occurs, or you need the original HTTP response, use `doAction()` to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.7.2.3.1.2.4 Troubleshooting

When using the Java SDK, if EDAS or the SDK client encounters an exception, the corresponding exception information is returned. An SDK client refers to either a provider or consumer that has the SDK installed. The exception information contains error details, such as error codes and error messages.

Among the errors returned by the EDAS Java SDK, you do not need to handle the SDK errors. Instead, you need only to handle EDAS-related exceptions based on the error messages.

- `ServerException` is the error message for EDAS.
- `ClientException` is the error message for the SDK client.

For example, if the following exception occurs, you can modify the `AccessKeyId` based on the error message.

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified
access key is not found.
```

If you need to handle SDK exceptions, develop your code by referring to the following example:

```

try {
    FooResponse response = client.getAcsResponse(request);
    // Handles the response.
    //...
} catch (ServerException e) {
    // You can add your own exception handling logic here.
    // For example, print the error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If the problem persists, you can open a ticket with the request ID included.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {

```

```
// You can add your own exception handling logic here.
// For example, print the error message.
System.out.println("ErrorCode=" + e.getErrCode());
System.out.println("ErrorMessage=" + e.getErrMsg());
}
```

2.7.2.3.1.2.5 Common errors

This topic describes how to troubleshoot common errors you may encounter during the use of SDKs.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot automatically obtain the endpoint of the called service in the specified region.	Check whether the provided region ID and endpoint are correct. After you have obtained the correct endpoint, you can run the following code to set the endpoint: <pre>DefaultProfile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response	The SDK response fails to be deserialized. In most cases, the cause is that the structure of the response received by the SDK does not conform to the API metadata, such as mismatched fields or incorrect formatting.	You can use the <code>client.doAction(request)</code> method to retrieve the original HTTP response.
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The request times out and all retry attempts fail.	In scenarios such as low network quality, we recommend that you increase the timeout period or the maximum number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError : InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect Recommend : <code>https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw</code>	The API only accepts HTTPS requests but not HTTP requests.	Before sending a request, add the following code: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.7.3 Obtain an AccessKey pair

You can obtain the AccessKey pair on the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center** >

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.7.4 Obtain an endpoint

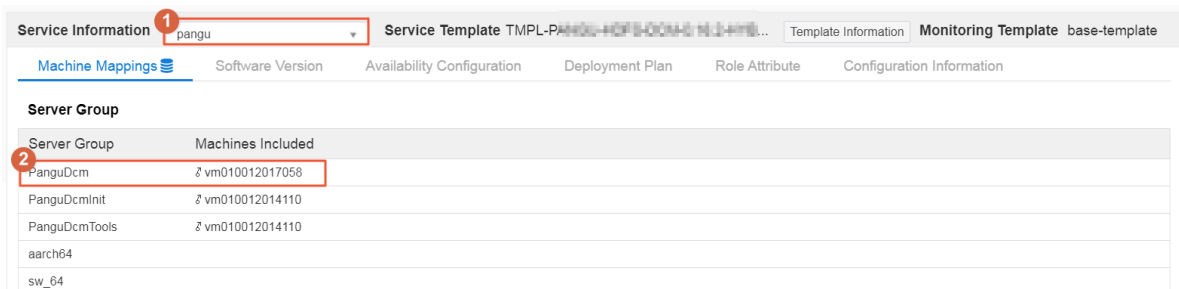

You can obtain the endpoint of a service in the Apsara Stack Operations console.

Procedure

1. Log on to the Apsara Stack Operations console.

For more information about how to log on to Apsara Stack Operations, see **Operations of basic platforms > Apsara Stack Operations > Log on to Apsara Stack Operations** in Operations Guide .

2. In the left-side navigation pane, click **Products**.
3. Click **Apsara Infrastructure Management Framework** to go to the Apsara Infrastructure Management Framework console.
4. In the top navigation bar, choose **Operations > Cluster Operations**.
5. On the **Cluster Operations** page that appears, enter PanguDcmCluster in **Cluster**.
6. Click **Cluster Configuration** in the Actions column corresponding to the cluster.
7. On the **Cluster Configuration** page that appears, perform the following operations:

- Select **pangu** from the **Service Information** drop-down list.
- In Server Group, click the hostname corresponding to PanguDcm.

8. In the **Machine List** dialog box that appears, click **TS**.

9. On the **TerminalService** page that appears, run the following command:

```
grep -r internet-domain /apsara/pangu_dcm/conf.global/kv.json
```

10. Take the endpoint "internet-domain": "example.site.com", displayed in step 9 as an example. You can use the format `alidfs.${internet-domain}` to obtain `alidfs.example.site.com`.

2.8 ApsaraDB for RDS

2.8.1 API reference

2.8.1.1 List of operations by function

The following tables list API operations available for use in RDS.

RDS instance management

Operation	Description
CreateDBInstance	Creates an RDS instance.
DeleteDBInstance	Releases an RDS instance.
RestartDBInstance	Restarts an RDS instance.
DescribeDBInstanceAttribute	Queries the details of an RDS instance.
DescribeDBInstances	Queries the instance list.

Operation	Description
ModifyDBInstanceSpec	Modifies the RDS instance type.
AllocateInstancePublicConnection	Applies for a public endpoint.
ReleaseInstancePublicConnection	Releases a public endpoint.
SwitchDBInstanceNetType	Applies for an internal endpoint.
DescribeDBInstanceNetInfo	Queries all endpoints.
ModifyDBInstanceConnectionString	Modifies an endpoint.
ModifyDBInstanceConnectionMode	Changes the RDS instance access mode.
ModifyDBInstanceNetworkType	Changes the RDS instance network type.
DescribeDBInstanceIPArrayList	Queries the IP whitelist of an RDS instance.
ModifySecurityIps	Modifies the IP whitelist of an RDS instance.
DescribeRegions	Queries the RDS region and zone information.
DescribeDBInstanceHAConfig	Queries the RDS zone information and data replication status.
MigrateToOtherZone	Migrates an RDS instance from one zone to another.
PurgeDBInstanceLog	Clears the logs of an RDS instance.
UpgradeDBInstanceEngineVersion	Upgrades the RDS instance version.
ModifyDBInstanceDescription	Modifies the description of an RDS instance.
ModifyDBInstanceMaintainTime	Modifies the maintenance window of an RDS instance.
ModifyDBInstanceHAConfig	Modifies the data replication and high availability policies of an RDS instance.
SwitchDBInstanceHA	Switches between the primary and secondary RDS instances.
CreateReadonlyDBInstance	Creates a read-only RDS instance.
DescribeDBInstanceSSL	Queries the SSL link of an RDS instance.
ModifyDBInstanceSSL	Modifies the SSL link of an RDS instance.
DescribeDBInstanceTDE	Queries the TDE status of an RDS instance.
ModifyDBInstanceTDE	Modifies the TDE status of an RDS instance.

RDS database management

Operation	Description
CreateDatabase	Creates a database.
DeleteDatabase	Deletes a database.
DescribeDatabases	Queries the database list.
ModifyDBDescription	Modifies the description of a database.

RDS account management

Operation	Description
CreateAccount	Creates an account.
DeleteAccount	Deletes an account.
DescribeAccounts	Queries the account list.
GrantAccountPrivilege	Grants permissions to an account.
RevokeAccountPrivilege	Revokes permissions from an account.
ModifyAccountDescription	Modifies the description of an account.
ResetAccountPassword	Resets the password of an account.
ResetAccount	Resets an account.

RDS backup and restoration

Operation	Description
CreateBackup	Creates a backup.
CloneDBInstance	Clones an RDS instance.
DescribeBackups	Queries the backup instance list.
CreateTempDBInstance	Creates a temporary instance.
DescribeBackupPolicy	Queries a backup policy.
ModifyBackupPolicy	Modifies a backup policy.
RestoreDBInstance	Restores a backup set to an instance.
DeleteBackup	Deletes data backup files.

RDS monitoring management

Operation	Description
DescribeResourceUsage	Queries the resource usage of an instance.
DescribeDBInstancePerformance	Queries the performance data of an instance.
DescribeDBInstanceMonitor	Queries the monitoring behaviors of an instance.
ModifyDBInstanceMonitor	Modifies the monitoring behaviors of an instance.

RDS parameter management

Operation	Description
DescribeParameterTemplates	Queries a database parameter template.
DescribeParameters	Queries the running database parameter list of the current instance.
ModifyParameter	Modifies the database parameter list.

RDS log management

Operation	Description
DescribeSlowLogs	Queries the slow log list.
DescribeSlowLogRecords	Queries slow log details.
DescribeErrorLogs	Queries error logs.
DescribeBinlogFiles	Queries binlogs.
DescribeSQLCollectorPolicy	Queries the SQL collection status.
ModifySQLCollectorPolicy	Changes the SQL collection status.
DescribeSQLLogRecords	Queries the SQL audit logs of an RDS instance.
DescribeSQLLogFiles	Queries the SQL audit file list.

RDS data migration

Operation	Description
ImportDatabaseBetweenInstances	Migrates data from other instances.
CancelImport	Cancels an import task.

RDS tag management

Operation	Description
AddTagsToResource	Binds a tag.
DescribeTags	Queries tags.
RemoveTagsFromResource	Unbinds a tag.

2.8.1.2 Make API requests

2.8.1.2.1 Request structure

This topic describes the request structure of RDS APIs.

Endpoints

The endpoint of the RDS API is `rds.example.com`. For more information about how to obtain a service endpoint, see [Obtain an endpoint](#).

Protocols

You can send requests over HTTP or HTTPS. We recommend that you send requests over HTTPS to enhance security.

Methods

The HTTP GET method can be used to send requests. Request parameters must be included in the request URL.

Request parameters

Each request must specify the action to be performed in the Action parameter. Each operation request must include common request parameters and the specific request parameters of the operation called.

Encoding

Requests and responses are encoded in UTF-8.

2.8.1.2.2 Common parameters

2.8.1.2.2.1 Common request parameters

Common request parameters must be included in the request of each API.

Parameter	Type	Required	Description
Format	String	No	The format of the response. Valid values: JSON and XML. Default value: XML.
Version	String	Yes	The API version. It is in the YYYY-MM-DD format. The current version is 2014-08-15.
AccessKeyId	String	Yes	The AccessKey ID provided to you by Alibaba Cloud.
Signature	String	Yes	The signature result string. For more information about the signature calculation method, see Request signatures .
SignatureMethod	String	Yes	The algorithm used to create the request signature. Valid value: HMAC-SHA1.
Timestamp	String	Yes	The request timestamp. The timestamp follows the ISO 8601 standard and uses UTC. It is in the YYYY-MM-DDThh:mm:ssZ format. For example, 20:00:00, August 15, 2013, UTC+8 will be written as 2013-08-15T12:00:00Z.
SignatureVersion	String	Yes	The signature algorithm version. The current version is 1.0.
SignatureNonce	String	Yes	A unique, randomly generated number used to prevent network replay attacks. You must use a different random number for each request.

Example

```
https://rds.example.com/  
? Format=xml  
&Version=2014-08-15  
&Signature=Pc5WB8gokVnxxxxx  
&SignatureMethod=HMAC-SHA1  
&SignatureNonce=15215528852396  
&SignatureVersion=1.0  
&AccessKeyId=key-test  
&OwnerId=12345678
```

```
&Timestamp=2014-10-10T12:00:00Z
```

2.8.1.2.2.2 Common response parameters

The system returns a unique RequestId for each API request, regardless of whether the API operation is successful.

Example

```
<? xml version="1.0" encoding="utf-8"? >
<!--Result root node-->
<API name + response>
  <!--Returned request tag-->
  <RequestId>4C4***38-****_****_****_*****6F216</RequestId>
  <!--Response data-->
</API name + response>
```

2.8.1.2.3 Responses

2.8.1.2.3.1 Success responses

The response data for API requests is displayed in a uniform format. In the response data, a 2xx HTTP status code indicates that the API operation is called.

The response data for called API operations is returned in either the XML or JSON format. You can add parameters to an API request to specify the format of the response data. Response data uses the XML format by default.

Sample responses in this topic are formatted with line breaks or indents for a clear view. The actual responses are not formatted in the same manner as these examples.

- Responses in the XML format include information about whether the call is successful, and details specific to the operation. Example:

```
<!--Result root node-->
<API name + response>
  <!--Response request tag-->
  <RequestId>4C467B38-****-447D-****-AC04*****16</RequestId>
  <!--Response data-->
</API name + response>
```

- JSON format

```
{ "RequestId": "4C467B38-****-447D-****-AC04*****16", /* Response Data */ }
```

2.8.1.2.3.2 Error responses

When an error occurs during an API call, no result data is returned. You can locate the cause of the error by referencing Error codes in Appendix.

When an error occurs on an HTTP request for an API operation, a 4xx or 5xx HTTP status code is returned.

The response body includes the error code and error message.

RequestId uniquely identifies the request and HostId indicates the ID of the site requested to be accessed. You can contact Alibaba Cloud customer service when the cause of the error cannot be found. We recommend that you provide HostId and RequestId to help us resolve the issue at the earliest opportunity.

XML format

```
<Error>
<RequestId>8906582E-****-****-A6C4-0E78*****5</RequestId>
<HostId>rds.example.com</HostId>
<Code>UnsupportedOperation</Code>
<Message>The specified action is not supported. </Message>
</Error>
```

JSON format

```
{ "RequestId": "7463B73D-****-4D19-****-6B8*****2EF",
  "HostId": "rds.example.com",
  "Code": "UnsupportedOperation",
  "Message": "The specified action is not supported."
}
```

2.8.1.2.4 Request signatures

ApsaraDB for RDS authenticates each access request. Therefore, a request must contain signature information whether submitted using HTTP or HTTPS. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

RDS performs symmetric encryption using the AccessKey ID and AccessKey Secret to verify the identity of a request sender.

The AccessKey pair is issued by Alibaba Cloud and can be applied for and managed through the official Alibaba Cloud website.

- The AccessKey ID indicates the identity of the visitor.
- The AccessKey Secret is used to encrypt signature strings and verify signature strings on the server. You must keep your AccessKey Secret confidential.

Perform the following steps to sign an access request:

1. Use request parameters to construct a canonicalized query string.**a. Sort all of the request parameters in alphabetic order.**

The request parameters include common request parameters and customized parameters for the API request, but exclude the Signature parameter in common request parameters.

**Note:**

When you use the GET method to submit a request, the request parameters are included as a part of the URI. The request parameters in the URI are placed after a question mark (?) and separated by ampersands (&).

b. Encode each parameter name and value.

Parameter names and values are encoded into a URL based on the UTF-8 character set.

The URL encoding rules are described as follows:

- Uppercase and lowercase letters, numbers, hyphens (-), underscores (_), periods (.), and tildes (~) are not required to be encoded.
- Other characters are encoded as %XY, where XY is the hexadecimal representation of the character in ASCII.

For example, double quotation marks (") are encoded as %22.

- Extended UTF-8 characters are encoded in the %XY%ZA... format.
- A space is encoded as %20, rather than the plus sign (+).

**Note:**

Most libraries that support URL encoding, such as `java.net.URLEncoder`, comply with the encoding rules for the "application/x-www-form-urlencoded" MIME type.

If this encoding method is used, replace the plus signs (+) in the encoded strings with %20, the asterisks (*) with %2A, and %7E with a tilde (~) to conform to the encoding rules.

c. Connect the encoded parameter names and values with equal signs (=).**d. Sort the equal sign-connected strings by their parameter names alphabetically and connect them with ampersands (&).**

2. Use the created canonicalized query string to construct a string for signature calculation based on the following rule:

```
StringToSign=
HTTPMethod + "&" +
percentEncode( "/" ) + "&" +
percentEncode(CanonicalizedQueryString)
```

- HTTPMethod: specifies to use the HTTP method to submit requests, such as GET.
 - percentEncode("/"): specifies the encoded value for the forward slash (/) based on the URL encoding rules described in the preceding step, which is %2F.
 - percentEncode(CanonicalizedQueryString): specifies the encoded canonicalized query string constructed in step 1, produced by following the URL encoding rules described in 1.b.
3. Use the previous signature string to calculate the HMAC value of the signature as defined in RFC 2104.

**Note:**

The key used for signature calculation is your AccessKey Secret. An ampersand (&) is added to the end of the key (ASCII: 38). The SHA-1 hashing is used.

4. Encode the HMAC value into a string based on the Base64 encoding rules. This encoded string is the signature value.
5. Add the signature value as the Signature parameter value to the request parameters to complete the request signing process.

**Note:**

The obtained signature value must use RFC 3986 URL encoding like other parameters before it can be submitted to the RDS server as the final request parameter value.

DescribeCdnService is used here as an example. The request URL before signing is:

```
http://rds.example.com/?TimeStamp=2013-06-01T10:33:56Z&Format=XML&
AccessKeyId=testid&Action=DescribeDBInstances&SignatureMethod=HMAC-SHA1
&RegionId=region1&SignatureNonce=NwDaxvLU6tFE0DVb&Version=2014-08-15&
SignatureVersion=1.0
```

After signing, the StringToSign is as follows:

```
GET&%2F&AccessKeyId%3Dtestid%26Action%3DDescribeDBInstances%26Format%
3DXML%26RegionId%3Dregion1%26SignatureMethod%3DHMAC-SHA1%26Signatur
```

```
eNonce%3DNwDAxvLU6tFE0DVb%26SignatureVersion%3D1.0%26TimeStamp%3D2013-06-01T10%253A33%253A56Z%26Version%3D2014-08-15
```

Assume that the AccessKey ID is testid, the AccessKey Secret is testsecret, and the key used for HMAC calculation is testsecret&. The calculated signature value is as follows:

```
BIPOMlu8LXBeZtLQkJTw6iFvw1E=
```

In this example, the request URL after signing is as follows.

The Signature parameter has been added to the URL.

```
http://rds.example.com/?TimeStamp=2013-06-01T10%3A33%3A56Z&Format=XML&AccessKeyId=testid&Action=DescribeDBInstances&SignatureMethod=HMAC-SH
```

2.8.1.3 Instance management

2.8.1.3.1 CreateDBInstance

Description

You can call this operation to create an RDS instance. For more information about the instance type, see Instance types in Appendix.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateDBInstance.
RegionId	String	Yes	The region ID of the instance. The region ID can be up to 50 characters in length. You can call the DescribeRegions operation to query available regions.
ZoneId	String	No	The zone ID of the instance. You can call the DescribeRegions operation to query available zones.
Engine	String	Yes	The type of the database. Valid values: MySQL, PostgreSQL, and PPAS.
EngineVersion	String	Yes	The version of the database engine. Valid values: MySQL: 5.6 and 5.7 PostgreSQL: 9.4 PPAS: 9.3 and 9.6

Parameter	Type	Required	Description
DBInstanceClass	String	Yes	The specifications of the instance.
DBInstanceStorage	Integer	Yes	The user-defined storage space. Valid values: MySQL HA edition: 5 to 2000 MySQL 5.7 basic edition: 20 to 1000 PostgreSQL or PPAS HA edition: 5 to 2000 This value must be a multiple of 5 GB. Unit: GB.
DBInstanceNetType	String	Yes	The network connection type of the instance. Valid values: Internet and Intranet.
DBInstanceDescription	String	No	The description of the instance. It can be up to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It cannot start with http:// or https://. It must start with a letter.
SecurityIPList	String	Yes	The IP addresses in an IP address whitelist. Separate multiple IP addresses with commas (.). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats of IP addresses are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or Classless Inter-Domain Routing (CIDR) blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.
PayType	String	Yes	The billing method of the instance. Valid values: Postpaid and Prepaid. Postpaid indicates pay-as-you-go and Prepaid indicates subscription.
Period	String	No	The unit of the subscription period. It is required if PayType is set to Prepaid. Valid values: Year and Month.
UsedTime	String	No	The number of the subscription units. It is required if PayType is set to Prepaid. Valid values: positive integers such as 1, 2, and 3.
ClientToken	String	Yes	The client token that is used to ensure the idempotence of the request.
InstanceNetworkType	String	No	The network type of the instance. Valid values: VPC and Classic. Default value: Classic.

Parameter	Type	Required	Description
Connection Mode	String	No	The access mode of the instance. Valid values: Performance and Safe. If no value is specified, the system automatically assigns an access mode.
VPCId	String	No	The ID of the VPC.
VSwitchId	String	No	The ID of the VSwitch.
PrivateIpAddress	String	No	The VPC IP address under the specified VSwitch. If no value is specified, the system automatically assigns a VPC IP address.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
DBInstanceId	String	The ID of the instance newly created.
OrderId	String	The ID of the order.
ConnectionString	String	The endpoint used to connect the database.
Port	String	The port used to connect the database.

Examples

Sample responses

- XML format

```
<CreateDBInstanceResponse>
  <OrderId>100789370xxxxx</OrderId>
  <ConnectionString>xxxxx.mysql.rds.aliyuncs.com </ConnectionString>
  <DBInstanceId>rds-xxxxx</DBInstanceId>
  <port>3306</port>
  <RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateDBInstanceResponse>
```

- JSON format

```
{ "OrderId": "100789370230206",
  "ConnectionString": "rds-xxxxx.mysql.rds.aliyuncs.com",
  "DBInstanceId": "rds-xxxxx",
  "Port": "3306",
```

```
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.3.2 DeleteDBInstance

Description

You can call this operation to release an RDS instance. Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not manually locked.
- The instance is a pay-as-you-go primary instance, read-only instance, disaster recovery instance, or temporary instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteDBInstance.
DBInstance Id	String	Yes	The ID of the instance to be released.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteDBInstance
&DBInstanceID=rds-xxxxx
&[Common request parameters]>
```

Sample responses

- XML format

```
<DeleteDBInstanceResponse>
  <RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
```

```
</DeleteDBInstanceResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.3.3 RestartDBInstance

Description

You can call this operation to restart an RDS instance. The instance will be restarted in 10 seconds.

If there are a large number of transactions that must be submitted or rolled back, the restart process may be delayed for a minute.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not performing a backup task.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RestartDBInstance.
DBInstance Id	String	Yes	The ID of the instance to be restarted.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

- XML format

```
<RestartDBInstanceResponse>  
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
```

```
</RestartDBInstanceResponse>
```

- JSON format

```
{"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.3.4 DescribeDBInstanceAttribute

Description

You can call this operation to query the details of a specified instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceAttribute.
DBInstance Id	String	Yes	The ID of the instance to be queried. Up to 30 IDs can be entered at a time. Separate multiple IDs with commas (,).

Response parameters

Parameter	Type	Example	Description
Items			The array that consists of DBInstance Attribute data.
└DBInstanceId	String	rm-bpvxxxxx	The ID of the instance.
└PayType	String	Postpaid	The billing method of the instance. Valid values: • Postpaid: pay-as-you-go • Prepaid: subscription
└DBInstance Type	String	Primary	The role of the instance. Valid values: • Primary: primary instance • Readonly: read-only instance • Guard: disaster recovery instance • Temp: temporary instance
└Category	String	Basic	The category of the instance. Valid values: • Basic: Basic Edition • Standard: High-availability Edition • Enterprise: Enterprise Edition

Parameter	Type	Example	Description
<code>InstanceNetworkType</code>	String	Classic	The network type of the instance. Valid values: - Classic: classic network instance - VPC: VPC instance
<code>RegionId</code>	String	cn-hangzhou	The region ID of the instance.
<code>ZoneId</code>	String	cn-hangzhou-a	The zone ID of the instance.
<code>ConnectionString</code>	String	rds-xxxxx.mysql.rds.aliyuncs.com	The endpoint used to connect the instance.
<code>Port</code>	String	3306	The port used to connect the instance.
<code>Engine</code>	String	MySQL	The type of the database.
<code>EngineVersion</code>	String	5.5	The version of the database.
<code>DBInstanceClassType</code>	String	s	The family of the instance. Valid values: - s: shared instance - x: common instance - d: dedicated instance - h: dedicated host
<code>DBInstanceClass</code>	String	rds.mys2.small	The type of the instance.
<code>DBInstanceMemory</code>	Long	240	The memory capacity of the instance. Unit: MB.
<code>DBInstanceStorage</code>	Integer	10	The storage space of the instance. Unit: GB.
<code>DBInstanceNetType</code>	String	Internet	The network connection type of the instance. Valid values: - Internet: public network - Intranet: internal network
<code>DBInstanceStatus</code>	String	Running	The status of the instance. For more information, see Instance states in Appendix.
<code>DBInstanceDescription</code>	String	Test instances	The description of the instance.

Parameter	Type	Example	Description
↳LockMode	String	Unlock	The lock status of the instance. Valid values: - Unlock: normal - ManualLock: locked manually - LockByExpiration: locked automatically upon expiration - LockByRestoration: locked automatically before instance rollback - LockByDiskQuota: locked automatically for full disk space
↳LockReason	String	N/A	The reason why the instance is locked.
↳DBMaxQuantity	Integer	200	The maximum number of databases that can be created for an instance.
↳AccountMaxQuantity	Integer	50	The maximum number of accounts that can be created for an instance.
↳CreationTime	String	2011-05-30T12:11:4Z	The time when the instance was created. The time is displayed in the YYYY-MM-DD'T'hh:mm:ssZ format. Example: 2011-05-30T12:11:4Z .
↳ExpireTime	String	N/A	The expiration time of the instance. This parameter is not returned for pay-as-you-go instances.
↳MaintainTime	String	00:00Z-02:00Z	The scheduled maintenance window of the instance. For example, 00:00Z-02:00Z indicates that routine maintenance can be performed from 00:00 to 02:00.
↳AvailabilityValue	String	100.0%	The availability status of the instance. Unit: %.
↳MaxIOPS	Integer	150	The maximum number of I/O operations per second (IOPS).

Parameter	Type	Example	Description
<code>└MaxConnections</code>	Integer	60	The maximum number of concurrent connections to the instance.
<code>└MasterInstanceid</code>	String	null	The ID of the primary instance. If this parameter is not returned (null), the instance is a primary instance.
<code>└IncrementalDataSourceDBInstanceid</code>	String	null	The instance ID of the incremental data source. For example, the incremental data source of a disaster recovery instance or read-only instance is the primary instance, and the incremental data source of the primary instance is null.
<code>└GuardDBInstanceid</code>	String	N/A	The ID of the disaster recovery instance attached to the instance.
<code>└TempDBInstanceid</code>	String	N/A	The ID of the temporary instance attached to the instance.
<code>└ReadOnlyDBInstanceids</code>		rr-xxxxx	The IDs of the read-only instances attached to the instance.
<code>└DBInstanceid</code>	String	rm-bpxxxxx	The ID of the instance.
<code>└VpcCloudInstanceid</code>	String	vpc-xxxxx	The ID of the VPC instance.
<code>└ResourceGroupid</code>	String	3653788125	The ID of the resource group.
<code>RequestId</code>	String	1AD222E9-E606-4A42-BF6D-8A4442913CEF	The ID of the request.

DBInstanceAttribute parameters

Note:

You can call the `DescribeDBInstanceHAConfig` operation to query the primary and secondary node information of the instance.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstanceAttribute
&DBInstanceid=rds-xxxxx
&<Common request parameters>
```

Sample success responses

JSON format

```

```

2.8.1.3.5 DescribeDBInstances

Description

You can call this operation to query instances and RAM-authorized instances.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeDBInstances	The operation that you want to perform. Set the value to DescribeDBInstances.
RegionId	String	Yes	cn-hangzhou	The region ID of the instance.
ConnectionMode	String	No	Performance	The access mode of the instance. Valid values: • Performance: standard access mode • Safe: safe access mode • If no value is specified, instances in both access modes are returned.

Parameter	Type	Required	Example	Description
DBInstanceType	String	No	Primary	The role of the instance. Valid values: • Primary: primary instance • Readonly: read-only instance • Guard: disaster recovery instance • Temp: temporary instance • If no value is specified, instance of all roles are returned.
InstanceNetworkType	String	No	Classic	The network type of the instance. Valid values: • VPC: VPC instance • Classic: classic network instance • If no value is specified, instance of both network types are returned.

Parameter	Type	Required	Example	Description
PageNumber	Integer	No	1	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.
PageSize	Integer	No	30	The number of entries to return on each page . Valid values: 30, 50, and 100 . Default value: 30.
Tags	String	No	{ "key1" : "value1" }	The tag of the instance, in the JSON format. The tag includes a key-value pair of TagKey and TagValue. TagValue can be left empty, but TagValue cannot . Example: { "key1" : "value1" }.

Response parameters

Parameter	Type	Example	Description
PageNumber	Integer	1	The number of the page returned.
TotalRecordCount	Integer	1	The total number of entries.
PageRecordCount	Integer	1	The number of instances on the current page.

Parameter	Type	Example	Description
Items			The array that consists of instance data.
^L DBInstanceCld	String	rm-xxxxx	The ID of the instance.
^L DBInstanceDescription	String	testforRemarks	The description of the instance.
^L PayType	String	Postpaid	The billing method of the instance. Valid values: - Postpaid: pay-as-you-go - Prepaid: subscription
^L DBInstanceType	String	Primary	The role of the instance. Valid values: - Primary: primary instance - ReadOnly: read-only instance - Guard: disaster recovery instance - Temp: temporary instance
^L InstanceNetworkType	String	Classic	The network type of the instance. Valid values: - Classic: classic network instance - VPC: VPC instance

Parameter	Type	Example	Description
└ConnectionMode	String	Performance	The access mode of the instance. Valid values: - Performance: standard access mode - Safe: safe access mode
└RegionId	String	cn-hangzhou	The region ID of the instance.
└ExpireTime	String	None	The expiration time of the instance. This parameter is not returned for pay-as-you-go instances.
└DBInstanceStatus	String	Intranet	The status of the instance. For more information, see Instance states in Appendix.
└Engine	String	MySQL	The type of the database.
└DBInstanceNetType	String	Internet	The network connection type of the instance. Valid values: - Internet: public network - Intranet: internal network

Parameter	Type	Example	Description
↳LockMode	String	Unlock	The lock status of the instance. Valid values: • Unlock: normal • ManualLock: locked manually • LockByExpiration: locked automatically upon expiration • LockByRestoration: locked automatically before instance rollback • LockByDiskQuota: locked automatically for full disk space
↳LockReason	String	None	The reason why the instance is locked.
↳MasterInstanceid	String	null	The ID of the primary instance. If this parameter is not returned (null), the instance is a primary instance.
↳GuardDBInstanceid	String	None	The ID of the disaster recovery instance attached to the instance.
↳TempDBInstanceid	String	None	The ID of the temporary instance attached to the instance.
↳VpcCloudInstanceid	String	vpc-xxxxxx	The ID of the VPC instance.
↳ReadOnlyDBInstanceids			None

Parameter	Type	Example	Description
DBInstanceId	String	rm-xxxxx	The ID of the instance.
RequestId	String	1AD222E9-E606-4A42-BF6D-8A4442913CEF	The ID of the request.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstances
&RegionId=cn-hangzhou
&Engine=MySQL
&<Common request parameters>
```

Sample success responses

- XML format

```
<DescribeDBInstancesResponse>
<PageRecordCount>2</PageRecordCount>

  "RequestId":"7463B73D-35CC-4D19-A010-6B8D65D242EF"}

```

2.8.1.3.6 ModifyDBInstanceSpec

Description

You can call this operation to change the type or storage space of instances. Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not performing a backup task.
- Either the instance type (DBInstanceClass) or storage space (DBInstanceStorage) parameter must be specified in the request.
- When reducing the amount of disk space, ensure that the target amount of disk space is no less than 1.1 times the actual space used.
- Only common and read-only instances allow specifications changes. Specifications of disaster recovery and temporary instances cannot be changed.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifyDBInstanceSpec	The operation that you want to perform. Set the value to ModifyDBInstanceSpec.
DBInstanceId	String	Yes	rm-bpxxxx	The ID of the instance.
PayType	String	Yes	Postpaid	The billing method of the instance. Valid values: - Postpaid: pay-as-you-go - Prepaid: subscription
AccessKeyId	String	No	LTAIKw8gqxxxxx	The AccessKey ID provided to you by Alibaba Cloud.
ClientToken	String	No	ETnLKlblzc zshOTUbOCz ijZNwHLYBQ	The client token that is used to ensure the idempotence of the request.
DBInstanceClass	String	No	rds.mys2.small	The type of the instance. For more information, see Instance types in Appendix.

Parameter	Type	Required	Example	Description
DBInstanceStorage	Integer	No	20	The user-defined storage space. This value must be a multiple of 5 GB. Unit: GB. Valid values: - MySQL, PostgreSQL, or PPAS High-availability Edition: 5 to 2000 - MySQL 5.7 Basic Edition: 20 to 1000
EffectiveTime	String	No	Immediate	The time when the changes take effect. Valid values: Immediate and MaintainTime. Default value: Immediate.
OwnerAccount	String	No	testuser@aliyun.com	The Apsara Stack tenant account.

Response parameters

Parameter	Type	Example	Description
RequestId	String	1AD222E9-E606-4A42-BF6D-8A4442913CEF	The ID of the request.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceSpec
&DBInstanceId=rds-xxxxx
&PayType=Postpaid
&DBInstanceStorage=10
```

&<Common request parameters>

Sample success responses

- XML format

```
<ModifyDBInstanceSpecResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyDBInstanceSpecResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

Sample error responses

JSON format

```
{ "Code": "UnsupportedOperation",
  "HostId": "rds.aliyuncs.com",
  "Message": "The specified action is not supported.",
  "RequestId": "7463B73D-35CC-4D19-A010-6B8D65D242EF" }
```

2.8.1.3.7 AllocateInstancePublicConnection

Description

You can call this operation to apply for a public endpoint for a specified instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AllocateInstancePublicConnection.
DBInstanceId	String	Yes	The ID of the instance for which the public endpoint is applied.
ConnectionStringPrefix	String	Yes	The endpoint to be used by the instance.
Port	String	Yes	The external port to be used by the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=AllocateInstancePublicConnection
&DBInstanceId=rds-xxxxx
&ConnectionStringPrefix=test0001
&Port=3306
&<Common request parameters>
```

Sample responses

- XML format

```
<AllocateInstancePublicConnectionResponse>
<RequestId>65BDA532-28AF-4122-AA39-B382721EEE64</RequestId>
</AllocateInstancePublicConnectionResponse>
```

- JSON format

```
{ "RequestId": "65BDA532-28AF-4122-AA39-B382721EEE64" }
```

2.8.1.3.8 ReleaseInstancePublicConnection

Description

You can call this operation to release the public endpoint of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ReleaseInstancePublicConnection.
DBInstanceId	String	Yes	The ID of the instance whose public endpoint is released.
CurrentConnectionString	String	Yes	The public endpoint.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=ReleaseInstancePublicConnection
&DBInstanceId=rds-xxxxx
&CurrentConnectionString=test0001.mysql.rds.example.com
&<Common request parameters>
```

Sample responses

- XML format

```
<ReleaseInstancePublicConnectionResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ReleaseInstancePublicConnectionResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.3.9 SwitchDBInstanceNetType

Description

You can call this operation to switch the network type of an instance between internal and public networks. After switching, the endpoint of the instance changes. You must modify the endpoint in the code and restart the application.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- There have been less than 20 switching operations performed within the last 24 hours.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to SwitchDBInstanceNetType.
DBInstanceId	String	Yes	The ID of the instance for which the network connection type is modified.
ConnectionStringPrefix	String	Yes	The unique endpoint to be used. It can be up to 30 characters in length and can contain lowercase letters, digits, and hyphens (-). It must start with a letter.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.3.10 DescribeDBInstanceNetInfo

Description

You can call this operation to query the connection information of a specified instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceNetInfo.
DBInstance Id	String	Yes	The ID of the instance whose connection information is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
DBInstanceNetInfos	List<DBInstanceAttribute>	The array that consists of DBInstance Attribute data.
InstanceNetworkType	String	VPC: VPC instance Classic: classic network instance

DBInstanceNetInfo parameters

Parameter	Type	Description
Connection String	String	The DNS connection string.
IPAddress	String	The IP address.
IPTYPE	String	Valid values for classic network instances: Inner and Public. Valid values for VPC instances: Private and Public.
Port	String	The port information.

Parameter	Type	Description
VPCId	String	The ID of the VPC.
VSwitchId	String	The ID of the VSwitch.

2.8.1.3.11 ModifyDBInstanceConnectionString

Description

You can call this operation to modify the endpoint and port of a connection string.

ApsaraDB for RDS provides the internal and public endpoints and allows both types to coexist in a specific access mode.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceConnectionString.
DBInstanceId	String	Yes	The ID of the instance.
CurrentConnectionString	String	Yes	The endpoint used by the instance.
ConnectionStringPrefix	String	No	The endpoint to be used by the instance.
Port	String	No	The port to be used by the instance.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.3.12 ModifyDBInstanceConnectionMode

Description

You can call this operation to modify the access mode of RDS instances. Two access modes are available for RDS:

- Standard access mode
- Safe access mode

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyDBInstanceConnectionMode</code> .
DBInstance Id	String	Yes	The ID of the instance for which the access mode is modified.
Connection Mode	String	Yes	The access mode of the instance. Performance: standard access mode. Safe: safe access mode.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.3.13 ModifyDBInstanceNetworkType

Description

You can call this operation to switch the network type of an RDS instance between VPC and classic network.

**Note:**

Only the classic network instances with the `ConnectionMode` set to `Safe` can have their network type switched to VPC.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyDBInstanceNetworkType</code> .
DBInstance Id	String	Yes	The ID of the instance for which the network type is modified.
InstanceNetworkType	String	Yes	The network type of the instance. VPC: VPC instance. Classic: classic network instance.
VPCId	String	No	The ID of the VPC.
VSwitchId	String	No	The ID of the VSwitch. This parameter is required if the value of <code>VPCId</code> is specified.

Parameter	Type	Required	Description
PrivateIpAddress	String	No	The VPC IP address that belongs to the specified VSwitch. If no value is specified, the system automatically assigns a VPC IP address based on VPCId and VSwitchId.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.3.14 DescribeDBInstanceIPArrayList

Description

You can call this operation to query the IP whitelist of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceIPArrayList.
DBInstanceId	String	Yes	The ID of the instance whose IP whitelist is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
Items	List<DBInstanceIPArray>	The array that consists of DBInstanceIPArray data.

DBInstanceIPArray parameters

Parameter	Type	Description
DBInstanceIPArrayName	String	The name of the IP whitelist.
DBInstanceIPArrayAttribute	String	The attribute of the IP whitelist. Default value: null. Whitelists tagged with "hidden" are not displayed in the console.

Parameter	Type	Description
SecurityIPList	String	The IP addresses in an IP address whitelist. Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats of IP addresses are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or Classless Inter-Domain Routing (CIDR) blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.

2.8.1.3.15 ModifySecurityIps

Description

You can call this operation to modify the IP whitelist of an instance.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not locked by the system.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifySecurityIps.
DBInstanceId	String	Yes	The ID of the instance whose IP whitelist is modified.
SecurityIps	String	No	The IP addresses in an IP address whitelist. Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats of IP addresses are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or Classless Inter-Domain Routing (CIDR) blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.
DBInstance IPArrayName	String	No	The name of the IP whitelist. If no value is specified, the whitelist named Default will be modified.
DBInstance IPArrayAttribute	String	No	The attribute of the IP whitelist. Default value: null. Whitelists tagged with "hidden" are not displayed in the console.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=ModifySecurityIps
&DBInstanceId=rds-xxxxx
&SecurityIps=192.168.1.2
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifySecurityIpsResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifySecurityIpsResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.3.16 DescribeRegions

Description

You can call this operation to query the available RDS regions and zones.

Before you call the CreateInstance operation, call this operation to query region IDs.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeRegions.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Regions	List<RDSRegion>	The array that consists of RDSRegion data.

RDSRegion parameters

Parameter	Type	Description
RegionId	String	The region ID.
ZoneId	String	The zone ID.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeRegions
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeRegionsResponse>
<Regions>
<RDSRegion>
<RegionId>cn-hangzhou</RegionId>
<ZoneId>cn-hangzhou-a</ZoneId>
</RDSRegion>
<RDSRegion>
<RegionId>cn-hangzhou</RegionId>
<ZoneId>cn-hangzhou-b</ZoneId>
</RDSRegion>
</Regions>
<RequestId>A36D9720-7902-42A4-B8B9-014A2135E6C3</RequestId>
</DescribeRegionsResponse>
```

- JSON format

```
{ "Regions":
  { "RDSRegion":
    [ {"RegionId": "cn-hangzhou",
      "ZoneId": "cn-hangzhou-a"},
      {"RegionId": "cn-hangzhou",
      "ZoneId": "cn-hangzhou-b"},
    ],
    "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"
  }
}
```

2.8.1.3.17 DescribeDBInstanceHAConfig

Description

You can call this operation to query the zone information and data replication status of instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceHAConfig.
DBInstance Id	String	Yes	The ID of the instance for which the zone information and data replication status are queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
DBInstanceCid	String	The ID of the instance for which the zone information and data replication status were queried.
SyncMode	String	The synchronization mode. Valid values: Sync, Semi-sync, and Async.
HAMode	String	The high availability mode. RPO: Data persistence is preferred. RTO: Instance availability is preferred.
HostInstanceInfos	List<NodeInfo>	The array that consists of NodeInfo data.

NodeInfo parameters

Parameter	Type	Description
NodeId	String	The unique ID of the primary or secondary node.
NodeType	String	The type of the node. Master: primary node. Slave: secondary node.
RegionId	String	The region ID of the instance.
ZoneId	String	The zone ID of the instance.
SyncStatus	String	The synchronization status of the instance. NotAvailable: A failure has occurred and synchronization is unavailable. Syncing: Synchronization is in process, with a probability of data loss during failovers. Synchronized: Synchronization is completed. NotSupport: Synchronization is not supported by the engine type or version.
LogSyncTime	String	The time when the secondary database receives logs.

Parameter	Type	Description
DataSyncTime	String	The time when the secondary database receives data.

2.8.1.3.18 PurgeDBInstanceLog

Description

You can call this operation to clear all binlogs for a MySQL instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to PurgeDBInstanceLog.
DBInstanceCld	String	Yes	The ID of the instance for which all binlogs are cleared.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=PurgeDBInstanceLog
&DBInstanceCld=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<PurgeDBInstanceLogResponse>
  <RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</PurgeDBInstanceLogResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.3.19 UpgradeDBInstanceEngineVersion

Description

You can call this operation to upgrade the database version of an instance. For example, you can upgrade the database version from MySQL 5.1 to MySQL 5.5.

If a read-only or disaster recovery instance is attached to the primary instance, you must first upgrade the database version of the attached instance.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The specified database version must be later than the current database version of the target instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to UpgradeDBInstanceEngineVersion.
DBInstanceCld	String	Yes	The instance to be upgraded.
EngineVersion	String	Yes	The database version to be upgraded to.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
TaskId	Integer	The ID of the task.

Examples

Request parameters

```
https://rds.example.com/?Action=UpgradeDBInstanceEngineVersion
&DBInstanceCld=rds-xxxxx
&EngineVersion=5.6
&<Common request parameters>
```

Response parameters

- XML format

```
<UpgradeDBInstanceEngineVersionResponse>
```

```
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<TaskId>124378</TaskId>
</UpgradeDBInstanceEngineVersionResponse>
```

- JSON format

```
{"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
 "TaskId": "124378" }
```

2.8.1.3.20 ModifyDBInstanceDescription

Description

You can call this operation to modify the description of an instance to identify the instance easily. For example, you can modify the description of an instance to Alibaba Cloud testing environment instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceDescription.
DBInstanceId	String	Yes	The ID of the instance whose description is modified.
DBInstanceDescription	String	Yes	The description of the instance.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceDescription
&DBInstanceId=rds-xxxxx
&DBInstanceDescription=testdescribe
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyDBInstanceDescriptionResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
```

```
</ModifyDBInstanceDescriptionResponse>
```

- JSON format

```
{"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.3.21 ModifyDBInstanceMaintainTime

Description

You can call this operation to modify the scheduled period for routine maintenance. You can set the maintenance window to an off-peak period.

Alibaba Cloud performs routine maintenance during the maintenance window to minimize the impact on your services.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceMaintainTime.
DBInstanceId	String	Yes	The ID of the instance whose maintenance window is modified.
MaintainTime	String	Yes	The maintenance window of the instance. Valid values: 22:00Z-02:00Z 02:00Z-06:00Z 06:00Z-10:00Z 10:00Z-14:00Z 14:00Z-18:00Z 18:00Z-22:00Z

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceMaintainTime  
&DBInstanceId=rds-xxxxx
```

```
&MaintainTime=22:00Z-02:00Z  
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyDBInstanceMaintainTimeResponse>  
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>  
</ModifyDBInstanceMaintainTimeResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.3.22 ModifyDBInstanceHAConfig

Description

You can call this operation to modify the instance data replication mode and high availability switching rules.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceHAConfig.
DBInstance Id	String	Yes	The ID of the instance for which the data replication mode and high availability switching rules are modified.
SyncMode	String	Yes	The synchronization mode of the instance. Valid values: Sync, Semi-sync, and Async.
HAMode	String	Yes	The HA mode of the instance. RPO: Data persistence is preferred. RTO: Instance availability is preferred.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.3.23 SwitchDBInstanceHA

Description

You can call this operation to change the database used as the primary database. RDS instances are composed of primary and secondary databases distributed across different servers. The new primary database bears the service traffic.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to SwitchDBInstanceHA.
DBInstanceId	String	Yes	The ID of the primary instance.
NodeId	String	Yes	The unique ID of the node. You can call the DescribeDBInstanceHAConfig operation to query the value of this parameter.
Force	String	Yes	Yes: forced. No: unforced. Default value: No.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.3.24 CreateReadOnlyDBInstance

Description

You call this operation to create a read-only instance for an RDS instance. Before you call this operation, ensure that the following requirements are met:

- The primary instance is in the running but not failover state.
- The database engine version of the primary instance must be MySQL 5.6, MySQL 5.7, PostgreSQL 10.0, or PPAS 9.3.
- The read-only instance must be in the same region as the primary instance.
- An RDS instance can have up to five read-only instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateReadOnlyDBInstance.
RegionId	String	Yes	The region ID of the instance. It can be up to 50 characters in length. You can call the DescribeRegions operation to query the most recent region list.

Parameter	Type	Required	Description
ZoneId	String	Yes	The zone ID of the instance. You can call the DescribeRegions operation to query the most recent zone list.
DBInstanceCid	String	Yes	The ID of the primary instance.
EngineVersion	String	Yes	The version of the database. Valid values: - MySQL: 5.6 and 5.7 - PostgreSQL: 10.0 - PPAS: 9.3
DBInstanceClass	String	Yes	The type of the instance. For more information, see Instance types in Appendix.
DBInstanceStorage	Integer	Yes	The user-defined storage space. Valid values: 5 to 1000. This value must be a multiple of 5 GB. Unit: GB.
DBInstanceDescription	String	No	The description of the instance. It must be 2 to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It cannot start with http:// or https://. It must start with a letter.
PayType	String	Yes	The billing method. Set the value to Postpaid.
ClientToken	String	Yes	The client token that is used to ensure the idempotence of the request.
InstanceNetworkType	String	No	The network type of the instance. Valid values: VPC and Classic. Default value: Classic.
VPCId	String	No	The ID of the VPC.
VSwitchId	String	No	The ID of the VSwitch.
PrivateIpAddress	String	No	The VPC IP address that belongs to the specified VSwitch. If no value is specified, the system automatically assigns a VPC IP address based on VPCId and VSwitchId.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
DBInstanceCid	String	The ID of the instance.
OrderId	String	The ID of the order.

Parameter	Type	Description
Connection String	String	The endpoint used to connect the database.
Port	String	The port used to connect the database.

Examples

Sample requests

```
https://rds.example.com/?Action=CreateReadOnlyDBInstance
&RegionId=cn-hangzhou
&ZoneId=cn-hangzhou-b
&DBInstanceId=rds-xxxxx
&EngineVersion=5.6
&DBInstanceClass=rds.mys2.small
&DBInstanceStorage=10
&PayType=Postpaid
&ClientToken=ETnLKxxxxx
&<[Common request parameters]>
```

Sample responses

- XML format

```
<CreateDBInstanceResponse>
<OrderId>10078937xxxxx</OrderId>
<ConnectionString>rds-xxxxx.mysql.rds.aliyuncs.com</ConnectionString>
<DBInstanceId>rds-xxxxx</DBInstanceId>
<port>3306</port>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateDBInstanceResponse>
```

- JSON format

```
{ "OrderId": "100789370230206",
  "ConnectionString": "rds-xxxxx.mysql.rds.aliyuncs.com",
  "DBInstanceId": "rds-xxxxx",
  "Port": "3306",
  "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.3.25 DescribeDBInstanceSSL

Description

This operation is only supported on MySQL 5.6 and MySQL 5.7.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceSSL.

Parameter	Type	Required	Description
DBInstanceCld	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Connection String	String	The connection string protected by the SSL certificate.
SSLExpireTime	String	The expiration time of the SSL certificate. The time is displayed in the YYYY-MM-DD'T'hh:mm:ssZ format.
RequireUpdate	String	Indicates whether an immediate upgrade is required. Valid values: Yes and No.
RequireUpdateReason	String	The reasons why an upgrade is recommended.

2.8.1.3.26 ModifyDBInstanceSSL**Description**

This operation is only supported on MySQL 5.6 and MySQL 5.7.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceSSL.
DBInstance Id	String	Yes	The ID of the instance.
Connection String	String	Yes	The connection string of the instance. Each instance can only have one connection string protected by the SSL certificate. The SSL certificate can be created or updated for the connection string.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Parameter	Type	Description
SSLExpireTime	String	The expiration time of the SSL certificate. The time is displayed in the YYYY-MM-DD'T'hh:mm:ssZ format.

2.8.1.3.27 DescribeDBInstanceTDE

Description

This operation is only supported on MySQL 5.6 and MySQL 5.7.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceTDE.
DBInstanceCld	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
TDEStatus	String	The TDE status of the instance. Valid values: Enabled and Disabled.
Databases	List<DataBase>	The array that consists of Database data.

DataBase parameters:

Parameter	Type	Description
DBName	String	The name of the database.
TDEStatus	String	The TDE status of the database. Valid values: Enabled and Disabled.

2.8.1.3.28 ModifyDBInstanceTDE

Description

This operation is only supported on MySQL 5.6 and MySQL 5.7. TDE can only be enabled on instances and cannot be disabled. You cannot specify the DBName value to modify the TDE status of a database.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceTDE.
DBInstanceCld	String	Yes	The ID of the instance.
TDEStatus	String	Yes	The TDE status of the instance. Valid values: Enabled and Disabled.
DBName	String	No	The name of the database. Up to 50 names can be entered in a single request. Separate multiple names with commas (,).

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.4 Database management

2.8.1.4.1 CreateDatabase

Description

You can call this operation to create a new database in an instance. Before you call this operation, ensure that the following requirements are met:

- The instance must be in the running state.
- The instance is not locked.
- The maximum number of databases in the instance is not reached.
- The instance is a primary instance.

**Note:**

This operation is not supported in PostgreSQL or PPAS. Users of PostgreSQL and PPAS instances can execute the CREATE DATABASE statement through SQL instead.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateDatabase.

Parameter	Type	Required	Description
DBInstanceId	String	Yes	The ID of the instance.
DBName	String	Yes	The unique name of the database. The name can be up to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For more information about invalid characters, see Forbidden keywords .
CharacterSetName	String	Yes	The character set. Valid values: MySQL: utf8, gbk, latin1, and utf8mb4
DBDescription	String	No	The description of the database. It must be 2 to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It cannot start with http:// or https://. It must start with a letter.

Response parameters

For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=CreateDatabase
&CharacterSetName=gbk
&DBName=testDB
&DBInstanceId=rds-xxxxx
&[Common request parameters]>
```

Sample responses

- XML format

```
<CreateDatabaseResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
```

```
</CreateDatabaseResponse>
```

- JSON format

```
{ "RequestID": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.4.2 DeleteDatabase

Description

You can call this operation to delete a database from an instance.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is a primary instance.

Note:

This operation is not supported on PostgreSQL or PPAS. Users of PostgreSQL and PPAS instances are permitted to perform the DROP DATABASE operation through SQL.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteDatabase.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
DBName	String	Yes	The name of the database.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteDatabase
&DBName=testDB
&DBInstanceId=rds-xxxxx
```

&<[Common request parameters]>

Sample responses

- XML format

```
<DeleteDatabaseResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</DeleteDatabaseResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.4.3 DescribeDatabases

Description

You can call this operation to query the database list information for a specified instance and database. If the search parameters are entered incorrectly, an error prompt is returned and the returned data is empty.

Note:

This operation is not supported on PostgreSQL or PPAS.

Request parameters

Parameter	Type	Require	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDatabases.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
DBName	String	No	The name of the database.
DBStatus	String	No	The status of the database. Valid values: Creating, Running, and Deleting.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Databases	List<Database>	The array that consists of Database data.

Database parameters

Parameter	Type	Description
DBName	String	The name of the database.
DBInstanceId	String	The ID of the instance to which the database belongs.
Engine	String	The role of the database instance.
DBStatus	String	The status of the database. Valid values: Creating, Running, and Deleting.
CharacterSetName	String	The character set.
DBDescription	String	The description of the database.
Accounts	List<AccountPrivilegeInfo>	The array that consists of AccountPrivilegeInfo data.
Account	String	The name of the account used to access the database.
AccountPrivilege	String	The permissions of the account on the database.

AccountPrivilegeInfo parameters

Parameter	Type	Description
Account	String	The name of the account used to access the database.
AccountPrivilege	String	The permissions of the account on the database.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDatabases
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeDatabasesResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<Databases>
<Database>
```

```
<Engine>MySQL</Engine>
<DBName>testdb</DBName>
<CharacterSetName>utf8</CharacterSetName>
<DBStatus>Creating</DBStatus>
<DBInstancelId>rds-xxxxx</DBInstancelId>
<Accounts>
<AccountPrivilegeInfo></AccountPrivilegeInfo>
</Accounts>
</Database>
</Databases>
</DescribeDatabasesResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
  "Databases":
  { "Database":
    [ { "Engine": "MySQL",
        "CharacterSetName": "utf8",
        "DBStatus": "Creating",
        "DBDescription": "",
        "DBInstancelId": "rds-xxxxx",
        "Accounts": { "AccountPrivilegeInfo": [] },
        "DBName": "testdb" } ] }
}
```

2.8.1.4.4 ModifyDBDescription

Description

You can call this operation to modify the description of a database to facilitate user records. For example, you can modify the description of a database to Instance database A for Alibaba Cloud testing environment.

Note:

This operation is not supported on PostgreSQL or PPAS.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBDescription.
DBInstancelId	String	Yes	The ID of the instance to which the database belongs.
DBName	String	Yes	The name of the database.
DBDescription	String	Yes	The description of the database.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBDescription
&DBInstanceId=rds-xxxxx
&DBInstanceDescription=testDBdescribe
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyDBDescriptionResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyDBDescriptionResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5 Account management

2.8.1.5.1 CreateAccount

Description

**Note:**

In the same instance, one account can manage multiple databases with different permissions.

You can call this operation to create an account for a database. Before you call this operation, ensure that the following requirements are met:

- The instance must be in the running state.
- The database must be in the running state.
- The instance is not locked.
- The maximum number of accounts for a single instance is not reached.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateAccount.
DBInstanceID	String	Yes	The ID of the instance.
AccountName	String	Yes	The unique name of the account. The name can be up to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For more information about invalid characters, see Forbidden keywords .
AccountPassword	String	Yes	The password for the account. It must be 6 to 32 characters in length and can contain letters, digits, and underscores (_).
AccountType	String	No	The type of the account. Valid values: Normal and Super. Default value: Normal. This parameter is only valid for MySQL 5.6 and MySQL 5.7. PostgreSQL and PPAS can each have only a single initial account. You need to use the initial account to log on to the database and create other types of accounts.
AccountDescription	String	No	The description of the account. It must be 2 to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It cannot start with http:// or https://. It must start with a letter.

Response parameters

For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=CreateAccount
&AccountName=testacc02
&AccountPassword=pwxxxxxx
&DBInstanceID=rds-xxxxxx
&<[Common request parameters]>
```

Sample responses

- XML format

```
<CreateAccountResponse>
```

```
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateAccountResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5.2 DeleteAccount

Description

You can call this operation to delete a database account.

The instance must be in the running state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteAccount.
DBInstance Id	String	Yes	The ID of the instance to which the database belongs.
AccountName	String	Yes	The unique name of the account. The name can be up to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For more information about invalid characters, see Forbidden keywords .

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteAccount
&DBInstanceId=rds-xxxxx
&AccountName=testacc01
&<[Common request parameters]>
```

Sample responses

- XML format

```
<DeleteAccountResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
```

```
</DeleteAccountResponse>
```

- JSON format

```
{ "RequestID": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5.3 DescribeAccounts

Description

You can call this operation to query the accounts for a specified instance and database or the information of a specified account.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccounts.
DBInstanceId	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
Accounts	List<DBInstanceAccount>	The array that consists of DBInstanceAccount data.

DBInstanceAccount parameters

Parameter	Type	Description
DBInstanceId	String	The ID of the instance to which the account belongs.
AccountName	String	The name of the database account.
AccountStatus	String	The account status. Valid values: Unavailable and Available.
AccountDescription	String	The description of the account.

Parameter	Type	Description
DatabasePrivileges	List<DatabasePrivilege>	The array that consists of DatabasePrivileges data.
AccountType	String	The type of the account. Valid values: Normal and Super.

DatabasePrivilege parameters

Parameter	Type	Description
DBName	String	The name of the database.
AccountPrivilege	String	The name of the database account.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeAccounts
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeAccountsResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<Accounts>
  <DBInstanceAccount>
    <AccountName>MySQL</AccountName>
    <DBInstanceId>testdb</DBInstanceId>
    <AccountStatus>utf8</AccountStatus>
    <AccountDescription>
</AccountDescription>
    <DatabasePrivileges>
</DatabasePrivilege></DatabasePrivilege>
    </DatabasePrivileges>
  </DBInstanceAccount>
</Accounts>
</DescribeAccountsResponse>
```

- JSON format

```
{ "Accounts":
  { "DBInstanceAccount":
    [ { "AccountDescription": "",
        "DBInstanceId": "rds-xxxxx",
        "DatabasePrivileges": { "DatabasePrivilege": [] },
        "AccountStatus": "Unavailable",
        "AccountName": "testaccount" } ] },
}
```

```
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5.4 GrantAccountPrivilege

Description

You can call this operation to grant database access permissions to accounts. A single account can be associated with one or more databases.

If the specified account already has access permissions on the specified database, the operation directly returns a successful response.

The instance must be in the running state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to GrantAccountPrivilege.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
AccountName	String	Yes	The name of the account.
DBName	String	Yes	The name of the database associated with the account.
AccountPrivilege	String	Yes	The permissions of the account. Valid values: ReadOnly and ReadWrite.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=GrantAccountPrivilege
&AccountName=testacc02
&AccountPrivilege=readwrite
&DBName=testdb03
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<GrantAccountPrivilegeResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</GrantAccountPrivilegeResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5.5 RevokeAccountPrivilege

Description

You can call this operation to revoke database access permissions from an account. Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The database is in the running state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>RevokeAccountPrivilege</code> .
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
AccountName	String	Yes	The name of the account.
DBName	String	Yes	The name of the database.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=RevokeAccountPrivilege
&AccountName=testacc02
&DBName=testdb03
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<RevokeAccountPrivilegeResponse>  
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>  
</RevokeAccountPrivilegeResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5.6 ModifyAccountDescription

Description

You can call this operation to modify the description of an account to facilitate user records. For example, you can modify the description of an account to Account A for Alibaba Cloud testing environment.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyAccountDescription</code> .
DBInstanceId	String	Yes	The ID of the instance for which the account description is modified.
AccountName	String	Yes	The unique name of the account. The name can be up to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For more information about invalid characters, see Forbidden keywords .
AccountDescription	String	Yes	The description of the account. It can be up to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It cannot start with <code>http://</code> or <code>https://</code> . It must start with a letter.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyAccountDescription
&DBInstanceId=rds-xxxxx
&AccountName=testacc01
&AccountDescription=testAccoutdescribe
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyAccountDescription>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyAccountDescription>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.5.7 ResetAccountPassword

Description

You can call this operation to reset the account password. Before you call this operation, ensure that the following requirements are met:

The instance is in the running state and not locked by the system.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ResetAccountPassword.
DBInstanceId	String	Yes	The ID of the instance for which the account password is reset.
AccountName	String	Yes	The name of the account.
AccountPassword	String	Yes	The new password. It must be 6 to 32 characters in length and can contain letters, digits, and underscores (_).

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

Examples

Sample requests

```
https://rds.example.com/?Action=ResetAccountPassword
&AccountName=testacc02
&AccountPassword=pwxxxxxx
&DBInstanceID=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<ResetAccountPasswordResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ResetAccountPasswordResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.5.8 ResetAccount

Description

You can call this operation to reset the initial account of an instance.

This operation is not applicable to MySQL 5.6 or MySQL 5.7 instances that do not have privileged accounts.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ResetAccount.
DBInstance Id	String	Yes	The ID of the instance.
AccountNam e	String	Yes	The name of the account.
AccountPas sword	String	Yes	The password for the account.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

2.8.1.6 Backup and restoration

2.8.1.6.1 CreateBackup

Description

You can call this operation to manually create a backup. Up to 10 backups can be created for an instance in a single day.

Before you call this operation, ensure that the following requirements are met:

- The instance must be in the running state.
- The most recent backup has been completed.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateBackup.
DBInstanceId	String	Yes	The ID of the instance.
BackupMethod	String	No	The backup method. Valid values: Logical and Physical. Default value: Physical. Logical backup cannot be used for instances without databases.
BackupStrategy	String	No	The logical backup range. db: single-database backup. instance: instance backup. This parameter is valid only when BackupMethod is set to Logical.
DBName	String	No	The name of the database for logical single-database backup. This parameter is valid only when BackupMethod is set to Logical and BackupStrategy is set to db.
BackupType	String	No	The backup type. Auto: specifies whether it is a full backup or an incremental backup through automatic calculation. FullBackup: specifies a full backup. Default value: Auto

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action= CreateBackup
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<CreateBackupResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateBackupResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

2.8.1.6.2 CloneDBInstance

Description

You can call this operation to clone a new instance with historical data based on the backup file of an existing instance or a specified time.

The new instance will have the same whitelist, SQL audit, alarm threshold, backup, and parameter settings as the existing instance.

The data in the new instance is the same as historical data in the backup file. The clone feature can only be used with MySQL engines.

Database account information is cloned differently for different account types:

- If a privileged account is used as the primary instance, instances that are cloned from it will also carry the same privileged account information.
- If a standard account is used as the primary instance, instances that are cloned from it will also carry the information of the account used when the backup file is generated or at the specified time.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CloneDBInstance.
DBInstanceCld	String	Yes	The ID of the instance to be cloned.
BackupId	String	No	The ID of the backup set. You can call the DescribeBackups operation to query backup set IDs.
RestoreTime	String	No	A point in time within the backup retention period to obtain a backup set from. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T16:00:00Z. Either BackupId or RestoreTime is required.
PayType	String	Yes	The billing method of the instance. Valid values: Postpaid and Prepaid. Postpaid indicates pay-as-you-go and Prepaid indicates subscription.
Period	String	No	The unit of the subscription period. It is required if PayType is set to Prepaid. Valid values: Year and Month.
UsedTime	String	No	The number of the subscription units. It is required if PayType is set to Prepaid. Valid values: positive integers such as 1, 2, and 3.
DBInstanceClass	String	No	The specifications of the instance. For more information, see Instance types in Appendix. This parameter is optional. If it is not specified, the new instance is of the same type as the primary instance.
DBInstanceStorage	String	No	The disk space. Unit: GB. This value must be a multiple of 5 GB. RDS instances of the dedicated host type: 3000 to 3000. RDS instances of other types: 5 to 2000.
InstanceNetworkType	String	No	The network type of the instance. Valid values: Classic and VPC. This value is the same as that of the primary instance by default.
VPCId	String	No	The ID of the VPC.
VSwtich ID	String	No	The ID of the VSwitch.
PrivateIpAddress	String	No	The IP address of the VPC under VSwitchId. If no value is specified, the system automatically assigns a VPC IP address.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
DBInstanceId		The ID of the instance cloned.
OrderId		The ID of the order.

2.8.1.6.3 DescribeBackups

Description

You can call this operation to search for a set of instance backups. The set of backups must be in the Success state, indicating that they can be used to restore an instance.

RDS provides backup files for you to download.

- When DownloadLink is NULL, RDS does not provide a download URL.
- When DownloadLink is not NULL, you can use this URL to download the backup file through Wget (with double quotation marks), a browser, or a user program. The expiration time for this URL is specified by LinkExpiredTime. Use it before the expiration time.

If the BackupSet has expired, the following error code is displayed:

```
<? xml version="1.0" encoding="UTF-8" ? ><Error><Code>AccessDenied</Code><Message>Request has expired. </Message><Expires>2012-12-25T09:47:52.000Z</Expires><ServerTime>2012-12-25T09:49:00.000Z</ServerTime><RequestId>50D9768CA801C2F102005C70</RequestId><HostId>oss-test.aliyun-inc.com</HostId></Error>
```

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBackups.
DBInstanceId	String	Yes	The ID of the instance for which the backup set is queried.
BackupId	Integer	No	The ID of the backup set.
BackupStatus	String	No	The status of the backup set. Valid values: Success and Failed.
BackupMode	String	No	The backup mode. Valid values: Automated and Manual.

Parameter	Type	Required	Description
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00Z.
EndTime	String	Yes	The end of the time range where the query is performed . Specify the time in the yyyy-MM-ddTHH:mm:ssZ format . Example: 2011-06-11T16:00Z. The end time must be later than the start time.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of backup sets on the current page.
Items	List<Backup>	The array that consists of Backup data.

2.8.1.6.4 CreateTempDBInstance

Description

**Note:**

You can create a temporary instance based on a backup set or a point in time within the past seven days. When a temporary instance is created, accounts and databases inherit the backup set data.

You can call this operation to create a temporary instance. Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not undergoing any migration tasks.
- The instance is not locked by the system.

- The current status of the instance backup set is Success.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateTempDBInstance.
DBInstanceId	String	Yes	The ID of the instance to be created.
BackupId	Integer	No	The ID of the backup set.
RestoreTime	String	No	The restoration time of the backup set. It can be any time within the past seven days that is more than 30 minutes before the current time. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC. Example: 2011-06-11T16:00:00Z.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
TempDBInstanceId	String	The ID of the temporary instance.

Examples

Sample requests

```
https://rds.example.com/?Action=CreateTempDBInstance
&BackupId=90262
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<CreateTempDBInstanceResponse>
  <RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
  <TempDBInstanceId>sub-xxxxx</TempDBInstanceId>
</CreateTempDBInstanceResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
```

```
"TempDBInstanceId":"sub-xxxxx"}
```

2.8.1.6.5 DescribeBackupPolicy

Description

You can call this operation to query the backup policy configured for the system. RDS periodically backs up an instance based on the user-defined system configuration.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBackupPolicy.
DBInstanceId	String	Yes	The ID of the instance for which the backup policy is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
BackupRetentionPeriod	String	The data backup retention period. Unit: days. Valid values: 1 to 30.
PreferredBackupTime	String	The backup time. The time is in the HH:mmZ to HH:mmZ format.
PreferredBackupPeriod	String	The backup day. Valid values: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday.
BackupLog	String	The log backup status. Valid values: Enable and Disabled.
LogBackupRetentionPeriod	String	The log backup retention period. Unit: days. Valid values: 1 to 30.

2.8.1.6.6 ModifyBackupPolicy

Description

You can call this operation to modify a backup policy. RDS periodically backs up instances based on the user-defined system configuration.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyBackupPolicy.
DBInstanceID	String	Yes	The ID of the instance for which the backup policy is modified.
PreferredBackupTime	String	Yes	The backup time. Format: HH:mmZ to HH:mmZ.
PreferredBackupPeriod	String	Yes	The backup day. Valid values: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday.
BackupRetentionPeriod	String	No	The data backup retention period. Unit: days. Valid values: 1 to 30. Default value: 7.
BackupLog	String	No	The log backup status. Valid values: Enable and Disabled. Default value: Enable.
LogBackupRetentionPeriod	String	No	The log backup retention period. It cannot exceed BackupRetentionPeriod. Unit: days. Valid values: 1 to 30. When you enable log backup, you can configure the log backup retention period. This operation is only supported on MySQL, PostgreSQL, and PPAS.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyBackupPolicy
&DBInstanceID=rds-xxxxx
&PreferredBackupTime=00:00Z—01:00Z
&PreferredBackupPeriod=Monday
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyBackupPolicyResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyBackupPolicyResponse>
```

- JSON format

```
{"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.6.7 DeleteBackup

Description

You can call this operation to delete data backup files that have been stored for longer than seven days or longer than the log backup retention period.

This operation only deletes the specified backup sets for the target instance. It does not delete the backup sets for associated instances, such as read-only, disaster recovery, or cloned instances.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- This operation is applicable only to MySQL, PostgreSQL, and PPAS instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteBackup.
DBInstanceId	String	Yes	The ID of the instance for which data backup files are deleted.
BackupId	String	Yes	The ID of the backup set. Backup set IDs can be obtained through DescribeBackups . You can enter up to 100 backup set IDs in a single request. Separate multiple IDs with commas (,). Only backup sets that are in the Enabled status can be deleted when you call the DescribeBackups operation.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.7 Monitoring management

2.8.1.7.1 DescribeResourceUsage

Description

You can call this operation to query the resource usage information of an instance. When this operation is called, the system returns the amount of space occupied by the specified instance.

DBInstanceId is used to obtain instance resource usage information.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeResourceUsage.
DBInstanceId	String	Yes	The ID of the instance for which the resource usage information is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
DBInstanceId	String	The ID of the instance for which the resource usage information was queried.
Engine	String	The type of the database.
DiskUsed	Integer	The total space occupied by both data files and log files. Unit: Byte. -1 indicates no data.
DataSize	Integer	The disk space that is used to store user data. Unit: Byte. -1 indicates no data.
LogSize	Integer	The disk space that is used to store log files. Unit: Byte. -1 indicates no data.
BackupSize	Integer	The total space occupied by backup data. Unit: Byte. -1 indicates no data.
ColdBackupSize	Integer	The total space occupied by cold backup data. Unit: Byte. -1 indicates no data.
SQLSize	Integer	The total space occupied by SQL data. Unit: Byte. -1 indicates no data.

2.8.1.7.2 DescribeDBInstancePerformance

Description

You can call this operation to query the performance metrics of an instance over a specified period of time based on the performance parameters.

There are three output formats based on different query time ranges:

- When the query time range is less than or equal to one day, performance metrics are displayed at one-minute intervals.
- Queries with the time range from one to seven days are not supported.
- When the query time range is greater than seven days but less than or equal to 15 days, performance metrics are displayed at one-hour intervals.
- Queries with the time range greater than 15 days but less than 30 days are not supported.
- When the query time range is greater than or equal to 30 days but less than or equal to one year, performance metrics are displayed at one-day intervals.

Note:

When the instance space usage key is MySQL_SpaceUsage, performance metric data can be queried only when the time range is less than or equal to one day.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstancePerformance.
DBInstanceId	String	Yes	The ID of the instance.
Key	Integer	Yes	The performance metrics. Separate performance metrics with commas (,). For more information, see Performance parameters .
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the YYYY-MM-DD'T'HH:mmZ format. Example: 2012-06-11T15:00Z.
EndTime	String	Yes	The end of the time range where the query is performed . Specify the time in the YYYY-MM-DD'T'HH:mmZ format. Example: 2012-06-11T15:00Z.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
DBInstanceid	String	The ID of the instance.
Engine	String	The type of the database.
StartTime	String	The beginning of the time range where the query was executed. The time is displayed in the YYYY-MM-DD'T'HH:mmZ format. Example: 2011-05-30T03:29Z.
EndTime	String	The end of the time range where the query was executed. The time is displayed in the YYYY-MM-DD'T'HH:mmZ format. Example: 2011-05-30T03:29Z. The end time must be later than the start time.
PerformanceKeys	List<PerformanceKey>	The array that consists of PerformanceKey data. Example: {perf1, perf2, perf3, ...}.

Examples**Sample requests**

```
https://rds.example.com/?Action=DescribeDBInstancePerformance
&DBInstanceid=rds-xxxxx
&key= MySQL_xxxxx
&StartTime=2013-01-11T15:00:00Z
&EndTime=2013-06-05T15:00:00Z
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeDBInstancePerformanceResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<DBInstanceID>rds-xxxxx</DBInstanceID>
<StartTime>2013-01-11T15:00:00Z</StartTime>
<EndTime>2013-10-17T15:00:00Z</EndTime>
<Engine>MySQL</Engine>
<PerformanceKeys>
<PerformanceKey>
<Key>MySQL_xxxxx</Key>
<Unit>KB</Unit>
<ValueFormat>recv_k&amp;sent_k</ValueFormat>
<Values><Values/>
</PerformanceKey>
</PerformanceKeys>
```

```
</DescribeDBInstancePerformanceResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
  "DBInstanceId": "rds-xxxxx",
  "StartTime": "2012-06-11T15:00Z",
  "EndTime": "2013-10-17T15:00Z",
  "Engine": "MySQL",
  "PerformanceKeys":
    { PerformanceKey[ {
      "Key": "MySQL_XXXXX",
      "Unit": "KB",
      "ValueFormat": "recv_k&sent_k",
      "Values": { "PerformanceValue": [ ] } } ] }
```

2.8.1.7.3 DescribeDBInstanceMonitor

Description

You can call this operation to query the monitoring behavior of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceMonitor.
DBInstanceId	String	Yes	The ID of the instance for which the monitoring behavior is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Period	String	The monitoring period. Unit: seconds.

2.8.1.7.4 ModifyDBInstanceMonitor

Description

You can call this operation to modify the monitoring behavior of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceMonitor.

Parameter	Type	Required	Description
DBInstanceCld	String	Yes	The ID of the instance for which the monitoring behavior is modified.
Period	String	Yes	The monitoring period. Unit: seconds. Valid values: 60 and 300. Default value: 300.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

2.8.1.8 Parameter management

2.8.1.8.1 DescribeParameterTemplates

Description

You can call this operation to query the parameter template list. The list includes parameter names, default parameter values, whether they can be modified, whether the database must be restarted for them to take effect, and regular expressions acting as parameter validation rules.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeParameterTemplates.
Engine	String	Yes	The type of the database. Set the value to MySQL.
EngineVersion	String	Yes	The version of the database. Valid values for MySQL databases: 5.6 and 5.7.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Parameter	Type	Description
Engine	String	The type of the database.
EngineVersion	String	The version of the database.
ParameterCount	Integer	The number of parameters.
Parameters	List<TemplateRecord>	The array that consists of TemplateRecord data . Format: {parameter1, parameter2, parameter3 , ...}.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeParameterTemplates
&Engine=MySQL
&EngineVersion=5.6
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeParameterTemplatesResponse>
<Engine>mysql</Engine>
<EngineVersion>5.6</EngineVersion>
<ParameterCount>1</ParameterCount>
<Parameters>
<TemplateRecord>
<CheckingCode>[0-100]</CheckingCode>
<ForceRestart>True</ForceRestart>
<Factor>1</Factor>
<ParameterDescription>test</ParameterDescription>
<ParameterName>fill factor</ParameterName>
<ParameterValue>0</ParameterValue>
<ForceModify>True</ForceModify>
<Unit>INT</Unit>
</TemplateRecord>
</Parameters>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</DescribeParameterTemplatesResponse>
```

- JSON format

```
{
  "Engine": "mysql",
  "EngineVersion": "5.6",
  "ParameterCount": 1,
  "Parameters": [
    {
      "TemplateRecord": {
        "ParameterDescription": "test",
        "ForceRestart": "True",
        "CheckingCode": "[0-100]",
        "Factor": "1",
        "ParameterName": "fill factor",
        "ParameterValue": "0",
        "ForceModify": "True",
```

```
"Unit": "INT" } }},
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.8.2 DescribeParameters

Description

You can call this operation to query the current instance parameter configuration.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeParameters.
DBInstanceCld	String	Yes	The ID of the instance for which parameters are queried.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Engine	String	The type of the database.
EngineVersion	String	The version of the database.
RunningParameters	List<DBInstanceParameter>	The array that consists of running DBInstanceParameter data. Format: { parameter1, parameter2, parameter3, ...}.
ConfigParameters	List<DBInstanceParameter>	The array that consists of synchronizing DBInstanceParameter data. Format: { parameter1, parameter2, parameter3, ...}.

Table 2-325: DBInstanceParameter parameters

Parameter	Type	Description
ParameterName	String	The name of the parameter.
ParameterValue	String	The value of the parameter.

Parameter	Type	Description
ParameterDescription	String	The description of the parameter.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeParameters
&DBInstanceID=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeParametersResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<Engine>mysql</Engine>
<EngineVersion>5.6</EngineVersion>
<RunningParameters>
<DBInstanceParameter>
<ParameterDescription>test</ParameterDescription>
<ParameterName>fill factor</ParameterName>
<ParameterValue>0</ParameterValue>
</DBInstanceParameter>
</RunningParameters>
<ConfigParameters>
<DBInstanceParameter>
<ParameterDescription>test1</ParameterDescription>
<ParameterName>fill factor</ParameterName>
<ParameterValue>50</ParameterValue>
</DBInstanceParameter>
</ConfigParameters>
</DescribeParametersResponse>
```

- JSON format

```
{ "ConfigParameters": {
  "DBInstanceParameter": [ {
    "ParameterDescription": "test",
    "ParameterName": "fill factor",
    "ParameterValue": "50" } ] },
  "Engine": "mysql",
  "EngineVersion": "5.6",
  "RunningParameters": {
    "DBInstanceParameter": [ {
      "ParameterDescription": "test1",
      "ParameterName": "fill factor",
      "ParameterValue": "0" } ] },
```

```
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

2.8.1.8.3 ModifyParameter

Description

You can call this operation to modify instance parameters. After you submit a request, RDS assigns a task to apply new parameters to the instance. If there are any parameter modifications that require the database to be restarted, RDS restarts the database.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not locked by the system.

There are three types of parameter values:

- 1 to 65,535: indicates a numerical range. Regular identification is used to extract the minimum and maximum values. The input parameter is then verified based on the extracted minimum and maximum values. The parameter must be a multiple of a divisible factor.
- utf8 | gbk | latin1: indicates a set value determination rule. Regular identification is used to extract the fixed value. The input parameter is then verified based on these fixed values.
- Others: These must be implemented with regular expressions.

Before assigning the task, RDS checks the parameter as follows:

1. Whether the parameter exist.
2. Whether the parameter can be modified.
3. Whether the parameter is valid.

If the parameter is invalid, RDS returns the 400 HTTP status code and information about the invalid parameter. Example:

```
{"HttpStatusCode":400,
"Code":"InvalidParameter.Format",
"Message":"Specified parameter is not valid.[auto_increment_increment:a,character_set_client:41]"}
```

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyParameter.
DBInstance Id	String	Yes	The ID of the instance for which parameters are modified.
Parameters	String	Yes	The JSON string for the parameter and its value. The parameter value must be of the string type. { "auto_increment_increment": "1", "character_set_client": "utf8" }.
Forcerestart	String	No	Specifies whether to forcibly restart the database. Valid values: true and false. If a parameter can take effect only after database restart, Forcerestart must be set to true. Otherwise, the parameter modification will not take effect. Default value: false.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyParameter
&DBInstanceId=rds-xxxxx
&Parameters={"key_buffer_size":"456","character_set_client":"gbk"}
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyParameterResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
```

```
</ModifyParameterResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC", }
```

2.8.1.9 Log management

2.8.1.9.1 DescribeSlowLogs

Description

You can call this operation to query the slow log summary of the databases in a specified instance over a specified period of time.

This operation supports querying by page.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSlowLogs.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
StartTime	String	Yes	The beginning of the date range where the query is performed. Specify the date in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
EndTime	String	Yes	The end of the date range where the query is performed. The end date must be later than the start date. Specify the date in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
DBName	String	No	The name of the database.

Parameter	Type	Required	Description
SortKey	String	No	The basis by which query results are sorted. Valid values: TotalExecutionCounts: in the descending order of execution times. TotalQueryTimes: in the descending order of the total execution duration. TotalLogicalReads: in the descending order of the total number of logical reads.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
Engine	String	The type of the database.
StartTime	String	The beginning of the date range where the query is performed. The date is in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
EndTime	String	The end of the date range where the query is performed. The date is in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL slow queries on the current page.
Items	List<SQLSlowLog>	The list of slow log statements.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeSlowLogs
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11Z
&EndTime=2011-12-11Z
&SortKey=TotalReadCounts
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeSlowLogsResponse>

"ReportTime":"2013-11-12Z " }]]}
```

2.8.1.9.2 DescribeSlowLogRecords

Description

You can call this operation to query the slow log details of the databases in a specified instance over a specified period of time. This operation is only supported on MySQL instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSlowLogRecords.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00Z.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T16:00Z.
DBName	String	No	The name of the database.
PageSize	Integer	No	The number of entries to return on each page. Valid values : 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
Engine	String	The type of the database.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL slow queries on the current page.

Parameter	Type	Description
Items	List<SQLSlowRecord>	-

SQLSlowLog parameters

Parameter	Type	Description
HostAddress	String	The host address to connect the database.
DBName	String	The name of the database.
SQLText	String	The query statement.
QueryTimes	Long	The execution time of the slow query. Unit: seconds.
LockTimes	Long	The lock time of the slow query. Unit: seconds.
ParseRowCounts	Long	The number of entries parsed.
ReturnRowCounts	Long	The number of entries returned.
ExecutionStartTime	String	The beginning of the time range where the query was executed . The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00:08Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeSlowLogRecords
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00Z
&EndTime=2011-06-11T16:00Z
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeSlowLogRecordsResponse>
  <RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>

      HostAddress: " 192.168.0.123" ,
      DBName: " test" ,
      SQLText: " update test.zxb set id=0 limit 1" ,
      QueryTimes: " 123" ,
      LockTimes: " 12" ,
      ParseRowCounts: " 125" ,
      ReturnRowCounts: " 1" ,
      ExecutionStartTime: " 2011-06-11T15:00:08Z"  }}}}
```

2.8.1.9.3 DescribeErrorLogs

Description

You can call this operation to query the error logs generated for an instance over a specified period of time.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeErrorLogs.
DBInstanceId	String	Yes	The ID of the instance for which error logs are queried.
StartTime	String	Yes	The beginning of the time range where the query is performed . Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T12:10Z.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T20:10Z.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30 , 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of error logs on the current page.
Items	List<ErrorLogs>	-

ErrorLogs parameters

Parameter	Type	Description
ErrorInfo	String	The error log information.
CreateTime	String	The time when the error log was generated. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T12:11:4Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeErrorLogs.  
&DBInstanceId=rds-xxxxx  
&StartTime=2011-06-11T15:00Z  
&EndTime=2011-06-11T20:00Z  
&<Common request parameters>
```

Sample responses

- XML format

```

informational message only; no user action is required" ,
    "CreateTime":" 2013-06-04T15:00:00" }]]}
```

2.8.1.9.4 DescribeBinlogFiles

Description

You can call this operation to query binlogs of a MySQL instance. This operation supports querying by page. RDS provides binlog files for you to download.

- When the DownloadLink is NULL, RDS does not provide a download URL.
- When DownloadLink is not NULL, you can use this URL to download the backup file through Wget (with double quotation marks), a browser, or a user program. The expiration time for this URL is specified by LinkExpiredTime. Use it before the expiration time.

If the BackupSet has expired, the following error code is displayed:

```
<Error>
<Code>AccessDenied</Code>
<Message>Request has expired. </Message>
<Expires>2012-12-25T09:47:52.000Z</Expires>
<ServerTime>2012-12-25T09:49:00.000Z</ServerTime>
<RequestId>50D9768CA801C2F102005C70</RequestId>
<HostId>oss-test.aliyun-inc.com</HostId>
</Error>
```

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBinlogFiles.
DBInstance Id	String	Yes	The ID of the instance for which binlogs are queried.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The end time must be later than the start time.

Parameter	Type	Required	Description
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
TotalRecordCount	Integer	The total number of binlog files.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of binlog files on the current page.
Items	List<BinLogFile>	-

BinLogFile parameters

Parameter	Type	Description
FileSize	Long	The size of a binlog file. Unit: Byte.
LogBeginTime	String	The beginning of the time range where the binlog was executed.
LogEndTime	String	The end of the time range where the binlog was executed.
DownloadLink	String	The HTTP-compliant download URL. If this parameter is set to NULL, no download URL exists.
HostInstanceId	String	The ID of the instance to which the binlog belongs. This parameter indicates whether the binlog is from the primary or secondary instance.
LinkExpiredTime	String	The URL expiration time. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00:00Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeBinlogFiles
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00:00Z
&EndTime=2013-06-05T15:00:00Z
&<Common request parameters>
```

Sample responses

    }
  }
}
```

2.8.1.9.5 DescribeSQLCollectorPolicy

Description

You can call this operation to check whether SQL collection is enabled for a specified RDS instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeSQLCollectorPolicy.
DBInstanceCld	String	Yes	The ID of the instance for which SQL collection is enabled or disabled.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
SQLCollect orStatus	String	Indicates whether SQL collection is enabled. Valid values: Enable and Disabled.

2.8.1.9.6 ModifySQLCollectorPolicy

Description

You can call this operation to enable or disable SQL collection for the specified RDS instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifySQLCollectorPolicy.
DBInstanceCld	String	Yes	The ID of the instance for which SQL collection is enabled or disabled.
SQLCollect orStatus	String	Yes	Specifies whether to enable SQL collection. Valid values: Enable and Disabled.

Response parameters

This operation returns only common response parameters. For more information, see [Common response parameters](#).

2.8.1.9.7 DescribeSQLLogRecords

Description

You can call this operation to query the SQL audit logs generated for an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSQLLogRecords.
DBInstance Id	String	Yes	The ID of the instance for which SQL audit logs are queried.
Database	String	No	The name of the database. All databases are selected by default.
User	String	No	The name of the user. All users are selected by default.
Form	String	No	The file generation form for audit logs. Valid values: File and Stream. If this parameter is set to File, only common parameters are returned, and you must call the DescribeSQLLogFiles operation to obtain the final download file address. If this parameter is set to Stream, data streams are returned. Default value: Stream.
QueryKeywords	String	No	The keywords used for query. Up to 10 keywords can be entered at a time. Separate multiple keywords with spaces.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The end time must be later than the start time.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, 100, and 200. Default value: 100.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

Parameter	Type	Description
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL logs on the current page.
Items	List<SQLRecord>	The array that consists of SQLRecord data.

SQLRecord parameters

Parameter	Type	Description
DBName	String	The name of the database.
AccountName	String	The name of the account.
HostAddress	String	The IP address of the client.
SQLText	String	The SQL statement.
TotalExecutionTimes	Long	The amount of time taken to execute the operation. Unit: microseconds.
ReturnRowCounts	Long	The number of entries returned.
ThreadID	String	The thread ID.
ExecuteTime	String	The execution time. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T12:11:20Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeSQLLogRecords
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00:00Z
&EndTime=2013-06-05T15:00:00Z
&<Common request parameters>
```

Sample responses

- XML format

```

        "AccountName": "accounttest",
        "DBName": "test"
      }
    ]
  },
  "ItemsCounts": 1
}
```

2.8.1.9.8 DescribeSQLLogFiles

Description

You can call this operation to query SQL audit files.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSQLLogFiles.
DBInstance Id	String	Yes	The ID of the instance for which SQL audit files are queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .
TotalRecordCount	Integer	The total number of entries.

Parameter	Type	Description
PageNumber	Integer	The number of the page returned.
PageRecord Count	Integer	The number of entries on the current page.
Items	List<LogFile>	The array that consists of audit file data.

LogFile parameters

Parameter	Type	Description
FileID	Integer	The ID of an audit log file.
DBInstanceID	String	The ID of the instance for which SQL audit files were queried.
LogStatus	String	The status of SQL audit files. Valid values: • Success • Failed • Generating
LogStartTime	String	The beginning of the time range where the audit log was executed.
LogEndTime	String	The end of the time range where the audit log was executed.
LogDownloadURL	String	The file download URL. If the download URL is unavailable, this parameter will be empty.
LogSize	Long	The size of an audit log file. Unit: Byte.

2.8.1.10 Data migration

2.8.1.10.1 ImportDatabaseBetweenInstances

Description

You can call this operation to migrate data from other RDS instances. This operation is only supported on MySQL instances.

MySQL instances support batch database migration. During migration, the source instance status changes to Migrating and the destination instance status changes to Importing Data.

Database migration is performed between different instances that belong to the same user. Before you call this operation, ensure that the following requirements are met:

- The instance must be in the running state.
- The database must be in the running state.

- The destination instance is not locked.
- The reserved storage space of the destination instance is greater than the space calculated by the formula: The used space of the destination instance - The database space of the destination instance + The database space of the source instance.
- Databases to be migrated exist in both the source and destination instances and are activated.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ImportDatabaseBetweenInstances.
DBInstanceid	String	Yes	The ID of the instance.
SourceDBInstanceid	String	Yes	The ID of the source instance, which cannot be the same as that of the destination instance.
DBInfo	String	Yes	The information about the database to be migrated, in JSON format. For MySQL instances, the parameter value is an array . Example: {"DBNames":["mydb","mydb2"]}. For MySQL instances, the names of the source and destination databases must be the same. In this example, data is migrated from the two databases mydb and mydb2 . These databases must exist in both the source and destination instances.

DBInfo parameters

Parameter	Type	Required	Description
DBNames	List	Yes	The names of databases to be migrated. Example: ["mydb","mydb2"].

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters .

Parameter	Type	Description
ImportId	Integer	The ID of the destination instance.

Examples

Sample requests

```
https://rds.example.com/?Action=ImportDatabaseBetweenInstances
&DBInstanceId=rds-xxxxx
&SourceDBInstanceId=rds-xxxxx
&{"DBNames":["mydb","mydb2"]}
&<Common request parameters>
```

Sample responses

- XML format

```
<ImportDatabaseBetweenInstancesResponse>

```

2.8.1.11 Tag management

2.8.1.11.1 AddTagsToResource

Description

You can call this operation to bind existing or newly created tags to instances. Before you call this operation, ensure that the following requirements are met:

Each tag is composed of a TagKey and a TagValue. The TagKey cannot be blank, but the TagValue can.

- The values of TagKey and TagValue cannot start with aliyun.
- The values of TagKey and TagValue are not case sensitive.
- The maximum length of TagKey is 64 characters and the maximum length of TagValue is 128 characters.
- Each instance can only be bound to a maximum of 10 tags. Each tag bound to the same instance must have a unique TagKey. If tags with duplicate TagKeys are bound to the same instance, the tag bound last overwrites the existing tag.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AddTagsToResource.
RegionId	String	Yes	The region ID of the instance for which a tag is be bound.
DBInstanceIds	String	Yes	The ID of the instance for which a tag is be bound. Up to 30 IDs can be entered in a single request. Separate multiple IDs with commas (,) Format: instance1,instance2,instance3.
Tags	JSON string	Yes	The tag pair to be bound. This parameter must include a TagKey, but does not need to include a corresponding TagValue. Up to five tag pairs can be entered in a single request. The TagKey is required, and TagValue is optional. Format: { "key1" : "value1" , "key2" : " " }.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

2.8.1.11.2 DescribeTags

Description

You can call this operation to view the bound tag information of an RDS instance belonging to the current account. This operation must meet the following requirements:

If a specified instance ID is provided, all tags bound to this instance are queried and the other filter criteria are ignored.

- If the TagKey of a key is provided without a TagValue, the results of all tags matching the TagKey criteria are returned.

- If both TagKey and TagValue are provided, only the results that match both parameters are returned.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTags.
RegionId	String	Yes	The region ID of the instance.
DBInstanceId	String	No	The name of the instance. If this parameter is provided, all the other filter criteria are ignored.
Tags	Json string	No	The tag pair. This parameter must include a TagKey , but does not need to include a corresponding TagValue. The TagKey cannot be blank, but the TagValue can. Format: {"key1":"value1 "}

Response parameters

Name	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Items	List<TagInfos>	The array that consists of tag data.

TagInfos parameters

Name	Type	Description
TagKey	String	The TagKey.
TagValue	String	The TagValue.
DBInstanceIds	List<DBInstanceIds>	The IDs of instances bound to this tag.

DBInstanceIds parameters

Name	Type	Description
DBInstanceIds	String	The name of the instance.

2.8.1.11.3 RemoveTagsFromResource

Description

You can call this operation to unbind tags from an instance. This operation must meet the following requirements:

A maximum of 10 tags can be unbound in a single request.

If a tag is unbound from all of its bound instances, the tag itself is automatically deleted.

If the TagKey of a key is provided without a TagValue, all tags matching the TagKey criteria are unbound.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RemoveTagsFromResource.
RegionId	String	Yes	The region ID of the instance.
DBInstanceId	String	Yes	The name of the instance.
Tags	Json string	Yes	The tag pair to be unbound. This parameter must include a TagKey, but does not need to include a corresponding TagValue. The TagKey cannot be blank, but the TagValue can. Format: {"key1":"value1 "}

Response parameters

Name	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .

2.8.1.12 RAM authorization

Use RAM for RDS resource authorization

All RDS instances created through an Apsara Stack tenant account are resources owned by that account. By default, you have full operation permissions on the resources under your account.

Resource Access Management (RAM) allows you to grant RAM users the access and management permissions on RDS resources owned by an Apsara Stack tenant account.

If you do not need to use RAM, ignore this topic.

Resource types in RAM

The only type of RDS resources that can be authorized through RAM is dbinstance. The following table lists the resource description method when the resources are authorized through RAM.

Resource	Resource description in authorization policy
Instance	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstance id acs:rds:\$regionid:\$accountid:dbinstance/ acs:rds:::dbinstance/

The \$regionid field must be the ID of a region or an asterisk (*). The \$instanceid field must be the ID of an instance or an asterisk (*). Similarly, \$account-id is the numerical ID of your Apsara Stack tenant account, which can be replaced by an asterisk (*).

Authorization operations in RAM

In RAM, the following operations can be authorized to an RDS resource.

Operation 1	Operation 2
CreateDBInstance	ModifyDBInstanceSpec
DeleteDBInstance	CreateReadonlyDBInstance
DescribeDBInstances	DescribeDBInstanceAttribute
SwitchDBInstanceNetType	RestartDBInstance
ModifyDBInstanceDescription	ModifySecurityIps
ModifyDBInstanceMaintainTime	UpgradeDBInstanceEngineVersion
PurgeDBInstanceLog	CreateDatabase
DeleteDatabase	DescribeDatabases
ModifyDBDescription	ModifyParameter
DescribeParameters	DescribeOptimizeAdviceByDBA
DescribeOptimizeAdviceOnMissIndex	ImportDataBaseBetweenInstances

Operation 1	Operation 2
CancelImport	CreateAccount
ResetAccountPassword	GrantAccountPrivilege
RevokeAccountPrivilege	DescribeAccounts
DeleteAccount	ModifyAccountDescription
CreateBackup	DescribeBackups
CreateTempDBInstance	DescribeBackupPolicy
ModifyBackupPolicy	DescribeResourceUsage
DescribeDBInstancePerformance	DescribeSlowLogs
DescribeSlowLogRecords	DescribeErrorLogs
DescribeBinlogFiles	DescribeSQLLogReports
DescribeSQLLogRecords	DescribeOptimizeAdviceOnStorage
DescribeOptimizeAdviceOnMissPK	DescribeOptimizeAdviceOnExcessIndex

**Note:**

All operations except DescribeRegions and DescribeParameterTemplates can be authorized.

RAM authentication rules of API operations

When you call API operations to access resources as a RAM user, the RDS backend checks whether the RAM user is granted the required permissions by querying RAM. The permissions to be checked are determined by the resources used by the API operation. The following table lists the authentication rules for each API operation.

Operation	Authentication rule
CreateDBInstance	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DeleteDBInstance	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeDBInstances	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
SwitchDBInstanceNetType	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid

Operation	Authentication rule
ModifyDBInstanceDescription	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyDBInstanceMaintainTime	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
PurgeDBInstanceLog	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DeleteDatabase	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyDBDescription	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CancelImport	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ResetAccountPassword	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
RevokeAccountPrivilege	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DeleteAccount	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CreateBackup	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CreateTempDBInstance	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyBackupPolicy	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeDBInstancePerformance	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeSlowLogRecords	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeBinlogFiles	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeSQLLogRecords	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeOptimizeAdviceOnMissPK	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid

Operation	Authentication rule
DescribeOptimizeAdviceOnMissIndex	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeParameters	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CreatePrepaidDBInstanceForChannel	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyPrepaidDBInstanceSpec	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CreatePostpaidDBInstanceForChannel	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyPostpaidDBInstanceSpec	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeDBInstanceAttribute	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
RestartDBInstance	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifySecurityIps	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
UpgradeDBInstanceEngineVersion	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CreateDatabase	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeDatabases	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ImportDataBaseBetweenInstances	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
CreateAccount	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
GrantAccountPrivilege	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeAccounts	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyAccountDescription	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid

Operation	Authentication rule
DescribeBackups	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeBackupPolicy	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeResourceUsage	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeSlowLogs	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeErrorLogs	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeSQLLogReports	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeOptimizeAdviceOnStorage	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeOptimizeAdviceOnExcess Index	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
DescribeOptimizeAdviceByDBA	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid
ModifyParameter	acs:rds:\$regionid:\$accountid:dbinstance/\$dbinstanceid

2.8.1.13 Appendix

2.8.1.13.1 Error codes on the client

2.8.1.13.1.1 Common errors

Error code	Error message	HTTP status code
MissingParameter	The input parameter "parameter name" that is mandatory for processing this request is not supplied.	400
InvalidParameter	The specified parameter "Action or Version" is not valid.	400
InvalidAccessKeyId.NotFound	The Access Key ID provided does not exist in our records.	404

Error code	Error message	HTTP status code
IncompleteSignature	The request signature does not conform to Aliyun standards.	400
IllegalTimestamp	The input parameter "Timestamp" that is mandatory for processing this request is not supplied.	400
InvalidOwnerId	The specified OwnerId is not valid.	400
InvalidOwnerAccount	The specified OwnerAccount is not valid.	400
InvalidOwner	OwnerId and OwnerAccount can't be used at one API access.	400
Throttling	Request was denied due to request throttling.	400
InvalidAction	The specified action is not valid.	403
ActionUnauthorized	The specified action is not available for you	403
UnsupportedHTTPMethod	This http method not supported.	403
UnsupportedParameter	The parameter "<parameter name>" is not supported .	400
Forbidden.InstanceNotFound	The specified Instance is not found.	404
Forbidden.RAM	User not authorized to operate on the specified resource, or this API doesn't support RAM.	403
Forbidden.NotSupportRAM	This action does not support accessed by RAM mode.	403
Forbidden.RiskControl	This operation is forbidden by Aliyun Risk Control system.	403
InsufficientBalance	Your account does not have enough balance.	400
Forbidden.Authentication	This operation is forbidden by Aliyun Realname Authentication system.	403
Invalid<parameter name>. ValueNotSupported	The specified parameter "parameter name" is not valid.	400
Invalid<parameter name>. Malformed	The specified parameter "parameter name n" is not valid.	400

Error code	Error message	HTTP status code
InvalidParameter	The specified parameter " parameter name n " is not valid.	400

2.8.1.13.1.2 Specific errors

Error code	Error message	HTTP status code
InvalidRegionId.NotFound	The DBInstanceId provided does not exist in our records.	404
InvalidSecurityIPList.Duplicate	The Security IP address is not in the available range or occupied.	400
InvalidSecurityIPListLength.Malformed	The quota of security ip exceeds.	400
InvalidEngineVersionInRegion.NotAvailable	The EngineVersion in the Region is not available.	403
InvalidEngineInRegion.NotAvailable	The Engine in the Region is not available.	403
InvalidDBInstanceClassInRegion.NotAvailable	The DBInstanceClass in the Region is not available.	403
OperationDenied	The resource is out of usage.	403
RegionUnauthorized	There is no authority to create instance in the specified region.	403
QuotaExceeded.CreateInstance	The quota of create instance exceeds.	403
InvalidDBInstanceId.NotFound	The DBInstanceId provided does not exist in our records.	404
MissingParameter	The input parameters "DBInstanceClass" and "DBInstanceStorage" all blank or no change.	400
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	400
OperationDenied.DBInstanceStorageReduce	The operation is not permitted due to reduce storage.	403

Error code	Error message	HTTP status code
OperationDenied.DBInstanceStatus	The operation is not permitted due to instance status.	403
DependencyViolation	The operation is not permitted due to instance mount read only or guard instance.	403
InvalidConnectionStringPrefix.Duplicate	The connection string is not in the available range or occupied.	400
QuotaExceeded.SwitchTime	The quota of switch time exceed.	400
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
InvalidSecurityIps.Duplicate	The quota of security ip exceeds.	400
OperationDenied.CurrentEngineVersion	The operation is not permitted due to specified current version.	400
OperationDenied.ReadOnlyDBInstanceLower	The operation is not permitted due to higher read only instance version.	403
OperationDenied.GuardDBInstanceLower	The operation is not permitted due to higher guard instance version.	403
OperationDenied.MasterDBInstanceState	The operation is not permitted due to status of master instance.	403
QuotaExceeded.DBName	The quota of db exceeds.	400
InvalidDBName.Duplicate	The Security db Name is not in the available range or occupied.	400
InvalidParameter.Keyword	The specified parameter "DBName" is keyword	400
OperationDenied.DBStatus	The operation is not permitted due to status of database.	403
OperationDenied.DBInstanceEngine	The operation is not permitted due to engine of instance.	403
FTPServiceUnavailable	The request has failed due to a temporary failure of the FTP server.	403
QuotaExceeded.Upload	The quota of file exceeds.	403
InvalidFileName.NotCompleted	The specified "FileName" is not completed.	404

Error code	Error message	HTTP status code
InvalidFileName.NotAvailable	The specified "FileName" is not Available.	404
QuotaExceeded.FileSize	The quota of file size exceeds.	403
QuotaExceeded.DBInstanceStorage	The quota of instance storage exceeds.	403
InvalidDBInfo.Malformed	The specified parameter "DBInfo" is not valid or db not exist.	400
OperationDenied.Region	The operation is not permitted due to different region.	403
OperationDenied.Engine	The operation is not permitted due to different engine.	403
OperationDenied.DBInstanceCld	The operation is not permitted due to DBInstanceCld and SourceDBInstanceCld is same.	403
InvalidTaskId.NotFound	The ImportId provided does not exist in our records.	400
OperationDenied.IncorrectTaskStatus	The operation is not permitted due to status of import.	403
InvalidAccountName.keyword	The specified parameter "AccountName" is a keyword.	400
InvalidAccountName.Duplicate	The Security db Name is not in the available range or occupied.	400
QuotaExceeded.AccountName	The quota of account exceeds.	403
OperationDenied.AccountStatus	The operation is not permitted due to status of account.	403
InvalidDBName.NotFound	The DBName provided does not exist in our records.	404
OperationDenied.AccountType	The operation is not permitted due to type of account.	403
OperationDenied.BackupJobExists	The operation is not permitted due to backup job exist.	403
OperationDenied.NoDatabase	The operation is not permitted due to no database.	403

Error code	Error message	HTTP status code
InvalidStartTimeAndEndTime.Malformed	The end time must be greater than the start time	400
OperationDenied.BackupJobExists	The operation is not permitted due to backup job exist.	403
InvalidBackupId.NotFound	The BackupId provided does not exist in our records.	404
OperationDenied.NotFoundBackup	The operation is not permitted due to no backup.	403
OperationDenied.BackupStatus	The operation is not permitted due to type of backup.	403
OperationDenied.BackupMethod	The operation is not permitted method of backup.	403
OperationDenied.TempDBInstanceExists	The operation is not permitted due to temp instance exist.	403
Forbidden.Authentication	The operation is forbidden by Aliyun Realname Authentication System.	403
IncorrectDBInstanceConnType	Current DB instance conn type does not support this operation.	404
IncorrectVpcId.Mismatch	The specified parameter "VpcId" is not valid.	400
IntranetNetTypeNotExists	Current DB instance net type does not support this operation.	404
InvalidDBInstanceName.NotFound	The DBInstanceId provided does not exist in our records.	403
InvalidConnectionMode.ValueNotSupported	The specified parameter "ConnectionMode" is not valid.	400
InvalidConnectionString.DuplicateSpecified	connection string already exists in the Aliyun RDS.	403
InvalidConnectionString.DuplicateSpecified	connection string or port want to be modified is the same with current net type.	400
InvalidConnectionStringPrefix.Duplicated	Specified connection string already exists in the Aliyun RDS.	403

Error code	Error message	HTTP status code
InvalidConnectionString.NotFound	Specified current connection string doesn't exist.	400
InvalidDBInstanceId.NotFound	The DBInstanceId provided does not exist in our records.	400
InvalidDBInstanceId.QuotaExceeded	The quota of instance id exceeds.	400
InvalidDBInstanceNetType.NotFound	The Specified DB instance net type is not found.	404
InvalidDBInstanceNetType.ValueNotSupported	The specified parameter "DBInstanceNetType" is not valid.	400
InvalidDBInstanceType.ValueNotSupported	The specified parameter "DBInstanceType" is not valid.	400
InvalidEngineVersion.Malformed	The specified parameter "EngineVersion" is not valid.	400
InvalidInstanceNetworkType.ValueNotSupported	The specified parameter "InstanceNetworkType" is not valid.	400
InvalidParameter	The specified parameter "dbInstanceId" is not valid.	400
InvalidPort.Malformed	Specified port is not valid.	400
InvalidPrivateIpAddress.Duplicated	Specified private IP address is duplicated.	400
InvalidPrivateIpAddress.Mismatch	Specified private IP address is not in the CIDR block of virtual switch.	400
InvalidVPCId.NotFound	Specified virtual vpc is not found.	400
InvalidVSwitchId.Mismatch	Specified instance and virtual switch are not in the same zone.	400
InvalidVSwitchId.NotFound	Specified virtual switch is not found in specified VPC.	400
NetTypeExists	Specified net type already existed.	400
NetTypeExists	Specified public net type already existed.	403
OperationDenied.DBInstanceNetType	The operation is not permitted due to net type of instance.	403

Error code	Error message	HTTP status code
OperationDenied.DBInstanceStatus	The operation is not permitted due to status of instance.	403
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	403
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
OperationDenied.Switch	Specified instance cannot be switched.	400
OperationDenied.Switch	Specified instance cannot be switched to VPC.	403
OperationDenied.SwitchToVPC	Specified instance cannot be switched to VPC.	403
OperationDenied	The resource is out of usage.	403
OperationDenied	The vpc cloudinstancelp is use, please check params.	406
OperationDenied	The vpc service is error, please check params.	400
PARAMETER_ERROR	The vpc request parameter may not be null .	406
PARAMETER_MUST_NOT_NULL	The parameter must not be null.	406
PublicConnectionExists	PublicConnection exists.	403
bpclzNoNotEqualsRdsMultlzNo	Specified vpc lzNo not equal rds lzNo.	400
OperationDenied.DBInstanceStatus	The operation is not permitted due to status of instance.	403
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	403
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
OperationDenied.Switch	Specified instance cannot be switched.	400
OperationDenied.SwitchToVPC	Specified instance cannot be switched to VPC.	403
OperationDenied	The resource is out of usage.	403

Error code	Error message	HTTP status code
OperationDenied	The vpc cloudinstancelp is use, please check params.	406
OperationDenied	The vpc service is error, please check params.	400
PARAMETER_ERROR	The vpc request parameter may not be null .	406
PARAMETER_MUST_NOT_NULL	The parameter must not be null.	406
PublicConnectionExists	PublicConnection exists.	403
bpclzNoNotEqualsRdsMultlzNo	Specified vpc lzNo not equal rds lzNo.	400

2.8.1.13.2 Error codes on the server

Error code	Error message	HTTP status code
ServiceUnavailable	The request has failed due to a temporary failure of the server.	503
InternalServerError	The request processing has failed due to some unknown error, exception or failure.	500

2.8.1.13.3 Instance states

State	Description
Creating	An instance is being created.
Running	An instance is in the running state.
Deleting	An instance is being deleted.
Rebooting	An instance is being restarted.
DBInstanceClassChanging	An instance is being upgraded or downgraded.
TRANSING	Data is being migrated.
EngineVersionUpgrading	Engine version is being upgraded.
TransingToOthers	Data is being migrated to other RDS instances.

State	Description
GuardDBInstanceCreating	A disaster recovery instance is being created.
Restoring	A backup is being restored.
Importing	Data is being imported.
ImportingFromOthers	Data is being imported from other RDS instances.
DBInstanceNetTypeChanging	The network type is being switched between Intranet and Internet.
GuardSwitching	The instance is undergoing disaster recover failover.
INS_CLONING	The instance is being cloned.

2.8.1.13.4 Performance parameters

ApsaraDB RDS for MySQL

API parameter	Description
MySQL_NetworkTraffic	The average inbound traffic to a MySQL instance per second and average outbound traffic from a MySQL instance per second. Unit: KB.
MySQL_QPSTPS	The average number of SQL statements executed per second and average number of transactions per second.
MySQL_Sessions	The number of active connections and total number of current connections.
MySQL_InnoDBBufferRatio	The read hit rate of the InnoDB buffer pool, utilization of the InnoDB buffer pool, and percentage of dirty data blocks in the InnoDB buffer pool.
MySQL_InnoDBDataReadWritten	The average volume of data that InnoDB reads per second and average volume of data that InnoDB writes per second. Unit: KB.
MySQL_InnoDBLogRequests	The average number of reads from the InnoDB buffer pool per second and average number of writes to the InnoDB buffer pool per second.
MySQL_InnoDBLogWrites	The average number of log write requests per second, average number of physical writes to log files per second, and average number of fsync() writes to log files per second.

API parameter	Description
MySQL_TempDiskTableCreates	The number of temporary tables automatically created in the hard drive during MySQL statement execution.
MySQL_MyISAMKeyBufferRatio	The average key buffer utilization of MyISAM per second, average key buffer read hit rate of MyISAM per second, and average key buffer write hit rate of MyISAM per second.
MySQL_MyISAMKeyReadWrites	The average number of data reads from the buffer pool by MyISAM per second, average number of data writes to the buffer pool by MyISAM per second, average number of data reads from the hard disk by MyISAM per second, and average number of data writes to the hard disk by MyISAM per second.
MySQL_COMDML	The average number of DELETE statements executed per second, average number of INSERT statements executed per second, average number of INSERT_SELECT statements executed per second, average number of REPLACE statements executed per second, and average number of REPLACE_SELECT statements executed per second, average number of SELECT statements executed per second, and average number of UPDATE statements executed per second.
MySQL_RowDML	The average number of rows read from the InnoDB table per second, average number of rows updated in the InnoDB table per second, average number of rows deleted from the InnoDB table per second, average number of rows inserted into the InnoDB table per second, and average number of physical writes to log files per second.
MySQL_MemCpuUsage	The CPU utilization and memory usage of a MySQL Instance within the entire operating system.
MySQL_IOPS	The IOPS of a MySQL instance.
MySQL_DetailedSpaceUsage	The disk space occupied by a MySQL instance, including ins_size (total space), data_size (data space), log_size (log space), tmp_size (temporary space), and other_size (system space).
slavestat	The latency of read-only instances.

2.8.1.13.5 Forbidden keywords

ApsaraDB RDS for MySQL

Parameter field	Keyword description
DBName/ AccountName	admin,aurora,replicator,xtrabak,root(MySQL5.5/5.6),mysql,test, eagleye,information_schema,guest,add,analyze,asc,between,blob, call,c hange,check,condition,continue,cross,current_timestamp,database, day_microsecond,dec,default,desc,distinct,double,e ach,enclosed,exit,fetch,float8,foreign,goto,having,hour_minute, ignore,infile,insensitive,int1,int4,interval,iterate,keys,lea ding,like,lines,localtimestamp,longblob,low_priority,mediumint, minute_microsecond,modifies,no_write_to_binlog,on, optionally,out,precision,purge,read,references,rename,require,revoke ,schema,select,set,spatial,sqlexception,sql_big_re sult,ssl,table,tinyblob,to,true,unique,update,using,utc_timestamp, varchar,when,with,xor,all,and,asensitive,bigint,both,c ascade,char,collate,connection,convert,current_date,current_user, databases,day_minute,decimal,delayed,describe,dis tinctrow,drop,else,escaped,explain,float,for,from,grant,high_priority, hour_second,in,inner,insert,int2,int8,into,join,kill,le ave,limit,load,lock,longtext,match,mediumtext,minute_second, natural,null,optimize,or,outer,primary,raid0,reads,regex p,repeat,restrict,right,schemas,sensitive,show,specific,sqlstate, sql_calc_found_rows,starting,terminated,tinyint,trailing, undo,unlock,usage,utc_date,values,varcharacter,where,write, year_month,alter,as,before,binary,by,case,character,colu mn,constraint,create,current_time,cursor,day_hour,day_second, declare,delete,deterministic,div,dual,elseif,exists,false, float4,force,fulltext,group,hour_microsecond,if,index,inout,int,int3, integer,is,key,label,left,linear,localtime,long,loop,me diumblob,middleint,mod,not,numeric,option,order,outfile,procedure, range,real,release,replace,return,rlike,second_mi crosecond,separator,smallint,sql,sqlwarning,sql_small_result,

2.8.1.13.6 Instance types

Instances of different editions, versions, and types each perform differently from one another.

Table 2-326: ApsaraDB RDS for MySQL instance types

Edition	Version	Instance family	Instance type	CPU and memory	Maximum connections	Maximum IOPS	Disk capacity	Zone-disaster recovery deployment
High-availability Edition	5.6 or 5.7	Dedicated instance (X8)	mysql.x8.medium.2	2 cores, 16 GB	2,500	4,500	250 GB	Single-data center deployment
			mysql.x8.large.2	4 cores, 32 GB	5,000	9,000	500 GB	
			mysql.x8.xlarge.2	8 cores, 64 GB	10,000	18,000	1 TB	
			mysql.x8.2xlarge.2	16 cores, 128 GB	20,000	36,000	2 TB	
		Dedicated instance (X4)	mysql.x4.large.2	4 cores, 16 GB	2,500	4,500	250 GB	Dual-data center deployment
			mysql.x4.xlarge.2	8 cores, 32 GB	5,000	9,000	500 GB	
			mysql.x4.2xlarge.2	16 cores, 64 GB	10,000	18,000	1 TB

		Dedicated host	rds.ppas.t3.d13	30 cores, 220 GB	4,000	20,000	3 TB	

2.8.1.13.7 Use Java to connect to an RDS for MySQL instance

This topic describes how to use Java to connect to an RDS for MySQL instance.

Use code to connect to an RDS for MySQL instance. See the following sample code.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

public class mysqlconnection {

    public static void main(String[] args) {

        Connection conn = null;
        String sql;
        String url = "jdbc:mysql://rdssoxxxxxxx.mysql.rds.aliyuncs.com:3306? zeroDateTi
meBehavior=convertToNull&";
        + "user=michael&password=password&useUnicode=true&";
        characterEncoding=UTF8";
        try {

            Class.forName("com.mysql.jdbc.Driver");
            conn = DriverManager.getConnection(url);
            Statement stmt = conn.createStatement();
            String sqlusedb="use test_5";

            int result1 = stmt.executeUpdate(sqlusedb);

            sql = "create table teacher(NO char(20),name varchar(20),primary key(NO))";
            int result = stmt.executeUpdate(sql);
            if (result != -1) {

                sql = "insert into teacher(NO,name) values('2016001','wangsan')";
                result = stmt.executeUpdate(sql);
                sql = "insert into teacher(NO,name) values('2016002','zhaosi')";
                result = stmt.executeUpdate(sql);
                sql = "select * from teacher";
                ResultSet rs = stmt.executeQuery(sql);
                System.out.println("Student ID\tName");
                while (rs.next()) {
                    System.out
                        .println(rs.getString(1) + "\t" + rs.getString(2));
                }
            }
        }
    }
}
```

```

    } catch (SQLException e) {
        System.out.println("MySQL misoperation");
        e.printStackTrace();
    } catch (Exception e) {
        e.printStackTrace();
    } finally {
        try {
            conn.close();
        } catch (SQLException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
}
}

```

2.8.2 SDK reference

2.8.2.1 Java SDK

2.8.2.1.1 Quick start

This topic describes how to obtain and use the RDS Java SDK.

Prerequisites

- You must have a RAM user account and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Java SDK. For more information about how to view and obtain your AccessKey pair in the Apsara Stack Operations console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).
- Apsara Stack Java SDK supports JDK 1.6 and later.

Install the Java SDK

If you use Apache Maven to manage Java projects, you only need to import the JAR file to the pom.xml file of the project.

To use the SDK of a service, you must install the service SDK and the SDK core library.

The SDK core library is V3.7.1. The SDK is V2.1.4.

```

<dependencies>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-core</artifactId>
    <version>3.7.1</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-core-3.7.1.jar</systemPath>
  </dependency>
  <dependency>
    <groupId>com.aliyun</groupId>

```

```
<artifactId>aliyun-java-rds</artifactId>
<version>2.1.4</version>
<scope>system</scope>
<systemPath>${project.basedir}/lib/aliyun-java-sdk-rds-2.1.4.jar</systemPath>
</dependency>
</dependencies>
```

Use the Java SDK

To call the Java SDK, perform the following operations:

1. Create a DefaultAcsClient instance and initialize it.
2. Create an API request and configure its parameters.
3. Initiate the request and handle its response or exception.

```
package com.testprogram;
import com.aliyuncs.profile.DefaultProfile;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.ecs.model.v20140526.*;
public class Main {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // Your region ID.
            "<your-access-key-id>", // Your AccessKey ID.
            "<your-access-key-secret>"); // Your AccessKey Secret.
        // Set the endpoint of the current service.
        profile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and configure its parameters.
        DescribeInstancesRequest request = new DescribeInstancesRequest();
        request.setPageSize(10);
        // Initiate the request and handle the response or exception.
        DescribeInstancesResponse response;
        try {
            response = client.getAcsResponse(request);
            for (DescribeInstancesResponse.Instance instance:response.getInstances()) {
                System.out.println(instance.getPublicIpAddress());
            }
        } catch (ServerException e) {
            e.printStackTrace();
        } catch (ClientException e) {
            e.printStackTrace();
        }
    }
}
} Enter your actual service information
```

2.8.2.1.2 Use the SDK

2.8.2.1.2.1 Install the Java SDK

This topic describes how to install and use the RDS Java SDK.

The RDS Java SDK supports JDK 1.6 and later. You can import the JAR file to install the JDK.

You can click [Here](#) to download the JAR file for VPC.

You can import the JAR file to install the VPC Java SDK regardless of the IDE (Eclipse or IntelliJ).

The installation method is as follows:

- Use Eclipse

To install the RDS Java SDK in an Eclipse project, perform the following operations:

1. Copy the downloaded `aliyun-java-sdk-rds.jar` file to your project folder.
2. Open your project in Eclipse, right-click the project, and choose **Properties** from the shortcut menu.
3. In the dialog box that appears, choose **Java Build Path > Libraries > Add JARs** to add the downloaded JAR file.
4. Click **Apply and Close**.

- Use IntelliJ

To install the RDS Java SDK in an IntelliJ project, perform the following operations:

1. Copy the downloaded `aliyun-java-sdk-rds.jar` file to your project folder.
2. Open your project in IntelliJ. In the menu bar, choose **File > Project Structure**.
3. Click **Apply**, and then **OK**.

2.8.2.1.2 Configure identity verification credentials

When using SDKs to access Apsara Stack services, you must provide an authorized Apsara Stack tenant account for identity verification.

The Java SDK supports the use of AccessKey pairs for identity verification. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use AccessKey pairs as credentials, you must configure your credentials when initializing the client.

Notice:

Ensure that code containing your AccessKey pair is kept confidential and is not disclosed, such as being uploaded to a public GitHub project. Otherwise, the information security of your Apsara Stack account may become compromised.

```
DefaultProfile profile = DefaultProfile.getProfile(
    "<your-region-id>", // Your region ID.
    "<your-access-key-id>", // Your AccessKey ID.
```

```
"<your-access-key-secret>"); // Your AccessKey Secret.
```

2.8.2.1.2.3 Initiate a request

This topic describes how to use the RDS Java SDK to initiate a request.

Procedure

1. Create an AcsClient instance.

```
IAcsClient client = new DefaultAcsClient(profile);
```

2. Create a request.

The naming convention for requests is `${apiName}Request`. **`${apiName}`** is the API name, such as `DescribeDBInstanceAttribute`.

When multiple SDKs are used, different requests may have the same name. Differentiate the requests based on the `PageSize` value.

```
DescribeDBInstanceAttributeRequest request = new DescribeDBInstanceAttributeReq  
uest();  
request.setPageSize(10);
```

3. Initiate the request and handle the response.

```
DescribeDBInstanceAttributeResponse response;  
try {  
    response = client.getAcsResponse(request);  
    for (DescribeDBInstanceAttributeResponse.Instance instance:response.getInstances  
()) {  
        System.out.println(instance.getPublicIpAddress());  
    }  
} catch (ServerException e) {  
    e.printStackTrace();  
} catch (ClientException e) {  
    e.printStackTrace();  
}
```

```
}
```

All returned fields are deserialized into the response. You can call `response.getXXX()` to obtain the response fields.

```
instanceStatus := response.getStatus()
```

However, if an exception occurs or you want to obtain the original HTTP response, use `doAction()` to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.8.2.1.2.4 Troubleshooting

The Java SDK returns corresponding errors when errors occur on the server side or the SDK side. These errors contain detailed error information, including the error code and the error message.

You do not need to handle the errors returned from the Java SDK. You only need to handle the errors returned by the server.

- `ServerException` indicates the error message generated on the server side.
- `ClientException` indicates the error message generated on the SDK side.

For example, if the following error occurs, you can modify the AccessKey ID based on the error message.

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified
access key is not found.
```

If you need to handle the client errors returned from the SDK side, see the following sample code:

```
try {
    FooResponse response = client.getAcsResponse(request);
    // Handle the response.
    // ...
} catch (ServerException e) {
    // You can add your own exception handling logic here.
    // For example, view the error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If the problem persists, you can submit a ticket with the request ID included.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {
    // You can add your own exception handling logic here.
    // For example, view the error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
```

```
}
```

2.8.2.1.2.5 Use CommonRequest

If no SDK is provided for the service API that you want to call, you can use CommonRequest to make API requests. The CommonRequest method allows you to call any service APIs.

Characteristics of CommonRequest calling

The CommonRequest calling method has the following characteristics:

- Light weight: You only need the core package to initiate the call, without downloading or installing the SDK of each product.
- Easy and convenient: You can call the latest API without updating the SDK.
- Fast iteration

Use CommonRequest

To initiate a CommonRequest request, you must obtain the values of the following parameters. You can obtain the values of these parameters from the API document of each product.

- Domain: the service address of a product
- Version: the version of the API, which is in the format of YYYY-MM-DD

You can obtain the API version from the common parameters in the API document of each product.

- API information: the name of the API to be called.

You must obtain the value of the **Action** parameter and use `request.ApiName = "<Action>"` to specify the API name.

Take the **RunInstances** API as an example. You must use `request.ApiName = "RunInstances"` to specify the API name when initiating a CommonRequest request.

You must obtain the value of the **PathPattern** parameter and use `request.PathPattern = "<PathPattern>"` to specify the RESTful path.

For example, if the **PathPattern** value of the GetClusterList API is `/clusters`, you must use `request.PathPattern = "/clusters"` to specify the RESTful path when initiating a CommonRequest request.

Example: Call an RPC API operation

The following sample code shows how to use the CommonRequest method to call

DescribeDBInstanceAttribute:

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a DefaultAcsClient client and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The region ID.
            "<your-access-key-id>", // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and configure its parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("rds.aliyuncs.com");
        request.setVersion("2014-05-26");
        request.setAction("DescribeDBInstanceAttribute");
        request.putQueryParameter("PageNumber", "1");
        request.putQueryParameter("PageSize", "30");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

Example: Call a RESTful API operation

The following sample code shows how to use the CommonRequest method to call the API operation to list all cluster instances:

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a DefaultAcsClient client and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The region ID.
            "<your-access-key-id>", // The AccessKey ID.
            "<your-access-key-secret>"); // The AccessKey secret.
        IAcsClient client = new DefaultAcsClient(profile);
```

```
// Create an API request and configure its parameters.
CommonRequest request = new CommonRequest();
request.setDomain("rds.aliyuncs.com");
request.setVersion("2015-12-15");
request.setUriPattern("/clusters");
try {
    CommonResponse response = client.getCommonResponse(request);
    System.out.println(response.getData());
} catch (ServerException e) {
    // TODO Auto-generated catch block
    e.printStackTrace();
} catch (ClientException e) {
    // TODO Auto-generated catch block
    e.printStackTrace();
}
}
```

2.8.2.1.2.6 Common errors

This topic describes how to troubleshoot common errors you may encounter during the use of SDKs.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot obtain the region endpoint of the called service.	Check whether the specified region ID and endpoint are correct. After obtaining the correct endpoint, run the following code to set the endpoint: DefaultProfile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");
SDK.JsonUnmarshalError	Failed to unmarshal response	The SDK response fails to be deserialized. In most cases, it is because the structure of the response received by the SDK does not conform to the API metadata, such as mismatched fields or incorrect formatting.	You can use the client.doAction(request) method to obtain the original HTTP response.

Error code	Error message	Cause	Solution
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The request has timed out and all retry attempts have failed.	In scenarios such as poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries.
SDK.ServerError: InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect. Recommend: https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API only accepts HTTPS requests. It does not accept HTTP requests.	You can add the following code to the request before it is sent: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.8.2.2 Python SDK

2.8.2.2.1 Quick start

This topic describes how to obtain and use the RDS Python SDK.

Prerequisites

- You must have a RAM user account and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Python SDK. For more information about how to view and obtain your AccessKey pair in the Apsara Stack Operations console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).

Install the Python SDK

To install the Python SDK, perform the following operations:

1. Install the SDK core library.

- If you are using Python V2.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core
```

- If you are using Python V3.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core-v3
```

2. Install the SDK.

Run the following command to install the RDS Python SDK:

```
pip install aliyun-python-sdk-rds
```

Use the Python SDK

To call the Python SDK, perform the following operations:

1. Create a client instance. When creating the client instance, you must obtain the Region ID, AccessKey ID, and AccessKey Secret.
2. Create an API request and configure its parameters.
3. Initiate the request and handle its response or exception.

```
#!/usr/bin/env python
#coding=utf-8

from aliyunsdkcore import client
from aliyunsdkcore.profile import region_provider
from aliyunsdkrds.request.v20140526 import DescribeDBInstanceAttributeRequest

# global config
region_id = 'xxxxx'
secret_id = 'xxxxx'
secret_key = 'xxxxx'

# product config
product_name = 'Rds'
endpoint = 'rds.example.com'

# create client
client.region_provider.modify_point(product_name, region_id, endpoint)
clt = client.AcsClient(secret_id, secret_key, region_id)

# setup request
request = DescribeDBInstanceAttributeRequest.DescribeDBInstanceAttributeRequest()
request.set_accept_format('json')

# get response
response = clt.do_action_with_exception(request)
```

```
print response
```

2.8.2.2.2 Use the SDK

2.8.2.2.2.1 Install the Python SDK

This topic describes how to install and use the RDS Python SDK.

The Python SDK supports Python V2.6.x, V2.7.x, V3.x, and later. You can use the following installation methods:

- Use pip (recommended)

Run the following commands to install the Python SDK through pip:

```
pip install aliyun-python-sdk-core # Install the SDK core library.  
pip install aliyun-python-sdk-rds # Install the RDS management library.
```

**Note:**

If you are using Python V3.x, use the `pip install aliyun-python-sdk-core-v3` command instead of the `pip install aliyun-python-sdk-core` command.

- Download the Python SDK source code from [Apsara Stack official website](#).

```
# Install the SDK core library.  
cd aliyun-python-sdk-core  
python setup.py install  
# Installing the RDS Python SDK.  
cd aliyun-python-sdk-rds  
python setup.py install
```

- Use the source code

1. [Download the SDK package](#) and extract it.

2. You can use one of the following methods to install the SDK package:

- Modify the `sys.path` variable, and add the directory that you want to search for. It is the directory where the SDK package has been extracted to. Example:

```
>>> import sys  
>>> sys.path.append('/Users/michael/my_py_scripts')
```

**Note:**

This modification takes effect only when the RDS instance is running.

- Configure the PYTHONPATH environment variable, and add the directory where you want to extract the SDK package to. The content of this environment variable is automatically added to the module search directory.

You can configure the PYTHONPATH environment variable similar to how you configure the Path environment variable.

- Place the extracted SDK package into the project. You can then use the Python SDK in the project.

2.8.2.2.2.2 Configure identity verification credentials

When using SDKs to access Apsara Stack services, you must provide an authorized Apsara Stack tenant account for identity verification.

The Python SDK supports the use of AccessKey pairs for identity verification. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use AccessKey pairs as credentials, you must configure your credentials when initializing the client.

Notice:

Ensure that code containing your AccessKey pair is kept confidential and is not exposed (such as being uploaded to a public GitHub project). Otherwise, the information security of your Apsara Stack tenant account may become compromised.

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

2.8.2.2.2.3 Initiate a request

This topic describes how to use the RDS Python SDK to initiate a request.

Procedure

1. Import the SDK of the RDS service.

```
from aliyunsdkcore import client
from aliyunsdkcore.profile import region_provider
from aliyunsdkrds.request.v20140526 import DescribeDBInstanceAttributeRequest
```

2. Create an AcsClient instance.

```
client.region_provider.modify_point(product_name, region_id, endpoint)
```

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

3. Create a Request object.

```
request = DescribeDBInstanceAttributeRequest.DescribeDBInstanceAttributeRequest()
request.set_accept_format('json')
```

4. Initiate the request and handle the response.

```
response = clt.do_action_with_exception(request)
print response
```

2.8.2.2.2.4 Set HTTPS requests

The Python SDK allows you to send API requests through HTTP and HTTPS.

When using the Python SDK, you can specify a default protocol (HTTP or HTTPS) for requests to different services, or set a global protocol for all requests.

Note:

The default protocol for each service takes precedence over the global protocol.

Add OpenSSL support

OpenSSL support is required to send HTTPS requests by using Python SDK. To send HTTPS requests through the Python SDK, you must add OpenSSL support in Python.

Run the `python -c "import ssl"` command to check whether your Python environment supports OpenSSL. If error message `ImportError: No module named ssl` does not appear, OpenSSL is already supported.

If OpenSSL is not supported, run the following command to install it:

```
pip install pyopenssl
```

Set the protocol to HTTP or HTTPS for a request

The following code shows how to set HTTPS as the protocol for a request.

```
request = CreateInstanceRequest.CreateInstanceRequest()
request.set_protocol_type("https")
# Valid values: https and http.
```

Set a global protocol for all service requests

The following code shows how to set a global protocol for all service requests:

```
import aliyunsdkcore.request
aliyunsdkcore.request.set_default_protocol_type("https")
```

```
# Create a request and call client.do_action_with_exception() to send the request.
```

2.8.2.2.2.5 Troubleshooting

The Python SDK returns corresponding errors when errors occur on the server side or the SDK side. These errors contain detailed error information, including the error code and the error message.

You do not need to handle the errors returned from the Python SDK. You only need to handle the errors returned by the server.

- `ServerException` indicates the error message generated on the server side.
- `ClientException` indicates the error message generated on the SDK side.

For example, if the following error occurs, you can modify the AccessKey ID based on the error message.

```
aliyun sdkcore.acs\_exception.exceptions.ServerException: HTTP Status: 404 Error: InvalidAccessKeyId.NotFound Specified access key is not found.
```

If you need to handle the client errors returned from the SDK side, see the following sample code:

```
try:
    response = client.do_action_with_exception(request)
except ServerException as e:
    // You can add your own exception handling logic here.
    // For example, view the error message.
    print e.get_http_status()
    print e.get_error_code()
    print e.get_error_msg()
```

2.8.2.2.2.6 Use CommonRequest

If no SDK is provided for the service API that you want to call, you can use `CommonRequest` to make API requests. The `CommonRequest` method allows you to call any service APIs.

Characteristics of `CommonRequest` calling

The `CommonRequest` calling method has the following characteristics:

- Light weight: You only need the core package to initiate the call, without downloading or installing the SDK of each product.
- Easy and convenient: You can call the latest API without updating the SDK.
- Fast iteration

Use CommonRequest

To initiate a CommonRequest request, you must obtain the values of the following parameters. You can obtain the values of these parameters from the API document of each product.

- Domain: the service address of a product
- Version: the version of the API, which is in the format of YYYY-MM-DD

You can obtain the API version from the common parameters in the API document of each product.

- API information: the name of the API to be called.

You must obtain the value of the **Action** parameter and use `request.ApiName = "<Action>"` to specify the API name.

Take the **RunInstances** API as an example. You must use `request.ApiName = "RunInstances"` to specify the API name when initiating a CommonRequest request.

You must obtain the value of the **PathPattern** parameter and use `request.PathPattern = "<PathPattern>"` to specify the RESTful path.

For example, if the **PathPattern** value of the GetClusterList API is `/clusters`, you must use `request.PathPattern = "/clusters"` to specify the RESTful path when initiating a CommonRequest request.

Example: Call an RPC API operation

The following sample code shows how Python V2.x uses the CommonRequest method to call **DescribeDBInstanceAttribute**:

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.request import CommonRequest
client = AcsClient('{your_access_key_id}', '{your_access_key_secret}', '{your_region_id}')
request = CommonRequest()
request.set_domain('rds.aliyuncs.com')
request.set_version('2014-05-26')
request.set_action_name('DescribeDBInstanceAttribute')
# or:
# request = CommonRequest(domain='rds.aliyuncs.com', version='2014-05-26',
# action_name='DescribeDBInstanceAttribute')
request.add_query_param('PageNumber', '1')
request.add_query_param('PageSize', '30')
```

```
response = client.do_action_with_exception(request)
```

Example: Call a RESTful API operation

The following sample code shows how Python V2.x uses the CommonRequest method to call the API to list all cluster instances:

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.request import CommonRequest
client = AcsClient('{your_access_key_id}', '{your_access_key_secret}', '{your_region_id}')
request = CommonRequest()
request.set_domain('cs.aliyuncs.com')
request.set_version('2015-12-15')
request.set_uri_pattern('/clusters')
# or:
# request = CommonRequest(domain='rds.aliyuncs.com', version='2014-05-26',
# uri_pattern='/clusters')
response = client.do_action_with_exception(request)
```

2.8.2.2.7 Common errors

This topic describes how to troubleshoot common errors you may encounter during the use of SDKs.

Error code	Error message	Cause	Solution
SDK.InvalidRegionId	Can not find endpoint to access.	The SDK cannot obtain the region endpoint of the called service.	Check whether the specified region ID and endpoint are correct. After you have obtained the endpoint, you can run the following code to set the endpoint: <pre>from aliyunsdkcore.profile import region_provider region_provider.modify_point('product_name', 'region_id', 'endpoint')</pre>
SDK.TimeoutError or	-	The request has timed out and all retry attempts have failed.	In scenarios such as poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError : InvalidProtocol .NeedSsl	Your request is denied as lack of ssl protect Recommend :https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API only accepts HTTPS requests. It does not accept HTTP requests.	You can add the following code to the request before it is sent: <pre>request.set_protocol_type('https')</pre>

2.8.2.3 PHP SDK

2.8.2.3.1 Quick start

Apsara Stack PHP SDK allows you to access RDS without performing complex programming operations. This topic describes how to obtain and use the RDS PHP SDK.

Prerequisites

- You must have a RAM user account and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Python SDK. For more information about how to view and obtain your AccessKey pair in the Apsara Stack Operations console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).
- Apsara Stack PHP SDK applies to PHP V5.3, V5.4, V5.5, V5.6, V7.0, and V7.1. You can run the **php -v** command to obtain the current PHP version number.

Install the PHP SDK

To install the PHP SDK, perform the following operations:

- Download the PHP SDK source code from [Apsara Stack official website](#).
- Add the PHP SDK reference to your code.

For example, if the PHP SDK is downloaded to `/path/to/aliyun-openapi-php-sdk`, run the following command:

```
require_once '/path/to/aliyun-openapi-php-sdk/aliyun-php-sdk-core/Config.php';
```

Use the PHP SDK

To call the PHP SDK, perform the following operations:

1. Create a DefaultAcsClient instance and initialize it.

When you create and initialize a DefaultAcsClient instance, you must provide the values of **Region ID**, **AccessKey ID**, and **AccessKey Secret**.

2. Create an API request and configure its parameters.
3. Initiate the request and handle its response or exception.

```
<? php
use Rds\Request\V20140526\DescribeDBInstanceAttributeRequest;
# Create a DefaultAcsClient instance and initialize it.
$clientProfile = DefaultProfile::getProfile(
    "<your-region-id>",          # Your region ID.
    "<your-access-key-id>",      # Your AccessKey ID.
    "<your-access-key-secret>"   # Your AccessKey Secret.
);
$client = new DefaultAcsClient($clientProfile);
# Set the endpoint of the current service.
$profile->endpoint = "your-region-id", "your-region-id", "product", "endpoint";
# Create an API request and configure its parameters.
$request = new DescribeDBInstanceAttributeRequest();
$request->setPageSize(10);
# Initiate the request and handle the response.
try {
    $response = $client->getAcsResponse($request);
    print_r($response);
} catch (ServerException $e) {
    print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
} catch (ClientException $e) {
    print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
}
?>
```

2.8.2.4 C# SDK

Prerequisites

Framework 2.0+

Download the SDK

Download the C# SDK source code from GitHub at <https://github.com/aliyun/aliyun-openapi-net-sdk>.

Install the SDK

1. Compile the C# SDK source code into a .dll file.
2. Right-click your Visual Studio project, and choose **Add Reference > Browse**. If you are using MonoDevelop, follow the MonoDevelop instructions to import the .dll file.
3. Select the .dll file and click **OK**. Then you can use Apsara Stack C# SDK in your project.

2.8.3 Obtain an endpoint

You can obtain a service endpoint in the Apsara Stack Cloud Management (ASCM) console.

Method 1

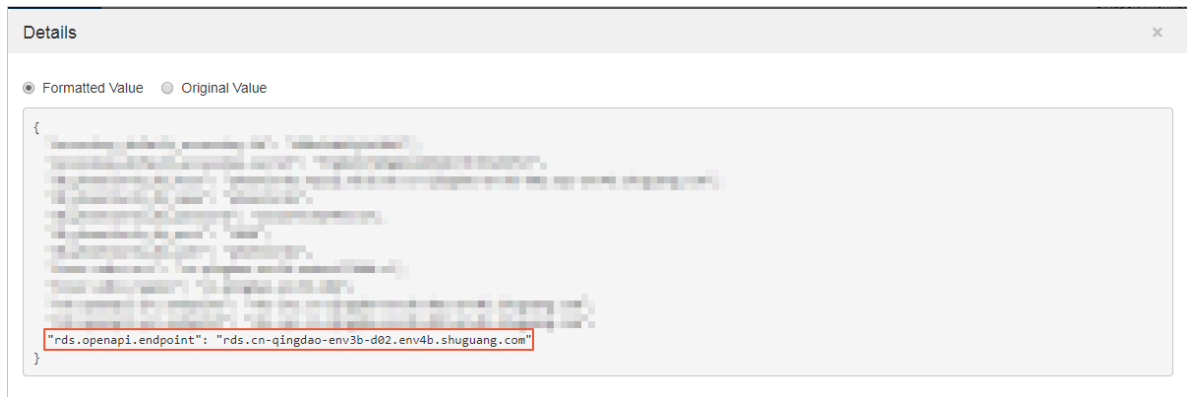

1. Log on to the Apsara Stack Operations console.

For more information about how to log on to the console, see Operations and Maintenance Guide. Specifically, navigate in the guide as follows: **Operations of basic platforms > Apsara Stack Operations (ASO) > Log on to Apsara Stack Operations.**

2. In the left-side navigation pane, choose **Products > Product List > Apsara Stack O&M**.
3. Click **Apsara Infrastructure Management Framework** to go to the Apsara Infrastructure Management Framework console.
4. In the top navigation bar, choose **Reports > System Reports**.
5. On the **System Reports** page, click **Registration Vars of Services**.
6. On the **Registration Vars of Services** page, find the rds-yaochi row, right-click the **Service Registration** column, and choose **Show More** from the shortcut menu.

[illegible]

7. In the **Details** dialog box that appears, find the RDS endpoint based on the key value of RDS, which is `rds.openapi.endpoint`.

Method 2

1. Log on to the Apsara Stack Operations console.

For more information about how to log on to the console, see Operations and Maintenance Guide. Specifically, navigate in the guide as follows: **Operations of basic platforms > Apsara Stack Operations (ASO) > Log on to Apsara Stack Operations**.

2. In the left-side navigation pane, choose **Products > Product List > Apsara Stack O&M**.
3. Click **Apsara Infrastructure Management Framework** to go to the Apsara Infrastructure Management Framework console.
4. In the top navigation bar, choose **Operations > Machine Operations** to go to the **Machine Operations** page.
5. In the hostname list, find the machine that hosts the Tianji cluster and click **Terminal** corresponding to the machine. Then, log on to the machine.

Machine Operations									
Search Allows fuzzy or batch search. Separate multiple machines with commas or space.				Reset	☐ Exact Match		Machine Bucket Change	Machine Online/Offline	Refresh
Hostname	IP	Cluster	Project	IDC	Room	Rack	Warranty	Status	Actions
vm010004020210		ECS-I08-A-eb37	ecs	amtest72				GOOD	Terminal Machine Operation
vm010004024227		ECS-I07-A-eb38	ecs	amtest72				GOOD	Terminal Machine Operation
vm0100040209131		BasicCluster-A-20191...	csb	amtest72				GOOD	Terminal Machine Operation
vm010004020177		ads-A-20191028-ese9	ads	amtest72				GOOD	Terminal Machine Operation

6. Run the following command in the machine to obtain the data in JSON format:

```
curl -l "http://127.0.0.1:7070/api/v3/column/c.sr.service_registration,c.sr.id?c.sr.service_registration"
```

```
vm010036041107
02.cloud.h14.amtest85,101h11209.cloud.h13.amtest85,101h11212.cloud.h13.amtest85,\"db-redis_ip_list\":\
\", \"ssl_encrypt_mode\": \"true\"}
},
{
  \"c.sr.id\": \"slb-controller\",
  \"c.sr.service_registration\": \"{\\\"slb.api.domain\\\":\\\"slb-api.env6.shuguang-ops.com\\\",\\\"slb_api_i
p_list\\\":\\\",\\\"slb_api_vip\\\":\\\",\\\"slb_master_ip_list\\\":\\\",\\\"slb_master_vip\\\":\\\",\\\"slb_monitor_ip_list\\\":\\\",\\\"
slbag.ip\\\":\\\",\\\"slbapi_db_host\\\":\\\"slbapi.mysql.env6.shuguang-ops.com\\\",\\\"slbapi_db_name\\\":
\\\"slbapi\\\",\\\"slbapi_db_password\\\":\\\"o3buknqtzSYeu5q\\\",\\\"slbapi_db_port\\\":\\\"3022\\\",\\\"slbapi_db_user\\\":
\\\"slbapi\\\",\\\"stats_db_host\\\":\\\"stats.mysql.env6.shuguang-ops.com\\\",\\\"stats_db_name\\\":\\\"stats\\\",\\\"stats_
db_password\\\":\\\"6onwomkeXZ7blis\\\",\\\"stats_db_port\\\":\\\"3024\\\",\\\"stats_db_user\\\":\\\"stats\\\",\\\"xuanyuan_db
_host\\\":\\\"xuanyuan.mysql.env6.shuguang-ops.com\\\",\\\"xuanyuan_db_name\\\":\\\"xuanyuan\\\",\\\"xuanyuan_db_passwo
rd\\\":\\\"xqqwSj5xmhv8kIwi\\\",\\\"xuanyuan_db_port\\\":\\\"3194\\\",\\\"xuanyuan_db_user\\\":\\\"xuanyuan\\\"}\"
},
{
  \"c.sr.id\": \"slb-keyserver\",
  \"c.sr.service_registration\": \"{\\\"slb_keyserver_hosts\\\":\\\"7CE731P3DP 101f06007.cloud.f
06.amtest85,7CE731P3DR 101f06014.cloud.f06.amtest85\\\"}\"
},
{
  \"c.sr.id\": \"slb-lvs\",
  \"c.sr.service_registration\": \"{\\\"host_list\\\":\\\"101f06001.cloud.f06.amtest85,101f06012.cloud.f06
.amtest85\\\",\\\"ip_list\\\":\\\",\\\"slb_lvs_hosts\\\":\\\"7CE731P3DE 101f06001.clou
d.f06.amtest85,7CE731P3DL 101f06012.cloud.f06.amtest85\\\"}\"
},
}
```

7. You can find the endpoint of the RDS instance based on the RDS ID (rds-yaochi) and the key value (rds.openapi.endpoint).

```
},
{
  \"c.sr.id\": \"rds-yaochi\", ID
  \"c.sr.service_registration\": \"{\\\"accesskey_default_accesskey-id\\\":\\\",\\\"accesskey_default_accesskey-secret\\\":\\\",
\\\",\\\"db_phoenixrds_db_host\\\":\\\",\\\"db_phoenixrds_db_name\\\":\\\",\\\"db_phoenixrds_db_password\\\":\\\",
\\\",\\\"db_phoenixrds_db_port\\\":\\\",\\\"db_phoenixrds_db_user\\\":\\\",\\\"inner-odbs-avz\\\":\\\",\\\"inner-odbs-region\\
\\\":\\\",\\\"rds.openapi-inc.endpoint\\\":\\\",\\\"rds.openapi.endpoint\\\":\\\",\\\"rds.env12.shuguang.com\\\"}\"
},
{
  \"key\", \"endpoint\"
}
```

2.8.4 Obtain an AccessKey pair

You can obtain AccessKey pairs in the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.9 KVStore for Redis

2.9.1 API reference

2.9.1.1 API overview

Table 2-329: Instance lifecycle management API operations

Operation	Description
CreateInstance	Creates an instance.
DeleteInstance	Releases an instance.
ModifyInstanceSpec	Changes the specifications of a specified instance.

Table 2-330: Instance management API operations

Operation	Description
DescribeInstanceAttribute	Queries detailed information about instances.
DescribeInstances	Queries basic information about instances.
DescribeRegions	Queries available regions.
DescribeSecurityIps	Queries the IP whitelist that allows connections to a specified instance from specified IP addresses or CIDR blocks.
FlushInstance	Clears an instance.

Operation	Description
ModifyInstanceAttribute	Sets the attribute for a specified instance.
ModifyInstanceMaintainTime	Changes maintenance time for a specified instance.
ModifySecurityIps	Changes the whitelist for a specified instance.
ModifyInstanceNetExpireTime	Changes the period for retaining a domain name of a specified classic network.
SwitchNetwork	Changes the type of a network.

Table 2-331: Backup and recovery API operations

Operation	Description
CreateBackup	Creates a backup.
ModifyBackupPolicy	Changes a backup policy.
DescribeBackupPolicy	Queries backup policies.
DescribeBackups	Queries available backups.
RestoreInstance	Restore a specified instance based on a specified backup set.

Table 2-332: Monitoring management API operations

Operation	Description
DescribeMonitorItems	Queries available monitoring metrics.
DescribeHistoryMonitorValues	Queries historical monitoring data.

Table 2-333: Parameter management API operations

Operation	Description
DescribeInstanceConfig	Queries parameters of a specified instance.
ModifyInstanceConfig	Changes parameters of a specified instance.

2.9.1.2 Request structure

Endpoints

The endpoint of KVStore for Redis API operations is `r-kvstore.example.com`.

For more information about how to obtain the endpoint, see [Obtain an endpoint](#).

**Note:**

The example.com field is a user-defined domain name used to access a project. You can request the domain name from the administrator.

Protocols

You can send API requests over HTTP or HTTPS. To secure data, we recommend that you send API requests over HTTPS.

Methods

The system allows you to send an HTTP GET request. In this request, the request URL must include the request parameters.

Request parameters

When you make an API request, you must specify the Action parameter as the operation, such as CreateInstance, that you want to perform. You also must specify common request parameters and specific request parameters of the specified operation.

Encoding

Requests and responses are encoded with the UTF-8 character set.

2.9.1.3 Common parameters

Common request parameters are used in each API operation.

Common request parameters

Table 2-334: Common request parameters

Parameter	Type	Required	Description
Format	String	Yes	The format of the response. Valid values: JSON and XML. Default value: XML.
Version	String	Yes	The version number of the API. Specify this parameter in a date format: YYYY-MM-DD. Set this parameter to 2015-01-01.
AccessKeyId	String	Yes	The AccessKey ID provided to you by Alibaba Cloud.

Parameter	Type	Required	Description
Signature	String	Yes	The result string of the signature. For more information about how to calculate a signature, see Request signatures .
SignatureMethod	String	Yes	The method of signing the request. Set this parameter to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC time format. For example, 20:00:00 on January 01, 2016 in China Standard Time (UTC +8) is written as 2016-01-01T12:00:00Z.
SignatureVersion	String	Yes	The version of the signature algorithm. Set this parameter to 1.0.
SignatureNonce	String	Yes	A unique random number. This parameter is used to prevent replay attacks. You must use different random numbers for different requests.

```
https://r-kvstore.example.com/
?Format=json
&Version=2015-01-01
&Signature=Pc5xxxxxxxxxxxxxxxxxx
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2016-01-01T12:00:00Z
```

Common response parameters

Each time you call an API operation, no matter whether the call is successful, the system returns the request ID (RequestId).

```
<? xml version="1.0" encoding="utf-8"? >
<!--The root node of the response-->
<Operation name+Response>
<!--The request ID returned--->
<RequestId>4C4fdsf38-3910-447D-87AD-AC078932216</RequestId>
<!--The result data returned-->
```

```
</Operation name+Response>
```

2.9.1.4 Responses

After you call an API operation, KVStore for Redis returns data in the same format. In the response, an HTTP status code in the 2xx format indicates that the call is successful. An HTTP status code in the 4xx or 5xx format indicates that the call failed. The system returns responses for successful calls in XML or JSON format. You can specify the response format in request parameters. The system uses the XML format by default.

Note:

The response examples in this topic have been formatted with line breaks or indents to provide a clear view. The responses in your actual running environments are not properly formatted as these examples.

Sample success response

The response in XML format includes a message that indicates whether the call is successful and the specific service data. An example is as follows:

```
<? xml version="1.0" encoding="utf-8"? >
<!--The root node of the response-->
<Operation name+Response>
<!--The request ID returned-->
<RequestId>4C4fdsf38-3910-447D-87AD-AC078932216</RequestId>
<!--The result data returned-->
</Operation name+Response>
```

JSON format

```
{
  "RequestId": "4C4fdsf38-3910-447D-87AD-AC078932216",
  /* The result data returned */
}
```

Sample error response

When an error occurs during an API call, no result data is returned. You can locate the cause of the error by referencing the attached list of error codes. If an error occurs when you call an operation over HTTP, an HTTP status code in the 4xx or 5xx format is returned. The returned message body includes the specific error code and error message. The message body also contains a globally unique request ID called RequestId and a target site

ID called HostId. If you cannot locate the cause, request Apsara Stack customer service, and provide the HostId and RequestId for troubleshooting.

```
<? xml version="1.0" encoding="UTF-8"? >
<Error>
<RequestId>8906582E-6722-409A-A6C4-0E7863B733A5</RequestId>
<HostId> r-kvstore.example.com</HostId>
<Code>UnsupportedOperation</Code>
<Message>The specified action is not supported. </Message>
</Error>
```

JSON format

```
{
  "RequestId": "7463B73D-35CC-4D19-A010-6B8D65D242EF",
  "HostId": " r-kvstore.example.com",
  "Code": "UnsupportedOperation",
  "Message": "The specified action is not supported."
}
```

2.9.1.5 Request signatures

KVStore for Redis authenticates each access request. You need to include a signature when you submit an HTTP or HTTPS request. KVStore for Redis authenticates the request sender identity by using symmetric encryption based on an AccessKey pair that consists of an AccessKey ID and an AccessKey Secret.

You can request and manage the AccessKey ID and the AccessKey Secret on the Alibaba Cloud website. The AccessKey ID indicates your identity. The AccessKey Secret is the key used to encrypt the signature string and to verify the signature string on the server. You must keep the AccessKey ID and AccessKey Secret confidential, and they are available only to Alibaba Cloud and yourself.

For more information about how to request the AccessKey pair, see [Obtain an AccessKey pair](#).

Sign an access request

To sign an access request, follow these steps:

1. Use request parameters to construct a canonicalized query string.
 - a. To construct a canonicalized query string, sort all request parameters by name in lexicographic order. These parameters include common request parameters and

customized API request parameters, but do not include the Signature parameter mentioned in the "Common request parameters" section.

Note:

When you use the GET method to submit requests, you specify these parameters in the request URI following the question mark (?) and connected with the ampersand (&).

b. Encode the name and value of each request parameter.

Perform URL encoding on the names and values by using the UTF-8 character set. The URL encoding rules are as follows:

- Uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
- Encode other characters in the %XY format, where XY indicates the ASCII code of the characters in hexadecimal format. For example, the English double quotation marks (") are encoded as %22.
- Extended UTF-8 characters are encoded into the %XY%ZA... format.
- The English space () is encoded as %20, rather than the plus sign (+).

Note:

Most libraries that support URL encoding, such as `java.net.URLEncoder`, follow the Multipurpose Internet Mail Extensions (MIME) encoding rules of `application/x-www-form-urlencoded`. To generate encoded strings as specified in these rules, after you perform the URL encoding, replace the plus signs (+) in the encoded strings with %20, the asterisks (*) with %2A, and %7E with the tilde (~).

c. Separate the encoded parameter names from their encoded values with equal signs (=).

d. Sort the equal sign-connected strings by parameter name in lexicographic order and connect them with ampersands (&).

2. Use this canonicalized query string to construct a string for signature calculation in the following way:

```
StringToSign=
HTTPMethod + "&" +
percentEncode( "/" ) + " &" +
```

```
percentEncode(CanonicalizedQueryString)
```

In this example,

- `HTTPMethod` specifies the HTTP method such as GET used to submit the request.
 - `percentEncode("/")` is the value (namely %2F) as the result of encoding the slash sign (/) according to the URL encoding rule described in step 1.b.
 - `percentEncode(CanonicalizedQueryString)` is the string as the result of encoding the canonicalized query string described in step 1 according to the URL encoding rules described in step 1.b.
3. As defined in RFC2104, use the preceding signature string to calculate the signature into an HMAC value.

Note:

The key that is used to calculate the signature is the AccessKey Secret appended with an ampersand (&) (ASCII: 38). The hash algorithm SHA1 is used in the calculation.

4. Encode the preceding HMAC value as a Base64 string to generate the signature value.
5. Set the Signature parameter in the request parameters to this signature value to sign the request.

Note:

When you submit the signature value to the KVStore for Redis instance as the final request parameter value, perform URL encoding on this parameter based on RFC3986 rules in the same way as you process other parameters.

Examples

If you call the DescribeDBInstances operation, the request URL before signing is as follows:

```
http://r-kvstore.example.com/?Timestamp=2013-06-01T10:33:56Z&Format=XML&
AccessKeyId=testid&Action=DescribeInstances&SignatureMethod=HMAC-SHA1&RegionId
=region1&SignatureNonce=NwDAxvLU6tFE0DVb&Version=2015-01-01&SignatureVersion=
1.0
```

The calculated StringToSign is as follows:

```
GET&%2F&AccessKeyId%3Dtestid&Action%3DDescribeInstances&Format%3DXML&
RegionId%3Dregion1&SignatureMethod%3DHMAC-SHA1&SignatureNonce%3DNwDAxvLU
```

```
6tFE0DVb&SignatureVersion%3D1.0&Timestamp%3D2013-06-01T10%253A33%253A56Z&Version%3D2015-01-01
```

In this example, if the AccessKey ID is testid and the AccessKey Secret is testsecret, the key used for HMAC calculation is testsecret&. Therefore, the calculated signature value is Blxxxxxxxxxxxxxxxxxxxxxxxxxx=.

The signed request URL that includes the Signature parameter is as follows:

```
http://r-kvstore.example.com/?Timestamp=2013-06-01T10%3A33%3A56Z&Format=XML&AccessKeyId=testid&Action=DescribeInstances&SignatureMethod=HMAC-SHA1&RegionId=region1&SignatureNonce=NwDAXvLU6tFE0DVb&SignatureVersion=1.0&Version=2015-01-01&Signature=BIPOMlxxxxxxxxxxxxxxxxxxu8LXBeZtLQkJTw6iFvw1E%3D
```

2.9.1.6 RAM-based authorization

2.9.1.6.1 Grant resource permissions to a RAM user

The instances that you create by using your Alibaba Cloud account are the resources owned by the account. An account has the full operation permissions on the resources under this account by default.

Alibaba Cloud Resource Access Management (RAM) allows you to grant the access and management permissions on resources under a cloud account to RAM users.

Note:

Ignore this topic if you do not use Resource Access Management (RAM).

2.9.1.6.2 Authorized resource types in RAM

KVStore for Redis only supports RAM authorization for Redis instances.

The following table lists the description of resources when you use RAM to authorize access permissions to these resources.

Resource	Resource description in authorization policy
Instance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid acs:kvstore:\$regionid:\$accountid:instance/ acs:kvstore:::instance/

All \$regionids must be the ID of a region or an asterisk (*). All \$instanceids must be the ID of an instance or an asterisk (*). Similarly, \$account-id is the numerical ID of your Apsara Stack tenant account, which can be replaced by an asterisk (*).

2.9.1.6.3 Operation permissions granted to a RAM user

You are authorized to call the following API operations to manage the specified resource as a Resource Access Management (RAM) user:

- CreateInstance
- DeleteInstance
- ModifyInstanceSpec
- RenewInstance
- RenewMultiInstance
- TransformToPrePaid
- ModifyInstanceAttribute
- FlushInstance
- DescribeInstances
- DescribeInstanceAttribute
- ModifyInstanceMaintainTime
- ModifySecurityIps
- SwitchNetwork
- ModifyInstanceNetExpireTime
- CreateBackup
- ModifyBackupPolicy
- DescribeBackupPolicy
- DescribeBackups
- RestoreInstance
- DescribeHistoryMonitorValues
- DescribeInstanceConfig
- ModifyInstanceConfig

2.9.1.6.4 API authentication rules

When you use API operations to access resources as a Resource Access Management (RAM) user, the system queries the RAM service and checks whether the RAM user is granted the required permissions.

Each API operation determines the resources for permission check according to the involved resources and the semantics of the API operation. The following table lists the authentication rules corresponding to different API operations.

Table 2-335: Authentication rules

Operation	Authentication rule
CreateDBInstance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
DeleteInstance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifyInstanceSpec	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
RenewInstance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
RenewMultiInstance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
TransformToPrePaid	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifyInstanceAttribute	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
FlushInstance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
DescribeInstances	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
DescribeInstanceAttribute	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifyInstanceMaintainTime	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifySecurityIps	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
SwitchNetwork	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifyInstanceNetExpireTime	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
CreateBackup	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifyBackupPolicy	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
DescribeBackupPolicy	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid

Operation	Authentication rule
DescribeBackups	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
RestoreInstance	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
DescribeHistoryMonitorValues	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
DescribeInstanceConfig	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid
ModifyInstanceConfig	acs:kvstore:\$regionid:\$accountid:instance/\$instanceid

2.9.1.7 Manage the lifecycle

2.9.1.7.1 CreateInstance

Description

You can call this operation to create an instance. For more information, see Instance specifications.

Request parameters

Table 2-336: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to CreateInstance.

Parameter	Type	Required	Description
InstanceName	String	No	The name of the instance. The name must be 2 to 128 characters in length and must start with a letter. The name cannot contain special characters or spaces. Special characters include @ / : = " < > { } []
Password	String	No	The password of the instance. The password must be a string of 8 to 30 characters in length and must contain uppercase letters, lowercase letters, and digits.  Note: Special characters are not supported, such as ! < > () [] { } , ` ~ . - _ @ # \$ % ^ & *
InstanceClass	String	Yes	The type of the requested KVStore for Redis instance. For more information, see Instance specifications.
RegionId	String	Yes	The region ID of the instance. You can query available data regions by calling the DescribeRegions operation.

Parameter	Type	Required	Description
Zoneld	String	No	The zone ID of the instance. You can call DescribeRegions to view available zones.
ChargeType	String	No	The billing method of the instance. Valid values: PrePaid and PostPaid. Default value: PostPaid.
Period	Long	No	The billing period of the instance. If you set the ChargeType parameter to PrePaid , you must also specify the Period parameter. Unit: month. Valid values: 1-9, 12, 24, and 36.
Token	String	No	The client token that is used to ensure the idempotence of requests. The value of this parameter is generated by the client and must be unique among different requests . The value is case-sensitive and can be up to 64 ASCII characters in length. For more information , see How to ensure idempotence.

Parameter	Type	Required	Description
NetworkType	String	No	The type of the network. Default value: Classic. Valid values: • Classic • VPC
VpcId	String	No	The ID of the VPC to which the instance belongs.
VSwitchId	String	No	The ID of the VSwitch .
PrivateIp	String	No	The private IP address of the instance.
SrcDBInstanceId	String	No	If an instance created based on a backup set generated by another instance is valid, specifies the ID of the instance that generates the backup set.
BackupId	String	No	If an instance created based on a backup set generated by another instance is valid, specifies the ID of the generated backup set. You can call DescribeBackups to query the value of BackupId.

Parameter	Type	Required	Description
InstanceType	String	No	The category of the instance. Valid values: Redis and Memcache. Default value: Redis.

Response parameters

Table 2-337: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
InstanceId	String	The ID of the instance, which is globally unique.
InstanceName	String	The name of the instance.

Note:

Due to the compatibility with earlier versions, this topic does not describe some returned fields such as Config and Region for the operation. Alibaba Cloud will delete these fields as needed in the future.

Sample requests

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=CreateInstance
&RegionId=cn-hangzhou
&Password=Qa123456
&InstanceClass=redis.master.small.default
```

Sample responses

```
{
  "InstanceId": "73xxxxxxxxxx",
  "InstanceName": "73xxxxxxxxxx"
}
```

2.9.1.7.2 DeleteInstance

Description

You can call this operation to delete a specified instance. This instance that you want to release must be in the following status:

- The instance is in the running state.
- The instance is not locked.

**Note:**

You cannot delete a subscription instance until the instance expires.

Request parameters**Table 2-338: Request parameters**

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DeleteInstance.
InstanceId	String	Yes	The globally unique ID of the specified instance.

Response parameters**Table 2-339: Response parameters**

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=DeleteInstance
&InstanceId=657xxxxxxxxxxxxx
```

Sample response

```
{
  "RequestId" : "C2225574-1D93-4F8A-B1D5-39FCBAA40660"
```

```
}
```

2.9.1.7.3 ModifyInstanceSpec

Description

You can call this operation to change the specifications of a specified instance. For more information about instance specifications, see Instance types.

Request parameters

Table 2-340: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyInstanceSpec.
InstanceId	String	Yes	The globally unique ID of the specified instance.
InstanceClass	String	Yes	The type of the specified instance. For more information , see Instance types.

Response parameters

Table 2-341: Response parameters

Parameter	Type	Description
<Common request parameters>	-	For more information, see Common parameters .
OrderId	String	The ID of the order that you have placed.

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=ModifyInstanceSpec
&InstanceId=736538d0a6894665
&InstanceClass= redis.master.mid.default
```

Sample response

```
{
  "OrderId" : "201294900260011"
  "RequestId" : "283746AF-82B3-4BFF-88CC-BF34CDE2732"
}
```

2.9.1.8 Manage instances

2.9.1.8.1 DescribeInstanceAttribute

Description

You can call this operation to query details of a specified instance.

Request parameters

Table 2-342: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common requests .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeInstanceAttribute.
InstanceId	String	Yes	The globally unique ID of the specified instance.

Response parameters

Table 2-343: Response parameters

Parameter	Type	Description
Instances	List	The array that contains the DBInstanceAttribute values.

DBInstanceAttribute parameters

Parameter	Type	Description
InstanceId	String	The globally unique ID of the instance that was queried.
InstanceName	String	The name of the instance that was queried.
Capacity	Long	The capacity that you have requested for the instance that was queried, in MB.
InstanceClass	String	The type of the instance that was queried.
Bandwidth	Long	The bandwidth limit of the instance that was queried, in Mbit/s.
Connections	Long	The maximum number of connections to the instance that was queried.
ConnectionDomain	String	The domain name of the instance that was queried . This domain name only supports connections over an internal network.
Port	Int	The port of the instance that was queried.
RegionId	String	The region where the instance that was queried was located. For more information, see DescribeRegions.

Parameter	Type	Description
Zoneld	String	The ID of the zone under the RegionId of the instance that was queried. For more information, see DescribeRegions.
InstanceStatus	String	The status of the instance that was queried. Possible values: • Normal: the instance that was queried was normal. • Creating: the instance that was queried was being created. • Changing: the instance that was queried was being changed. • Inactive: the instance that was queried was disabled.
ChargeType	String	The billing method of the instance that was queried. Possible values: PrePaid and PostPaid.
CreateTime	String	The time when the instance that was queried was created. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time is displayed in UTC time format.
EndTime	String	The time when the subscription instance that was queried was about to expire. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time is displayed in UTC time format.

Parameter	Type	Description
NetworkType	String	The type of the network where the instance that was queried was located. Possible values: CLASSIC or VPC.
VpcId	String	The ID of the VPC where the instance that was queried was located.
VSwitchId	String	The ID of the VSwitch for the instance that was queried.
PrivateIpAddress	String	The private IP address of the instance that was queried.
MaintainStartTime	String	The time when maintenance can be started.
MaintainEndTime	String	The time when maintenance can be ended.
SecurityIPList	String	The IP whitelist for the instance that was queried.
AvailabilityValue	String	The availability metrics of the current month for the instance that was queried.

**Note:**

Due to the compatibility with earlier versions, this topic does not describe some returned fields such as Config and Region for the operation. Alibaba Cloud will delete these fields as needed in the future. In this case, do not rely on the returned fields that this topic has not described when you call this operation.

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=DescribeInstanceAttribute
&InstanceId=7xxxxxxxxxxx
```

Sample response

```
{
  "Instances": {
    "DBInstanceAttribute": [{
```

```

    "Bandwidth" : 128,
    "Capacity" : 512,
    "ConnectionDomain" : "de5d88e34d004211.m.cnhzalicm10pub001.r-
kvstore.example.com.com",
    "Connections" : 300,
    "Zoneld" : "cn-qingdao-b",
    "InstanceId" : "dxxxxxxxxxx",
    "InstanceName" : "xxxxxx",
    "InstanceStatus" : "Available",
    "InstanceClass" : "redis.master.mid.default",
    "Port" : 11211,
    "QPS" : 4500,
    "RegionId" : "cn-qingdao",
    "ChargType": "PostPaid",
    "NetworkType": "CLASSIC"
    "MaintainStartTime": "02:00Z",
    "MaintainEndTime": "06:00Z",
    "SecurityIPList": "192.168.0.1",
    "AvailabilityValue": "100%"
  }}
}
"RequestId" : "283746AF-82B3-4BFF-88CC-BF34CDE2732"
}

```

2.9.1.8.2 DescribeInstances

Description

You can call this operation to query one or more instances under a specified account.

Request parameters

Table 2-344: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	-	See Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeInstances.

Parameter	Type	Required	Description
InstanceIds	String	No	The globally unique ID of the target instance. This parameter is required when you specify an instance ID. To query multiple instances, separate the identifiers of these instances with commas (.). If the parameter value is left blank, the system queries all instances under the specified account by default.
InstanceStatus	String	No	The instance status of the specified instance: Valid values: • Normal: the specified instance is normal. • Creating: the specified instance is being created. • Changing: the specified instance is being changed. • Inactive: the specified instance is disabled.

Parameter	Type	Required	Description
ChargeType	String	No	The billing method of the specified instance. Valid values: • PrePaid: the subscription billing method. • PostPaid: the pay-as-you-go billing method.
RegionId	String	Yes	You can call the DescribeRegions operation to query the RegionId value.
InstanceType	String	No	The type of the engine for the specified instance. Valid values: • Memcache: specifies an instance of Memcache type. • Redis: specifies an instance of Redis type.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1. Default value : 1.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 1 to 50. Default value: 10.

Parameter	Type	Required	Description
NetworkType	String	No	The type of the network where the specified instance is located. Valid values: • CLASSIC: specifies an instance in a classic network. • VPC: specifies an instance in a VPC.

Response parameters

Table 2-345: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
Instances	List	The array that contains the instances that were queried.
TotalCount	Integer	The total number of instances that were queried.
PageNumber	Integer	The number of the page returned.
PageSize	Integer	The number of entries returned on each page.

Instance parameters

Parameter	Type	Description
InstanceId	String	The globally unique ID of the instance that was queried.
InstanceName	String	The name of the instance that was queried.
Capacity	Long	The capacity that you have requested for the instance that was queried, in MB.
InstanceClass	String	The type of the instance that was queried.

Parameter	Type	Description
Bandwidth	Long	The bandwidth limit of the instance that was queried, in Mbit/s.
Connections	Long	The maximum number of connections to the instance that was queried.
ConnectionDomain	String	The domain name of the instance that was queried . This domain name only supports connections over an internal network.
Port	Int	The port of the instance that was queried.
UserName	String	The username of the instance that was queried.
RegionId	String	The region where the instance that was queried was located.
Zoneld	String	The ID of the zone under the RegionId of the instance that was queried.

Parameter	Type	Description
InstanceStatus	String	The status of the instance that was queried. Possible values: • Normal: the instance that was queried was normal. • Creating: the instance that was queried was being created. • Changing: the instance that was queried was being changed. • Inactive: the instance that was queried was disabled. • Transforming: the instance that was queried was being transformed. • BackupRecovering: the instance that was queried was being backed up and restored. • MinorVersionUpgrading: the minor version of the instance that was queried was being upgraded.
ChargeType	String	The billing method of the instance that was queried. Possible values: PrePaid and PostPaid.
CreateTime	String	The time when the instance that was queried was created. The time follows the ISO 8601 standard in the <code>YYYY-MM-DDThh:mm:ssZ</code> format. The time is displayed in UTC time format.

Parameter	Type	Description
EndTime	String	The time when the subscription instance that was queried was about to expire. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time is displayed in UTC time format.
NetworkType	String	The type of the network where the instance that was queried was located. Possible values: CLASSIC or VPC.
VpcId	String	The ID of the VPC where the instance that was queried was located.
VSwitchId	String	The ID of the VSwitch for the instance that was queried.
PrivateIpAddr	String	The private IP address of the instance that was queried.

**Note:**

Due to the compatibility with earlier versions, this topic does not describe some returned fields such as Config for the operation. Alibaba Cloud will delete these fields as needed in the future. In this case, do not rely on the returned fields that this topic has not described when you call this operation.

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=DescribeInstances
&PageNumber=1
&PageSize=10
&InstanceId=dexxxxxxxxxx1
```

Sample response

```
{
  "Instances" : {
    "Instance" : [{
      "Bandwidth" : 128,
      "Capacity" : 512,
```

```

    "ConnectionDomain" : "de5d88e34d004211.m.cnhzalicm10pub001.r-
kvstore.example.com",
    "Connections" : 300,
    "ZoneId" : "cn-qingdao-b",
    "InstanceId" : "dxxxxxxxxxx1",
    "InstanceName" : "xxxxxx",
    "InstanceStatus" : "Available",
    "InstanceClass" : "redis.master.mid.default",
    "Port" : 11211,
    "RegionId" : "cn-qingdao",
    "UserName" : "xxxxxxxxxx"
    "NetworkType": "CLASSIC"
  "ChargeType": "PostPaid"
}
],
"PageNumber" : 1,
"PageSize" : 10,
"TotalCount" : 1,
"RequestId" : "969D0A1D-C91A-4837-9F70-49785DF9BDCE"
}

```

2.9.1.8.3 DescribeRegions

Description

You can call this operation to query regions where you can create instances.

Request parameters

Table 2-346: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeRegions.

Response parameters

Table 2-347: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Parameter	Type	Description
RegionIds	List	The RegionIds parameter is a list. Every element in this list consists of the RegionId and ZoneIds. ZoneIds is a string , and multiple ZoneId values are separated with commas (,).

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=DescribeRegions
```

Sample response

```
{
  "RequestId": "535A88D3-5408-4B29-AFD4-07319D97EBC4",
  "RegionIds":
  {
    {
      "ZoneIds": "cn-qingdao-b",
      "RegionId": "cn-qingdao",
    },
    {
      "ZoneIds": "cn-shenzhen-a",
      "RegionId": "cn-shenzhen",
    },
    {
      "ZoneIds": "cn-hangzhou-d,cn-hangzhou-b",
      "RegionId": "cn-hangzhou"
    },
    {
      "ZoneIds": "cn-beijing-a",
      "RegionId": "cn-beijing"
    }
  }
}
```

2.9.1.8.4 DescribeSecurityIps

Description

You can call this operation to query the list of IP addresses or CIDR blocks that you can use to connect to an instance.

Request parameters

Table 2-348: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeSecurityIps.
InstanceId	String	Yes	The name of the specified instance.

Response parameters

Table 2-349: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
SecurityIpGroups	List	The list of whitelisted IP addresses or CIDR blocks for the instance that was queried.

SecurityIpGroups parameters

Table 2-350: SecurityIpGroups parameters

Parameter	Type	Description
SecurityGroupName	String	The name of the IP whitelist that was queried.

Parameter	Type	Description
SecurityIpList	String	The list of whitelisted IP addresses or CIDR blocks that were queried. A maximum of 1,000 IP addresses or CIDR blocks are displayed. IP addresses or CIDR blocks are separated with commas (,), such as 0.0.0.0/0,10.23.12.24 (IPv4 addresses) or 10.23.12.24/24 (Classless Inter-Domain Routing or CIDR notation). In the CIDR notation, 10.23.12.24 represents the IPv4 address 10.23.12.24. Its subnet mask is 255.255.255.0. The slash (/) and the following number 24 represent 24 leading 1 bits in the subnet mask and its associated routing prefix. The length of the routing prefix ranges from 1 to 32.

Sample request

```
https://r-kvstore.example.com/  
? <Common request parameters>  
&Action= DescribeSecurityIps  
&InstanceId=6xxxxxxxxxxxxxxx
```

Sample response

```
{  
  "SecurityIpGroups" : {  
    "SecurityIpGroup" : [{  
      "SecurityGroupName" : "ipsecuritytest",  
      "SecurityIpList" : "10.xx.xx. 24"  
    }  
  ]  
},
```

```
"RequestId" : "969D0A1D-C91A-4837-9F70-49785DF9BDCE"
}
```

2.9.1.8.5 FlushInstance

Description

You can call this operation to clear data stored on an instance. The cleared data cannot be restored.

This is an asynchronous operation. After you call this operation, the system returns the result immediately. The system clears data in the background.

Request parameters

Table 2-351: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	-	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to FlushInstance.
InstanceId	String	Yes	The globally unique ID of the specified instance.

Response parameters

Table 2-352: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= FlushInstance
```

```
&InstanceId=65xxxxxxxx
```

Sample response

```
{
  "RequestId" : "96893674-E50C-495D-AB0E-2F12C1E0FD45"
}
```

2.9.1.8.6 ModifyInstanceAttribute

Description

You can call this operation to modify attributes of an instance, such as the name or the password of the instance.

Request parameters

Table 2-353: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	-	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyInstanceAttribute.
InstanceId	String	Yes	The globally unique ID of the specified instance.

Parameter	Type	Required	Description
InstanceName	String	No	The instance name that you want to change to. The name must be a string of 2 to 128 characters in length and must start with an uppercase or lowercase letter or Chinese character. Special characters, such as at signs (@), slashes (/), colons (:), equal signs (=), quotation marks ("), angle brackets (<>), braces ({}), brackets ([]), and spaces, are not supported.

Parameter	Type	Required	Description
NewPassword	String	No	The password of the specified instance. The password must be a string of 8 to 30 characters in length and must contain uppercase letters, lowercase letters, and numbers.  Note: Special characters, such as exclamation points (!), angle brackets (<>), parentheses (()), brackets ([]), braces {}, commas (,), backticks (`), tildes (~), periods (.), hyphens (-), underscores (_), at signs (@), number signs (#), dollar signs (\$), percent signs (%), carets (^), ampersands (&), and asterisks (*), are not supported.

Response parameters

Table 2-354: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= ModifyInstanceAttribute
```

```
&InstanceId=65xxxxxxxxxx  
&NewPassword=Qa12345678  
&InstanceName=TestInstance
```

Sample response

```
{  
  "RequestId" : "E3B35BEA-9EB0-402C-88CF-C46CCCC1EE59"  
}
```

2.9.1.8.7 ModifyInstanceMaintainTime

Description

You can call this operation to modify maintenance time for an instance. Alibaba Cloud may perform routine maintenance for the instance during the specified maintenance time.

Request parameters**Table 2-355: Request parameters**

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyInstanceMaintainTime.
InstanceId	String	Yes	The globally unique ID of the specified instance.
MaintainStartTime	String	Yes	The start time of the maintenance to be performed.
MaintainEndTime	String	Yes	The end time of the maintenance to be performed.

Response parameters

Table 2-356: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action=ModifyInstanceMaintainTime
&InstanceId=65xxxxxxxxx
&MaintainStartTime=02:00Z
&MaintainEndTime=06:00Z
```

Sample response

```
{
  "RequestId" : "A099747A-0826-499D-9422-381C07337F73"
}
```

2.9.1.8.8 ModifyInstanceNetExpireTime

Description

You can call this operation to prolong the maximum period where the IP address in a classic network is retained if you switch an instance from the classic network to a Virtual Private Cloud (VPC) and retain the IP address in the classic network.

Request parameters

Table 2-357: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyInstanceNetExpireTime.

Parameter	Type	Required	Description
InstanceId	String	Yes	The globally unique ID of the specified instance.
ConnectionString	String	Yes	The domain name of the specified classic network.
ClassicExpiredDays	String	Yes	The maximum number of days where the IP address in a specified classic network is retained. Valid values: 14, 30, 60, and 120.

Response parameters

Table 2-358: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= ModifyInstanceNetExpireTime
&ConectionString= fdafas32323ed.redis.rds.aliyuncs.com
&InstanceId=fdxxxxxxxxxxx
& ClassicExpiredDays=120
```

Sample response

```
{
  "RequestId" : "AAAF99B1-69ED-4E80-8CD5-272C09E46ACF"
}
```

2.9.1.8.9 ModifySecurityIps

Description

You can call this operation to set the IP whitelist for an instance, so that only authorized ECS IP addresses or CIDR blocks can be used to connect to the instance.

Request parameters

Table 2-359: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifySecurityIps.
InstanceId	String	Yes	The globally unique ID of the specified instance.
SecurityIps	String	Yes	The list of whitelisted IP addresses or CIDR blocks that you want to modify.
SecurityIp GroupName	String	Yes	The name of the specified whitelist group.

Response parameters

Table 2-360: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= ModifySecurityIps
&InstanceId=65xxxxxxxxxxx
&SecurityIps=1.x.x. 1,2.x.x. 2
```

```
&SecurityIpGroupName=testgroup
```

Sample response

```
{
  "RequestId" : "AAAF99B1-69ED-4E80-8CD5-272C09E46ACF"
}
```

2.9.1.8.10 SwitchNetwork

Description

You can call this operation to switch the network type of an instance. You can switch an instance from a classic network to a Virtual Private Cloud (VPC).

Request parameters

Table 2-361: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to SwitchNetwork.
InstanceId	String	Yes	The globally unique ID of the specified instance.
TargetNetworkType	String	Yes	The type of the network that you want to switch to. - VPC - Classic You can only switch from a classic network to a VPC. In this case, set this parameter to VPC.

Parameter	Type	Required	Description
VpcId	String	No	The ID of the VPC that you want to switch to.
VSwitchId	String	No	The ID of the VSwitch ID for the VPC that you want to switch to. This parameter is required if you have set VpcId.
RetainClassic	String	No	Specifies whether to retain the IP address in the classic network. Valid values: • True: the classic network IP address is retained. • False: the classic network IP address is not retained. Default value: False.
ClassicExpiredDays	String	No	The maximum number of days where the IP address in the classic network are retained. Unit: days. Valid values: 14, 30, 60, and 120. This parameter is required if you have set RetainClassic to True.

Response parameters

Table 2-362: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= SwitchNetwork
&InstanceId=fdaxxxxxxxxxxx
&TargetNetworkType=VPC
&VpcId=fadsfa
&VSwitchId=131ed
&RetainClassic=True
&ClassicExpiredDays=30
```

Sample response

```
{
  "RequestId" : "AAAF99B1-69ED-4E80-8CD5-272C09E46ACF"
}
```

2.9.1.9 Backup and recovery

2.9.1.9.1 CreateBackup

Description

You can call this operation to create a backup. This is an asynchronous operation. After you call this operation, the system returns the result immediately. The system creates the backup in the background.

Request parameters

Table 2-363: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set this parameter to CreateBackup.
InstanceId	String	Yes	The ID of the specified instance.

Response parameters

Table 2-364: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= CreateBackup
&InstanceId= de5d8xxxxxxxxxx
```

Sample response

```
{
  "RequestId" : "5C97648D-C85F-4D58-A71F-7B6750856BF7"
}
```

2.9.1.9.2 ModifyBackupPolicy

Description

You can call this operation to modify a backup policy.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to ModifyBackupPolicy.
InstanceId	String	Yes	The ID of the instance to which the backup file belongs.
PreferredBackupTime	String	Yes	The period of time to execute backup. Specify the time in the HH:mmZ-HH:mmZ format.
PreferredBackupPeriod	String	Yes	The period of data backup. Valid values: - Monday - Tuesday - Wednesday - Thursday - Friday - Saturday - Sunday

Response parameters

Table 2-365: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample requests

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= ModifyBackupPolicy
&InstanceId= de5xxxxxxxxxx
&PreferredBackupTime=00:00Z-04:00Z
&PreferredBackupPeriod= Saturday
```

Sample responses

```
{
```

```
"RequestId" : "5C97648D-C85F-4D58-A71F-7B6750856BF7"
}
```

2.9.1.9.3 DescribeBackupPolicy

Description

You can call this operation to query a backup policy that you have specified. You can query the backup details of an instance, such as the backup cycle and backup time.

Request parameters

Table 2-366: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeBackupPolicy.
InstanceId	String	Yes	The ID of the specified instance.

Response parameters

Table 2-367: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
BackupRetentionPeriod	String	The maximum number of days where backups of the specified instance were retained.
PreferredBackupTime	String	The time of the backup for the specified instance in the HH:mmZ-HH:mm Z format.

Parameter	Type	Description
PreferredBackupPeriod	String	The backup cycle for the specified instance. Possible values: - Monday - Tuesday - Wednesday - Thursday - Friday - Saturday - Sunday
PreferredNextBackupTime	String	The time of the next backup for the specified instance.

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= DescribeBackupPolicy
&InstanceId= de5d8xxxxxxxxxxxxxx
```

Sample response

```
{
  "BackupRetentionPeriod": "7"
  "PreferredBackupTime": "06:00Z-07:00Z"
  "PreferredNextBackupTime": "2017-10-19T06:16Z"
  "PreferredBackupPeriod": "Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday"
  "RequestId" : "5C97648D-C85F-4D58-A71F-7B6750856BF7"
}
```

2.9.1.9.4 DescribeBackups

Description

You can call this operation to query the details of a backup file, such as the backup start time, file size, backup mode, and download address.

Request parameters

Table 2-368: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DescribeBackups.
InstanceId	String	Yes	The ID of the instance to which the backup file belongs.
BackupId	String	No	The ID of the backup set.
PageSize	String	Yes	The number of entries to return on each page. Valid values: 30, 50, and 100.
PageNumber	String	Yes	The number of the page to return. Valid values: any non-zero positive integer.
StartTime	String	Yes	The beginning of the time range to query.
End time.	String	Yes	The end of the time range to query.

Response parameters

Table 2-369: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Parameter	Type	Description
Backups	List	An array consisting of Backup data.
PageNumber	Integer	The number of the returned page.
TotalCount	Integer	The total number of backups .
PageSize	Integer	The number of entries returned on each page.

Backup parameter structure

Table 2-370: Backup parameter structure

Parameter	Type	Description
BackupId	String	The ID of the backup set.
BackupDBNames	String	The name of the database that is backed up.
BackupStatus	String	The status of the backup set. • Success • Failed
BackupStartTime	String	The beginning of the time range where the data was backed up.
BackupEndTime	String	The end of the time range where the data was backed up.
BackupType	String	The type of the backup. Valid values: • FullBackup • IncrementalBackup
BackupMode	String	The mode of the backup. Valid values: • Automated • Manual

Parameter	Type	Description
BackupMethod	String	The method of the backup. Valid values: - Logical - Physical
BackupDownloadURL	String	The download URL of the backup file.
BackupSize	String	The size of the backup set.

Sample requests

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= DescribeBackups
&InstanceId= de5xxxxxxxxxxxxx
&PageNumber=1
&PageSize=10
&InstanceId=de5xxxxxxxxxxxxx
```

Sample responses

```
{
  {
    "Backups" : {
      "Backup" : [{
        "BackupId": "111111111",
        "BackupDBNames": "all",
        "BackupStatus": "Success",
        "BackupType": "FullBackup",
        "BackupStartTime": "2017-10-18T10:34:52Z",
        "BackupEndTime": "2017-10-18T10:36:06Z",
        "BackupMode": "Manual",
        "BackupMethod": "Physical",
        "BackupDownloadURL": "https://rdsxxx-st-v2.oss-cn-shenzhen.example.com/
custins1111111/xxxxxxxxx_data_20171018183408.rdb",
        "BackupSize": "1024"
      }
    ]
  },
  "PageNumber" : 1,
  "PageSize" : 10,
  "TotalCount" : 1,
  "RequestId" : "5C97648D-C85F-4D58-A71F-711111111117"
}
```

2.9.1.9.5 RestoreInstance

Description

You can call this operation to restore data to a primary instance based on a backup set.

**Note:**

Calling this operation will cause overwriting data on the specified instance with backup data. Proceed with caution.

Request parameters**Table 2-371: Request parameters**

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to RestoreInstance.
InstanceId	String	Yes	The ID of the specified instance.
BackupId	String	Yes	Backup set ID

Response parameters**Table 2-372: Response parameters**

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= RestoreInstance
&InstanceId= de5dxxxxxxxxxxxxx
&BackupId=fdaxxxxxx
```

Sample response

```
{
  "RequestId" : "AFA391BF-808F-4DA6-80A2-A382108A0945"
```

```
}
```

2.9.1.10 Manage monitoring

2.9.1.10.1 DescribeMonitorItems

Description

You can call this operation to query available monitoring metrics. The result is returned in the <parameter:unit> format.

Request parameters

Table 2-373: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeMonitorItems.

Response parameters

Table 2-374: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
MonitorItems	List	The list of monitoring metrics that were queried.

Sample request

```
https://r-kvstore.example.com
?<Common request parameters>
&Action=DescribeMonitorItems
```

Sample response

```
{
  "MonitorItems" : {
```

```

    "MonitorItem" : [{
      "MonitorKey" : "GetQ",
      "Unit" : "Counts/s"
    }, {
      "MonitorKey" : "Flush",
      "Unit" : "Counts/s"
    }, {
      "MonitorKey" : "UsedMemCache",
      "Unit" : "Bytes"
    }, {
      "MonitorKey" : "ReplaceQ",
      "Unit" : "Counts/s"
    }
  ],
  "RequestId" : "B906A893-58A3-4644-AC2D-A2C9B08706C1"
}

```

2.9.1.10.2 DescribeHistoryMonitorValues

Description

You can call this operation to query historical monitoring data of an instance.

Request parameters

Table 2-375: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeHistoryMonitorValues.
InstanceId	String	Yes	The ID of the specified instance.

Parameter	Type	Required	Description
StartTime	String	Yes	The beginning of the time range where the historical monitoring data is queried. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC time format.
EndTime	String	Yes	The end of the time range where the historical monitoring data is queried. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC time format. The value of EndTime must be greater than or equal to that of StartTime.
IntervalForHistory	String	Yes	The interval for collecting monitoring data. Monitoring samples were collected every N minutes. Valid values : 01m, 05m, 15m, and 60m.
MonitorKeys	String	No	The key of the specified metric . You can call the DescribeMonitorItems operation to query the value of this parameter.

Response parameters

Table 2-376: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
MonitorHistory	String	The monitoring data returned in the JSON format. For more information, see DescribeMonitorItems.  Note: To improve the data transmission efficiency, only metrics whose values are not 0 have been returned. All metrics that are not displayed have been set to the default value 0.

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= DescribeHistoryMonitorValues
&InstanceId= de5xxxxxxxxxxxxx
&EndTime=2014-11-27T12%3A02%3A00Z
&StartTime=2014-11-27T12%3A00%3A00Z
&IntervalForHistory=01m
```

Sample response

```
{
  "MonitorHistory" :
  [{"2014-11-27T12:00:00Z":{"IsConnectControl":false,"IsFlowControl":false,"ItemCount":1,"
  QuotaConnection":500,"QuotaFlow":15360,"QuotaMemCache":1073741824,"QuotaQps":
  9000,"UsedMemCache":14},
  "2014-11-27T12:01:00Z":{"IsConnectControl":false,"IsFlowControl":false,"ItemCount":1,"
  QuotaConnection":500,"QuotaFlow":15360,"QuotaMemCache":1073741824,"QuotaQps":
  9000,"UsedMemCache":14},
  "2014-11-27T12:02:00Z":{"IsConnectControl":false,"IsFlowControl":false,"ItemCount":1,"
  QuotaConnection":500,"QuotaFlow":15360,"QuotaMemCache":1073741824,"QuotaQps":
  9000,"UsedMemCache":14}
  }],
  "RequestId" : "5C97648D-C85F-4D58-A71F-7B6750856BF7"
```

```
}
```

2.9.1.11 Manage parameters

2.9.1.11.1 DescribeInstanceConfig

Description

You can call this operation to query parameters of an instance.

Request parameters

Table 2-377: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to DescribeInstanceConfig.
InstanceId	String	Yes	The ID of the specified instance.

Response parameters

Table 2-378: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .
Config	String	The parameters of the specified instance that was queried. For more information, see Instance configurations .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= DescribeInstanceConfig
```

```
&InstanceId= de5dxxxxxxxxxxxx
```

Sample response

```
{
  "Config": {"EvictionPolicy": "volatile-lru", "hash-max-ziplist-entries": 512,
    "hash-max-ziplist-value": 64, "list-max-ziplist-entries": 512,
    "list-max-ziplist-value": 64, "set-max-intset-entries": 512,
    "zset-max-ziplist-entries": 128, "zset-max-ziplist-value": 64},
  "RequestId": "59A58517-F8FF-44E5-B90F-F386DB3E4AB8"
}
```

2.9.1.11.2 ModifyInstanceConfig

Description

You can call this operation to modify a parameter of an instance.

Request parameters

Table 2-379: Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyInstanceConfig.
InstanceId	String	Yes	The ID of the specified instance.
Config	String	Yes	The parameter of the specified instance that you want to modify. The value of this parameter must be in the JSON string format. For more information, see Instance configurations .

Response parameters

Table 2-380: Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common parameters .

Sample request

```
https://r-kvstore.example.com
? <Common request parameters>
&Action= ModifyInstanceConfig
&InstanceId= de5xxxxxxxxxxxxx
&Config={"hash-max-ziplist-entries":"512"}
```

Sample response

```
{
  "RequestId":"59A58517-F8FF-44E5-B90F-F386DB3E4AB8"
}
```

2.9.1.12 Appendixes

2.9.1.12.1 Instance types

Types of KVStore for Redis instances

Table 2-381: Standard plan

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description	Zone-disaster recovery deployment
1 GB standard primary/secondary edition for zone-disaster recovery	redis.logic.sharding.drredisdb1g.1db.0rodb.4proxy.default	10,000	10	Single-core	Primary/secondary instance for zone-disaster recovery	Deployed across two zones in one region

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description	Zone-disaster recovery deployment
2 GB standard primary/secondary edition for zone-disaster recovery	redis.logic.sharding.drredisdb2g.1db.0rodb.4proxy.default	10,000	16	Single-core	Primary/secondary instance for zone-disaster recovery	Deployed across two zones in one region
4 GB standard primary/secondary edition for zone-disaster recovery	redis.logic.sharding.drredisdb4g.1db.0rodb.4proxy.default	10,000	24	Single-core	Primary/secondary instance for zone-disaster recovery	Deployed across two zones in one region
8 GB standard primary/secondary edition for zone-disaster recovery	redis.logic.sharding.drredisdb8g.1db.0rodb.4proxy.default	10,000	24	Single-core	Primary/secondary instance for zone-disaster recovery	Deployed across two zones in one region
16 GB standard primary/secondary edition for zone-disaster recovery	redis.logic.sharding.drredisdb16g.1db.0rodb.4proxy.default	10,000	32	Single-core	Primary/secondary instance for zone-disaster recovery	Deployed across two zones in one region

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description	Zone-disaster recovery deployment
32 GB standard primary/secondary edition for zone-disaster recovery	redis.logic.sharding.drredisdb32g.1db.0rodb.4proxy.default	10,000	32	Single-core	Primary/secondary instance for zone-disaster recovery	Deployed across two zones in one region

Table 2-382: Premium plan

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description	Zone-disaster recovery deployment
1 GB advanced primary/secondary edition	redis.master.small.special2x	20,000	48	Single-core	Primary/secondary instance	Deployed in one zone
2 GB advanced primary/secondary edition	redis.master.mid.special2x	20,000	48	Single-core	Primary/secondary instance	Deployed in one zone
4 GB advanced primary/secondary edition	redis.master.stand.special2x	20,000	48	Single-core	Primary/secondary instance	Deployed in one zone
8 GB advanced primary/secondary edition	redis.master.large.special1x	20,000	48	Single-core	Primary/secondary instance	Deployed in one zone

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description	Zone-disaster recovery deployment
16 GB advanced primary/secondary edition	redis.master.2xlarge.special1x	20,000	48	Single-core	Primary/secondary instance	Deployed in one zone
32 GB advanced primary/secondary edition	redis.master.4xlarge.special1x	20,000	48	Single-core	Primary/secondary instance	Deployed in one zone

Table 2-383: Cluster edition

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description
16 GB cluster edition	redis.sharding.small.default	80,000	384	4-core	High-performance cluster instance
32 GB cluster edition	redis.sharding.mid.default	80,000	384	8-core	High-performance cluster instance
64 GB cluster edition	redis.sharding.large.default	80,000	384	8-core	High-performance cluster instance
128 GB cluster edition	redis.sharding.2xlarge.default	160,000	768	16-core	High-performance cluster instance

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description
256 GB cluster edition	redis.sharding.4xlarge.default	160,000	768	16-core	High-performance cluster instance

Table 2-384: Cluster edition for zone-disaster recovery

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description
16 GB cluster edition for zone-disaster recovery	redis.logic.sharding.drredisdb16g.8db.0rodb.8proxy.default	80,000	384	8-core	Cluster instance for zone-disaster recovery
32 GB cluster edition for zone-disaster recovery	redis.logic.sharding.drredisdb32g.8db.0rodb.8proxy.default	80,000	384	8-core	Cluster instance for zone-disaster recovery

Instance type	Service code	Maximum number of connections	Maximum bandwidth (MB)	Processing capability	Description
256 GB cluster edition for zone-disaster recovery	redis.logic.sharding.drredisrdb256g.16db.0rdb.16proxy.default	160,000	768	16-core	Cluster instance for zone-disaster recovery

2.9.1.12.2 Error codes

Description	Error code	Error message	HTTP status code
The error message returned because RAM users are not authorized to call the API operation.	Forbidden.RAM	User not authorized to operate on the specified resource, or this API doesn't support RAM.	403
The error message returned because the operation is unavailable for RAM users.	Forbidden.NotSupportRAM	This action does not support accessed by RAM mode.	403
The error message returned because an exception or error occurs on the server.	ServiceUnavailable	The request has failed due to a temporary failure of the server.	503
The error message returned because the instance status that you specified does not exist.	InvalidStatus.NotFound	The Status provided does not exist in our records.	404
The error message returned because the specified value of the parameter is invalid.	InvalidParameter	The specified parameter InstanceName is not valid.	400

Description	Error code	Error message	HTTP status code
The error message returned because you are not authorized to call the administrator-specific API operations.	Forbidden. NotAdminUser	User not authorized to operate on the specified API as you are not the	403
The error message returned because the parameter is missing.	MissingParameter	Specified parameter is missing.	400
The error message returned because neither InstanceName nor NewPassword is specified.	MissingParameter	InstanceName /NewPassword at least one is mandatory for this action.	400
The error message returned because OwnerId is not specified for this operation.	MissingParameter	The input parameter OwnerId, OwnerAccount that is mandatory for processing this request	403
The error message returned because the specified Token parameter is invalid.	InvalidToken. Malformed	The Specified parameter "Token" is not valid.	400
The error message returned because the specified InstanceName parameter is invalid.	InvalidInstanceName. Malformed	The Specified parameter "InstanceName" is not valid.	400
The error message returned because the specified Password parameter is invalid.	InvalidPassword. Malformed	The Specified parameter "Password" is not valid."	400
The error message returned because the specified Instances parameter is invalid.	InvalidInstances. Malformed	The Specified parameter "Instances" is not valid.	400

Description	Error code	Error message	HTTP status code
The error message returned because the specified StartTime parameter is invalid.	InvalidStartTime.Malformed	The Specified parameter "StartTime" is not valid.	400
The error message returned because the specified EndTime parameter is invalid.	InvalidEndTime.Malformed	The Specified parameter "EndTime" is not valid.	400
The error message returned because the specified InstanceIds parameter is invalid.	InvalidInstanceIds.Malformed	The Specified parameter "InstanceIds" is not valid.	400
The error message returned because your balance is insufficient to perform the current operation.	InsufficientBalance	Your account does not have enough balance.	400
The error message returned because your account fails to pass the real-name authentication.	RealNameAuthenticationError	Your account has not passed the real-name authentication yet.	403
The error message returned because your instance quota has been exhausted.	QuotaExceeded	Living afterpay instances quota exceeded.	400
The error message returned because the capacity configuration is invalid.	InvalidCapacity.NotFound	The Capacity provided does not exist in our records.	400
The error message returned because the ClientToken parameter used for this request has already been used for a different request.	IdempotentParameterMismatch	Request uses a client token in a previous request but is not identical to that request.	400

Description	Error code	Error message	HTTP status code
The error message returned because the inventory of instances in the specified zone is insufficient.	QuotaNotEnough	Quota not enough in this zone.	400
The error message returned because you are not authorized to call the order-class API operations.	Forbidden.SubUser	The specified action is not available for you.	403
The error message returned because the Apsara Stack risk control system denies this access request.	Forbidden.RiskControl	This operation is forbidden by Aliyun Risk Control system.	403
The error message returned because the specified region does not exist.	InvalidRegion.NotFound	The RegionId or ZoneId provided does not exist in our records.	404
The error message returned because the specified ZoneId parameter is invalid.	InvalidZoneId.NotFound	The ZoneId provided is invalid.	400
The error message returned because the ID of the instance does not exist.	InvalidInstanceId.NotFound	The InstanceId provided does not exist in our records.	404
The error message returned because the password is incorrect.	IncorrectPassword	The Password provided is not correct.	400
The error message returned because the service is unavailable.	ServiceNotSupported	The specified service is not supported.	400

Description	Error code	Error message	HTTP status code
The error message returned because a renewal and configuration change order has not taken effect.	HasRenewChangeOrder	This instance has a renewChange order.	400
The error message returned because an internal error occurred.	InternalServerError	The request processing has failed due to some unknown error.	500
The error message returned because the specified backup time is invalid.	InvalidPreferredBackupTime	Specified preferred backup time is not valid.	400
The error message returned because the specified backup type is invalid.	InvalidBackupType.Format	Specified backup type is not valid.	400
The error message returned because the specified backup method is invalid.	InvalidBackupMethod.Format	Specified backup method is not valid.	400
The error message returned because the backup task already exists.	BackupJobExists	A backup job already exists in the specified DB instance.	400
The error message returned because the maximum number of daily backup operations has been reached.	BackupTimesExceeded	Exceeding the daily backup times of this DB instance.	400
The error message returned because no parameters are specified.	ParameterLeastAssociate	Must input at least one optional parameter.	400

Description	Error code	Error message	HTTP status code
The error message returned because the specified backup period is invalid.	InvalidBackupRetentionPeriod.Malformed	Specified backup retention period is not valid.	400
The error message returned because the specified next backup time is invalid.	InvalidPreferredBackupTime.Format	Specified preferred backup time is not valid.	400
The error message returned because the specified backup period is invalid.	InvalidPreferredBackupPeriod.Malformed	Specified backup period is not valid.	400
The error message returned because the operation is not supported by the current instance type.	IncorrectDBInstanceType	Current DB instance type does not support this operation	400
The error message returned because the specified key is invalid.	InvalidKey.Malformed	Specified key is not valid.	400
The error message returned because the nonce signature is used and cannot be used again.	SignatureNonceUsed	Specified signature nonce was used already.	400
The error message returned because no virtual IP address can be assigned.	AllocateVpcIp.NotEnough	Ip resource is not enough	400
The error message returned because instances of the specified type cannot be created in the zone.	Zone.NotSupport	Specified zone does not support creating with instance class.	400

Description	Error code	Error message	HTTP status code
The error message returned because the code for the instance type is invalid.	MissingClassCode	Capacity or InstanceClass is mandatory for this action.	400
The error message returned because the specified instance type is not supported.	InvalidDBInstanceClass.NotFound	Specified DB instance class is not found.	404
The error message returned because the instance is locked.	IncorrectDBInstanceLockMode	Current DB instance lock mode does not support this operation.	400
The error message returned because the ID of the backup set does not exist.	InvalidBackupSetID.NotFound	Specified backup set ID does not exist.	400
The error message returned because the operation is not supported while the instance is in the current state.	IncorrectDBInstanceState	Current DB instance state does not support this operation.	400
The error message returned when the available resource capacity in the specified instance is insufficient.	InsufficientResourceCapacity	There is insufficient capacity available for the requested instance.	400
The error message returned because the specified end time is invalid.	InvalidEndTime.Format	Specified end time is not valid.	400
The error message returned because the specified duration for reserving a classic IP address is invalid.	InvalidClassicExpiredDays.Format	The specified classicExpiredDays format is not valid.	400

Description	Error code	Error message	HTTP status code
The error message returned because the operation is not supported while the backup set is in the current state.	IncorrectBackupSetState	Current backup set state does not support operations.	400
The error message returned when the specified whitelist is not correct in format.	InvalidSecurityIPListFormat	Specified security IP list format is not valid .	400

2.9.1.12.3 Instance configurations

Table 2-385: KVStore for Redis instance configurations

Parameter	Description	Value
maxmemory-policy	The eviction policy that a KVStore for Redis instance uses to evict data when the memory exceeds the threshold. KVStore for Redis supports six data eviction policies.	• VolatileLRU: only evicts original data that has Time To Live (TTL) configured based on the Least Recently Used (LRU) algorithm. • VolatileTTL: only evicts data that has TTL configured based on the TTL values in ascending order. • AllKeysLRU: evicts original data based on the LRU algorithm. • VolatileRandom: only evicts original data that has TTL configured randomly. • AllKeysRandom: evicts original data randomly. • NoEviction: evicts no data, but returns an error message when you write new data to the instance.

Parameter	Description	Value
hash-max-ziplist-entries	A hash object uses ziplist encoding only if the hash object meets both of the following conditions: • The number of key-value pairs stored in the hash object is smaller than or equal to the value of list-max-ziplist-entries. • The string lengths of keys and values in all key-value pairs stored in the hash object are smaller than or equal to the value of list-max-ziplist-value.	Default value: 512.
hash-max-ziplist-value	A hash object uses ziplist encoding only if the hash object meets both of the following conditions: • The number of key-value pairs stored in the hash object is smaller than or equal to the value of list-max-ziplist-entries. • The string lengths of keys and values in all key-value pairs stored in the hash object are smaller than or equal to the value of list-max-ziplist-value.	Default value: 64.

Parameter	Description	Value
list-max-ziplist-entries	A list object uses ziplist encoding only if the list object meets both of the following conditions: • The number of key-value pairs stored in the list object is smaller than or equal to the value of list-max-ziplist-entries. • The string lengths of keys and values in all key-value pairs stored in the list object are smaller than or equal to the value of list-max-ziplist-value.	Default value: 512.
list-max-ziplist-value	A list object uses ziplist encoding only if the list object meets both of the following conditions: • The number of key-value pairs stored in the list object is smaller than or equal to the value of list-max-ziplist-entries. • The string lengths of keys and values in all key-value pairs stored in the list object are smaller than or equal to the value of list-max-ziplist-value.	Default value: 64.
set-max-intset-entries	A set object uses intset encoding only if: the number of entries is smaller than or equal to the value of set-max-intset-entries and all entries are decimal integers.	Default value: 512.

Parameter	Description	Value
zset-max-ziplist-entries	A zset object uses ziplist encoding only if the zset object meets both of the following conditions: • The number of key-value pairs stored in the zset object is smaller than or equal to the value of zset-max-ziplist-entries. • The string lengths of keys and values in all key-value pairs stored in the zset object are smaller than or equal to the value of zset-max-ziplist-value.	Default value: 128.
zset-max-ziplist-value	A zset object uses ziplist encoding only if the zset object meets both of the following conditions: • The number of key-value pairs stored in the zset object is smaller than or equal to the value of zset-max-ziplist-entries. • The string lengths of keys and values in all key-value pairs stored in the zset object are smaller than or equal to the value of zset-max-ziplist-value.	Default value: 64.

Parameter	Description	Value
notify-keyspace-events	The keyspace notifications allow clients to subscribe to channels or modes to receive events where Redis datasets were modified in some way.	• K: the keyspace notifications. All notifications are prefixed with <code>__keyspace\@__</code>. • E: the keyevent notifications. All notifications are prefixed with <code>__keyevent@__</code>. • g: the notifications about general commands that are non-type specific, such as DEL, EXPIRE, and RENAME. • \$: the string command notifications. • l: the list command notifications. • s: the set command notifications. • h: the hash command notifications. • z: the sorted set command notifications. • x: the expiration events. The system sends an expiration event after the system deletes an expired key. • e: the eviction events. The system sends an eviction event after the system evicts a key according to the maxmemory policy. • A: the alias for g\$lshzxe.

2.9.2 SDK reference

2.9.2.1 Java SDK

2.9.2.1.1 Quick start

This topic describes how to obtain and use KVStore for Redis Java SDK.

Prerequisites

- You have an authorized Alibaba Cloud account and an AccessKey pair that includes an AccessKey ID and an AccessKey Secret. For more information about how to obtain and view your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- You have obtained the service endpoint. For more information, see [Obtain an endpoint](#).
- The Java SDK supports JDK V1.6 and later.

Install the Java SDK

If you use Apache Maven to manage Java projects, you only need to import JAR files to pom.xml of the project.

To use the service development kit, you must install the SDK core library and the service SDK

The version of the core library is 3.7.1, and the version of the KVStore for RedisSDK is 2.0.3.

```
<dependencies>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-core</artifactId>
    <version>3.7.1</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-core-3.7.1.jar</systemPath>
  </dependency>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-r-kvstore</artifactId>
    <version>2.0.3</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-r-kvstore-2.0.3.jar</
systemPath>
  </dependency>
</dependencies>
```

Use the Java SDK

The following example shows how to use the Java SDK:

1. Create a DefaultAcsClient instance and initialize the instance.
2. Create an API request and set parameters.
3. Initiate the request and process a success response or an error response.

```
package com.testprogram;
import com.aliyuncs.profile.DefaultProfile;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
```

```

import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.r_kvstore.model.v20150101.DescribeInstanceAttributeRequest;
import com.aliyuncs.r_kvstore.model.v20150101.DescribeInstanceAttributeResponse;
public class Main {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize the instance.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The name of the region where your instance is located.
            "<your-access-key-id>", // The AccessKey ID of your account.
            "<your-access-key-secret>"); // The AccessKey Secret of your account.
        // Set the endpoint of the current service.
        /** your-region-id =cn-hangzhou; product = redis ; endpoint = r-kvstore.aliyuncs.
        com */
        profile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");
        IAcClient client = new DefaultAcsClient(profile);
        // Create an API request and set parameters.
        DescribeInstanceAttributeRequest request = new DescribeInstanceAttributeRequest();
        request.setInstanceId("r-m5xxxxxxxxxxxxxx");
        // Initiate the request and process a success response or an error response.
        DescribeInstanceAttributeResponse response;
        try {
            response = client.getAcsResponse(request);
            for (DescribeInstancesResponse.Instance instance: response.getInstances()) {
                System.out.println(instance.getPublicIpAddress());
            }
        } catch (ServerException e) {
            e.printStackTrace();
        }
        catch (ClientException e) {
            e.printStackTrace();
        }
    }
}

```

2.9.2.1.2 Use the Java SDK

2.9.2.1.2.1 Install the Java SDK

This topic describes how to install and use KVStore for Redis Java SDK.

The Java SDK supports JDK V1.6 and later. You can import JAR files to install the Java SDK.

Click [here](#) to download the KVStore for Redis JAR files.

If you use Eclipse or IntelliJ as an integrated development environment, install the KVStore for Redis Java SDK by importing the JAR files.

The installation methods are described as follows:

- Use Eclipse

To install KVStore for Redis Java SDK based on Eclipse, follow these steps:

1. Copy the downloaded `aliyun-java-sdk-r-kvstore-2.0.3.jar` file to your project folder.
2. In Eclipse, open your project, right-click the project, and then select **Properties** from the shortcut menu.
3. In the dialog box that appears, choose **Java Build Path > Libraries > Add JARs** to add the downloaded JAR files.
4. Click **Apply and Close**.

- Use IntelliJ

To install KVStore for Redis Java SDK based on IntelliJ, follow these steps:

1. Copy the downloaded `aliyun-java-sdk-r-kvstore-2.0.3.jar` file to your project folder.
2. In IntelliJ, open your project. In the menu bar, choose **File > Project Structure**.
3. Click **Apply** and then click **OK**.

2.9.2.1.2.2 Configure authentication credentials

To use Alibaba Cloud SDKs to access Apsara Stack resources, you must provide an authorized Alibaba Cloud account to verify your identity.

The Java SDK supports identity verification based on AccessKey pairs. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use an AccessKey pair as the credential, you must configure your credential when you initialize the client.

Notice:

Do not disclose any code containing your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your Alibaba Cloud account may be compromised.

```
DefaultProfile profile = DefaultProfile.getProfile(
    "<your-region-id>", // The ID of the region where your instance is located.
    "<your-access-key-id>", // The AccessKey ID of your account.
    "<your-access-key-secret>"); // The AccessKey Secret of your account.
```

2.9.2.1.2.3 Make API requests

This topic describes how to use KVStore for Redis Java SDK to make a request.

Procedure

1. Create an AcsClient.

```
IAcsClient client = new DefaultAcsClient(profile);
```

2. Create a request.

The Request class is named in the following way: `${apiName}Request`. In this naming convention, `${apiName}` specifies the name of an API operation, such as `DescribeInstances`.

When you use multiple service SDKs, different requests may have the same class name. Distinguish the requests by service package.

```
DescribeInstancesRequest request = new DescribeInstancesRequest();
request.setPageSize(10);
```

3. Initiate the request and process the response.

```
DescribeInstancesResponse response;
    try {
        response = client.getAcsResponse(request);
        for (DescribeInstancesResponse.Instance instance:response.getInstances
    ) {
        System.out.println(instance.getPublicIpAddress());
        }
    } catch (ServerException e) {
        e.printStackTrace();
    } catch (ClientException e) {
        e.printStackTrace();
    }
```

All the returned fields are deserialized into the response. You can directly use `response.getXXX()` to obtain the fields in the response.

```
instanceStatus := response.getStatus()
```

If an error occurs, or you require the original HTTP response, you can use `doAction()` to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.9.2.1.2.4 Process errors

If an error occurs on the server side or SDK side, the Apsara Stack Java SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Generally, you are not required to handle the errors returned by the Apsara Stack Java SDK. You are only required to handle the errors on the server side according to the error message.

- `ServerException` is the error message on the server side.
- `ClientException` is the error message on the SDK side.

For example, if the following error occurs, modify the ID of `AccessKey` according to the detailed error message.

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified access key is not found.
```

To handle the errors returned by the Apsara Stack Java SDK, see the following code example for reference:

```
try {
    FooResponse response = client.getAcsResponse(request);
    // Handle the response.
    // ...
} catch (ServerException e) {
    // Add your own error handling logic here.
    // For example, print the detailed error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If the problem is tricky, open a ticket and provide the RequestId for us.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {
    // Add your own error handling logic here.
    // For example, print the detailed error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
}
```

2.9.2.1.2.5 Use `CommonRequest` to make a request

If no SDK is available when you want to call an API operation of a service, you can make a request by using `CommonRequest`. `CommonRequest` allows you to call any API operations.

Benefits

`CommonRequest` has the following benefits:

1. **Lightweight:** you only need to download the core package. You do not need to download and install any SDK.
2. **Easy to use:** you can use the latest API operations without updating the corresponding SDK.
3. **Efficient iteration.**

Use `CommonRequest` to call an API operation

To make a `CommonRequest` request, you must obtain the values of the following parameters. You can obtain these values from the API documents.

- **Domain:** the endpoint of your service.

- Version: the version of the target API in the format of YYYY-MM-DD.

You can obtain the API version from the common parameters in the API documents.

- Parameters of an API operation: in this example, you want to call the DescribeInstances operation.

You must obtain the **Action** parameter and specify the API operation name by using `request.ApiName = "<DescribeInstances>"`.

To initiate a CommonRequest request for **DescribeInstances**, you must specify the API operation name by using `request.ApiName = "DescribeInstances"`.

You must obtain the **PathPattern** parameter and specify the RESTful path by using `request.PathPattern = "<PathPattern>"`.

For example, the **PathPattern** parameter of the API operation for querying all cluster instances is set to `/clusters`. When you initiate a CommonRequest request, you must specify the RESTful path by using `request.PathPattern = "/clusters"`.

Example: call an RPC API operation

The following example shows how to use CommonRequest to call the

DescribeInstanceStatus API operation of KVStore for Redis:

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize the instance.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The ID of the region where your instance is located.
            "<your-access-key-id>", // The AccessKey ID of your account.
            "<your-access-key-secret>"); // The AccessKey Secret of your account.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and set parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("r-kvstore.aliyuncs.com");
        request.setVersion("2015-01-01");
        request.setAction("DescribeInstances");
        request.putQueryParameter("PageNumber", "1");
        request.putQueryParameter("PageSize", "30");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
        }
    }
}
```

```
e.printStackTrace();
}
}
```

Example: call a RESTful API operation

The following example shows how to use CommonRequest to call the operation of KVStore for Redis to query all cluster instances.

```
import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
public class Sample {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize the instance.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // The ID of the region where your instance is located.
            "<your-access-key-id>", // The AccessKey ID of your account.
            "<your-access-key-secret>"); // The AccessKey Secret of your account.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and set parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("r-kvstore.aliyuncs.com");
        request.setVersion("2015-01-01");
        request.setUriPattern("/clusters");
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        } catch (ClientException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
        }
    }
}
```

}

2.9.2.1.2.6 Common errors

This topic describes the common errors when you use Java SDK and how to troubleshoot the problems based on the corresponding causes and solutions.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot automatically obtain the endpoint of the called service in the specified region.	Check whether the provided region ID and endpoint are correct. After obtaining the correct endpoint, use the following code to set the endpoint: <pre>DefaultProfile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response	The SDK response fails to be deserialized. In most cases, the cause is that the structure of the response received by the SDK does not conform to the API metadata, such as mismatched fields or incorrect formatting.	You can use the <code>client.doAction(request)</code> method to obtain the original HTTP response.
SDK.TimeoutError	The request timed out 4 times (3 for retry), perhaps we should have the threshold raised a little?	The request has timed out and all retry attempts have failed.	In scenarios such as poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError:InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect Recommend :https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API only accepts HTTPS requests and does not accept HTTP requests.	You can add the following code to the request before it is sent: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.9.2.2 Python SDK

2.9.2.2.1 Quick start

This topic describes how to obtain and use the Redis Python SDK.

Prerequisites

- You must have an Apsara Stack account and an AccessKey pair (AccessKey ID and AccessKey Secret) to use Python SDK. For more information about how to obtain and view your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- For more information about how to obtain an endpoint, see [Obtain an endpoint](#).

Install the Python SDK

To install the Python SDK, follow these steps:

1. Install the SDK core library.

- If you are using Python 2.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core
```

- If you are using Python 3.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core-v3
```

2. Install the Redis SDK.

Run the following command to install the Redis Python SDK:

```
pip install aliyun-python-sdk-r-kvstore
```

Use the Python SDK

The following example shows how to use the Python SDK:

1. Create a client instance. When you create the client, you must set the region ID, AccessKey ID, and AccessKey Secret.
2. Create an API request and configure its parameters.
3. Initiate the request and process the response or exceptions.

```
#!/usr/bin/env python
#coding=utf-8

from aliynsdcore import client
from aliynsdcore.profile import region_provider
from aliynsdkecs.request.v20140526 import DescribeInstancesRequest

# global config
region_id = 'xxxxx'
secret_id = 'xxxxx'
secret_key = 'xxxxx'

# product config
product_name = redisa
endpoint = 'r-kvstore.aliyuncs.com'

# create client
client.region_provider.modify_point(product_name, region_id, endpoint)
clt = client.AcsClient(secret_id, secret_key, region_id)

# setup request
request = DescribeInstancesRequest.DescribeInstancesRequest()
request.set_accept_format('json')

# get response
response = clt.do_action_with_exception(request)

print response
```

2.9.2.2.2 Use the Python SDK

2.9.2.2.1 Install the Python SDK

This topic describes how to install and use KVStore for Redis Python SDK.

The Python SDK supports Python V2.6.x, 2.7.x, 3.x, and later. You can install the SDK in any of the following ways:

- Use pip (recommended)

To use pip to install the SDK, run the following commands:

```
pip install aliyun-python-sdk-core # Install the core library of the Alibaba Cloud SDK.
pip install aliyun-python-sdk-r-kvstore # Install the library that manages
KVStore for Redis.
```

Note:

If you use Python V3.x, run the `pip install aliyun-python-sdk-core-v3` command instead of the `pip install aliyun-python-sdk-core` command.

- Download the SDK code from the [Apsara Stack website](#) and install the SDK.

```
# Install the core library of the SDK.
cd aliyun-python-sdk-core
python setup.py install
# Install the KVStore for Redis SDK.
cd aliyun-python-sdk-r-kvstore
python setup.py install
```

- Use the source code

1. [Download the SDK package](#) and decompress the package.

2. Install the SDK in any of the following ways:

- Modify the `sys.path` file and add the directory where you decompress the package to the file, as follows:

```
>>> import sys
>>> sys.path.append('/Users/michael/my_py_scripts')
```

Note:

This setting takes effect only when the KVStore for Redis instance is running.

- Set the PYTHONPATH environment variable to the directory where you decompress the package. The system automatically adds the content of this environment variable to the module search directory.

You can set the PYTHONPATH environment variable in the same way as you set the Path environment variable.

- Place the decompressed SDK package in the project. Afterward, you can directly use the Python SDK in the project.

2.9.2.2.2 Configure authentication credentials

To use Alibaba Cloud SDKs to access Apsara Stack resources, you must provide an authorized Alibaba Cloud account to verify your identity.

The Python SDK supports identity verification based on AccessKey pairs. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use an AccessKey pair as the credential, you must configure your credential when you initialize the client.

Notice:

Do not disclose any code containing your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your Alibaba Cloud account may be compromised.

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

2.9.2.2.3 Make API requests

This topic describes how to use KVStore for Redis Python SDK to make an API request.

Procedure

1. Import the SDK of the target service.

```
DescribeInstances
from aliyunsdkcore import client
    from aliyunsdkcore.profile import region_provider
    from aliyunsdkecs.request.v20150101 import DescribeInstancesRequest
```

2. Create an AcsClient.

```
client.region_provider.modify_point(product_name, region_id, endpoint)
```

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

3. Create a Request object.

```
request = DescribeInstancesRequest.DescribeInstancesRequest()  
request.set_accept_format('json')
```

4. Initiate the request and process the response.

```
response = clt.do_action_with_exception(request)  
  
print response
```

2.9.2.2.4 Set HTTPS requests

The Python SDK allows you to make API requests over HTTP and HTTPS.

When you use the Python SDK, you can specify an HTTP or HTTPS protocol for a request, or set a global protocol for all requests.

Note:

The default HTTP or HTTPS protocol for each service takes precedence over the global protocol.

Add OpenSSL dependencies

The HTTPS protocol for the Python SDK is dependent on the OpenSSL library in Python.

To use the Python SDK to send HTTPS requests, you must add OpenSSL dependencies in Python.

Run the `python -c "import ssl"` command to verify that the Python SDK supports OpenSSL. If the error message `ImportError: No module named ssl` is not returned, the Python SDK has supported OpenSSL.

If OpenSSL is not available, run the following command to install OpenSSL:

```
pip install pyopenssl
```

Specify an HTTP or HTTPS protocol for a request

The following example shows how to specify an HTTPS protocol for a request:

```
request = CreateInstanceRequest.CreateInstanceRequest()  
request.set_protocol_type("https")
```

```
# Valid values: "https" or "http".
```

Specify a default global protocol for all requests

The following example shows how to set a default global protocol for all requests:

```
import aliynsdckore.request
aliynsdckore.request.set_default_protocol_type("https")
# Create a request and call client.do_action_with_exception() to send the request.
```

2.9.2.2.2.5 Process errors

When you use Alibaba Cloud Python SDK, if an error occurs in your application server or in the Python SDK, the SDK returns the corresponding error. The error message contains error details, such as an error code and an error message.

You do not need to process Python SDK errors. You only need to process server errors according to server error messages.

- `ServerException` indicates a server error.
- `ClientException` indicates an SDK error.

For example, if the following error occurs, you can modify the AccessKey ID according to the error message.

```
aliynsdckore.acs\_exception.exceptions.ServerException: HTTP Status: 404 Error:
InvalidAccessKeyId.NotFound Specified access key is not found.
```

If you need to process Python SDK errors, write your code as follows:

```
try:
    response = client.do_action_with_exception(request)
except ServerException as e:
    # Add your logic that you use to process the error here.
    # For example, print the error message.
    print e.get_http_status()
    print e.get_error_code()
    print e.get_error_msg()
```

2.9.2.2.2.6 Use CommonRequest

If no SDK is provided for the service API that you want to call, you can use `CommonRequest` to make API requests. You can use `CommonRequest` to call any API operations.

Features

`CommonRequest` has the following features:

1. **Lightweight:** You only need to download the core package. You do not need to download and install the service SDKs.
2. **Easy to use:** You can call the latest APIs without the need to update the SDKs.

3. Fast iteration.

Use CommonRequest

To use CommonRequest to initiate a request, you need to set the following parameters. You can obtain the values of the following parameters from the API documentation:

- domain: the endpoint of the service.
- version: the version of the API. It is in the YYYY-MM-DD format.

You can obtain the API version from common parameters in the API documentation.

- API information: The name of the API operation that you want to call is DescribeInstances.

You must obtain the value of the **Action** parameter, and use `request.ApiName = "<DescribeInstances>"` to specify the API that you want to call.

For example, to initiate a CommonRequest request for **DescribeInstances**, you must use `request.ApiName = "DescribeInstances"` to specify the API operation name.

You must obtain the value of the **PathPattern** parameter, and use `request.PathPattern = "<PathPattern>"` to specify the RESTful path.

For example, the **PathPattern** parameter of the API operation for querying all cluster instances is set to `/clusters`. When you initiate a CommonRequest request, you must specify the RESTful path by using `request.PathPattern = "/clusters"`.

Example: call an RPC API operation

The following code demonstrates how Python 2.x uses the CommonRequest method to call the **DescribeInstanceStatus** API operation of KVStore for Redis:

```
from aliyunsdkcore.client import AcsClient
    from aliyunsdkcore.request import CommonRequest
    client = AcsClient('{your_access_key_id}', '{your_access_key_secret}', '{your_region_id}')
    request = CommonRequest()
    request.set_domain('r-kvstore.aliyuncs.com')
    request.set_version('2015-01-01')
    request.set_action_name('DescribeInstances')
    # or:
    # request = CommonRequest(domain='r-kvstore.aliyuncs.com', version='2015-01-01', action_name='DescribeInstances')
    request.add_query_param('PageNumber', '1')
    request.add_query_param('PageSize', '30')
```

```
response = client.do_action_with_exception(request)
```

Example: call an RESTful API operation

The following code demonstrates how Python 2.x uses the CommonRequest method to call the API operation of KVStore for Redis to list all cluster instances.

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.request import CommonRequest
client = AcsClient('{your_access_key_id}', '{your_access_key_secret}', '{your_region_id}')
request = CommonRequest()
request.set_domain('r-kvstore.aliyuncs.com')
request.set_version('2015-01-01')
request.set_uri_pattern('/clusters')
# or:
# request = CommonRequest(domain='r-kvstore.aliyuncs.com', version='2015-01-01', uri_pattern='/clusters')
```

```
response = client.do_action_with_exception(request)
```

2.9.2.2.2.7 Common errors

This topic lists the causes and solutions for some common errors you may encounter when you use the SDK.

Error code	Error message	Cause	Solution
SDK. InvalidRegionId	Can not find endpoint to access.	The error message returned because the SDK failed to automatically obtain the endpoint of the requested service in the specified region.	Check whether the specified region ID and endpoint are correct. After you obtain the endpoint, set the endpoint in the following way: <pre>from aliyunsdkcore.profile import region_provider region_provider.modify_point('product_name', 'region_id', 'endpoint')</pre>
SDK. TimeoutError	—	The error message returned because the request timed out and all retries failed.	In scenarios such as low network quality, we recommend that you increase the timeout period or the maximum number of retries.

Error code	Error message	Cause	Solution
SDK. ServerError : InvalidPro tocol. NeedSsl	Your request is denied as lack of ssl protect. Recommend :https ://error -center. aliyun.com /status/ search? Keyword= InvalidPro tocol. NeedSsl &source= PopGw	The error message returned because you made an HTTP request. The API operation only accepts HTTPS requests.	Before you send a request, add the following code: <pre>request.set_protocol_type('https')</pre>

2.9.2.3 PHP SDK

2.9.2.3.1 Quick start

Alibaba Cloud PHP SDK allows you to easily connect to KVStore for Redis instead of complex programming. This topic describes how to obtain and use the PHP SDK.

Prerequisites

- You have an authorized Alibaba Cloud account and an AccessKey pair that includes an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- You have obtained the service endpoint. For more information, see [Obtain an endpoint](#).
- The PHP SDK applies to PHP V5.3, V5.4, V5.5, V5.6, V7.0, and V7.1. You can run the **php -v** command to obtain the current PHP version number.

Install the PHP SDK

To install the PHP SDK, follow these steps:

- Download the PHP SDK source code from the [Apsara Stack website](#).

2. Add the PHP SDK reference to your code.

In this example, the PHP SDK is downloaded to `/path/to/aliyun-openapi-php-sdk`.

```
require_once '/path/to/aliyun-openapi-php-sdk/aliyun-php-sdk-core/Config.php';
```

Use the PHP SDK

The following example shows how to use the PHP SDK:

1. Create a DefaultAcsClient instance and initialize the instance.

When you create and initialize a DefaultAcsClient instance, you must provide the values of **Region ID**, **AccessKeyId**, and **AccessKeySecret**.

2. Create an API request and set parameters.

3. Initiate the request and process a success response or an error response.

```
<? php

    use R_kvstore\Request\V20150101\DescribeInstancesRequest;

    # Create a DefaultAcsClient instance and initialize the instance.
    $clientProfile = DefaultProfile::getProfile(
located.    "<your-region-id>"          # The ID of the region where your instance is
    "<your-access-key-id>"          # The AccessKey ID of your account.
    "<your-access-key-secret>"      # The AccessKey Secret of your account.
    );
    $client = new DefaultAcsClient($clientProfile);

    # Set the endpoint of your service.
    $profile->endpoint = "your-region-id", "your-region-id", "product",
"endpoint";
    # Create an API request and set parameters.
    $request = new DescribeInstancesRequest();
    $request->setPageSize(10);

    # Initiate a request and process the response.
    try {
        $response = $client->getAcsResponse($request);
        print_r($response);
    } catch (ServerException $e) {
        print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
    } catch (ClientException $e) {
        print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
    }
    ?>
```

2.9.2.4 Go SDK

2.9.2.4.1 Quick start

Alibaba Cloud Go SDK allows you to easily connect to KVStore for Redis instead of complex programming. This topic describes how to obtain and use the Go SDK.

Prerequisites

- You have an authorized Alibaba Cloud account and an AccessKey pair that includes an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- You have obtained the service endpoint. For more information, see [Obtain an endpoint](#).

Install the Go SDK

1. Download the Go SDK source code from the [Apsara Stack website](#).
2. Decompress the source code to the directory where your GO_PATH file is located.

Use the Go SDK

The following example shows how to use the Go SDK:

1. Create a client instance.
2. Create an API request and set parameters.
3. Initiate the request and process a success response or an error response.

```
package main

import (
    "github.com/aliyun/alibaba-cloud-sdk-go/services/r-kvstore"
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"
    "fmt"
)

func main() {
    // Create an r-kvstoreClient instance.
    r-kvstoreClient, err := r-kvstore.NewClientWithAccessKey(
        "<your-region-id>", // The ID of the region where your instance is
        "<your-access-key-id>", // The AccessKey ID of your account.
        "<your-access-key-secret>") // The AccessKey Secret of your account.
    if err != nil {
        // Process an error response.
        panic(err)
    }

    // Set the endpoint of your service.
    request.Domain = "endpoint"
    // Create an API request and set parameters.
    request := r-kvstore.CreateDescribeInstancesRequest()
    // Set request.PageSize to 10.
    request.PageSize = requests.NewInteger(10)
    // Initiate the request and process an error response.
    response, err := r-kvstoreClient.DescribeInstances(request)
    if err != nil {
        // Process an error response.
        panic(err)
    }
}
```

```
    }
    fmt.Println(response)
}
```

2.9.2.4.2 Use the Go SDK

2.9.2.4.2.1 Install the Go SDK

This topic describes how to install KVStore for Redis Go SDK.

The Go SDK supports Go V1.7 and later. To install the Go SDK, follow these steps:

1. Download the Go SDK source code from the [Apsara Stack website](#).
2. Decompress the source code to the directory where your GO_PATH file is located.

2.9.2.4.2.2 Configure authentication credentials

To use Alibaba Cloud SDKs to access Apsara Stack resources, you must provide an authorized Alibaba Cloud account to verify your identity.

The Go SDK supports identity verification based on AccessKey pairs. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use an AccessKey pair as the credential, you must configure your credential when you initialize the client.

Notice:

Do not disclose any code containing your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your Alibaba Cloud account may be compromised.

```
// Create an r-kvstoreClient instance.
ecsClient, err := r-kvstore.NewClientWithAccessKey(
    "<your-region-id>", // The ID of the region where your instance is located.
    "<your-access-key-id>", // The AccessKey ID of your account.
    "<your-access-key-secret>") // The AccessKey Secret of your account.
```

If you want to customize Config or use a credential other than an AccessKey pair, you must first create a Credential object to save the credential. Afterward, submit the Credential object when initializing the client.

```
// Customize Config.
config := NewConfig()
// Create a Credential object.
credential := &credentials.BaseCredential{
    AccessKeyId:    "<your-access-key-id>",
    AccessKeySecret: "<your-access-key-secret>",
}
// Initialize the client.
```

```
client, err := NewClientWithOptions("cn-hangzhou", config, credential)
```

2.9.2.4.2.3 Make API requests

This topic describes how to use KVStore for RedisGo SDK to make an API request.

1. Import the Go SDK of KVStore for Redis.

```
import github.com/aliyun/alibaba-cloud-sdk-go/services/ecs
```

2. Create a KVStore for Redis client that contains all API operations of KVStore for Redis.

```
r-kvstoreClient := r-kvstore.NewClientWithAccessKey(
    "<your-region-id>",
    "<your-access-key-id>",
    "<your-access-key-secret>")
```

3. Use the `xxx.CreateXXXRequest` method to create a request.

This method is named in the following way: `${service}.Create${apiName}Request`. In this naming convention,

- The **`${service}`** field specifies the lower-case service name, such as `r-kvstore`.
- The **`${apiName}`** field specifies the name of an API operation, such as `DescribeInstanceAttribute`.

```
request := r-kvstore.CreateDescribeInstanceAttributeRequest()
request.InstanceId = ""
```

4. Initiate the request.

```
response, err := r-kvstoreClient.DescribeInstanceAttribute(request)
```

5. Process the response.

All the returned fields are deserialized into the response. You can directly use `response.GetXXX()` to obtain the fields in the response.

```
instanceStatus := response.Status
```

If the error (`err != nil`) occurs, or you require the original HTTP response, you can obtain the original response in the following ways:

```
// Obtain the original HTTP response. The response type is *http.Response.
httpResponse := response.GetOriginHttpResponse()

// Obtain the status code of the original HTTP response. The response type
is int.
statusCode := response.GetHttpStatus()

// Obtain the header of the original HTTP response. The response type is
map[string][]string.
headers := response.GetHttpHeaders()
```

```

byte.    // Obtain the content of the original HTTP response. The response type is []
        contentType := response.GetHttpContentBytes()

        // Obtain the content of the original HTTP response and transcode the
        content to a string based on UTF-8. The response type is string.
        contentType := response.GetHttpContentString()

```

2.9.2.4.2.4 Process errors

When an error occurs in your application server or in Alibaba Cloud Go SDK, Alibaba Cloud Go SDK returns the corresponding error information, including the `ClientError` and `ServerError` under the `sdk.errors` package. These errors are based on standard Go error API. You can process errors that Alibaba Cloud Go SDK returns in the same way as you process standard Go errors.

ClientError

When an error occurs in a SDK where an automatic call fails, the SDK returns a `ClientError` message.

The following code shows how to determine and obtain the error message in `ClientError`:

```

response, err := r-kvstoreClient.DescribeInstances(request)
if clientError, ok := err.(*errors.ClientError); ok{
    // Obtain the error code.
    clientError.ErrorCode()
    // Obtain the error description.
    clientError.Message()
    // Obtain the original error. The returned value may be nil.
    clientError.OriginError()
}

```

ServerError

When the SDK receives an error response from your application server, the SDK encapsulates the response into a `ServerError` message and returns the message to your application.

Note:

In this case, you can still obtain the original HTTP response from the response.

The following code shows how to determine and obtain the error message in `ServerError` and the response:

```

response, err := r-kvstoreClient.DescribeInstances(request)
if serverError, ok := err.(*errors.ServerError); ok{
    // Obtain the error code.
    serverError.ErrorCode()
    // Obtain the error description.
    serverError.Message()
}

```

```
// Obtain the original HTTP response.
response.GetOriginHttpResponse()
}
```

2.9.2.4.2.5 Custom configurations

The topic lists the configurations that you can customize when you use the Go SDK.

Configuration

The Go SDK allows you to customize the configuration in the following way:

```
config := NewConfig().
    WithEnableAsync(true).
    WithGoRoutinePoolSize(5).
    WithMaxTaskQueueSize(1000)
client, err := ecs.NewClientWithOptions("<region-id>", config, credential)
```

Note:

The `config` module of the Go SDK does not support the following request:

```
config := &Config{EnableAsync: true,}
```

Supported custom configurations

The following table lists the custom configurations that the Go SDK supports.

Parameter	Default value	Description
AutoRetry	true	Whether to enable the automatic retry feature.
MaxRetryTime	3	The maximum number of retries. If the automatic retry feature is enabled, the maximum time consumption for a single call is: Timeout (MaxRetryTime + 1)
Timeout	10time.Second	The timeout value. The timeout period covers the entire lifecycle of a call, including establishing a connection, redirecting a request, and reading a response. If the value is set to 0, no timeout occurs.
HttpTransport	nil	This parameter enables the configuration of <code>net/http .client</code> . You can configure <code>http.client</code> by using this parameter to establish a persistent connection.
EnableAsync	false	Whether to enable the asynchronous request feature.

Parameter	Default value	Description
MaxTaskQueueSize	1000	This parameter takes effect only when you specify the following configuration: EnableAsync=true. When a queue is full, the system blocks new requests .
GoRoutinePoolSize	5	This parameter takes effect only when you specify the following configuration: EnableAsync=true.

2.9.2.4.2.6 Make asynchronous requests

Due to the concurrency of the Go language, we recommend that you control the concurrent requests of Go SDKs in your applications. Alibaba Cloud Go SDK provides the concurrent request method that you can use directly. The SDK controls concurrent requests.

Enable the concurrency feature of an SDK client

In the following example, the Credential object specifies the user credential.

```
// The maximum number of concurrent requests.
poolSize := 10

// The maximum number of cacheable requests.
maxTaskQueueSize := 10000

// Enable asynchronous requests when you create a SDK client.
config := sdk.NewConfig().
    WithEnableAsync(true).
    WithGoRoutinePoolSize(poolSize).           // Optional. Default value: 5.
    WithMaxTaskQueueSize(maxTaskQueueSize)    // Optional. Default value: 1000

// Use the custom configuration to initialize the client.
ecsClient, err := ecs.NewClientWithOptions("<your-region-id>", config, credential)

// Or enable asynchronous requests after you initialize the client.
client.EnableAsync(poolSize, maxTaskQueueSize)
```

Make asynchronous requests

You can make asynchronous Go SDK requests in the following ways:

- Use channel as the response value.

```
// this will not block
responseChannel, errChannel := client.FooWithChan(request)
// this will block
response := <-responseChannel
err = <-errChanne
```

- Use callback to control callbacks.

```
// this will not block
blocker := client.FooWithCallback(request, func(response *FooResponse, err error) {
```

```
// handle the response and err
}
)
// The blocker of (chan int) type is used to control synchronization. A response value
// of 1 indicates that the call is successful. A response value of 0 indicates that the call
// has failed.
// When <-blocker returns 0, the error message in err is passed to callback.
// this will block
result := <-blocker
```

2.9.2.4.2.7 Use CommonRequest to make a request

If no SDK is available when you want to call an API operation of a service, you can make a request by using CommonRequest. CommonRequest allows you to call any API operations.

Example: call an RPC API operation

The following example shows how to use CommonRequest to call the

DescribeInstanceStatus API operation of KVStore for Redis:

```
package main

import (
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk/r-kvstore"
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk"
    "fmt"
)

func main() {
    client, err := sdk.NewClientWithAccessKey("{your_access_key_id}", "{
your_access_key_id}", "{your_access_key_id}")
    if err != nil {
        panic(err)
    }

    request := r-kvstore.NewCommonRequest()
    request.Domain = "r-kvstore.aliyuncs.com"
    request.Version = "2015-01-01"
    // You must specify a value for the ApiName(Action) parameter, because this
    is an RPC API operation.
    request.ApiName = "DescribeInstanceStatus"
    request.QueryParams["PageNumber"] = "1"
    request.QueryParams["PageSize"] = "30"
    response, err := client.ProcessCommonRequest(request)
    if err != nil {
        panic(err)
    }
    fmt.Print(response.GetHttpContentString())
}
```

```
}
```

2.9.2.4.2.8 Common errors

This topic lists the causes and solutions for some common errors you may encounter when you use the SDK.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The error message returned because the SDK failed to automatically obtain the endpoint of the requested service in the specified region.	Check whether the specified region ID and endpoint are correct. After you obtain the endpoint, you can run the following code to set the endpoint: <pre>request.Domain = "<endpoint>"</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response, but you can get the data via response.GetHttpStatusCode() and response.GetHttpContentString()	The error message returned because the SDK failed to deserialize the response. The possible cause is that the structure of the response received by the SDK was different from that specified by ApiMeta. For example, the fields did not match or the format was invalid.	For more information, see Parse the response .

Error code	Error message	Cause	Solution
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The error message returned because the request timed out and all retry attempts failed.	- If you use the SDK in multi-region scenarios or poor network conditions, we recommend that you increase the timeout value or the maximum number of retries. - If the problem persists even in excellent network conditions, we recommend that you submit a ticket.
SDK.AsyncFunctionNotEnabled	Async function is not enabled in client, please invoke 'client.EnableAsync()' function	The error message returned because you used an asynchronous function when the asynchronous request had not been enabled.	Enable the asynchronous request feature. For more information, see Make asynchronous requests .

Parse the response

If the SDK failed to deserialize the response, you can ignore the error and extract the original HTTP response to obtain the response attributes.

Note:

Alibaba Cloud Go SDK has a dependency on JMESPath. Therefore, when the response content is in the JSON format, you can directly use JMESPath to parse the response.

```
response, err := client.CreateInstance(request)
if err != nil {
    // Process the error.
    if clientErr, isClientErr := err.(*errors.ClientError); isClientErr {
        if clientErr.ErrorCode() == errors.JsonUnmarshalErrorCode {
            // You can obtain the data in the original response by using the following
            encapsulation method.
            // The HTTP status code in the response. Type: integer.
            statusCode := response.GetHttpStatus()
            // The HTTP header in the response. Type: map[string][]string.
            responseHeader := response.GetHttpHeaders()
        }
    }
}
```

```
// The response body content. Type: []byte.  
responseBytes := response.GetHttpContentBytes()  
// The response body content. Type: string, equivalent to `string(response.  
GetHttpContentBytes())`.  
responseContent := response.GetHttpContentString()  
// You can also directly obtain the original response. Type: net/http.Response.  
httpResponse := response.GetOriginHttpResponse()  
}  
}  
}
```

2.9.2.5 .NET SDK

2.9.2.5.1 Quick start

Alibaba Cloud .NET SDK allows you to easily connect to KVStore for Redis instead of complex programming. This topic describes how to obtain and use the .NET SDK.

Prerequisites

- You have an authorized Alibaba Cloud account and an AccessKey pair that includes an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- You have obtained the service endpoint. For more information, see [Obtain an endpoint](#).
- The .NET SDK applies to .NET Framework 4.0 and later.

Install the .NET SDK

To use the service development kit, you must install the SDK core library and the service SDK. For example, to call the KVStore for Redis SDK, you must obtain and install the SDK core library and the KVStore for Redis SDK. You can install the .NET SDK in any of the following methods:

- Add a DLL reference
 1. Download the compressed package that contains a DLL file from [Developer Resources](#), and decompress the package to obtain the DLL file.
 2. Right-click your project in the Solution Explorer of Visual Studio and select **Reference**.
 3. In the menu that appears, click **Add Reference**.
 4. In the dialog box that appears, click **Browse**, select the downloaded DLL file, and then click **Confirm**.

- Add a project reference
 1. Download the source code of the .NET SDK from [Apsara Stack official website](#).
 2. Find the aliyun-net-openapi-XXX subfolder in the downloaded folder, and then locate the `\\*.csproj` file. This is the .NET project file. For example, the `aliyun-net-openapi-r-kvstore` subfolder contains the `aliyun-net-sdk-r-kvstore.csproj` file.
 3. In Visual Studio, right-click your solution.
 4. Choose **Add > Existing Projects**.
 5. In the dialog box that appears, select the corresponding .NET project file from downloaded source code, such as `aliyun-net-sdk-ecs.csproj`, and click **Open**.
 6. Right-click your project and choose **Reference > Add Reference**.

Use the .NET SDK

The following example shows how to use the .NET SDK:

1. Create a `DefaultAcsClient` instance and initialize the instance.
2. Create an API request and set parameters.
3. Initiate the request and process a success response or an error response.

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Profile;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.R_kvstore.Model.V20150101;

class TestProgram
{
    static void Main(string[] args)
    {
        // Create a client to initiate a request.
        IClientProfile profile = DefaultProfile.GetProfile(
            "<your-region-id>",
            "<your-access-key-id>",
            "<your-access-key-secret>");
        DefaultAcsClient client = new DefaultAcsClient(profile);
        try
        {
            // Set the endpoint of the current service.
            profile.setEndpoint("your-region-id", "your-region-id", "product", "
endpoint");
            DefaultAcsClient client = new DefaultAcsClient(profile);
            try
            {
                // Create a request.
                DescribeInstancesRequest request = new DescribeInstancesRequest();
                request.PageSize = 10;
                // Initiate the request and obtain the response.
                DescribeInstancesResponse response = client.GetAcsResponse(request);
                System.Console.WriteLine(response.TotalCount);
            }
            catch (ServerException ex)
            {
                System.Console.WriteLine(ex.ToString());
            }
        }
    }
}
```

```
}  
catch (ClientException ex)  
{  
    System.Console.WriteLine(ex.ToString());  
}  
}
```

2.9.2.5.2 Use the .NET SDK

2.9.2.5.2.1 Install the .NET SDK

This topic describes how to install KVStore for Redis .NET SDK.

You can install the .NET SDK in any of the following methods:

- Add a DLL reference
 1. Download the compressed package that contains a DLL file from [Developer Resources](#), and decompress the package to obtain the DLL file.
 2. Right-click your project in the Solution Explorer of Visual Studio and select **Reference**.
 3. In the menu that appears, click **Add Reference**.
 4. In the dialog box that appears, click **Browse**, select the downloaded DLL file, and then click **Confirm**.
- Add a project reference
 1. Download the source code of the .NET SDK from [Apsara Stack official website](#).
 2. Find the aliyun-net-openapi-XXX subfolder in the downloaded folder, and then locate the `\\*.csproj` file. This is the .NET project file. For example, the `aliyun-net-openapi-r-kvstore` subfolder contains the `aliyun-net-sdk-r-kvstore.csproj` file.
 3. In Visual Studio, right-click your solution.
 4. Choose **Add > Existing Projects**.
 5. In the dialog box that appears, select the corresponding .NET project file from downloaded source code, such as `aliyun-net-sdk-ecs.csproj`, and click **Open**.
 6. Right-click your project and choose **Reference > Add Reference**.

2.9.2.5.2.2 Configure authentication credentials

To use Alibaba Cloud SDKs to access Apsara Stack resources, you must provide an authorized Alibaba Cloud account to verify your identity.

The .NET SDK supports identity verification based on AccessKey pairs. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

To use an AccessKey pair as the credential, you must configure your credential when you initialize the client.

**Notice:**

Do not disclose any code containing your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your Alibaba Cloud account may be compromised.

```
IClientProfile clientProfile = DefaultProfile.GetProfile(
    "<your-region-id>", // The ID of the region where your instance is located.
    "<your-access-key-id>", // The AccessKey ID of your account.
    "<your-access-key-secret>"); // The AccessKey Secret of your account.
```

2.9.2.5.2.3 Make API requests

This topic describes how to use KVStore for Redis .NET SDK to make an API request.

1. Create a default client instance.

```
DefaultAcsClient client = new DefaultAcsClient(clientProfile);
```

2. Create a request.

The Request class is named in the following way: `${apiName}Request`. In this naming convention, `${apiName}` specifies the name of an API operation, such as `DescribeInstances`.

When you use multiple service SDKs, different requests may have the same class name. Distinguish the requests by service package.

```
DescribeInstancesRequest request = new DescribeInstancesRequest();
```

```
request.PageSize = 10;
```

3. Initiate the request and process the response.

```
DescribeInstancesResponse response = client.GetAcsResponse(request);
```

All the returned fields are deserialized into the response. You can directly use `response`. `getXXX()` to obtain the fields in the response.

```
System.Console.WriteLine(response.TotalCount);
```

2.9.2.5.2.4 Process errors

When you use Alibaba Cloud .NET SDK, if an error occurs in your application server or in the .NET SDK, the SDK returns the corresponding error. The error contains error details, such as an error code and an error message.

You do not need to process SDK errors. You only need to process server errors according to server error messages.

- `ServerException` indicates a server error.
- `ClientException` indicates an SDK error.

For example, if the following error occurs, you can modify the AccessKey ID according to the error message.

```
InvalidAccessKeyId.NotFound : Specified access key is not found.
```

If you need to process .NET SDK errors, write your code as follows:

```
try
{
    CreateInstanceResponse response = client.GetAcsResponse(request);
    // Process the response.
    // ...
}
catch (ServerException e)
{
    // Add your logic that you use to process the error here.
    // For example, print the error message when the error occurs.
    Console.WriteLine("ErrorCode=" + e.ErrorCode);
    Console.WriteLine("ErrorMessage=" + e.ErrorMessage);
    // If the problem persists, you can submit a ticket and provide the request ID to request
    technical support.
    Console.WriteLine("ErrorCode=" + e.RequestId);
}
catch (ClientException e)
{
    // Add your logic that you use to process the error here.
    // For example, print the error message when the error occurs.
    Console.WriteLine("ErrorCode=" + e.ErrorCode);
    Console.WriteLine("ErrorMessage=" + e.ErrorMessage);
}
```

```
}
```

2.9.2.5.2.5 Use CommonRequest to make a request

If no SDK is available when you want to call an API operation of a service, you can make a request by using CommonRequest. CommonRequest allows you to call any API operations.

Benefits

CommonRequest has the following benefits:

1. **Lightweight:** you only need to download the core package. You do not need to download and install any SDK.
2. **Easy to use:** you can use the latest API operations without updating the corresponding SDK.
3. **Efficient iteration.**

Use CommonRequest to call an API operation

To make a CommonRequest request, you must obtain the values of the following parameters. You can obtain these values from the API documents.

- **Domain:** the endpoint of your service.
- **Version:** the version of the target API in the format of YYYY-MM-DD.

You can obtain the API version from the common parameters in the API documents.

- **Parameters of an API operation:** the name of the operation that you want to call.

You must obtain the **Action** parameter and specify the API operation name by using `request.ApiName = "<Action>"`.

To initiate a CommonRequest request for **Runinstances**, you must specify the API operation name by using `request.ApiName = "RunInstances"`.

You must obtain the **PathPattern** parameter and specify the RESTful path by using `request.PathPattern = "<PathPattern>"`.

For example, the **PathPattern** parameter of the API operation for querying all cluster instances is set to `/clusters`. When you initiate a CommonRequest request, you must specify the RESTful path by using `request.PathPattern = "/clusters"`.

Example: call an RPC API operation

The following example shows how to use CommonRequest to call the **DescribeInstances** API operation of KVStore for Redis:

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.Core.Profile;

class Sample
{
    static void Main(string[] args)
    {
        // Create a client instance to initiate a request.
        IClientProfile profile = DefaultProfile.GetProfile(
            "<your-region-id>",
            "<your-access-key-id>",
            "<your-access-key-secret>");
        DefaultAcsClient client = new DefaultAcsClient(profile);

        try
        {
            // Create a request.
            CommonRequest request = new CommonRequest();
            request.Domain = "r-kvstore.aliyuncs.com";
            request.Version = "2015-01-01";

            // You must specify a value for the ApiName(Action) parameter, because this is
            // an RPC API operation.
            request.Action = "DescribeInstances";
            request.AddQueryParameters("PageNumber", "1");
            request.AddQueryParameters("PageSize", "30");

            // Initiate the request and obtain the response.
            CommonResponse response = client.GetCommonResponse(request);
            System.Console.WriteLine(response.Data);
        }
        catch (ServerException ex)
        {
            System.Console.WriteLine(ex.ToString());
        }
        catch (ClientException ex)
        {
            System.Console.WriteLine(ex.ToString());
        }
    }
}
```

Example: call a RESTful API operation

The following example shows how to use CommonRequest to call the operation of KVStore for Redis to query all cluster instances.

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.Core.Profile;

class Sample
{
    static void Main(string[] args)
```

```
{
    // Create a client instance to initiate a request.
    IClientProfile profile = DefaultProfile.GetProfile(
        "<your-region-id>",
        "<your-access-key-id>",
        "<your-access-key-secret>");
    DefaultAcsClient client = new DefaultAcsClient(profile);

    try
    {
        // Create a request.
        CommonRequest request = new CommonRequest();
        request.Domain = "r-kvstore.aliyuncs.com";
        request.Version = "2015-01-01";

        // You must specify a value for the UriPattern parameter, because this is a
        Restful API operation.
        request.UriPattern = "/clusters";

        // Initiate the request and obtain the response.
        CommonResponse response = client.GetCommonResponse(request);
        System.Console.WriteLine(response.Data);
    }
    catch (ServerException ex)
    {
        System.Console.WriteLine(ex.ToString());
    }
    catch (ClientException ex)
    {
        System.Console.WriteLine(ex.ToString());
    }
}
```

2.9.2.5.2.6 Common errors

This topic lists the causes and solutions for some common errors you may encounter when you use the SDK.

Error code	Cause	Solution
SDK.InvalidRegionId	The error message returned because the SDK failed to automatically obtain the endpoint of the requested service in the specified region.	Check whether the specified endpoint is correct.
InvalidAccessKeyId.NotFound	The error message returned because the specified AccessKey ID was invalid.	Check whether your AccessKey ID is correct.

Error code	Cause	Solution
SDK.ConnectionReset	The error message returned because the endpoint was not accessible when you initiated a request.	Make sure that your network is available.
SDK.InvalidProfile	The error message returned because the DefaultProfile parameter that you provided when initializing DefaultAcsClient was invalid.	Make sure that the DefaultProfile parameter object that you provide has been properly initialized and had the corresponding parameters configured.
SDK.SessionTokenExpired	The error message returned because the DefaultProfile parameter that you provided when initializing DefaultAcsClient was invalid.	Make sure that the SessionToken parameter is valid. The validity period of this parameter is one hour.
SignatureDoesNotMatch	The error message returned because the SessionToken you provided was invalid or expired.	Make sure that the DefaultProfile parameter object that you provide has been properly initialized and had the corresponding parameters configured.
SDK.InvalidProfile	The error message returned because the AccessKey Secret did not match the AccessKey ID.	Make sure that the AccessKey Secret is valid.

2.9.2.6 Obtain an AccessKey pair

You can obtain the AccessKey pair on the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.

2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.9.2.7 Obtain an endpoint

You can obtain the product endpoint in Apsara Stack Operations.

Procedure

1. Log on to the Apsara Stack Operations console.

For more information about how to log on to the console, see Operations and Maintenance Guide. Specifically, navigate in the guide as follows: **Operations of basic platforms > Apsara Stack Operations (ASO) > Log on to Apsara Stack Operations**.

2. In the left-side navigation pane, choose **Products > Product List > Apsara Stack O&M**.
3. Click **Apsara Infrastructure Management Framework** to go to the Apsara Infrastructure Management Framework console.
4. In the top navigation bar, choose **Operations > Machine Operations** to go to the **Machine Operations** page.

2.10 ApsaraDB for MongoDB

2.10.1 List of operations by function

2.10.1.1 Lifecycle management

API	Description
CreateDBInstance	Creates a replica set instance.
ModifyDBInstanceSpec	Modifies specifications for a replica set instance.
DeleteDBInstance	Releases a replica set instance.
RenewDBInstance	Renews a replica set instance.

2.10.1.2 Instance management

API	Description
DescribeRegions	Queries the list of available regions.
DescribeDBInstances	Queries the list of instances.
RestartDBInstance	Restarts an instance.
ModifyDBInstanceMaintainTime	Modifies the maintenance time of an instance.
ModifyDBInstanceDescription	Modifies the description of an instance.
DescribeDBInstanceAttribute	Queries the details of an instance.
ModifyDBInstanceNetworkType	Modifies the network type of an instance.
ModifyDBInstanceNetExpireTime	Prolongs the retention period of the classic network endpoint.

2.10.1.3 Account management

Operation	Description
DescribeAccounts	Queries accounts.
ResetAccountPassword	Resets the password of an account.

2.10.1.4 Database security management

API	Description
DescribeSecurityIps	Queries the IP address whitelist for an instance.

API	Description
ModifySecurityIps	Modifies the IP address whitelist for an instance.
DescribeAuditRecords	Queries audit logs.
DescribeAuditFiles	Queries audit log files.

2.10.1.5 Backup and restoration management

API	Description
DescribeBackupPolicy	Queries a backup policy.
ModifyBackupPolicy	Modifies a backup policy.
CreateBackup	Creates a backup.
DescribeBackups	Queries the list of backups.
RestoreDBInstance	Restores a backup set to an instance.

2.10.1.6 Monitoring alert management

API	Description
DescribeDBInstancePerformance	Queries the instance performance data.

2.10.2 Make API requests

2.10.2.1 Request structure

Endpoints

The service endpoint of ApsaraDB for MongoDB APIs is `mongodb.example.com`.

Protocols

You can send requests over HTTP or HTTPS. We recommend that you use HTTPS for enhanced security.

Methods

The HTTP GET method can be used to send requests. Request parameters must be included in the request URL.

Parameters

Each request must specify the action to be performed (such as CreateDBInstance) in the Action parameter. Each action must include both the common request parameters that are used for all API requests as well as the specific request parameters of the API being called.

Encoding

Requests and responses are encoded in UTF-8.

2.10.2.2 Common parameters

Common request parameters must be included in the request of each API.

2.10.2.2.1 Common request parameters

Request parameters

Parameter	Type	Required	Description
Format	String	Yes	The format of the returned data. Valid values: JSON and XML . Default value: XML.
Version	String	Yes	The API version, in the format of YYYY-MM-DD. The current version is 2015-12-01.
AccessKeyId	String	Yes	The AccessKey ID provided by Alibaba Cloud for you to access services.
Signature	String	Yes	The signature result string. For more information about signature calculation methods, see the "Sign signatures" topic .
SignatureMethod	String	Yes	The algorithm used to create the request signature. Valid value : HMAC-SHA1.

Parameter	Type	Required	Description
Timestamp	String	Yes	The request timestamp. The timestamp uses UTC and complies with the ISO8601 standard . The format is YYYY-MM-DDThh:mm:ssZ . Example: 2016-01-01T12:00:00Z.
SignatureVersion	String	Yes	The signature algorithm version. The current version is 1.0.
SignatureNonce	String	Yes	A unique, randomly generated number used to prevent network replay attacks. You must use a different random number for each request.

Examples

```
https://mongodb.example.com/  
? Format=json  
&Version=2015-12-01  
&Signature=Pc5WBxxxxxxxx  
&SignatureMethod=HMAC-SHA1  
&SignatureNonce=15215528852396  
&SignatureVersion=1.0  
&AccessKeyId=key-test  
&Timestamp=2016-01-01T12:00:00Z
```

2.10.2.2.2 Common response parameters

The system returns a unique RequestId for each API request, regardless of whether the API operation is successful.

Examples

```
<? xml version="1.0" encoding="utf-8"? >  
<!--Result root node-->  
<API name + response>  
<!--Returned request tag-->
```

```
<RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
<!--Response-->
</API name + response>
```

2.10.2.2.2.1 Responses

The response data for API requests is displayed in a uniform format. In the response data, HTTP status code 2xx indicates that the API operation is successful. HTTP status code 4xx or 5xx indicates that the API operation fails. The response data for called API operations is returned in either the XML or JSON format. You can add parameters to an API request to specify the format of the response data. Response data uses the XML format by default. The response examples in this topic are formatted with line breaks or indents for a clear view. Actual response data is not formatted in the same manner as these examples.

2.10.2.2.2.1.1 Successful response examples

Responses in the XML format include information about whether the operation is successful, and details specific to the operation. Examples:

```
<? xml version="1.0" encoding="utf-8"? >
<!--Result root node-->
<API name + response>
<!--Returned request tag-->
<RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
<!--Response-->
</API name + response>
```

JSON format

```
{
  "RequestId": "4C4fdsf38-3910-447D-87AD-AC078932216",
  /* Response */
}
```

2.10.2.2.2.1.2 Error response examples

If you experience an error when calling APIs, no response data is returned. You can locate the cause of the error on the server by referring to Appendix Error codes. When an error occurs on an HTTP request for an API operation, HTTP status code 4xx or 5xx is returned. The response body contains the error code, the error message, a globally unique request ID (RequestId), and the ID of the site accessed by the request (HostId).

You can contact Alibaba Cloud customer service when the cause of the error cannot be found. We recommend that you provide the HostId and RequestId of the request to help us resolve the issue at the earliest opportunity.

Examples:

```
<? xml version="1.0" encoding="UTF-8"? >
```

```
<Error>
<RequestId>8906582E-6722-409A-A6C4-0E7863B733A5</RequestId>
<HostId>mongodb.example.com</HostId>
<Code>UnsupportedOperation</Code>
<Message>The specified action is not supported. </Message>
</Error>
```

JSON format

```
{
  "RequestId": "7463B73D-35CC-4D19-A010-6B8D65D242EF",
  "HostId": "mongodb.example.com",
  "Code": "UnsupportedOperation",
  "Message": "The specified action is not supported."
}
```

2.10.2.3 Sign signatures

ApsaraDB for MongoDB authenticates the sender identity of each request that it receives. Therefore, you must include a signature in HTTP or HTTPS requests. ApsaraDB for MongoDB performs symmetric encryption to verify the request sender's identity by using the AccessKey ID and AccessKey Secret. The AccessKey ID and AccessKey Secret are officially issued to visitors by Alibaba Cloud. Visitors can apply for and manage them on the official Alibaba Cloud website. The AccessKey ID indicates the identity of the visitor. The AccessKey Secret is used by the client to encrypt signature strings and used by the server to verify signature strings. You must keep your AccessKey Secret confidential. Perform the following steps to sign an access request:

1. Use request parameters to construct a canonicalized query string.
 - a. To construct a canonicalized query string, sort all request parameters by name in alphabetic order. These parameters include common request parameters and customized API request parameters , but do not include the Signature parameter.

Notice:

If a request is submitted using the GET method, these parameters are placed in the request section after a question mark (?) in the request URI and connected with ampersands (&).

- b. Encode the name and value of each request parameter. Perform UTF-8 URL encoding on the names and values of each request parameter. The URL encoding rules are described as follows:
- Uppercase letters (A-Z), lowercase letters (a-z), digits (0-9), hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
 - Extended UTF-8 characters are encoded in the %XY%ZA... format. A space is encoded as %20, rather than the plus sign (+).

**Notice:**

Most libraries that support URL encoding, such as `java.net.URLEncoder`, comply with the MIME encoding rules of `application/x-www-form-urlencoded`. If this encoding method is used, replace the plus signs (+) in the encoded strings with %20, the asterisks (*) with %2A, and %7E with a tilde (~) to conform to the encoding rules.

- c. Connect the encoded parameter names and values with equal signs (=).
- d. Sort the equal sign-connected strings by their parameter names alphabetically and connect them with ampersands (&).
2. Use the created canonicalized query string to construct a string for signature calculation based on the following rules:

```
StringToSign=
HTTPMethod + "&" +
percentEncode("/") + "&" +
percentEncode(CanonicalizedQueryString)
```

In the preceding example, `HTTPMethod` indicates the HTTP method that is used to submit a request, such as GET. `percentEncode("/")` is the encoded value ("%2F") of a forward slash (/). The encoding follows the URL encoding rules described in the previous step. `percentEncode(CanonicalizedQueryString)` is the string constructed using the canonicalized query string. The encoding follows the URL encoding rules described in the previous step.

3. Use the signature string to calculate the HMAC value of the signature as defined by RFC 2104.

**Notice:**

The key used for signature calculation is your AccessKey Secret with an ampersand (&) added at the end. The corresponding number of an ampersand (&) is 38 in ASCII codes. The string is then hashed with the SHA1 hash algorithm.

4. Encode the HMAC value into a string based on the Base64 encoding rules. This encoded string is the signature value.
5. Add the signature value as the Signature parameter value to the request parameters to complete the request signing process.

**Notice:**

When the obtained signature value is submitted to the RDS server as the final request parameter value, the value must undergo URL encoding based on RFC 3986 rules like other parameters.

DescribeCdnService is used here as an example. The request URL before signing is:

```
http://mongodb.example.com/?Timestamp=2016-01-01T10:33:56Z&Format=XML
&AccessKeyId=testid&Action=DescribeInstances&SignatureMethod=HMAC-SHA1&
RegionId=region1&SignatureNonce=NwDaxvLU6tFE0DVb&Version=2015-12-01&
SignatureVersion=1.0
```

The StringToSign placed after the signature is as follows:

```
GET&%2F&AccessKeyId%3Dtestid&Action%3DDescribeInstances&Format%3DXML
&RegionId%3Dregion1&SignatureMethod%3DHMAC-SHA1&SignatureNonce%
3DNwDaxvLU6tFE0DVb&SignatureVersion%3D1.0&Timestamp%3D2013-06-01T10%
253A33%253A56Z&Version%3D2015-01-01
```

Assume that the AccessKey ID is testid, the AccessKey Secret is testsecret, and the Key used for HMAC calculation is testsecret&. The calculated signature value is as follows:

BIPOMlu8LXBeZtLQkJTw6iFvw1E=

The signed request URL with the Signature parameter added is as follows:

```
http://mongodb.example.com/?TimeStamp=2016-01-01T10%3A33%3A56Z&Format
=XML&AccessKeyId=testid&Action=DescribeInstances&SignatureMethod=HMAC-SHA1
```

```
&RegionId=region1&SignatureNonce=NwDAXvLU6tFE0DVb&SignatureVersion=1.0&Version=2015-12-01&Signature=Pc5WBxxxxxxx
```

2.10.3 Lifecycle management

2.10.3.1 CreateDBInstance

2.10.3.1.1 Description

- This API supports replica set instances only.
- This API supports both data restoration and instance clone functions.

2.10.3.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateDBInstance.
RegionId	String	Yes	The region ID of the instance. It can be up to 50 characters in length. You can call the DescribeRegions operation to query the latest region list.
ZoneId	String	No	The zone ID of the instance. You can call the DescribeRegions operation to query the latest zone list.
Engine	String	Yes	The type of the database. Set the value to MongoDB.
EngineVersion	String	Yes	The version of the database. Set the value to 3.2.
StorageEngine	String	No	The storage engine. Valid values: WiredTiger and RocksDB. Default value: WiredTiger.
DBInstanceClass	String	Yes	The specifications of the instance. For more information, see Instance specifications.
DBInstanceStorage	Integer	Yes	The custom storage space. Valid values : 5 to 1000 for ApsaraDB for MongoDB instances. You can only specify this value in 5 GB increments. Unit: GB.
DBInstanceDescription	String	No	The description of the instance. This parameter must be 2 to 256 characters in length. It must start with a letter and can contain letters, digits, underscores (_), and hyphens (-).

Parameter	Type	Required	Description
SecurityIPList	String	No	The IP addresses in an IP address whitelist . Separate multiple IP addresses with commas (,). You can add a maximum of 1 ,000 different IP addresses to a whitelist. Supported formats of IP addresses are IP addresses such as %, 0.0.0.0/0 and 10.23 .12.24 or Classless Inter-Domain Routing (CIDR) blocks such as 10.23.12.24/24. / 24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits. 0.0.0.0/0 indicates that all IP addresses are allowed. Default value: 0.0.0 .0/0.
AccountPassword	String	No	The password of the root account. The password must be 6 to 32 characters in length and can contain letters, digits, and underscores (_).
ChargeType	String	No	The billing method of the instance. Valid values: PrePaid and PostPaid. PrePaid: subscription. PostPaid: pay-as-you-go. Default value: PostPaid.
Period	Integer	No	The expiration time of a subscription instance. This parameter must be specified when ChargeType is set to PrePaid. Valid values: 1, 2, 3, 4, 5, 6, 7, 8, 9, 12, 24, and 36 . Unit: month.
ClientToken	String	Yes	The client token that is used to ensure idempotence of the request. The value of this parameter is generated by the client and is unique among different requests. The maximum length is 64 ASCII characters . For more information, see How to ensure idempotence.
NetworkType	String	No	The network type of the instance. Valid values: Classic and VPC. Default value: Classic.
VpcId	String	No	The ID of the VPC. If NetworkType is set to VPC, this parameter is required.
VSwitchId	String	No	The ID of the VSwitch. If NetworkType is set to VPC, this parameter is required.

Parameter	Type	Required	Description
DBInstanceId	String	No	The ID of the source instance. This parameter can only be specified when this operation is called to clone instances.
BackupId	String	No	The ID of the specified backup set.
RestoreTime	String	No	The time when the cloned instance is restored.

2.10.3.1.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.
DBInstanceCid	String	The ID of the instance to be queried.
OrderId	String	The ID of an order.

2.10.3.2 ModifyDBInstanceSpec

2.10.3.2.1 Description

This API supports replica set instances only.

2.10.3.2.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceSpec.
DBInstanceCid	String	Yes	The ID of the instance whose configuration is to be modified.

Parameter	Type	Required	Description
DBInstanceClass	String	No	The specifications of the instance. For more information, see Appendix Instance specifications.
OrderType	String	No	The type of the configuration change. Valid values: UPGRADE and DOWNGRADE. Default value: DOWNGRADE. This parameter is applicable to subscription instances only.
DBInstanceStorage	Integer	No	The storage capacity of the instance. Valid values: 5 to 1,000. Unit: GB. The value can be increased in increments of 5 GB.

2.10.3.2.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.
OrderId	String	The ID of an order.

2.10.3.3 DeleteDBInstance

2.10.3.3.1 Description

This API supports replica set instances only.

2.10.3.3.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DeleteDBInstance.
DBInstanceCld	String	Yes	The ID of the instance to be deleted.

2.10.3.3.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.3.4 RenewDBInstance

2.10.3.4.1 Description

This API supports replica set instances only.

2.10.3.4.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to RenewDBInstance.
DBInstanceCld	String	Yes	The ID of the instance to be renewed.
Period	Integer	Yes	The renewal period of the instance. Valid values: 1, 2, 3, 4, 5, 6, 7, 8, 9, 12, 24, and 36.

Parameter	Type	Required	Description
ClientToken	String	Yes	The token used to guarantee the idempotence of requests.

2.10.3.4.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.
OrderId	String	The ID of an order.

2.10.4 Instance management

2.10.4.1 DescribeRegions

2.10.4.1.1 Description

This API supports replica set instances only.

2.10.4.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeRegions.
RegionId	String	No	The ID of the region to be queried.
ZoneId	String	No	The ID of the zone in the target region.

2.10.4.1.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.4.1.3.1 Region data structure

Parameter	Type	Description
RegionId	String	The ID of the region where an instance resides, such as cn-beijing.
Zones	List<Zones>	The list of zones.

2.10.4.1.3.2 Zones

Parameter	Type	Description
ZoneId	String	The ID of the zone, such as cn-beijing-a.
VpcEnabled	String	Indicates whether the VPC is available.

2.10.4.2 DescribeDBInstances

2.10.4.2.1 Description

This API supports replica set instances only.

2.10.4.2.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeDBInstances .
RegionId	String	Yes	The ID of the region where an instance resides. You can use the DescribeRegions function to view available regions.
Engine	String	No	The database type of the instance. Valid value: MongoDB.

Parameter	Type	Required	Description
DBInstanceType	String	No	The queried instance type. Valid values : sharding and replicate. Default value: replicate.
PageSize	Integer	No	The number of records on each page. Valid values : 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The page number to request, which must be any integer greater than 0. Default value: 1.

2.10.4.2.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.
DBInstances	List<DBInstance>	The array consisting of ApsaraDB for MongoDB instances.

2.10.4.2.3.1 DBInstance data structure

Parameter	Type	Description
DBInstanceCld	String	The ID of the instance.
DBInstanceDescription	String	The description of the instance.
RegionId	String	The region ID of the instance .
Zoneld	String	The zone ID of the instance.
Engine	String	The database type of the instance.
EngineVersion	String	The database version of the instance.

Parameter	Type	Description
DBInstanceClass	String	The specifications of the instance.
DBInstanceStorage	Integer	The storage capacity of the instance.
DBInstanceStatus	String	The status of the instance. For more information, see Instance states.
ChargeType	String	The billing method of the instance. Valid values: PrePaid and PostPaid. PrePaid: subscription. PostPaid: pay-as-you-go.
NetworkType	String	The network type of the instance. Valid values: Classic and VPC.
CreationTime	String	The time when the instance was created. The time is in the yyyy-MM-ddTHH:mm:ssZ format and displayed in UTC.
ExpireTime	String	The time that the instance is scheduled to expire.
DBInstanceType	String	The instance type. Valid values: sharding and replicate.
MongosList	List<Mongos>	The array that consists of mongos nodes.
ShardList	List<Shard>	The array that consists of shard nodes.
LastDowngradeTime	Integer	The time of the last configuration downgrade.

2.10.4.2.3.2 Mongos

Parameter	Type	Description
NodeId	String	The ID of a mongos node.
NodeDescription	String	The description of the mongos node.

Parameter	Type	Description
NodeClass	String	The specifications of the mongos node.

2.10.4.2.3.3 Shard

Parameter	Type	Description
NodeId	String	The ID of a shard node.
NodeDescription	String	The description of the shard node.
NodeClass	String	The specifications of the shard node.
NodeStorage	Integer	The storage capacity of the shard node.

2.10.4.3 RestartDBInstance

2.10.4.3.1 Description

This API supports replica set instances only.

2.10.4.3.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to RestartDBInstance.
DBInstanceIdentifier	String	Yes	The ID of the instance to be restarted.

2.10.4.3.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.4.4 ModifyDBInstanceMaintainTime

2.10.4.4.1 Description

This API supports replica set instances only.

2.10.4.4.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceMaintainTime.
DBInstanceID	String	Yes	The ID of the instance for which to modify maintenance time.
StartTime	String	Yes	The start time of the maintenance period.
EndTime	String	Yes	The end time of the maintenance period.

2.10.4.4.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.4.5 ModifyDBInstanceDescription

2.10.4.5.1 Description

This API supports replica set instances only.

2.10.4.5.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyDBInstanceDescription.

Parameter	Type	Required	Description
DBInstanceCld	String	Yes	The name of the instance.
DBInstanceDescription	String	Yes	The description of the instance. • The description cannot start with http:// or https://. • It must start with a letter. • It must be 2 to 256 characters in length and can contain letters, underscores (_), hyphens (-), and digits.

2.10.4.5.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.4.6 DescribeInstanceAttribute

2.10.4.6.1 Description

This API supports replica set instances only.

2.10.4.6.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDB InstanceAttribute.

Parameter	Type	Required	Description
DBInstanceCid	String	Yes	The ID of one or more instances to be queried. You can enter a maximum of 30 IDs at a time. Separate multiple IDs by using commas (,).

2.10.4.6.3 Response parameters

2.10.4.6.3.1 DBInstance parameters

Parameter	Type	Description
DBInstanceCid	String	The ID of the instance to be queried.
DBInstanceDescription	String	The description of the instance.
RegionId	String	The ID of the region where the instance resides.
ZonId	String	The ID of the zone to which the instance belongs.
Engine	String	The database type of the instance.
EngineVersion	String	The database version of the instance.
DBInstanceClass	String	The specifications of the instance.
DBInstanceStorage	String	The storage capacity of the instance.
DBInstanceStatus	String	The status of the instance. For more information, see Appendix Instance statuses.
ChargeType	String	The billing method of the instance. Valid values: PrePaid and PostPaid.
ReplicaSetName	String	The name of the replica set for the instance.

Parameter	Type	Description
CreationTime	String	The time when the instance is created.
ExpireTime	String	The time that the instance is scheduled to expire. Pay-As-You-Go instances never expire.
MaintainStartTime	String	The start time of instance maintenance.
MaintainEndTime	String	The end time of instance maintenance.
NetworkType	String	The network type of the instance. Valid values: Classic and VPC.
DBInstanceType	String	The instance type. Valid values: sharding and replicate.
LastDowngradeTime	Integer	The time of the most recent configuration downgrade.

2.10.4.7 DescribeReplicaSetRole

2.10.4.7.1 Description

This API supports replica set instances only.

2.10.4.7.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeReplicaSetRole.
DBInstanceId	String	Yes	The ID of the instance to be queried.

2.10.4.7.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.
DBInstanceCld	String	The ID of the instance to be queried.
ReplicaSets	List<ReplicaSet>	The list of replica set roles.

2.10.4.7.3.1 ReplicaSetRole data structure

Parameter	Type	Description
ReplicaSetRole	String	The role of the replica set instance node. Valid values: Primary and Secondary.
ConnectionDomain	String	The domain name used to connect the instance.
ConnectionPort	String	The port used to connect the instance.
ExpiredTime String	String	The remaining duration of the classic network address of the current instance. Unit: seconds.
NetworkType	String	The network type of the instance. • VPC • Classic • Public
ReplicaSets	List<ReplicaSet>	A list of roles that belong to the replica set instance node.

2.10.4.8 ModifyDBInstanceNetworkType

2.10.4.8.1 Description

This API supports replica set instances only.

2.10.4.8.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceNetworkType.
DBInstanceCid	String	Yes	The ID of the instance for which you want to modify the network type.
RetainClassic	String	No	Indicates whether to retain the classic network endpoint . Valid values: True and False.
ClassicExpiredDays	Integer	No	The retention period of the classic network endpoint. Unit: day. Maximum value: 180. When RetainClassic is set to True, this parameter must be specified.
VpcId	String	No	The ID of the VPC to which the instance belongs. This parameter must be specified if you are changing the network type of an instance from classic network to VPC.
VSwitchId	String	No	The ID of the VSwitch . This parameter must be specified if you are changing the network type of an instance from classic network to VPC.

2.10.4.8.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.4.9 ModifyDBInstanceNetExpireTime

2.10.4.9.1 Description

This API supports replica set instances only.

2.10.4.9.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceNetExpireTime.
DBInstanceCld	String	Yes	The ID of the instance for which the endpoint expiration time is to be modified.
ConnectionString	String	Yes	The domain name used to connect to the instance.
ClassicExp endExpiredDays	Integer	Yes	The number of days for which the classic network endpoint is retained.

2.10.4.9.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.5 Account management

2.10.5.1 ResetAccountPassword

2.10.5.1.1 Description

This API supports replica set instances only.

2.10.5.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ResetAccountPassword.
DBInstanceCld	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account.
AccountPassword	String	Yes	The new password . It must be 6 to 32 characters in length and can contain letters, digits, and underscores (_).

2.10.5.1.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.5.2 DescribeAccounts

2.10.5.2.1 Description

This API supports replica set instances only.

2.10.5.2.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeAccounts.
DBInstanceid	String	Yes	The ID of the instance to be queried.
AccountName	String	Yes	The name of the account used to access the instance.

2.10.5.2.3 Response parameters

Parameter	Type	Description
Accounts	List<Account>	The array consisting of accounts.

2.10.5.2.3.1 Account data structure

Parameter	Type	Description
DBInstanceid	String	The ID of the instance.
AccountName	String	The name of the account.
AccountStatus	String	The status of the account. Valid values: Unavailable and Available.
AccountDescription	String	The description of the account.

2.10.5.3 ModifyAccountDescription

2.10.5.3.1 Description

This API supports replica set instances only.

2.10.5.3.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAccountDescription.
DBInstanceID	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account.
AccountDescription	String	Yes	The description of the account. • The description cannot start with http:// or https://. • It must start with a letter. • It must be 2 to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-).

2.10.5.3.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.6 Database security management

2.10.6.1 DescribeSecurityIps

2.10.6.1.1 Description

This API supports replica set instances only.

2.10.6.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeSecurityIps.
DBInstanceCld	String	Yes	The ID of the instance to be queried.

2.10.6.1.3 Response parameters

Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see Common response parameters.
SecurityIps	String	The default whitelist.
SecurityIpGroups	List<SecurityIpGroup>	The list of IP address groups.

SecurityIpGroup parameters

Parameter	Type	Description
SecurityIpGroupName	String	The name of the IP whitelist.
SecurityIpList	String	The list of IP addresses.
SecurityIpAttribute	String	The attribute of the IP whitelist. The default value is an empty string.

2.10.6.2 ModifySecurityIps

2.10.6.2.1 Description

This API supports replica set instances only.

2.10.6.2.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifySecurityIps.
DBInstanceCld	String	Yes	The ID of the instance.
SecurityIps	String	Yes	The IP addresses in an IP address whitelist. Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats of IP addresses are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or Classless Inter-Domain Routing (CIDR) blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.
ModifyMode	String	Yes	The modification mode. Valid values: - Cover, - Add, and - Delete.
SecurityIp GroupName	String	No	The name of the group to be modified . Default value: default.

Parameter	Type	Required	Description
SecurityIpGroupAttribute	String	No	The attribute of the IP address group. Default value: null.

2.10.6.2.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.6.3 DescribeAuditRecords

2.10.6.3.1 Description

This API supports replica set instances only.

2.10.6.3.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAuditRecords.
DBInstanceId	String	Yes	The ID of the instance.
NodeId	String	No	The ID of mongos or shard. If this parameter is not specified, no result is returned. You do not need to specify this parameter for nodes of replica set instances.

Parameter	Type	Required	Description
StartTime	String	Yes	The beginning of the time range to query. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC.
EndTime	String	Yes	The end of the time range to query. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC.
Database	String	No	The database to be queried. By default , all databases are queried.
User	String	No	The username to be queried. By default, all users are queried.
Form	String	No	The file or stream to be downloaded . If you set this parameter to File , only common parameters are returned. In this case, you need to call the DescribeSQLLogFiles operation to obtain the final URL to download the file. If you set this parameter to Stream , the data stream is returned. Default value: Stream.

Parameter	Type	Required	Description
QueryKeywords	String	No	The keywords used for a query. Use spaces to separate multiple keywords . You can specify a maximum of 10 keywords.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Valid values: any non-zero positive integer . Default value: 1.

2.10.6.3.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see Common response parameters.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the current page.
PageRecordCount	Integer	The number of SQL logs on the current page.
Items	List<SQLRecord>	The array that consists of SQLRecord data.
TotalRecordCount	Integer	The total number of entries.

SQLRecord parameters

Parameter	Type	Description
DBName	String	The name of the database.
AccountName	String	The name of the account.

Parameter	Type	Description
HostAddress	String	The IP address of the client.
Syntax	String	The executed statement.
TotalExecutionTimes	Long	The amount of time taken to execute the operation. Unit: microseconds.
ReturnRowCounts	Long	The number of entries returned.
ExecuteTime	String	The execution time. The time is in the yyyy-MM-dd THH:mm:ssZ format and displayed in UTC.
ThreadID	String	The ID of the thread.
Node	String	The node on which the statement is executed. If you specify this parameter, the information about primary and secondary nodes is returned for a replica set instance, while for a sharded cluster instance the information about each mongos is returned.

2.10.6.4 DescribeAuditFiles

2.10.6.4.1 Description

This API supports replica set instances only.

2.10.6.4.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeAuditFiles.
DBInstanceId	String	Yes	The ID of the instance for which to describe audit files.

Parameter	Type	Required	Description
Nodeld	String	No	The ID of a mongos or shard node in a sharded cluster instance. If this parameter is not specified, both a mongos ID and a shard ID are displayed. This parameter cannot be used for replica set instances.

2.10.6.4.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see Common parameters.
TotalRecordCount	Integer	The total number of records.
PageNumber	Integer	The number of the current page.
PageRecordCount	Integer	The number of records on the current page.
Items	List<LogFile>	An array that consists of LogFile data.

LogFile parameters

Parameter	Type	Description
FileID	Integer	The ID of the file.
DBInstanceID	String	The name of the instance.
LogStatus String	String	Success: The log file is archived. - Failed: The log file failed to be archived. - Generating: The log file is being archived. - Initializing: Log archiving has not started yet.

Parameter	Type	Description
LogStartTime	String	The beginning of the time range where the log audit was executed.
LogEndTime	String	The end of the time range where the log audit was executed.
LogDownloadURL	String	The URL to download audit logs. If the download URL is unavailable, this parameter will be empty.
LogSize	Long	The size of the audit log file. Unit: Byte.

2.10.7 Backup and restoration management

2.10.7.1 DescribeBackupPolicy

2.10.7.1.1 Description

This API supports replica set instances only.

2.10.7.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBackupPolicy.
DBInstanceID	String	Yes	The ID of the instance for which to describe the backup policy.

2.10.7.1.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see Common parameters.

Parameter	Type	Description
BackupRetentionPeriod	String	The number of days for which backup files can be retained.
PreferredBackupTime	String	The period of time to execute backup. The format is HH:mmZ-HH:mm Z.
PreferredBackupPeriod	String	The time cycle to execute backup. Valid values: - Monday - Tuesday - Wednesday - Thursday - Friday - Saturday - Sunday

2.10.7.2 ModifyBackupPolicy

2.10.7.2.1 Description

This API supports replica set instances only.

2.10.7.2.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set this parameter to ModifyBackupPolicy.
DBInstanceID	String	Yes	The ID of the instance.
PreferredBackupTime	String	Yes	The period of time to execute backup. Specify the time in the HH:mmZ-HH:mmZ format.

Parameter	Type	Required	Description
PreferredBackupPeriod	String	Yes	The time cycle to execute backup. Valid values: - Monday - Tuesday - Wednesday - Thursday - Friday - Saturday - Sunday

2.10.7.2.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.7.3 CreateBackup

2.10.7.3.1 Description

This API supports replica set instances only.

2.10.7.3.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to CreateBackup.
DBInstanceID	String	Yes	The ID of the instance for which to create a backup.

2.10.7.3.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.
BackupId	String	The ID of a backup.

2.10.7.4 DescribeBackups

2.10.7.4.1 Description

This API supports replica set instances only.

2.10.7.4.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeBackups.
DBInstanceCld	String	Yes	The ID of the instance to be queried.
StartTime	String	Yes	The start time of data returned by a query. The format is YYYYMM-DD'T'HH:mmZ. Example: 2011-06-11T15:00Z.
EndTime	String	Yes	The end time of data returned by a query. The format is YYYYMM-DD'T'HH:mmZ. Example: 2011-06-11T16:00Z.
BackupId	Integer	No	The ID of a backup.

Parameter	Type	Required	Description
NodeId	String	No	The ID of a shard node. This parameter applies only to sharded cluster instances.
PageSize	Integer	No	The number of records on each page. Valid values : 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The page number to request, which must be any integer greater than 0. Default value: 1.

2.10.7.4.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see Common response parameters.
Items	List<Backup>	The array that consists of backups.
PageNumber	Integer	The number of the returned page.
TotalCount	Integer	The total number of backups .
PageSize	Integer	The number of entries returned per page.

Backup data structure

Parameter	Type	Description
BackupDBNames (TBD)	String	The list of databases in a backup set. Separate multiple databases with commas (,), such as "Db1,Db2,Db3...". It is used to check whether a full backup is performed.
BackupId	Integer	The ID of a backup.
BackupStatus	String	The status of the backup task. Valid values: • Success: The backup task is completed. • Failed: The backup task fails.
BackupStartTime	String	The beginning of the backup time range. The time is in the yyyy-MM-ddTHH:mm:ssZ format and displayed in UTC.
BackupEndTime	String	The end of the backup time range. The time is in the yyyy-MM-ddTHH:mm:ssZ format and displayed in UTC.
BackupType	String	The type of the backup. Valid values: • FullBackup • IncrementalBackup
BackupMode	String	The backup mode. Valid values: • Automated: indicates an automatic backup. • Manual: indicates a manual backup.

Parameter	Type	Description
BackupMethod	String	The method of the backup. Valid values: • Logical • Physical
BackupDownloadURL	String	The download URL of the backup file. If the download URL is unavailable, the value is an empty string.
BackupSize	Long	The size of the backup file. Unit: Byte.

2.10.7.5 RestoreDBInstance

2.10.7.5.1 Description

This API supports replica set instances only.

2.10.7.5.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to RestoreDBInstance.
DBInstanceCld	String	Yes	The ID of the instance to be queried. Only replica set instances are supported.
BackupId	String	Yes	The ID of a backup.

2.10.7.5.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see the "Common response parameters" topic.

2.10.8 Performance monitoring management

2.10.8.1 DescribeDBInstancePerformance

2.10.8.1.1 Description

This API supports replica set instances only.

2.10.8.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstancePerformance.
DBInstanceIdentifier	String	Yes	The ID of the instance.
StartTime	String	Yes	The beginning of the time range to query. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC.
EndTime	String	Yes	The end of the time range to query. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC.
ReplicaSetRole	String	Yes	The role of a replica set. Valid values : Primary and Secondary.
Key	String	Yes	The monitoring metrics for database performance. Separate multiple metrics with commas (,). For more information about the metrics, see Performance metrics.

2.10.8.1.3 Response parameters

Parameter	Type	Description
Common response parameters	-	For more information, see Common response parameters.
DBInstanceCld	String	The ID of the instance.
Engine	String	The database type of the instance.
StartTime	String	The beginning of the time range to query. The time is in the yyyy-MM-ddTHH:mm:ssZ format and displayed in UTC.
EndTime	String	The end of the time range to query. The time is in the yyyy-MM-ddTHH:mm:ssZ format and displayed in UTC.
PerformanceKeys	List<PerformanceKey>	The array that consists of performance metrics. It is in the {perf1, perf2, perf3, ...} format.

PerformanceKey parameters

Parameter	Type	Description
Key	String	The name of a metric.
Unit	String	The unit of a metric.
ValueFormat	String	The format of a value. • If a value is null, VALUE will be returned. • If multiple metrics return in the parameter value, these metrics will be separated with ampersands (&), such as com_delete&com_insert&com_insert_select&com_replace.

Parameter	Type	Description
Values	List<PerformanceValue>	The array that consists of the metric values. It is in the {value1, value2, ...} format.

PerformanceValue parameters

Parameter	Type	Description
Value	String	The value of a metric.
date	String	The calculation time. The time is in the yyyy-MM-dd THH:mm:ssZ format and displayed in UTC.

2.10.9 Appendix

2.10.9.1 Error codes

Description	Error code	Error message	HTTP status code
The error message returned because unauthorized users call the operation.	Forbidden.RAM	User not authorized to operate on the specified resource, or this API doesn't support RAM.	403
The error message returned because this operation is not available for RAM users.	Forbidden. NotSupportRAM	This action does not support accessed by RAM mode.	403
The error message returned because an exception or error occurs on the server.	ServiceUnavailable	The request has failed due to a temporary failure of the server.	503
The error message returned because the instance status that you specified does not exist.	InvalidStatus. NotFound	The Status provided does not exist in our records.	404

Description	Error code	Error message	HTTP status code
The error message returned because the specified value of the parameter is invalid.	InvalidParameter	The specified parameter "InstanceName" is not valid.	400
The error message returned because a normal user other than an administrator calls the management operation.	Forbidden. NotAdminUser	User not authorized to operate on the specified API as you are not the	403
The error message returned because the parameter is missing.	MissingParameter	Specified parameter is missing.	400
The error message returned because neither the InstanceName nor NewPassword parameter is specified.	MissingParameter	InstanceName /NewPassword at least one is mandatory for this action.	400
The error message returned because the OwnerId parameter is not specified.	MissingParameter	The input parameter "\$ParameterName" that is mandatory for processing this request is not supplied.	403
The error message returned because the specified Token parameter is invalid.	InvalidToken. Malformed	The Specified parameter \"Token\" is not valid.	400
The error message returned because the specified InstanceName parameter is invalid.	InvalidInstanceName. Malformed	The Specified parameter \"InstanceName\" is not valid.	400

Description	Error code	Error message	HTTP status code
The error message returned because the specified Password parameter is invalid.	InvalidPassword.Malformed	The Specified parameter \"Password\" is not valid.	400
The error message returned because the specified Instances parameter is invalid.	InvalidInstances.Malformed	The Specified parameter \"Instances\" is not valid.	400
The error message returned because the specified StartTime parameter is invalid.	InvalidStartTime.Malformed	The Specified parameter \"StartTime\" is not valid.	400
The error message returned because the specified EndTime parameter is invalid.	InvalidEndTime.Malformed	The Specified parameter \"EndTime\" is not valid.	400
The error message returned because the specified InstanceIds parameter is invalid.	InvalidInstanceIds.Malformed	The Specified parameter \"InstanceIds\" is not valid.	400
The error message returned because your balance is insufficient to perform the current operation.	InsufficientBalance	Your account does not have enough balance.	400
The error message returned because your account fails to pass the real-name authentication.	RealNameAuthenticationError	Your account has not passed the real-name authentication yet.	403
The error message returned because your instance quota has been exhausted.	QuotaExceed	Living afterpay instances quota exceeded.	400
The error message returned because the capacity configuration is invalid.	InvalidCapacity.NotFound	The Capacity provided does not exist in our records.	400

Description	Error code	Error message	HTTP status code
The error message returned because a different request uses a client token that was used for a previous request.	IdempotentParameterMismatch	Request uses a client token in a previous request but is not identical to that request.	400
The error message returned because the inventory of instances in the specified zone is insufficient.	QuotaNotEnough	Quota not enough in this zone.	400
The error message returned because you are not authorized to call the order-class API.	Forbidden.SubUser	The specified action is not available for you.	403
The error message returned because the Apsara Stack risk control system denies this access request.	Forbidden.RiskControl	This operation is forbidden by Aliyun Risk Control system.	403
The error message returned because the specified region does not exist.	InvalidRegion.NotFound	The RegionId or ZoneId provided does not exist in our records.	404
The error message returned because the specified ZoneId parameter is invalid.	InvalidZoneId.NotFound	The ZoneId provided is invalid.	400
The error message returned because the specified instance ID does not exist.	InvalidInstanceId.NotFound	The InstanceId provided does not exist in our records.	404
The error message returned because the password is incorrect.	IncorrectPassword	The Password provided is not correct.	400

Description	Error code	Error message	HTTP status code
The error message returned because the service is unavailable.	ServiceNotSupported	The specified service is not supported.	400
The error message returned because a renewal and configuration change order has not taken effect.	HasRenewChangeOrder	This instance has a renewChange order.	400
The error message returned because an internal error has occurred.	InternalServerError	The request processing has failed due to some unknown error.	500
The error message returned because the specified backup time is invalid.	InvalidPreferredBackupTime	Specified preferred backup time is not valid.	400
The error message returned because the specified backup type is invalid.	InvalidBackupType.Format	Specified backup type is not valid.	400
The error message returned because the specified backup method is invalid.	InvalidBackupMethod.Format	Specified backup method is not valid.	400
The error message returned because the backup task already exists.	BackupJobExists	A backup job already exists in the specified DB instance.	400
The error message returned because the maximum number of daily backup operations has been reached.	BackupTimesExceeded	Exceeding the daily backup times of this DB instance.	400

Description	Error code	Error message	HTTP status code
The error message returned because no parameters are specified.	ParameterLeastAssociate	Must input at least one optional parameter.	400
The error message returned because the specified backup period is invalid.	InvalidBackupRetentionPeriod.Malformed	Specified backup retention period is not valid.	400
The error message returned because the specified next backup time is invalid.	InvalidPreferredBackupTime.Format	Specified preferred backup time is not valid.	400
The error message returned because the specified backup period is invalid.	InvalidPreferredBackupPeriod.Malformed	Specified backup period is not valid.	400
The error message returned because the operation is not supported by the current instance type.	IncorrectDBInstanceType	Current DB instance type does not support this operation.	400
The error message returned because the specified key is invalid.	InvalidKey.Malformed	Specified key is not valid.	400
The error message returned because the nonce signature is used and cannot be used again.	SignatureNonceUsed	Specified signature nonce was used already.	400
The error message returned because no more virtual IP address can be assigned.	AllocateVpcIp.NotEnough	Ip resource is not enough	400

Description	Error code	Error message	HTTP status code
The error message returned because instances of the specified type cannot be created in the zone.	Zone.NotSupport	Specified zone does not support creating with instance class.	400
The error message returned because the code for the instance type is invalid.	MissingClassCode	Capacity or InstanceClass is mandatory for this action.	400
The error message returned because the specified instance type is not supported.	InvalidDBInstanceClass.NotFound	Specified DB instance class is not found.	404
The error message returned because the instance is locked.	IncorrectDBInstanceLockMode	Current DB instance lock mode does not support this operation.	400
The error message returned because the backup set ID does not exist.	InvalidBackupSetID.NotFound	Specified backup set ID does not exist.	400
The error message returned because the operation is not supported while the instance is in the current state.	IncorrectDBInstanceState	Current DB instance state does not support this operation.	400
The error message returned because the available resource capacity in the specified instance is insufficient.	InsufficientResourceCapacity	There is insufficient capacity available for the requested instance.	400
The error message returned because the specified end time is invalid.	InvalidEndTime.Format	Specified end time is not valid.	400

Description	Error code	Error message	HTTP status code
The error message returned because the duration for the reserved classic IP address is invalid.	InvalidClassicExpireDays.Format	The specified classicExpiredDays format is not valid.	400
The error message returned because the operation is not supported while the backup set is in the current state.	IncorrectBackupSetState	Current backup set state does not support operations.	400
The error message returned because the specified whitelist is not correct in format.	InvalidSecurityIPList.Format	Specified security IP list format is not valid.	400

2.11 AnalyticDB for PostgreSQL

2.11.1 API reference

2.11.1.1 List of operations by function

Table 2-386: Instance management

Operation	Description
CreateDBInstance	Creates an instance.
DeleteDBInstance	Deletes an instance.
DescribeDBInstanceAttribute	Lists all attributes of an instance.
DescribeDBInstances	Returns a list of instances.
DescribeRegions	Returns a list of available regions and zones.
DescribeResourceUsage	Returns the resource usage of an instance.
ModifyDBInstanceConnectionMode	Modifies the connection mode of an instance.
ModifyDBInstanceDescription	Modifies the description of an instance.

Operation	Description
ModifyDBInstanceMaintainTime	Modifies the maintenance period of an instance.
RestartDBInstance	Restarts an instance.
DescribeDBInstancePerformance	Returns the performance data of an instance.

Table 2-387: Database management

Operation	Description
DeleteDatabase	Deletes a database.
DescribeAccounts	Returns the account information of a database.
ModifyAccountDescription	Modifies the description of a database.

Table 2-388: Account management

Operation	Description
CreateAccount	Creates an account.
ResetAccountPassword	Resets the password of an account.

Table 2-389: Security management

Operation	Description
DescribeDBInstanceIPArrayList	Returns a whitelist of IP addresses that are allowed to access an instance.
ModifySecurityIps	Modifies the whitelist of IP addresses.

Table 2-390: Log management

Operation	Description
DescribeSlowLogRecords	Returns the details of a slow query log.
DescribeSQLCollectorPolicy	Checks the SQL collection status.
DescribeSQLLogFiles	Returns a list of SQL audit files.
DescribeSQLLogRecords	Returns a SQL audit log for an instance.
ModifySQLCollectorPolicy	Modifies the SQL collection status for an instance.

Table 2-391: Network management

Operation	Description
AllocateInstancePublicConnection	Allocates a public network connection string for an instance.
DescribeDBInstanceNetInfo	Returns the network connection information of an instance.
ModifyDBInstanceConnectionString	Modifies the connection string and the port.
ModifyDBInstanceNetworkType	Switches the network connection type of an instance.
ReleaseInstancePublicConnection	Releases the public connection string of an instance.

2.11.1.2 Request structure

To make an API call is to send an HTTP GET request to the API server with request parameters based on the description of the corresponding API operation. The processing results are returned in the response.

Endpoints

The endpoint of the AnalyticDB for PostgreSQL API is `gpdb.example.com`.

For more information about how to obtain the endpoint, see [Obtain an endpoint](#).

Protocols

You can send requests over HTTP or HTTPS. To ensure higher security, we recommend that you send operation requests over HTTPS. Some password-related operations only support HTTPS.

Methods

The system allows you to send HTTP GET requests. This requires request parameters to be included in the request URL.

Parameters

When you make an API request, you must specify the Action parameter as the operation, such as `CreateDBInstance`, that you want to perform. You must also specify common request parameters and the request parameters specific to this operation.

Encoding

Requests and responses are encoded by using the UTF-8 character set.

2.11.1.3 Common parameters

Common request parameters

Common request parameters must be included in all AnalyticDB for PostgreSQL API requests.

Table 2-392: Common request parameters

Parameter	Type	Required	Description
Format	String	No	The format in which to return the response. Valid values: JSON and XML. Default value: XML
Version	String	Yes	The version number of the API. Specify the version in the YYYY-MM-DD format. The current version is 2018-07-23.
AccessKeyId	String	Yes	The AccessKey ID provided to you by Alibaba Cloud.
Signature	String	Yes	The signature string of the current request. For more information about how signatures are calculated, see Request signatures .
SignatureMethod	String	Yes	The encryption method of the signature string . Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard. The time must be in UTC. The format is as follows: YYYY-MM-DDThh:mm:ssZ For example, 2013-01-10T12:00:00Z indicates 20:00:00, January 10, 2013, China Standard Time (UTC+8).
SignatureVersion	String	Yes	The version of the signature encryption algorithm. Set the value to 1.0.
SignatureNonce	String	Yes	A unique, random number used to prevent replay attacks. You must use different numbers for different requests.

Examples

<https://gpdb.example.com/>

```
?Format=xml
&Version=2013-08-15
&Signature=Pcxxxxxxxxxxxxxxxxxxxxxx
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2013-06-01T12:00:00Z
```

Common response parameters

Every response returns a unique RequestID regardless of whether the call is successful.

Examples:

```
<? xml version="1.0" encoding="utf-8"? >
<!--Result Root Node-->
<Interface Name+Response>
  <!--Return Request Tag-->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!--Return Result Data-->
</Interface Name+Response>
```

2.11.1.4 Responses

After the operation is called, data is returned in a unified format. A returned HTTP status code of 2xx indicates that the call was successful. A returned HTTP status code of 4xx or 5xx indicates that the call failed.

For a successful call, the formats of returned data are XML and JSON. When a request is sent, an external system can customize parameters to specify the format of data to be returned. The default format is XML. The response examples in this topic are formatted with line breaks or indents for a clear view. Actual response data is not formatted in the same manner as these examples.

Sample success responses

XML format

The XML response includes a message that indicates whether the request is successful and the specific service data. Example:

```
<? xml version="1.0" encoding="utf-8"? >
<!--The root node of the response-->
<API name + Response>
  <!--The returned request tag-->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!--The returned result-->
```

`</API name + Response>`**JSON format**

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /*The returned result*/
}
```

Sample error responses

No result is returned after the API call fails. You can locate the cause of the error by referring to the [appendix](#).

When a request failed, an HTTP response containing an HTTP status code (4xx or 5xx) is returned. The returned message body contains the specific error code and error message. The message body also contains a globally unique RequestId and the HostId of the site you request to access. If you are unable to find the error cause, you can contact Alibaba Cloud customer service and provide the HostId and RequestId to help solve the problem as quickly as possible.

XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<Error>
  <RequestId>8906582E-6722-409A-A6C4-0E7863B733A5</RequestId>
  <HostId>gpdb.example.com</HostId>
  <Code>UnsupportedOperation</Code>
  <Message>The specified action is not supported. </Message>
</Error>
```

JSON format

```
{
  "RequestId": "7463B73D-35CC-4D19-A010-6B8D65D242EF",
  "HostId": "gpdb.example.com",
  "Code": "UnsupportedOperation",
  "Message": "The specified action is not supported."
}
```

2.11.1.5 Request signatures

AnalyticDB for PostgreSQL authenticates each access request. Therefore, each request sent over HTTP or HTTPS must contain signature information. AnalyticDB for PostgreSQL performs symmetric encryption by using the AccessKey ID and AccessKey Secret to verify the identity of request senders. The AccessKey ID and AccessKey Secret are officially issued to you by Alibaba Cloud. You can apply for and manage them on the Alibaba Cloud official website. The AccessKey ID is used to confirm the identity of the user. The AccessKey Secret

is the key used to encrypt signature strings and used by the server to verify the signature strings. The AccessKey must be kept confidential.

For more information about how to obtain the AccessKey pair, see [Obtain an AccessKey pair](#).

Follow these steps to sign an access request:

1. Use request parameters to construct a canonicalized query string.
 - a. To construct a canonicalized query string, sort all request parameters by name in alphabetic order. These parameters include common request parameters and customized API request parameters, but do not include the Signature parameter.

**Note:**

When you use the GET method to submit requests, these parameters constitute the parameter field of the request URI following the question mark (?) and connected by the ampersand (&).

- b. Encode the name and value of each request parameter. Perform URL encoding on the names and values by using the UTF-8 character set. The URL encoding rules are as follows:
 - Uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
 - Encode other characters in the format of %XY. XY represents the ASCII code in hexadecimal notation of the characters. For example, double quotation marks (") are encoded as %22.
 - Extended UTF-8 characters are encoded in the %XY%ZA... format.
 - Encode the space as %20 rather than the plus sign (+).

**Note:**

Libraries that support URL encoding (such as `java.net.URLEncoder` in Java) are encoded based on the rules for the `application/x-www-form-urlencoded` of the MIME type. If this encoding method of the MIME type is used, replace the plus signs

(+) in the encoded strings with %20, the asterisks (*) with %2A, and %7E with a tilde (~) to conform to the preceding encoding rules.

- c. Connect the encoded parameter name and value by using an equal sign (=).
 - d. Sort the parameter name and value pairs connected by equal signs (=) in alphabetical order and connect the pairs with ampersands (&).
2. Use the created canonicalized query string to construct a string for signature calculation based on the following rules:

```
StringToSign= HTTPMethod + "&" + percentEncode("/") + "&" +
percentEncode(CanonicalizedQueryString)
```

HTTPMethod specifies an HTTP-style request such as GET.

percentEncode("/") specifies the encoded value for the character "/" according to the URL encoding rules described in step 1.b, that is %2F.

percentEncode(CanonicalizedQueryString) specifies the encoded string of the canonicalized query string constructed in step 1, produced by following the URL encoding rules described in step 1.b.

3. As defined in [RFC 2104](#), the preceding signature string is used to calculate the HMAC value of the signature.

Note:

The key used for signature calculation is your AccessKey Secret. An ampersand (&) (38 in ASCII codes) is added to the end of the key. The SHA-1 hashing algorithm is used.

4. Encode the preceding HMAC value as a Base64 string to obtain the signature value.
5. Add the signature value to the request parameters as the signature parameter. The request signing process is completed.

Note:

When the obtained signature value is submitted to the AnalyticDB for PostgreSQL server as the final request parameter value, the URL encoding must be performed for the value in compliance with the [RFC 3986](#) rules. Take DescribeDBInstances as an example, the request URL before signing is:

```
http://gpdb.example.com/?Timestamp=2013-06-01T10:33:56Z&Format=XML&AccessKeyId=testid&Action=DescribeDBInstances&SignatureMethod=HMAC-SHA1&Regi
```

```
onId=region1&SignatureNonce=NwDAXvLU6tFE0DVb&Version=2014-08-15&SignatureVersion=1.0
```

The calculated StringToSign is:

```
GET&%2F&AccessKeyId%3Dtestid%26Action%DescribeDBInstances%26Format%3DXML%26RegionId%3Dregion1%26SignatureMethod%3DHMAC-SHA1%26SignatureNonce%3DNwDAXvLU6tFE0DVb%26SignatureVersion%3D1.0%26Timestamp%3D2013-06-01T10%253A33%253A56Z%26Version%3D2014-08-15
```

Assume that the AccessKey ID is testid, the AccessKey Secret is testsecret, and the key used to calculate the HMAC value is testsecret&. The calculated signature value is:

```
GfQRtWbwdE8sp7q9lBgZyutVht8=
```

The signed request URL with the Signature parameter added is as follows:

```
http://gpdb.example.com/?Timestamp=2012-12-26T10%3A33%3A56Z&Format=XML&AccessKeyId=testid&Action=DescribeDBInstances&SignatureMethod=HMAC-SHA1&RegionId=region1&SignatureNonce=NwDAXvLU6tFE0DVb&Version=2012-09-13&SignatureVersion=1.0&Signature=Gfxxxxxxxxxxxxxxxxxxxxxx
```

2.11.1.6 RAM authorization

2.11.1.6.1 Use RAM to authorize resources

All instances created through an Apsara Stack tenant account are resources owned by that account. An account has the full operation permissions on resources under the account by default.

Resource Access Management (RAM) allows you to grant RAM users the access and management permissions on resources owned by an Apsara Stack tenant account.

Note:

If you do not need to use RAM, skip this procedure.

2.11.1.6.2 Resources that can be authorized in RAM

Only one type of AnalyticDB for PostgreSQL resource can be authorized in RAM: DBInstance.

The following table lists the descriptions of resources when you use RAM to authorize access permissions to these resources:

Table 2-393: Resource description

Resource	Resource description in the authorization policy
DBInstance	acs:gpdb:\$regionid: \$accountid:dbinstance/\$dbinstanceid acs:gpdb:\$regionid:\$accountid:dbinstance/* acs:gpdb:* : *:dbinstance/*

**Note:**

- All \$regionids must be the ID of a region or *.
- All \$instanceids must be the ID of an instance or *.
- All \$accountid must be the ID of a resource owner or *.

2.11.1.6.3 Operations that can be authorized in RAM

You can use RAM to authorize access permissions to AnalyticDB for PostgreSQL resources. All operations except the DescribeRegions operation can be authorized.

2.11.1.6.4 Authentication rules of API operations

When you call API operations to access resources as a RAM user, AnalyticDB for PostgreSQL checks whether the RAM user is granted the required permissions by querying Resource Access Management (RAM).

When you call API operations to access resources as a RAM user, AnalyticDB for PostgreSQL checks with RAM whether you are granted the required permissions. The permissions to be checked are determined by the resources used by the API operation. For more information about authentication rules for each API operation, see [Table 2-394: Authentication rules of API operations](#).

Table 2-394: Authentication rules of API operations

Operation	Authentication rule
CreateDBInstance	acs:gpdb:\$regionid: dbinstance /\$*
DeleteDBInstance	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid
DescribeDBInstanceAttribute	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid

Operation	Authentication rule
DescribeDBInstances	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid
DescribeRegions	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid
DescribeResourceUsage	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid
ModifyDBInstanceConnectionMode	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid
ModifyDBInstanceDescription	acs:gpdb:\$regionid: \$accountid:dbinstance /\$dbinstanceid

2.11.1.7 Instance management

2.11.1.7.1 CreateDBInstance

Description

You can call this operation to create an AnalyticDB for PostgreSQL instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	CreateDBInstance

Parameter	Type	Required	Description
RegionId	String	Yes	Specifies a region for the instance, such as cn-hangzhou . You can call the DescribeRegions operation to query the most recent region list.
ZoneId	String	Yes	Specifies a zone for the instance, such as cn-hangzhou-d. You can call the DescribeRegions operation to query the most recent region list.
InstanceNetworkType	String	Yes	The network type of the instance. Valid values: Classic and VPC. Default value: Classic.
VPCId	String	No	The ID of the VPC. If you set InstanceNetworkType to VPC, you must also specify the VPCId parameter . The specified region of the VPC must be the same as RegionId .
VSwitchId	String	No	The ID of the VSwitch. If you set InstanceNetworkType to VPC, you must also specify the VSwitchId parameter . The specified zone of the VSwitch must be the same as ZoneId.

Parameter	Type	Required	Description
DBInstanceClass	String	Yes	The type of the instance. For more information, see Instance types .
DBInstanceGroupCount	String	Yes	The number of compute groups in the AnalyticDB for PostgreSQL instance.
DBInstanceDescription	String	No	The description of the instance. The description cannot exceed 256 characters in length.
SecurityIPList	String	No	The IP addresses that are allowed to access the instance. Default value: 127.0.0.1.
ClientToken	String	Yes	The client token that is used to perform idempotency check.

Response parameters

Parameter	Type	Description
<Common response parameters>	String	For more information about response parameters, see Common response parameters.
DBInstanceCld	String	The ID of the instance.
OrderId	String	The ID of the order.

Sample requests

```
https://gpdb.example.com/?Action=CreateDBInstance
&Engine=gpdb
&RegionId=cn-hangzhou
&ZoneId=cn-hangzhou-b
&InstanceNetworkType=Classic
&DBInstanceClass=gpdb.group.segsdx1
&DBInstanceGroupCount=2
&ClientToken=f918f59c-89be-42ee-bb86-d027243b2cfb
```

<Common request parameters>

Sample success responses

XML format

```
<CreateDBInstanceResponse>
  <dbInstanceId>gp-xxxxxxxxxxxxxx</dbInstanceId>
  <orderId>xxxxxxxxxxxxxx</orderId>
</CreateDBInstanceResponse>
```

JSON format

```
{
  "dbInstanceId": "gp-xxxxxxxxxxxxxx",
  "orderId": "xxxxxxxxxxxxxx"
}
```

2.11.1.7.2 DeleteDBInstance

Description

You can call this operation to delete an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DeleteDBInstance.
DBInstanceId	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=DeleteDBInstance
```

```
&DBInstanceID=gp-xxxxxxxxxxxxxxxxx  
&<Common request parameters>
```

Sample success responses

XML format

```
<DeleteDBInstanceResponse>  
  <RequestId>65BDA532-28AF-4122-AA39-B382721EEE64</RequestId>  
</DeleteDBInstanceResponse>
```

JSON format

```
{"RequestId": "65BDA532-28AF-4122-AA39-B382721EEE64"}
```

2.11.1.7.3 DescribeDBInstanceAttribute

Description

You can call this operation to query the details of an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceAttribute.
DBInstanceID	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.
Items	List<DBInstanceAttribute>	The list of instance details.

Table 2-395: DBInstanceAttribute parameters

Parameter	Type	Description
AvailabilityValue	String	The service availability of the current instance. Unit: %.
ConnectionMode	String	• Performance: standard mode • Safty: safe mode
ConnectionString	String	The connection string to connect to the database.
CreationTime	String	The time when the instance is created. It is in the YYYY-MM-DDThh:mm:ssZ format, such as 2011-05-30T12:11:4Z.
DBInstanceClass	String	The type of the instance.
DBInstanceClassType	String	The instance family. Valid values: • s: shared instance • x: general-purpose instance • d: dedicated instance • h: dedicated host instance
DBInstanceCpuCores	String	The number of CPU cores.
DBInstanceDescription	String	The description of the instance.
DBInstanceDiskMBPS	Long	The maximum disk throughput of a compute group. Unit: Mbit/s.
DBInstanceGroupCount	String	The number of compute groups.
DBInstanceCld	String	The ID of the instance.
DBInstanceMemory	Long	The memory capacity of the instance. Unit: MB.

Parameter	Type	Description
DBInstanceNetType	String	• Internet: the public network • Intranet: the internal network
DBInstanceStatus	String	For more information about the instance status, see Instance states .
DBInstanceStorage	Long	The disk space of an instance. Unit: GB.
Engine	String	• Internet: the public network • Intranet: the internal network
EngineVersion	String	The version of the database engine.
ExpireTime	String	The expiration time of the instance.
HostType	String	The disk type of compute groups. • 0: SSD • 1: SATA
InstanceNetworkType	String	• Classic: classic network • VPC: Virtual Private Cloud

Parameter	Type	Description
LockMode	String	• Unlock: The instance is not locked. • ManualLock: The instance is locked manually. • LockByExpiration: The instance is locked automatically after the instance expires. • LockByRestoration: The instance is locked automatically before a rollback of the instance. • LockByDiskQuota: The instance is locked automatically when the disk space is full.
MaintainEndTime	String	The end of the time range where the instance is maintained.
MaintainStartTime	String	The start of the time range where the instance is maintained.
MaxConnections	Integer	The maximum number of concurrent connections to an instance.
Port	String	The port number to connect to the instance.
RegionId	String	The region where the instance is located.
SecurityIPList	String	The IP addresses that are allowed to access the instance.
VpcId	String	The ID of the VPC where ClassicLink is enabled.
ZoneId	String	The zone where the instance is located.

Sample requests

```
https://gpdb.example.com/?Action=DescribeDBInstanceAttribute
&DBInstanceId=gp-xxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```

2.11.1.7.4 DescribeDBInstances

Description

You can call this operation to query the list of instances.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DescribeDBInstances .

Parameter	Type	Required	Description
RegionId	String	Yes	The region where the instance is located . You can call the DescribeRegions operation to query the most recent region list.
Engine	String	No	The engine of the database. Default value: PostgreSQL.
DBInstanceType	String	No	The role of the instance. Valid values: • Primary: primary instances • Readonly: read-only instances • Guard: disaster recovery instances • Temp: temporary instances • If you do not specify this parameter, all instances will be returned.
DBInstanceDescription	String	No	The description of the instance.

Parameter	Type	Required	Description
InstanceNetworkType	String	No	The network type of the instance. Valid values: • VPC: Virtual Private Cloud • Classic: classic network • If you do not specify this parameter, instances of all network types will be returned.
ConnectionMode	String	No	• Standard: standard mode • Safe: safe mode • If you do not specify this parameter, instances of both modes will be returned.
Tags	String	No	The name of the tag that is assigned to an instance. It is a JSON string. The tag includes a key-value pair of TagKey and TagValue. You must specify TagKey, and you can specify TagValue as needed. It is in the {"key1": "value1"} format.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30

Parameter	Type	Required	Description
PageNumber	Integer	No	The number of the page to return. Valid values: any non-zero positive integer . Default value: 1

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters.
PageNumber	Integer	The page number of the returned page.
TotalRecordCount	Integer	The total number of entries.
PageRecordCount	Integer	The number of entries on the current page.
Items	List<DBInstance>	The array consisting of DBInstance data.

Table 2-396: DBInstance parameters

Parameter	Type	Description
DBInstanceCld	String	The ID of the instance.
DBInstanceDescription	String	The description of the instance.
InstanceNetworkType	String	- VPC: Virtual Private Cloud - Classic: classic network
ConnectionMode	String	- Standard: standard mode - Safe: safe mode
RegionId	String	The region ID of the instance .
Zoneld	String	The zone ID of the instance.

Parameter	Type	Description
ExpireTime	String	The time when the instance is scheduled to expire. Pay-as-you-go instances do not expire.
DBInstanceStatus	String	For more information, see Instance states .
Engine	String	The engine of the database.
EngineVersion	String	The version of the database engine.
DBInstanceNetType	String	• Internet: the public network • Intranet: the internal network
LockMode	String	• Unlock: The instance is not locked. • ManualLock: The instance is locked manually. • LockByExpiration: The instance is locked automatically after the instance expires. • LockByRestoration: The instance is locked automatically before a rollback of the instance. • LockByDiskQuota: The instance is locked automatically when the disk space is full.
LockReason	String	The reason why the instance is locked.
CreateTime	String	The time when you create an instance.
VPCId	String	The ID of the VPC.
VSwitchId	String	The ID of the VSwitch.

Sample requests

```
https://gpdb.example.com/?Action=DescribeDBInstances
&RegionId=cn-hangzhou
&<Common request parameters>
```

Sample success responses

2.11.1.7.5 DescribeRegions

Description

You can call this operation to query available regions and zones. You must call the DescribeRegions operation to query the available regions before calling the CreateDBInstance operation.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DescribeRegions.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters .
Regions	List<Region>	The list of regions.

Table 2-397: Region parameters

Parameter	Type	Description
RegionId	String	The data center in the specified region.
Zones	List<Zones>	The list of zones.

Table 2-398: Zone parameters

Parameter	Type	Description
ZoneId	String	The zone where the instance is located.
VpcEnabled	Boolean	Indicates whether the VPC in the zone is available.

Sample requests

```
https://gpdb.example.com/?Action=DescribeRegions
&<Common request parameters>
```

Sample responses**XML format**

```
<DescribeRegionsResponse>
  <RequestId>FF8EB261-5447-4B1B-9F14-294CEA008A9F</RequestId>

2.11.1.7.6 DescribeResourceUsage

Description

You can call this operation to query the disk space that is used by an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to DescribeResourceUsage.
DBInstanceID	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	For more information about response parameters, see Common response parameters.
DBInstanceID	String	The ID of the instance.
Engine	String	The engine of the database.
DiskUsed	Integer	The total space occupied by both data files and log files . Unit: Byte. -1 indicates no space is used.
DataSize	Integer	The disk space that is used to store data files. Unit: Byte. -1 indicates no space is used .
LogSize	Integer	The disk space that is used to store log files. Unit: Byte. -1 indicates no space is used.
BackupSize	Integer	The disk space that is used to store backup files. Unit: Byte. -1 indicates no space is used.

Sample requests

```
https://gpdb.example.com/?Action=DescribeResourceUsage
&DBInstanceId=gp-xxxxxxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<DescribeResourceUsageResponse>
  <DBInstanceId>gp-xxxxxxxxxxxxxxxxxx</DBInstanceId>
  <RequestId>860FBA9E-BFFD-493E-91A1-2349B9D74AE7</RequestId>
  <LogSize>201326592</LogSize>
  <DataSize>83886080</DataSize>
  <BackupSize>26624</BackupSize>
  <Engine>gpdb</Engine>
  <DiskUsed>285212672</DiskUsed>
</DescribeResourceUsageResponse>
```

JSON format

```
{
  "DBInstanceId": "gp-xxxxxxxxxxxxxxxxxx",
  "RequestId": "860FBA9E-BFFD-493E-91A1-2349B9D74AE7",
  "LogSize": 201326592,
  "DataSize": 83886080,
  "BackupSize": 26624,
  "Engine": "gpdb",
  "DiskUsed": 285212672
}
```

2.11.1.7.7 ModifyDBInstanceConnectionMode

Description

You can call this operation to modify the access mode of an instance. The following modes are supported:

- Standard mode
- Safe mode

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceConnectionMode.
DBInstanceID	String	Yes	The ID of the instance.
ConnectionMode	String	Yes	- Standard - Safe

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifyDBInstanceConnectionMode
&DBInstanceID=gp-xxxxxxxxxxxxxxxxxx
&ConnectionMode=Safe
&<Common request parameters>
```

Sample success responses

XML format

```
<BaseResponse>
  <RequestId>8361E350-4CCC-4D28-B020-55B4DCB75D3B</RequestId>
</BaseResponse>
```

JSON format

```
{
  "RequestId": "8361E350-4CCC-4D28-B020-55B4DCB75D3B",
```

```
}
```

2.11.1.7.8 ModifyDBInstanceDescription

Description

You can call this operation to modify the description of an instance to help identify the instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceDescription.
DBInstanceCld	String	Yes	The ID of the instance.
DBInstanceDescription	String	Yes	The description of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifyDBInstanceDescription
&DBInstanceCld=gp-xxxxxxxxxxxxxxxxxx
&DBInstanceDescription=testInstanceDescribe
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifyDBInstanceDescriptionResponse>
```

```
<RequestId>107BE202-D1A2-479E-98E0-A892B472562F</RequestId>
</ModifyDBInstanceDescriptionResponse>
```

JSON format

```
{
  "RequestId": "107BE202-D1A2-479E-98E0-A892B472562F"
}
```

2.11.1.7.9 ModifyDBInstanceMaintainTime

Description

You can call this operation to modify the maintenance window of an instance. Typically, it is set to the off-peak hours to minimize the impact on services. Alibaba Cloud will perform routine maintenance for instances at the specified maintenance time.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceMaintainTime.
DBInstanceId	String	Yes	The ID of the instance.
StartTime	String	Yes	The start time of the maintenance window. For example, 02:00Z.
EndTime	String	Yes	The end time of the maintenance window. For example, 03:00Z. The end time must be later than the start time.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifyDBInstanceMaintainTime
&DBInstanceId=gp-xxxxxxxxxxxxxxxxxx
&StartTime=02:00Z
&EndTime=03:00Z
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifyDBInstanceMaintainTimeResponse>
  <RequestId>CA9A34C8-AC95-413B-AC6A-CEBF67429CCA</RequestId>
</ModifyDBInstanceMaintainTimeResponse>
```

JSON format

```
{
  "RequestId": "CA9A34C8-AC95-413B-AC6A-CEBF67429CCA"
}
```

2.11.1.7.10 RestartDBInstance

Description

You can call this operation to restart an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to RestartDBInstance.

Parameter	Type	Required	Description
DBInstanceCld	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=RestartDBInstance
&DBInstanceCld=gp-xxxxxxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<RestartDBInstance>
  <RequestId>A7356493-7141-4393-8951-CDA8AB5D67EC</RequestId>
</RestartDBInstance>
```

JSON format

```
{
  "RequestId": "A7356493-7141-4393-8951-CDA8AB5D67EC"
}
```

2.11.1.7.11 DescribeDBInstancePerformance

Description

You can call this operation to query the specified performance metrics for an instance over a period of time.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDB InstancePerformance .
DBInstanceid	String	Yes	The ID of the instance.
Key	String	Yes	The performance metrics. Separate multiple performance metrics with commas (.). For more information, see Performance parameters .
StartTime	String	Yes	The start time of a period during which you need to query the metrics, for example, 2018-06-11T15:00Z.
EndTime	String	Yes	The end time of a period during which you need to query the metrics, for example, 2018-06-11T16:00Z.

Response parameters

Parameter	Type	Description
<Common response parameters>	None	For more information, see Common response parameters .
DBInstanceid	String	The ID of the instance.
Engine	String	The type of the database.

Parameter	Type	Description
StartTime	String	The start time of a period during which you need to query the metrics. It is in the YYYY-MM-DDTHH:mmZ format, for example, 2018-05-30T03:29Z.
EndTime	String	The end time of a period during which you need to query the metrics. It is in the YYYY-MM-DDTHH:mmZ format, for example, 2018-05-30T05:29Z. The end time must be later than the start time.
PerformanceKeys	List<PerformanceKey>	The array that contains the performance metrics. It is in the {perf1, perf2, perf3, ...} format.

Table 2-399: PerformanceKey parameters

Parameter	Type	Description
Key	String	The performance metric.
Unit	String	The unit of the metric.
ValueFormat	String	The format of a value. • If this parameter is null, the values of performance metrics are returned. • If this parameter is not null, multiple metrics are parsed and separated with ampersands (&), for example, com_delete&com_insert&com_insert_select&com_replace.
GroupValues	List<GroupValue>	The array that contains the metric values. It is in the {value1, value2, ...} format.

Table 2-400: GroupValue parameters

Parameter	Type	Description
Name	String	The name of the group.
Values	List<Value>	List of values, such as { value1, value2, ...}.

Table 2-401: Value parameters

Parameter	Type	Description
Value	String	The value of the performance metric.
Date	String	The time when the metric value was recorded. Unit: milliseconds.

Sample requests

```
https://gpdb.example.com/?Action=DescribeDBInstancePerformance
&DBInstanceId=gp-xxxxxxxxxxxxx
&key=CpuUsage,MemoryUsage,Gpdb_SpaceUsage,Gpdb_IOPS,Gpdb_session
&EndTime=2018-07-09T03:43Z
&StartTime=2018-07-08T03:43Z
&<Common request parameters>
```

Sample success responses**XML format**

```
<DescribeDBInstancePerformanceResponse>
  <RequestId>5E85244A-AB47-46A3-A3AD-5F307DCB407E</RequestId>

2.11.1.8 Database management

2.11.1.8.1 DeleteDatabase

Description

You can call this operation to delete a database from an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DeleteDatabase.
DBInstanceCld	String	Yes	The ID of the instance.
DBName	String	Yes	The name of the database.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=DeleteDatabase
&DBName=testdb01
&DBInstanceCld=gp-xxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<DeleteDatabaseResponse>
  <RequestId>07F6177E-6DE4-408A-BB4F-0723301340F3</RequestId>
</DeleteDatabaseResponse>
```

JSON format

```
{
  "RequestId": "07F6177E-6DE4-408A-BB4F-0723301340F3"
```

```
}
```

2.11.1.8.2 DescribeAccounts

Description

You can call this operation to query the information of a database account.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DescribeAccounts.
AccountName	String	No	The name of the account.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.
Accounts	List<DBInstanceAccount>	The array that consists of DBInstanceAccount data.

Table 2-402: DBInstanceAccount parameters

Parameter	Type	Description
DBInstanceCld	String	The ID of the instance.
AccountName	String	The name of the account.

Parameter	Type	Description
AccountStatus	String	The statuses of the account are as follows: • 0: indicates that the account is being created. • 1: indicates that the account is being used. • 3: indicates that the account is being deleted.
AccountDescription	String	The description of the account.

Sample requests

```
https://gpdb.example.com/?Action=DescribeAccounts
&DBInstanceId=gp-xxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<DescribeAccountsResponse>
  <RequestId>7565770E-7C45-462D-BA4A-8A5396F2CAD1</RequestId>
  <Accounts>
    <DBInstanceAccount>
      <AccountName>testaccount_1</AccountName>
      <DBInstanceId>gp-xxxxxxxxxxxxx</DBInstanceId>
      <AccountStatus>1</AccountStatus>
      <AccountDescription></AccountDescription>
    </DBInstanceAccount>
  </Accounts>
</DescribeAccountsResponse>
```

JSON format

```
{
  "Accounts": {
    "DBInstanceAccount": [
      {
        "AccountDescription": "",
        "DBInstanceId": "gp-xxxxxxxxxxxxx",
        "AccountStatus": "1",
        "AccountName": "testaccount_1"
      }
    ]
  },
  "RequestId": "7565770E-7C45-462D-BA4A-8A5396F2CAD1"
```

```
}
```

2.11.1.8.3 ModifyAccountDescription

Description

You can call this operation to modify the description of a database account to help identify the account.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAccountDescription.
DBInstanceID	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account. It must be unique and meet the following requirements: • The name must start with a letter. • The name can contain lowercase letters, digits, and underscores (_). • The name can be up to 16 characters in length. • The name cannot contain reserved keywords.

Parameter	Type	Required	Description
AccountDescription	String	Yes	Specifies the description of the account. The description must meet the following requirements: • The description must start with a letter. • The description cannot start with http:// or https://. • The description can contain letters , underscores (_), hyphens (-), and digits. • The description must be 2 to 256 characters in length.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifyAccountDescription
&DBInstanceId=gp-xxxxxxxxxxxxxx
&AccountName=testAccout
&AccountDescription=testAccoutdescribe
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifyAccountDescriptionResponse>
  <RequestId>99BBBD5E-B5D8-4FC8-B8BF-FB1A0A38BBA2</RequestId>
```

```
</ModifyAccountDescriptionResponse>
```

JSON format

```
{
  "RequestId": "99BBBD5E-B5D8-4FC8-B8BF-FB1A0A38BBA2"
}
```

2.11.1.9 Account management

2.11.1.9.1 CreateAccount

Description

You can call this operation to create an account for a database.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to CreateAccount.
DBInstanceCld	String	Yes	The ID of the instance.
DatabaseName	String	No	The name of the database.
AccountName	String	Yes	The name of the account.
AccountPassword	String	Yes	The password for the account.
AccountDescription	String	No	The description of the account.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=CreateAccount
&AccountName=testacc02
&AccountPassword=pw1234
&DBInstanceId=gp-xxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<CreateAccountResponse>
  <RequestId>D4D4BE8A-DD46-440A-BFCD-EE31DA81C9DD</RequestId>
</CreateAccountResponse>
```

JSON format

```
{
  "RequestId": "D4D4BE8A-DD46-440A-BFCD-EE31DA81C9DD"
}
```

2.11.1.9.2 ResetAccountPassword

Description

You can call this operation to reset the password for your account. Before calling this operation, make sure that the following conditions are met:

- The instance is in the running state.
- The instance is not locked.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ResetAccountPassword.
DBInstanceId	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account.
AccountPassword	String	Yes	The new password for the account . The password must be 8 to 32 characters in length. The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include ! @ # \$ % ^ & * () _ + - =

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ResetAccountPassword
&AccountName=testaccount_1
&AccountPassword=Testaccount_1
&DBInstanceId=gp-xxxxxxxxxxxxxx
```

&<Common request parameters>

Sample success responses

XML format

```
<ResetAccountPasswordResponse>
  <RequestId>187C80FC-75C4-477C-BBF2-A368A36D041C</RequestId>
</ResetAccountPasswordResponse>
```

JSON format

```
{
  "RequestId": "187C80FC-75C4-477C-BBF2-A368A36D041C"
}
```

2.11.1.10 Security management

2.11.1.10.1 DescribeDBInstanceIPArrayList

Description

You can call this operation to query the IP addresses that are allowed to access an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceIPArrayList.
DBInstanceid	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information about response parameters, see Common response parameters.

Parameter	Type	Description
Items	List<DBInstanceIPArray>	The IP addresses that are allowed to access the instance.

Table 2-403: DBInstanceIPArray parameters

Parameter	Type	Description
DBInstanceIPArrayName	String	The name of the IP address whitelist.
DBInstanceIPArrayAttribute	String	This parameter is null by default. You can use this parameter to distinguish whitelists that have different attributes. The console does not display whitelists that have the attribute.
SecurityIPList	String	The IP addresses listed in the whitelist. You can add up to 1,000 IP addresses to the whitelist. Separate multiple IP addresses with commas (,). The formats are as follows: • 0.0.0.0/0. • 10.23.12.24 (IP addresses). • Classless Inter-Domain Routing (CIDR) blocks, such as 10.23.12.24/24, where /24 indicates the prefix of the CIDR block is 24-bit. You can replace 24 with a value ranging from 1 to 32.

Sample requests

```
https://gpdb.example.com/?Action=DescribeDBInstanceIPArrayList
&DBInstanceId=gp-xxxxxxxxxxxxxx
```

<Common request parameters>

Sample success responses**XML format**

```
<DescribeDBInstanceIPArrayListResponse>
  <RequestId>CB7AA0BF-BE41-480E-A3DC-C97BF85A391B</RequestId>
  <Items>
    <DBInstanceIPArray>
      <groupName>default</groupName>
      <groupTag></groupTag>
      <securityIPList>127.0.0.1</securityIPList>
    </DBInstanceIPArray>
  </Items>
</DescribeDBInstanceIPArrayListResponse>
```

JSON format

```
{
  "Items":{
    "DBInstanceIPArray":[
      {
        "groupName":"default",
        "groupTag": "",
        "securityIPList": "127.0.0.1"
      }
    ]
  },
  "RequestId": "CB7AA0BF-BE41-480E-A3DC-C97BF85A391B"
}
```

2.11.1.10.2 ModifySecurityIps**Description**

You can call this operation to modify the IP addresses that are allowed to access an instance. Before calling this operation, make sure that the following conditions are met:

- The instance is in the running state.
- The instance is not locked.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to ModifySecurityIps.

Parameter	Type	Required	Description
DBInstanceCid	String	Yes	The ID of the instance.
SecurityIps	String	Yes	The IP addresses listed in the whitelist. You can add up to 1,000 IP addresses to the whitelist. Separate multiple IP addresses with commas (.). The formats are as follows: 0.0.0.0/0. 10.23.12.24 (IP addresses). - Classless Inter-Domain Routing (CIDR) blocks, such as 10.23.12.24/24, where / 24 indicates the prefix of the CIDR block is 24-bit. You can replace 24 with a value ranging from 1 to 32.
DBInstanceIPArrayName	String	No	The name of the whitelist. If you do not enter a name, IP addresses are added to the default whitelist.  Note: You can create up to 50 whitelists for an instance.

Parameter	Type	Required	Description
DBInstanceIPArrayAttribute	String	No	The attribute of the IP address whitelist. It is null by default. You can use this parameter to distinguish whitelists that have different attributes. The console does not display whitelists that have the hidden attribute.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifySecurityIps
&DBInstanceId=gp-xxxxxxxxxxxxxx
&SecurityIps=192.168.0.1
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifySecurityIpsResponse>
  <RequestId>871C698F-B43D-4D1D-ACD6-DF56B0F89978</RequestId>
</ModifySecurityIpsResponse>
```

JSON format

```
{
  "RequestId": "871C698F-B43D-4D1D-ACD6-DF56B0F89978"
}
```

2.11.1.11 Log management

2.11.1.11.1 DescribeSlowLogRecords

Description

You can call this operation to query slow query logs of a database in an instance over a period of time.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSlowLogRecords.
DBInstanceCld	String	Yes	The ID of the instance.
StartTime	String	Yes	The start time of the query. Specify the time in the YYYY-MM-DDTHH:mmZ format, for example, 2011-06-11T15:00Z.
EndTime	String	Yes	The end time of the query. Specify the time in the YYYY-MM-DDTHH:mmZ format, for example, 2011-06-11T16:00Z. The end time must be later than the start time.
SQLId	Long	No	The ID of the SQL query.
DBName	String	No	The name of the database.

Parameter	Type	Required	Description
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Valid values: any non-zero positive integer. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.
Engine	String	The engine of the database.
TotalRecordCount	Integer	The total number of slow SQL queries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL slow queries on the current page.
Items	List<SQLSlowRecord>	The details of slow query logs.

Table 2-404: SQLSlowRecord parameters

Parameter	Type	Description
HostAddress	String	The IP address of the host that you use to connect to the database.
DBName	String	The name of the database.
SQLText	String	The SQL statement.
QueryTimes	Long	The execution time of the slow query. Unit: seconds.

Parameter	Type	Description
LockTimes	Long	The lock duration of the query. Unit: seconds.
ParseRowCounts	Long	The number of entries parsed.
ReturnRowCounts	Long	The number of entries returned.
ExecutionStartTime	String	The beginning of the time range where the statement is executed. It is in the YYYY-MM-DDTHH:mm:ssZ format, for example, 2011-06-11T15:00:08Z.

Sample requests

```
https://gpdb.example.com/?Action=DescribeSlowLogRecords
&DBInstanceId=gp-xxxxxxxxxxxxxx
&StartTime=2018-07-09T08:00Z
&EndTime=2018-07-09T09:00Z
&<Common request parameters>
```

Sample success responses

XML format

```
<DescribeSlowLogRecordsResponse>
  <RequestId>542BB8D6-4268-45CC-A557-B03EFD7AB30A</RequestId>
  <Engine>gpdb</Engine>
  <PageNumber>1</PageNumber>
  <PageRecordCount>1</PageRecordCount>
  <TotalRecordCount>1</TotalRecordCount>
  <Items>
    <SQLSlowRecord>
      <HostAddress>192.168.0.123</HostAddress>
      <DBName>test</DBName>
      <SQLText> update test.zxb set id=0 limit 1</SQLText>
      <QueryTimes>123</QueryTimes>
      <LockTimes>12</LockTimes>
      <ParseRowCounts>125</ParseRowCounts>
      <ReturnRowCounts>1</ReturnRowCounts>
      <ExecutionStartTime>2018-07-09T09:00:08Z</ExecutionStartTime>
    </SQLSlowRecord>
  </Items>
</DescribeSlowLogRecordsResponse>
```

JSON format

```
{
  "RequestId": "542BB8D6-4268-45CC-A557-B03EFD7AB30A",
  "Engine": "gpdb",
  "PageNumber": 1,
```

```
"PageRecordCount":1,
"TotalRecordCount":1,
"Items":{
  "SQLSlowRecord":[
    {
      "HostAddress":"192.168.0.123",
      "DBName":"test",
      "SQLText":" update test.zxb set id=0 limit 1",
      "QueryTimes":"123",
      "LockTimes":"12",
      "ParseRowCounts":"125",
      "ReturnRowCounts":"1",
      "ExecutionStartTime":"2018-07-09T09:00:08Z"
    }
  ]
}
```

2.11.1.11.2 DescribeSQLCollectorPolicy

Description

You can call this operation to check whether the SQL collection feature is enabled for an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DescribeSQLCollector Policy.
DBInstanceid	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information about response parameters, see Common response parameters.

Parameter	Type	Description
SQLCollectorStatus	String	- Enabled: specifies to enable SQL collection. - Disabled: specifies whether to disable SQL collection.

Sample requests

```
https://gpdb.example.com/?Action=DescribeSQLCollectorPolicy
&DBInstanceId=gp-xxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<DescribeSQLCollectorPolicyResponse>
  <RequestId>ABB39CC3-4488-4857-905D-2E4A051D0521</RequestId>
  <SQLCollectorStatus>Enable</SQLCollectorStatus>
</DescribeSQLCollectorPolicyResponse>
```

JSON format

```
{
  "RequestId": "ABB39CC3-4488-4857-905D-2E4A051D0521",
  "SQLCollectorStatus": "Enable"
}
```

2.11.1.11.3 DescribeSQLLogFiles

Description

You can call this operation to query the list of SQL audit log files.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to DescribeSQLLogFiles.

Parameter	Type	Required	Description
DBInstanceID	String	Yes	The ID of the instance.
FileName	String	No	The name of the file.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Valid values: any non-zero positive integer. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of entries on the current page.
Items	List<LogFile>	The array that consists of audit file data.

Table 2-405: LogFile parameters

Parameter	Type	Description
FileID	Integer	The name of an audit log file.

Parameter	Type	Description
LogStatus	String	- NoStart: The database has not started generating audit log files. - Generating: The database is generating audit log files. - Success: The database has generated audit log files. - Failed: The database fails to generate audit log files.
LogStartTime	String	The beginning of the time range where an audit log starts to record data.
LogEndTime	String	The end of the time range where an audit log stops recording data.
LogDownloadURL	String	The download URL of audit log files. If the download URL is unavailable, an empty string is returned.
LogSize	Long	The size of the audit log file. Unit: Bytes.

Sample requests

```
https://gpdb.example.com/?Action=DescribeSQLLogFiles
&DBInstanceId=gp-xxxxxxxxxxxxxx
&<Common request parameters>
```

Sample success responses

XML format

```
<DescribeSQLLogFilesResponse>
  <Items></Items>
  <PageNumber>1</PageNumber>
  <TotalRecordCount>0</TotalRecordCount>
  <RequestId>66E164C1-D7F2-4D85-849D-E2883FCFFBA5</RequestId>
  <PageRecordCount>0</PageRecordCount>
```

```
</DescribeSQLLogFilesResponse>
```

JSON format

```
{
  "Items":{
    "LogFile":[
      ]
    },
  "PageNumber":1,
  "TotalRecordCount":0,
  "RequestId":"66E164C1-D7F2-4D85-849D-E2883FCFFBA5",
  "PageRecordCount":0
}
```

2.11.1.11.4 DescribeSQLLogRecords

Description

You can call this operation to query the SQL audit logs generated for an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSQLLogRecords.
DBInstanceID	String	Yes	The ID of the instance.
Database	String	No	The database to be queried. All databases are queried by default.
User	String	No	The username to be queried. All users are queried by default.

Parameter	Type	Required	Description
Form	String	No	- File: generates audit log files. If you set this parameter to File, only common response parameters will be returned. Therefore, you need to call the DescribeSQLLogFiles operation to obtain the download URL of audit log files. - Stream: generates data streams. Default value: Stream.
QueryKeywords	String	No	The keywords used for query. Up to 10 keywords can be entered at a time. Separate multiple keywords with spaces.
StartTime	String	Yes	The start time of the audit logs to be queried. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format.
EndTime	String	Yes	The end time of the audit logs to be queried. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The end time must be later than the start time.

Parameter	Type	Required	Description
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Valid values: any non-zero positive integer. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL log entries on the current page.
Items	List<SQLRecord>	N/A

Table 2-406: SQLRecord parameters

Parameter	Type	Description
DBName	String	The name of the database.
AccountName	String	The name of the account.
HostAddress	String	The IP address of the client.
SQLText	String	The SQL statement recorded in the log.
TotalExecutionTimes	Long	The time consumed to execute the statement. Unit: milliseconds.

Parameter	Type	Description
ReturnRowCounts	Long	The number of entries returned.
ThreadID	String	The ID of the thread.
ExecuteTime	String	The time when the statement is executed. It is in the yyyy-MM-ddTHH:mm:ssZ format, for example, 2011-05-30T12:11:20Z.

Sample requests

```
https://gpdb.example.com/?Action=DescribeSQLLogRecords
&DBInstanceId=gp-xxxxxxxxxxxxxx
&StartTime=2018-07-09T04:50:20Z
&EndTime=2018-07-09T08:50:20Z
&<Common request parameters>
```

Sample success responses

XML format

```
<DescribeSQLLogRecordsResponse>
  <Items></Items>
  <TotalRecordCount>0</TotalRecordCount>
  <PageNumber>1</PageNumber>
  <RequestId>9B24F29F-BA7F-47A3-838E-C6A993888388</RequestId>
  <PageRecordCount>0</PageRecordCount>
</DescribeSQLLogRecordsResponse>
```

JSON format

```
{
  "Items":{
    "SQLRecord":[
    ]
  },
  "TotalRecordCount":0,
  "PageNumber":1,
  "RequestId":"9B24F29F-BA7F-47A3-838E-C6A993888388",
  "PageRecordCount":0
}
```

2.11.1.11.5 ModifySQLCollectorPolicy

Description

You can call this operation to enable or disable the SQL collection feature for the instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to ModifySQLC collectorPolicy.
DBInstanceId	String	Yes	The ID of the instance.
SQLCollectorStatus	String	Yes	- Enabled: specifies to enable SQL collection. - Disabled: specifies whether to disable SQL collection.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see DescribeSQLLogFiles .

Sample requests

```
https://gpdb.example.com/?Action=ModifySQLCollectorPolicy
&DBInstanceId=gp-xxxxxxxxxxxxxx
&SQLCollectorStatus=Enable
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifySQLCollectorPolicyResponse>
  <RequestId>4FA1F1D1-50A6-4F60-9A78-5752F2076A53</RequestId>
</ModifySQLCollectorPolicyResponse>
```

JSON format

```
{
  "RequestId": "4FA1F1D1-50A6-4F60-9A78-5752F2076A53"
}
```

2.11.1.12 Network management**2.11.1.12.1 AllocateInstancePublicConnection****Description**

You can call this operation to specify the prefix of a public connection string of an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to AllocateInstancePublicConnection.
DBInstanceID	String	Yes	The ID of the instance.
ConnectionStringPrefix	String	Yes	Specifies the connection string that contains the prefix.
Port	String	Yes	Specifies the port number. Valid values : 3200 to 3999.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=AllocateInstancePublicConnection
&DBInstanceId=gp-xxxxxxxxxxxxx
&ConnectionStringPrefix=gp-bp1v8537p9k010lx6o
&Port=3432
&<Common request parameters>
```

Sample success responses

XML format

```
<AllocateInstancePublicConnectionResponse>
  <RequestId>ADD6EA90-EECB-4C12-9F26-0B6DB58710EF</RequestId>
</AllocateInstancePublicConnectionResponse>
```

JSON format

```
{
  "RequestId": "ADD6EA90-EECB-4C12-9F26-0B6DB58710EF"
}
```

2.11.1.12.2 DescribeDBInstanceNetInfo

Description

You can call this operation to query the connection information of an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceNetInfo.
DBInstanceId	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>		For more information, see Common response parameters.
DBInstanceNetInfos	List<DBInstanceNetInfo>	The connection information of the instance.
InstanceNetworkType	String	- Classic: classic network - VPC: Virtual Private Cloud

Table 2-407: DBInstanceNetInfo

Parameter	Type	Description
ConnectionString	String	The DNS endpoint.
IPAddress	String	The IP address of the instance.
IPType	String	- The type of IP address of a classic network instance . Valid values: Inner and Public. - The type of IP address of a VPC instance. Valid values: Private and Public .
Port	String	The port information.
VPCId	String	The ID of the VPC.
VSwitchId	String	The ID of the VSwitch. Multiple IDs are separated with commas (,).

Sample requests

```
https://gpdb.example.com/?Action=DescribeDBInstanceNetInfo
&DBInstanceId=gp-xxxxxxxxxxxxxx
```

<Common request parameters>

Sample success responses**XML format**

```
<DescribeDBInstanceNetInfoResponse>
  <instanceNetworkType>Classic</instanceNetworkType>
  <DBInstanceNetInfos>
    <DBInstanceNetInfo>
      <DBInstanceNetType>1</DBInstanceNetType>
      <connectionString>gp-xxxxxxxxxxxxx.gpdb.rds.example.com</connectionString>
      <ipAddress>127.0.0.1</ipAddress>
      <port>3432</port>
      <userVisible>1</userVisible>
    </DBInstanceNetInfo>
  </DBInstanceNetInfos>
  <RequestId>7565770E-7C45-462D-BA4A-8A5396F2CAD1</RequestId>
</DescribeDBInstanceNetInfoResponse>
```

JSON format

```
{
  "instanceNetworkType": "Classic",
  "DBInstanceNetInfos": {
    "DBInstanceNetInfo": [
      {
        "DBInstanceNetType": "1",
        "connectionString": "gp-xxxxxxxxxxxxx.gpdb.rds.example.com",
        "ipAddress": "127.0.0.1",
        "port": "3432",
        "userVisible": 1
      }
    ]
  },
  "RequestId": "7565770E-7C45-462D-BA4A-8A5396F2CAD1"
}
```

2.11.1.12.3 ModifyDBInstanceConnectionString**Description**

You can call this operation to modify the endpoint and the port of an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceConnectionString.
DBInstanceCld	String	Yes	The ID of the instance.
CurrentConnectionString	String	Yes	The endpoint used by the instance.
ConnectionStringPrefix	String	Yes	The endpoint to be used by the instance.
Port	String	No	The port to be used by the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifyDBInstanceConnectionString
&DBInstanceCld=gp-xxxxxxxxxxxxx
&CurrentConnectionString=gp-bp1gjo105888f3b69.gpdb.rds.example.com
&ConnectionStringPrefix=gp-bp1gjo105888f3b69new
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifyDBInstanceConnectionStringResponse>
  <RequestId>29B0BF34-D069-4495-92C7-FA6D94528A9E</RequestId>
</ModifyDBInstanceConnectionStringResponse>
```

JSON format

```
{
  "RequestId": "29B0BF34-D069-4495-92C7-FA6D94528A9E"
```

```
}
```

2.11.1.12.4 ModifyDBInstanceNetworkType

Description

You can call this operation to switch the network type of the instance between VPC and classic network.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceNetworkType.
DBInstanceId	String	Yes	The ID of the instance.
InstanceNetworkType	String	Yes	Specifies the type of the network. Valid values: - VPC: Virtual Private Cloud - Classic: classic network
VPCId	String	No	The ID of the VPC.
VSwitchId	String	No	The ID of the VSwitch. If you specify the VPCId parameter, you must also specify this parameter.

Parameter	Type	Required	Description
PrivateIpAddress	String	No	You can specify the IP address of the VPC to which the VSwitch belongs . If no IP address is specified, the system automatically assigns an IP address based on the VPCId and VSwitchId.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ModifyDBInstanceNetworkType
&DBInstanceId=gp-xxxxxxxxxxxxx
&InstanceNetworkType=VPC
&<Common request parameters>
```

Sample success responses

XML format

```
<ModifyDBInstanceNetworkTypeResponse>
  <RequestId>2d0c35a9-f5da-44ba-852d-741e27b7eb0b</RequestId>
</ModifyDBInstanceNetworkTypeResponse>
```

JSON format

```
{
  "RequestId": "2d0c35a9-f5da-44ba-852d-741e27b7eb0b"
}
```

2.11.1.12.5 ReleaseInstancePublicConnection

Description

You can call this operation to release the public endpoint of an instance.

Request parameters

Parameter	Type	Required	Description
<Common request parameters>	-	Yes	For more information, see Common parameters .
Action	String	Yes	The operation that you want to perform . Set the value to ReleaseInstancePublicConnection.
DBInstanceId	String	Yes	The ID of the instance.
CurrentConnectionString	String	Yes	The public endpoint of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	For more information, see Common response parameters.

Sample requests

```
https://gpdb.example.com/?Action=ReleaseInstancePublicConnection
&DBInstanceId=gp-xxxxxxxxxxxxxx
&CurrentConnectionString=gp-xxxxxxxxxxxxxx.gpdb.rds.example.com
&<Common request parameters>
```

Sample success responses

XML format

```
<ReleaseInstancePublicConnectionResponse>
  <RequestId>9CEF7037-4158-4A65-BEC7-2A1541F6FE74</RequestId>
</ReleaseInstancePublicConnectionResponse>
```

JSON format

```
{
  "RequestId": "9CEF7037-4158-4A65-BEC7-2A1541F6FE74"
}
```

2.11.1.13 Appendix

2.11.1.13.1 Error codes

2.11.1.13.1.1 Client error codes

Common errors

Error code	Error message	HTTP status code
MissingParameter	The input parameter "parameter name" that is mandatory for processing this request is not supplied.	400
InvalidParameter	The specified parameter "Action or Version" is not valid.	400
InvalidAccessKeyId.NotFound	The Access Key ID provided does not exist in our records.	404
IncompleteSignature	The request signature does not conform to Aliyun standards.	400
IllegalTimestamp	The input parameter "Timestamp" that is mandatory for processing this request is not supplied.	400
InvalidOwnerId	The specified OwnerId is not valid.	400
InvalidOwnerAccount	The specified OwnerAccount is not valid.	400
InvalidOwner	OwnerId and OwnerAccount can't be used at one API access.	400
Throttling	Request was denied due to request throttling.	400
InvalidAction	The specified action is not valid.	403
ActionUnauthorized	The specified action is not available for you.	403
UnsupportedHTTPMethod	This http method not supported.	403
UnsupportedParameter	The parameter "<parameter name>" is not supported.	400
Forbidden.InstanceNotFound	The specified DB instance does not exist.	404
Forbidden.RAM	The user is not authorized to operate the specified resource, or this operation does not support RAM.	403
Forbidden.NotSupportRAM	This action does not support accessed by RAM mode.	403

Error code	Error message	HTTP status code
Forbidden. RiskControl	This operation is forbidden by Aliyun Risk Control system.	403
InsufficientBalance	Your account does not have enough balance.	400
Forbidden. Authentication	This operation is forbidden by Aliyun Realname Authentication system.	403
Invalid<parameter name>.ValueNotSupported	The specified parameter "parameter name" is not valid.	400
Invalid<parameter name>.Malformed	The specified parameter "parameter name" is not valid.	400
InvalidParameter	The specified parameter "parameter name" is not valid.	400

Specific errors

Error code	Error message	HTTP status code
InvalidRegionId. NotFound	The DBInstanceId provided does not exist in our records.	404
InvalidSecurityIPList. Duplicate	The Security IP address is not in the available range or occupied.	400
InvalidSecurityIPListLength.Malformed	The security IP address is beyond the available range or is already used.	400
InvalidEngineVersionInRegion.NotAvailable	The EngineVersion in the Region is not available.	403
InvalidEngineInRegion.NotAvailable	The Engine in the Region is not available.	403
InvalidDBInstanceClassInRegion.NotAvailable	The DBInstanceClass in the Region is not available.	403
OperationDenied	The resource is out of usage.	403
RegionUnauthorized	There is no authority to create instance in the specified region.	403
QuotaExceeded. CreateInstance	The quota of create instance exceeds.	403

Error code	Error message	HTTP status code
InvalidDBInstanceId.NotFound	The specified DBInstanceId does not exist.	404
MissingParameter	The input parameters "DBInstanceClass" and "DBInstanceStorage" all blank or no change.	400
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	400
OperationDenied.DBInstanceStorageReduce	The operation is not permitted due to reduce storage.	403
OperationDenied.DBInstanceStatus	The operation is not permitted due to instance status.	403
DependencyViolation	The operation is not permitted due to instance mount read only or guard instance.	403
InvalidConnectionStringPrefix.Duplicate	The connection string is not in the available range or occupied.	400
QuotaExceeded.SwitchTime	The quota of switch time exceed.	400
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
InvalidSecurityIps.Duplicate	The quota of security ip exceeds.	400
OperationDenied.CurrentEngineVersion	The operation is not permitted due to specified current version.	400
OperationDenied.ReadOnlyDBInstanceLower	The operation is not permitted due to higher read only instance version.	403
OperationDenied.GuardDBInstanceLower	The operation is not permitted due to higher guard instance version.	403
OperationDenied.MasterDBInstanceState	The status of the specified master instance does not support this operation.	403
QuotaExceeded.DBName	The quota of db exceeds.	400

Error code	Error message	HTTP status code
InvalidDBName. Duplicate	The specified DB name is invalid or already exists.	400
InvalidParameter. Keyword	The specified DBName is a reserved keyword.	400
OperationDenied. DBStatus	The status of the database does not support this operation.	403
OperationDenied. DBInstanceEngine	The operation is not permitted due to engine of instance.	403
FTPServiceUnavailable	The service is unavailable now; wait several minutes and try again.	403
QuotaExceeded. Upload	The quota of file exceeds.	403
InvalidFileName. NotCompleted	The specified "FileName" is not completed.	404
InvalidFileName. NotAvailable	The specified "FileName" is not Available.	404
QuotaExceeded. FileSize	The quota of file size exceeds.	403
QuotaExceeded. DBInstanceStorage	The quota of instance storage exceeds.	403
InvalidDBInfo. Malformed	The specified parameter "DBInfo" is not valid or db not exist.	400
OperationDenied. Region	The operation is not permitted due to different region.	403
OperationDenied. Engine	The operation is not permitted due to different engine.	403
OperationDenied. DBInstanceCid	The operation is not permitted due to DBInstanceCid and SourceDBInstanceCid is same.	403
InvalidTaskId. NotFound	The ImportId provided does not exist in our records.	400
OperationDenied. IncorrectTaskStatus	The operation is not permitted due to status of import.	403
InvalidAccountName. .keyword	The specified AccountName is a reserved keyword.	400

Error code	Error message	HTTP status code
InvalidAccountName.Duplicate	The specified AccountName already exists.	400
QuotaExceeded.AccountName	The quota of account exceeds.	403
OperationDenied.AccountStatus	The status of the account does not support this operation.	403
InvalidDBName.NotFound	The specified database does not exist.	404
OperationDenied.AccountType	The operation is not permitted due to type of account.	403
OperationDenied.BackupJobExists	You cannot perform this operation; a backup job exists.	403
OperationDenied.NoDatabase	The operation is not permitted due to no database.	403
InvalidStartTimeAndEndTime.Malformed	The EndTime must be later than or equal to the StartTime.	400
OperationDenied.BackupJobExists	You cannot perform this operation; a backup job exists.	403
InvalidBackupId.NotFound	The BackupId provided does not exist in our records.	404
OperationDenied.NotFoundBackup	The operation is not permitted due to no backup.	403
OperationDenied.BackupStatus	The operation is not permitted due to type of backup.	403
OperationDenied.BackupMethod	The operation is not permitted method of backup.	403
OperationDenied.TempDBInstanceExists	You cannot perform this operation; a temp instance exists.	403
Forbidden.Authentication	The operation is forbidden by Aliyun Realname Authentication System.	403
IncorrectDBInstanceConnType	Current DB instance conn type does not support this operation.	404
IncorrectVpcId.Mismatch	The specified parameter "VpcId" is not valid.	400

Error code	Error message	HTTP status code
IntranetNetTypeNotExists	Current DB instance net type does not support this operation.	404
InvalidDBInstanceName.NotFound	The DBInstanceId provided does not exist in our records.	403
InvalidConnectionMode.ValueNotSupported	The specified parameter "ConnectionMode" is not valid.	400
InvalidConnectionString.DuplicateSpecified	connection string already exists in the Aliyun RDS.	403
InvalidConnectionString.DuplicateSpecified	connection string or port want to be modified is the same with current net type.	400
InvalidConnectionStringPrefix.Duplicated	The specified connection string already exists.	403
InvalidCurrentConnectionString.NotFound	Specified current connection string doesn't exist.	400
InvalidDBInstanceId.NotFound	The specified DBInstanceId does not exist.	400
InvalidDBInstanceId.QuotaExceeded	The quota of instance id exceeds.	400
InvalidDBInstanceNetType.NotFound	The Specified DB instance net type is not found.	404
InvalidDBInstanceNetType.ValueNotSupported	The specified parameter "DBInstanceNetType" is not valid.	400
InvalidDBInstanceType.ValueNotSupported	The specified parameter "DBInstanceType" is not valid.	400
InvalidEngineVersion.Malformed	The specified parameter "EngineVersion" is not valid.	400
InvalidInstanceNetworkType.ValueNotSupported	The specified parameter "InstanceNetworkType" is not valid.	400
InvalidParameter	The specified parameter "dbInstanceId" is not valid.	400

Error code	Error message	HTTP status code
InvalidPort. Malformed	Specified port is not valid.	400
InvalidPrivateIpAddress. Duplicated	Specified private IP address is duplicated.	400
InvalidPrivateIpAddress. Mismatch	Specified private IP address is not in the CIDR block of virtual switch.	400
InvalidVPCId. NotFound	The specified connection string or port does not match the current network type.	400
InvalidVSwitchId. Mismatch	Specified instance and virtual switch are not in the same zone.	400
InvalidVSwitchId. NotFound	Specified virtual switch is not found in specified VPC.	400
NetTypeExists	Specified net type already existed.	400
NetTypeExists	Specified public net type already existed.	403
OperationDenied. DBInstanceNetType	The network type of the specified instance does not support this operation.	403
OperationDenied. DBInstanceStatus	The specified connection string or port does not match the current network type.	403
OperationDenied. DBInstanceType	The operation is not permitted due to type of instance.	403
OperationDenied. LockMode	The instance is locked.	403
OperationDenied. Switch	Specified instance cannot be switched.	400
OperationDenied. Switch	Specified instance cannot be switched to VPC.	403
OperationDenied. SwitchToVPC	Specified instance cannot be switched to VPC.	403
OperationDenied	The requested resource is sold out in the specified zone; try other types of resources or other regions and zones.	403
OperationDenied	The vpc cloudinstanceIp is use, please check params.	406
OperationDenied	The vpc service is error, please check params.	400

Error code	Error message	HTTP status code
PARAMETER_ERROR	The vpc request parameter may not be null.	406
PARAMETER_MUST_NOT_NULL	The parameter must not be null.	406
PublicConnectionExists	PublicConnection exists.	403
bpcIzNoNotEqualsRdsMultIzNo	Specified vpc IzNo not equal rds IzNo.	400
IncorrectDBInstanceState	CurrentDB instance state does not support this operation.	403
IncorrectDBInstanceType	CurrentDB instance type does not support this operation.	400
IncorrectDBInstanceLockMode	CurrentDB instance lock mode does not support this operation.	400
ParamNotSupportedForCurrentVersion	Parameter is not supported for current version.	400
InvalidStatus.Format	MigrateTask Status is not valid.	400
EngineVersionNotSupported	EngineVersion specified cannot be replicate with the source DB Instance.	400
EngineNotSupported	Engine specified cannot be supported the operation.	400
ConnectionModeNotSupported	ConnectionMode specified cannot be replicate with the source DB Instance.	400
InvalidConfigurationValue.Malformed	Specified ConfigurationValue is not valid.	403
InvalidConfigurationValueStatus.Malformed	Specified ProxyConfigurationValue (status) is not valid.	403
InvalidConfigurationValueOrther.Malformed	Specified ProxyConfigurationValue (check_interval_seconds or max_failed_login_attempts or blocking_seconds) is not valid.	403
ProxyConnectionPersistExists	Specified same ProxyConnectionPersist already exists.	400

Error code	Error message	HTTP status code
ProxyConnectionPersist.NotFound	Specified same ProxyConnectionPersist already exists.	400
ProxyConnectionPersist.NotFound	Specified ProxyConnectionPersist is not found.	400
ProxyConnectionPersistParametersInvalid	ProxyConnectionPersist parameter out of range	400
InvalidConfigValue	ProxyConnectionPersist parameter config table not exists or data error.	400
InvalidDBInstance.NotFound	Specified instance does not exist or not support.	400
ProxyConnectionPersist.NotFound	Specified ProxyConnectionPersist is not found.	400
ProxyConnectionPersistParametersInvalid	ProxyConnectionPersist parameter out of range.	400
InvalidConfigValue	parameter config table not exists or data error.	400

2.11.1.13.1.2 Server error codes

Error code	Error message	HTTP status code
ServiceUnavailable	The request has failed due to a temporary failure of the server.	503
InternalServerError	The request processing has failed due to some unknown error, exception or failure.	500

2.11.1.13.2 Instance types

Table 2-408: Instance types

Instance type	vCPU	Memory (MB)	Storage space (GB)	Storage space (Mbit/s)	Disk type
gpdb.group.segsdx1	1	8,192	80	150	SSD
gpdb.group.segsdx2	2	16,384	160	300	SSD
gpdb.group.segsdx16	16	131,072	1,280	2,400	SSD

2.11.1.13.3 Performance parameters

Table 2-409: Performance parameters

API parameter	Description
Gpdb_IOPS	The input/output operations per second (IOPS) of the instance. It is in the data_iops&write_iops&read_iops format.
IOPSUsage	The IOPS usage rate of the instance.
CpuUsage	The CPU utilization of the instance.
ConnectionUsage	The connection usage rate of the instance.
Gpdb_session	The number of connections to the instance.
Gpdb_SpaceUsage	The disk usage of the instance. Unit: MB. It is in the ins_size&data_size&log_size&other_size format.
DiskUsage	The disk usage rate of the instance.
Gpdb_BPS	The bytes per second (BPS) size of the instance. Unit: byte. It is in the data_bps&write_bps&read_bps format.
BPSUsage	The BPS usage rate of the instance.
MemoryUsage	The memory usage rate of the instance.
Gpdb_memory	The memory usage of the instance. Unit: MB.

2.11.1.13.4 Instance states

Table 2-410: Instance states

State	Description
Creating	The instance is being created.
Running	The instance is in the running state.
Deleting	The instance is being deleted.
Rebooting	The instance is being restarted.
DBInstanceClassChanging	The instance specifications are being changed.
Transferring	The instance is being migrated.
EngineVersionUpgrading	The engine version is being upgraded.
TransferringToOtherInstance	The data is being migrated to other instances of AnalyticDB for PostgreSQL.
GuardDBInstanceCreating	The disaster recovery instance is being created .
Restoring	The instance is being restored from the backup .
Importing	The data is being imported.
ImportingFromOtherInstance	The data is being imported from other instances of AnalyticDB for PostgreSQL.
DBInstanceNetTypeChanging	The network type is being changed.
GuardSwitching	The instance is undergoing disaster recover failover.

2.11.1.13.5 Terms

Table 2-411: Terms

Term	Full name	Description
DBInstance	database instance	A database service process that takes up physical memory independently . You can configure different memory size and disk space. The memory size determines the performance of the instance, such as the IOPS and connections.

Term	Full name	Description
DBInstanceCld	database instance ID	A globally unique name that identifies an instance.
Group	compute group	A compute group is the minimum computing and resource storage unit of an AnalyticDB for PostgreSQL database that you can purchase.
DBInstanceClass	group instance class	The group types are as follows: • gpdb.group.segsdx1: 1 vCPU, 8 GB of memory, and 80 GB of SSD storage space. • gpdb.group.segsdx2: 2 vCPUs, 16 GB of memory, and 160 GB of SSD storage space. • gpdb.group.segsdx16: 16 vCPUs, 128 GB of memory, and 1.28 TB of SSD storage space. In addition to a segment, each type of compute group has a mirror node that has the same specifications as the segment.

Term	Full name	Description
DBInstanceGroupCount	group count	The number of compute groups indicates the number of AnalyticDB for PostgreSQL groups in the instance that you have purchased. For example: If the value of DBInstanceClass is gpdb.group.segsdx2, the instance has two compute groups. Total available resources: 4 vCPUs, 32 GB of memory, and 320 GB of SSD storage space. For resource and performance reasons, the valid value of DBInstanceGroupCount strictly corresponds to DBInstanceClass: - gpdb.group.segsdx1: 2 - gpdb.group.segsdx2: 2, 4, and 8 - gpdb.group.segsdx16: 2 and 4
DB Account	database account	An account identifies the access permissions of a database. A database can be created with multiple accounts, and an account can be associated with multiple databases.
AccountName	database account name	The name of a database account identifies the account. The name must be unique among all the database accounts that are in the same instance.
Region	region	The region indicates the data center in the specified region.

2.11.2 SDK reference

2.11.2.1 Java SDK

2.11.2.1.1 Quick start

This topic describes how to obtain and use the AnalyticDB for PostgreSQL Java SDK.

Preparation

- You must have an Apsara Stack account and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Java SDK. For more information about how to view and obtain your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- For more information about how to obtain the service endpoint, see [Obtain an endpoint](#).
- The Apsara Stack Java SDK supports JDK 1.6 and later.

Installation

If you use Apache Maven to manage Java projects, you only need to import the JAR file to the pom.xml file of the project.

To use the SDK of a service, you must install the service SDK and the SDK core library.

The version of the SDK core library is 3.7.1, and the version of the AnalyticDB for PostgreSQL SDK is 3.7.1.

```
<dependencies>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-core</artifactId>
    <version>3.7.1</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-core-3.7.1.jar</systemPath>
  </dependency>
</dependencies>
```

Usage

The following code provides an example of how to use the Java SDK:

1. Create and initialize a DefaultAcsClient instance.
2. Create an API request and configure the parameters.
3. Initiate the request and handle the response or exception.

```
import com.example.CommonRequest;
import com.example.CommonResponse;
import com.example.DefaultAcsClient;
import com.example.exceptions.ClientException;
import com.example.exceptions.ServerException;
import com.example.http.FormatType;
import com.example.http.MethodType;
import com.example.profile.DefaultProfile;
import com.example.profile.IClientProfile;
```

```

public class CommonTest {
    private static final String regionId = "your-region-id";
    private static final String userAccessKeyId = "your-access-key-id";
    private static final String userAccessKeySecret = "your-access-key-secret";
    private static final String crEndpointDomain = "cr-endpoint-domain";

    public static void main(String[] args) throws Exception {

        // Create and initialize a DefaultAcsClient instance.
        IClientProfile profile = DefaultProfile.getProfile(regionId, userAccessKeyId,
userAccessKeySecret);
        DefaultProfile.addEndpoint(regionId, regionId, "cr", crEndpointDomain);
        DefaultAcsClient client = new DefaultAcsClient(profile);

        // Create an API request and configure the parameters.
        CommonRequest request = new CommonRequest();
        request.setDomain("cr.cn-hangzhou.example.com");
        request.setVersion("2016-06-07");
        request.setUriPattern("/users");
        request.setMethod(MethodType.PUT);
        String content = "{\"User\":{\"Password\":\"As123456\"}}\n";
        request.setHttpContent(content.getBytes(), "UTF-8", FormatType.JSON);

        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            e.printStackTrace();
        } catch (ClientException e) {
            e.printStackTrace();
        }
    }
}

```

2.11.2.1.2 Use the Java SDK

2.11.2.1.2.1 Install the Java SDK

This topic describes how to install and call the Java SDK of AnalyticDB for PostgreSQL.

The Apsara Stack Java SDK supports JDK V1.6 and later. You can import JAR files to install the JDK.

Click [here](#) to download JAR files of AnalyticDB for PostgreSQL.

If you are using Eclipse or IntelliJ as the integrated development environment, install the AnalyticDB for PostgreSQL Java SDK by importing the JAR files.

The installation methods are as follows:

- Use Eclipse

Complete the following steps to install the AnalyticDB for PostgreSQL Java SDK in Eclipse projects:

1. Copy the downloaded `aliyun-java-sdk-gpdb-version.jar` file to your project folder.
2. Open your project in Eclipse, right-click the project, and choose **Properties** from the shortcut menu.
3. In the dialog box that appears, choose **Java Build Path > Libraries > Add JARs** to add the downloaded JAR file.
4. Click **Apply and Close**.

- Use IntelliJ

Complete the following steps to install the Apsara Stack Java SDK in IntelliJ projects:

1. Copy the downloaded `aliyun-java-sdk-gpdb-version.jar` file to your project folder.
2. Open your project in IntelliJ. In the menu bar, choose **File > Project Structure**.
3. Click **Apply**, and then click **OK**.

2.11.2.1.2.2 Configure authentication credentials

When using Apsara Stack SDKs to access Apsara Stack services, you must provide an Apsara Stack account for authentication.

The Java SDK supports authentication through an AccessKey pair. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

If you want to use your AccessKey pair to access Apsara Stack, you must configure the AccessKey pair as a credential when you initialize the client.

**Notice:**

Do not disclose any code that may contain your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your Apsara Stack account may be compromised.

```
DefaultProfile profile = DefaultProfile.getProfile(  
    "<your-region-id>",    // The ID of the region where your instance is located.  
    "<your-access-key-id>", // The AccessKey ID of your account.
```

```
"<your-access-key-secret>"); // The AccessKey Secret of your account.
```

2.11.2.1.2.3 Initiate a request

This topic describes how to initiate a request by calling the Java SDK of AnalyticDB for PostgreSQL.

Procedure

1. Create an AcsClient instance.

```
IACSClient client = new DefaultAcsClient(profile);
```

2. Create a request.

The naming convention for requests is `${apiName}Request`. **`${apiName}`** indicates the API operation name, such as `DescribeDBInstances`.

When the SDKs of multiple services are used, different requests may have the same name. Differentiate the requests by SDK package.

```
DescribeDBInstancesRequest request = new DescribeDBInstancesRequest();  
request.setPageSize(10);
```

3. Initiate a request and handle the response.

```
DescribeDBInstancesResponse response;  
try {  
    response = client.getAcsResponse(request);  
    for (DescribeDBInstancesResponse.Instance instance:response.getInstances()) {  
        System.out.println(instance.getPublicIpAddress());  
    }  
} catch (ServerException e) {  
    e.printStackTrace();  
} catch (ClientException e) {  
    e.printStackTrace();  
}
```

```
}
```

All returned fields are deserialized into the response. You can call `response.getXXX()` to obtain the response fields.

```
instanceStatus := response.getStatus()
```

However, if an exception occurs or if you require the original HTTP response, you can use `doAction()` to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.11.2.1.2.4 Troubleshooting

If an error occurs on the server side or SDK side, the Apsara Stack Java SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Generally, you are not required to handle the errors returned by the Apsara Stack Java SDK. You are only required to handle the errors on the server side according to the error message.

- `ServerException` is the error message on the server side.
- `ClientException` is the error message on the SDK side.

For example, if the following error occurs, modify the ID of AccessKey according to the detailed error message.

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified access key is not found.
```

To handle the errors returned by the Apsara Stack Java SDK, see the following code example for reference:

```
try {
    FooResponse response = client.getAcsResponse(request);
    // Handle the response.
    // ...
} catch (ServerException e) {
    // Add your own error handling logic here.
    // For example, print the detailed error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If the problem is tricky, open a ticket and provide the RequestId for us.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {
    // Add your own error handling logic here.
    // For example, print the detailed error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
}
```

}

2.11.2.1.2.5 Common errors

This topic describes the common errors when you use Java SDK and how to troubleshoot the problems based on the corresponding causes and solutions.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot automatically obtain the endpoint of the called service in the specified region.	Check whether the provided region ID and endpoint are correct. After obtaining the correct endpoint, use the following code to set the endpoint: <pre>DefaultProfile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response	The SDK response fails to be deserialized. In most cases, the cause is that the structure of the response received by the SDK does not conform to the API metadata, such as mismatched fields or incorrect formatting.	You can use the <code>client.doAction(request)</code> method to obtain the original HTTP response.
SDK.TimeoutError	The request timed out 4 times (3 for retry), perhaps we should have the threshold raised a little?	The request has timed out and all retry attempts have failed.	In scenarios such as poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError:InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect Recommend :https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API only accepts HTTPS requests and does not accept HTTP requests.	You can add the following code to the request before it is sent: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.11.2.2 Python SDK

2.11.2.2.1 Quick start

This topic describes how to obtain and use the AnalyticDB for PostgreSQL Python SDK.

Preparation

- You must have an Apsara Stack account and an AccessKey pair (AccessKey ID and AccessKey Secret) to use the Python SDK. For more information about how to view and obtain your AccessKey pair in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- For more information about how to obtain the service endpoint, see [Obtain an endpoint](#).

Install the Python SDK

To install the Python SDK, perform the following operations:

1. Install the SDK core library.

- If you are using Python V2.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core
```

- If you are using Python V3.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core-v3
```

2. Install the AnalyticDB for PostgreSQL SDK.

The following code shows how to install the AnalyticDB for PostgreSQL SDK:

```
pip install aliyun-python-sdk-rds
```

Usage

The following code provides an example of how to use the Python SDK:

1. Create a client instance. When you create the client instance, you must obtain the region ID, AccessKey ID, and AccessKey Secret.
2. Create an API request and configure the parameters.
3. Initiate the request and handle the response or exception.

```
from aliyunsdkcore import client
from aliyunsgpdpdb.request.v20160101 import DescribeDBInstancesRequest

# global config
region_id = 'xxxxx'
secret_id = 'xxxxx'
secret_key = 'xxxxx'

# product config
product_name = 'AnalyticDB for PostgreSQL'

# setup request
request = DescribeDBInstancesRequest.DescribeDBInstances()

# get response
response = clt.do_action_with_exception(request)
```

```
print response
```

2.11.2.2.2 Use the Python SDK

2.11.2.2.2.1 Install the Python SDK

This topic describes how to install and use the AnalyticDB for PostgreSQL Python SDK.

The Python SDK supports Python V2.6.x, 2.7.x, 3.x, and later. The following installation methods are supported:

- Use pip (recommended)

Run the following commands to install the Python SDK by using pip:

```
pip install aliyun-python-sdk-core # Install the Apsara Stack SDK core library.  
pip install aliyun-python-sdk-gpdb # Install the AnalyticDB for PostgreSQL SDK.
```

Note:

If you are using Python V3.x, use the `pip install aliyun-python-sdk-core-v3` command instead of the `pip install aliyun-python-sdk-core` command.

- Use GitHub

Run the following commands to install the Python SDK by using GitHub:

```
git clone https://github.com/aliyun/aliyun-openapi-python-sdk.git  
# Install the SDK core library.  
cd aliyun-python-sdk-core  
python setup.py install  
# Install the AnalyticDB for PostgreSQL SDK.  
cd aliyun-python-sdk-gpdb  
python setup.py install
```

- Use the source code

1. [Download the SDK package](#) and decompress it.

2. You can use one of the following methods to install the SDK package:

- Modify the `sys.path` variable and add the directory that you need to search for. It is the directory where the SDK package has been decompressed to. Example:

```
>>> import sys  
>>> sys.path.append('/Users/michael/my_py_scripts')
```

Note:

This modification takes effect only when the instance is running.

- Configure the PYTHONPATH environment variable and add the directory where you need to decompress the SDK package to. The content of this environment variable is automatically added to the module search directory.

The configuration of the environment variable PYTHONPATH is similar to that of the environment variable Path.

- Place the decompressed SDK package in the project. The Python SDK is now available to be used in your project.

2.11.2.2.2.2 Configure authentication credentials

When using Apsara Stack SDKs to access Apsara Stack services, you must provide an Apsara Stack account for authentication.

The Python SDK supports authentication through an AccessKey pair. For more information about how to obtain an AccessKey pair, see [Obtain an AccessKey pair](#).

If you want to use your AccessKey pair to access Apsara Stack, you must configure the AccessKey pair as a credential when you initialize the client.

Notice:

Do not disclose any code that may contain your AccessKey pair. For example, do not commit the code to public GitHub projects. Otherwise, your Apsara Stack account may be compromised.

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

2.11.2.2.2.3 Initiate a request

This topic describes how to initiate a request by calling the Python SDK of AnalyticDB for PostgreSQL.

Procedure

1. Import the SDK of the service.

```
from aliyunsdkcore import client
from aliyunsdkgpdb.request.v20160101
import DescribeDBInstancesRequest
```

2. Create an AcsClient instance.

```
client = AcsClient(
    "<your-access-key-id>",
    "<your-access-key-secret>",
    "<your-region-id>"
```

```
);
```

3. Create a request and configure the required parameters.

```
request = DescribeDBInstancesRequest.DescribeDBInstances()
```

4. Initiate an API request and display the response.

```
response = client.do_action_with_exception(request)
print response
```

2.11.2.2.2.4 Set HTTPS requests

The Python SDK allows you to make API requests over HTTP and HTTPS.

When using the Python SDK, you can specify a default protocol (HTTP or HTTPS) for requests to different services, or set a global protocol for all requests.

Note:

The default HTTP or HTTPS protocol for each service takes precedence over the global protocol.

Add OpenSSL support

The HTTPS protocol for Python SDK is supported by the OpenSSL of Python. To send HTTPS requests by using the Python SDK, you must add OpenSSL support in Python.

Run the `python -c "import ssl"` command to check whether your Python environment supports OpenSSL. If the error message `ImportError: No module named ssl` is not displayed, OpenSSL is supported.

If OpenSSL is not supported, run the following command to install OpenSSL:

```
pip install pyopenssl
```

Specify the HTTP or HTTPS protocol for a request

The following example shows how to specify the HTTPS protocol for a request:

```
request = DescribeDBInstancesRequest.DescribeDBInstances()
request.set_protocol_type("https")
# Valid values: "https" and "http".
```

Set a global protocol for all requests

The following example shows how to set a default global protocol for all requests:

```
import aliyunsdkcore.request
aliyunsdkcore.request.set_default_protocol_type("https")
```

```
# Create a request and call client.do_action_with_exception() to send the request.
```

2.11.2.2.5 Troubleshooting

If an error occurs on the server side or SDK side when you use the Python SDK, the Python SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Generally, you are not required to handle the errors returned by the Python SDK. You are only required to handle the errors on the server side according to the error message.

- `ServerException` is the error message on the server side.
- `ClientException` is the error message on the SDK side.

For example, if the following error occurs, modify the ID of AccessKey according to the detailed error message.

```
aliyun sdkcore.acs\_exception.exceptions.ServerException: HTTP Status: 404 Error: InvalidAccessKeyId.NotFound Specified access key is not found.
```

To handle the errors returned by the Python SDK, see the following code example for reference:

```
try:
    response = client.do_action_with_exception(request)
except ServerException as e:
    # Add your own error handling logic here.
    # For example, print the detailed error message.
    print e.get_http_status()
    print e.get_error_code()
```

```
print e.get_error_msg()
```

2.11.2.2.2.6 Common errors

This topic lists the causes and solutions for some common errors you may experience when you use the SDK.

Error code	Error message	Cause	Solution
SDK.InvalidRegionId	Can not find endpoint to access.	The error message returned because the SDK failed to automatically obtain the endpoint of the requested service in the specified region.	Check whether the specified region ID and endpoint are correct. After you have obtained the endpoint, you can run the following code to set the endpoint: <pre>from aliyunsdkcore.profile import region_provider region_provider.modify_point('product_name', 'region_id', 'endpoint')</pre>
SDK.TimeoutError	—	The error message returned because the request timed out and all retries failed.	In low network quality scenarios, we recommend that you increase the timeout period or the maximum number of retries.
SDK.ServerError: InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect. Recommend: https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The error message returned because you made an HTTP request. The API only accepts HTTPS requests.	Before you send a request, add the following code: <pre>request.set_protocol_type('https')</pre>

2.11.2.3 Obtain an AccessKey pair

You can obtain the AccessKey pair on the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.11.2.4 Obtain an endpoint

You can obtain the product endpoint in Apsara Stack Operations.

Procedure

1. Log on to Apsara Stack Operations.
For how to log on to Apsara Stack Operations, see **Operations of basic platforms > Apsara Stack Operations > Log on to Apsara Stack Operations** in Operations Guide .
2. Click **Products** in the left-side navigation pane.
3. Choose **Apsara Infrastructure Management Framework** in the product list to go to the Apsara Infrastructure Management Framework page.
4. Choose **Operations > Machine Operations**. The **Machine Operations** page appears.

5. Select a machine and then click **Terminal** to log on to the machine.

a55e09106.cloud.e10.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E10		GOOD		Terminal	Machine Operation

6. Run the command **curl -l "http://127.0.0.1:7070/api/v3/column/c.sr.service_registration,c.sr.id?c.sr.service_registration"** to obtain JSON data.

[illegible]

7. You can find the endpoint of AnalyticDB for PostgreSQL by using the ID (gpdb-yaochi) and key value (gp.openapi.endpoint) of the AnalyticDB for PostgreSQL service.

```
{
  "c.sr.id": "gpdb-yaochi", ID
  "c.sr.service_registration": "{\"gp.openapi-inc.endpoint\": \"gpdb-inc.env6.shuguang.com\", \"gp.openapi.endpoint\": \"gpdb.env6.shuguang.com\"}" endpoint
},
```

2.12 Data Transmission Service (DTS)

2.12.1 API reference

2.12.1.1 Call OpenAPI

2.12.1.1.1 API overview

This topic describes the APIs that DTS OpenAPI supports.

Data migration APIs

API	Description
ConfigureMigrationJob	Configures a migration task.
StartMigrationJob	Starts or restarts a migration task.
SuspendMigrationJob	Suspends a migration task.
StopMigrationJob	Stops a migration task.
DeleteMigrationJob	Deletes a migration task.
DescribeMigrationJobStatus	Queries the status of a migration task.
DescribeMigrationJobDetail	Queries the details of a migration task.
DescribeMigrationJobs	Queries the list of migration tasks.

Data synchronization APIs

API	Description
CreateSynchronizationJob	Purchases a synchronization instance.
ConfigureSynchronizationJob	Configures a synchronization task.
StartSynchronizationJob	Starts a synchronization task.
SuspendSynchronizationJob	Suspends a synchronization task.
DeleteSynchronizationJob	Deletes a synchronization task.
ModifySynchronizationObject	Modifies the list of objects to be synchronized.
DescribeObjectModifyStatus	Queries the modification status of the list of objects to be synchronized.
DescribeSynchronizationJobStatus	Queries the running status of a synchronization task.
DescribeSynchronizationJobs	Queries the list of synchronization tasks.
DescribeInitializationStatus	Queries the initialization status of a synchronization task.

Data subscription APIs

API	Description
CreateSubscriptionInstance	Purchases a subscription channel.
ConfigureSubscriptionInstance	Configures a subscription channel.
StartSubscriptionInstance	Starts a subscription task.
DeleteSubscriptionInstance	Releases a subscription channel.
DescribeSubscriptionInstanceStatus	Queries the status of a subscription channel.
DescribeSubscriptionInstances	Queries the list of subscription instances .
ModifySubscriptionObject	Modifies the list of objects to be subscribed.
ModifyConsumptionTimestamp	Modifies the consumption checkpoint.

2.12.1.2 Data migration APIs

2.12.1.2.1 ConfigureMigrationJob

2.12.1.2.1.1 Overview

You can call this operation to configure a data migration task, including the source and destination instances and the objects to be migrated.

Before a migration task is started, you can call this operation repetitively to modify task configurations.

2.12.1.2.1.2 Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ConfigureMigrationJob.
MigrationJobId	String	Yes	The ID of the migration task.
MigrationJobName	String	No	The name of the migration task.

Parameter	Type	Required	Description
SourceEndpoint. InstanceType	String	Yes	The type of the source instance in the migration task. Valid values: • RDS: an ApsaraDB for RDS instance • ECS: a user-created database that is hosted on an ECS instance • LocalInstance: a user-created database in an on-premises IDC • MongoDB: an ApsaraDB for MongoDB instance

Parameter	Type	Required	Description
SourceEndpoint.Region	String	Yes	The region of the source instance. If it is a user-created database, you can select the region that is closest to your data center. Valid values: - cn-hangzhou: Alibaba Cloud in the China (Hangzhou) region - cn-shanghai: Alibaba Cloud in the China (Shanghai) region - cn-qingdao: Alibaba Cloud in the China (Qingdao) region - cn-beijing: Alibaba Cloud in the China (Beijing) region - cn-zhangbei: Alibaba Cloud in the China (Zhangbei) region - cn-shenzhen: Alibaba Cloud in the China (Shenzhen) region - cn-hongkong: Alibaba Cloud in the China (Hong Kong) region - us-west-1: Alibaba Cloud in the US (Silicon Valley) region - us-east-1: Alibaba Cloud in the US (Virginia) region - ap-southeast-1: Alibaba Cloud in the Singapore region - cn-hangzhou-finance-1: Finance Cloud in the China (Hangzhou) region - cn-qingdao-finance-1: Finance Cloud in the China (Qingdao) region - cn-shanghai-finance-1: Finance Cloud in the China (Shanghai) region - cn-shenzhen-finance-1: Finance Cloud in the China (Shenzhen) region - me-east-1: Alibaba Cloud in the UAE (Dubai) region - en-central-1: Alibaba Cloud in the Germany (Frankfurt) region

Parameter	Type	Required	Description
SourceEndpoint.InstanceId	String	No	The ID of the source instance. - If you specify the value of the SourceEndpoint.InstanceType parameter as RDS, the value of the SourceEndpoint.InstanceId parameter is the ID of an RDS instance. - If you specify the value of the SourceEndpoint.InstanceType parameter as ECS, the value of the SourceEndpoint.InstanceId parameter is the ID of an ECS instance. - If you specify the value of the SourceEndpoint.InstanceType parameter as MongoDB, the value of the SourceEndpoint.InstanceId parameter is the ID of an ApsaraDB for MongoDB instance.
SourceEndpoint.EngineName	String	No	The database type of the source instance. This parameter is required if the value of the SourceEndpoint.InstanceType parameter is not RDS. Valid values: MySQL, SQLServer, PostgreSQL, Oracle, MongoDB, and Redis.
SourceEndpoint.IP	String	No	The endpoint of the source instance. This parameter is required if the source instance is a user-created database.
SourceEndpoint.Port	String	No	The port on which the source instance is listening. This parameter is required if the source instance is a user-created database.
SourceEndpoint.OracleSID	String	No	The SID of the source Oracle database.
SourceEndpoint.DatabaseName	String	No	The database name of the source instance used for establishing a connection if the source instance is a PostgreSQL or MongoDB database.
SourceEndpoint.UserName	String	Yes	The username that is used to access the source instance.
SourceEndpoint.Password	String	Yes	The password that is used to access the source instance.

Parameter	Type	Required	Description
SourceEndpoint.OwnerID	String	Yes	The UID of the Apsara Stack tenant account that owns the source instance. This parameter is required if the source instance is an RDS instance and uses a different Apsara Stack tenant account from that of the destination instance.
SourceEndpoint.Role	String	Yes	The authorization role granted by the Apsara Stack tenant account holder of the source instance to the Apsara Stack tenant account of the destination instance. This parameter is required if the source instance is an RDS instance and uses a different Apsara Stack tenant account from that of the destination instance. For more information about role permissions and how to grant a role, see Create a cross-account migration or synchronization task .
DestinationEndpoint.InstanceType	String	Yes	The type of the destination instance specified in the migration task. Valid values: • RDS: an RDS instance • ECS: a user-created database on ECS • LocalInstance: a user-created database in an on-premises IDC • MongoDB: an ApsaraDB for MongoDB instance • Redis: a KVStore for Redis instance

Parameter	Type	Required	Description
DestinationEndpoint. Region	String	Yes	The region of the destination instance. If it is a user-created database, you can select the region that is closest to your data center. Valid values: - cn-hangzhou: Alibaba Cloud in the China (Hangzhou) region - cn-shanghai: Alibaba Cloud in the China (Shanghai) region - cn-qingdao: Alibaba Cloud in the China (Qingdao) region - cn-beijing: Alibaba Cloud in the China (Beijing) region - cn-zhangbei: Alibaba Cloud in the China (Zhangbei) region - cn-shenzhen: Alibaba Cloud in the China (Shenzhen) region - cn-hongkong: Alibaba Cloud in the China (Hong Kong) region - us-west-1: Alibaba Cloud in the US (Silicon Valley) region - us-east-1: Alibaba Cloud in the US (Virginia) region - ap-southeast-1: Alibaba Cloud in the Singapore region - cn-hangzhou-finance-1: Finance Cloud in the China (Hangzhou) region - cn-qingdao-finance-1: Finance Cloud in the China (Qingdao) region - cn-shanghai-finance-1: Finance Cloud in the China (Shanghai) region - cn-shenzhen-finance-1: Finance Cloud in the China (Shenzhen) region - me-east-1: Alibaba Cloud in the UAE (Dubai) region - en-central-1: Alibaba Cloud in the Germany (Frankfurt) region

Parameter	Type	Required	Description
DestinationEndpoint.InstanceID	String	No	The ID of the destination instance. - If you specify the value of the DestinationEndpoint.InstanceType parameter as RDS, the value of the DestinationEndpoint.InstanceID parameter is the ID of an RDS instance. - If you specify the value of the DestinationEndpoint.InstanceType parameter as ECS, the value of the DestinationEndpoint.InstanceID parameter is the ID of an ECS instance. - If you specify the value of the DestinationEndpoint.InstanceType parameter as MongoDB, the value of the DestinationEndpoint.InstanceID parameter is the ID of an ApsaraDB for MongoDB instance. - If you specify the value of the DestinationEndpoint.InstanceType parameter as Redis, the value of the DestinationEndpoint.InstanceID parameter is the ID of a KVStore for Redis instance.
DestinationEndpoint.EngineName	String	No	The database type of the destination instance. This parameter is required if the destination instance is a user-created database. Valid values: MySQL, PostgreSQL, MongoDB, and Redis.
DestinationEndpoint.IP	String	No	The endpoint of the destination instance. This parameter is required if the destination instance is a user-created database.
DestinationEndpoint.Port	String	No	The port on which the destination instance is listening. This parameter is required if the destination instance is a user-created database.
DestinationEndpoint.DatabaseName	String	No	The database name of the destination instance used for establishing a connection. This parameter is required if the destination instance is a PostgreSQL or MongoDB database.
DestinationEndpoint.UserName	String	Yes	The username that is used to access the destination instance.

Parameter	Type	Required	Description
DestinationEndpoint.Password	String	Yes	The password that is used to access the destination instance.
MigrationMode.StructureInitialization	Boolean	Yes	Specifies whether the migration task performs schema migration. Valid values: - true: yes - false: no
MigrationMode.DataInitialization	Boolean	Yes	Specifies whether the migration task performs full data migration. Valid values: - true: yes - false: no
MigrationMode.DataSynchronization	Boolean	Yes	Specifies whether the migration task performs incremental data synchronization. Valid values: - true: yes - false: no
MigrationObject	List	Yes	The objects to be migrated. For more information, see the MigrationObject parameter definition section.

2.12.1.2.1.3 MigrationObject parameter definitions

The MigrationObject parameters are defined as JSON strings. Certain regular expressions can be used in the object configuration.

The MigrationObject parameter definitions are as follows:

```
MigrationObject:{
  DBName:'The name of the database to be migrated',
  NewDBName:'The mapped name of the database to be migrated in the destination instance'
  SchemaName:'The name of the schema to be migrated',
  NewSchemaName:'The mapped name of the schema to be migrated in the destination instance',
  TableIncludes:[{
    TableName: 'The name of the table to be migrated',
    NewTableName:'The mapped name of the table to be migrated in the destination instance',
    FilterCondition:'where condition',
    ColumnIncludes:[{
      ColumnName:'The name of the column that needs to be migrated in the table',
      NewColumnName:'The mapped name of the column that needs to be migrated in the destination instance'
    }]
    ColumnExcludes:[{
      ColumnName:'The name of the column that does not need to be migrated in the table'
    }]
  }]
}
```

```

    }}
  }}
  TableExcludes:[{
    TableName:'The name of the table that does not need to be migrated in the
    database'
  }}
}

```

SchemaName and NewSchemaName are applicable only to SQLServer. DBName and NewDBName are used to specify the names of other databases.

If you only specify DBName but do not specify lower levels of objects, all objects in the database are migrated.

If you specify DBName and some lower levels of objects, the objects that are not specified are not migrated by default.

You can use the following regular expressions to define different object names:

- A period (.) matches any single character except '\r\n'.
- An asterisk (*) matches zero or more occurrences of a subexpression which occurs before . h.*llo matches strings such as hllo and heeeello.
- A question mark (?) matches zero or one occurrence of a subexpression which occurs before. h.? llo matches hllo and hello, but not haello.
- The [characters] character set matches any character included in the braces. For example , h[aello] matches hallo and hello.
- The [^characters] negative character set does not match any character included in the braces. For example, h[^ae]llo matches hcillo and hdllo, but not hallo or hello.
- The [character1-character2] character range matches any character included in the range from character1 to character2, such as [0-9] and [a-z].

2.12.1.2.1.4 Response parameters

Name	Type	Description
Common response parameters	-	The request ID.

2.12.1.2.1.5 Example

The following example shows how to use the Java SDK to configure a migration task.

```

private static void configureMigrationJob(String MigrationJobId){
    String MigrationJobName="jiangliutest";
    /*Source Endpoint*/
    String SourceEndpoint_InstanceType="RDS";
    String SourceEndpoint_Region="cn-hangzhou";
}

```

```

String SourceEndpoint_InstanceID="rm-xxxxxxxxxxxxxxxxxx";
String SourceEndpoint_UserName="*****";
String SourceEndpoint_Password="*****";
/*Destination Endpoint*/
String DestinationEndpoint_InstanceType="RDS";
String DestinationEndpoint_InstanceID="rm-xxxxxxxxxxxxxxxxxx";
String DestinationEndpoint_UserName="*****";
String DestinationEndpoint_Password="*****";
Boolean MigrationMode_StructureInitialization=true;
Boolean MigrationMode_DataInitialization=true;
Boolean MigrationMode_DataSynchronization=true;
String MigrationObject="[\\\"DBName\\\":\\\"jiangliutest\\\",\\\"NewDBName\\\":\\\"jiangliutest\\\",
    + \"\\\"TableIncludes\\\":[{\\\"TableName\\\":\\\"t1\\\",\\\"NewTableName\\\":\\\"t1\\\"}]}]";
ConfigureMigrationJobRequest request = new ConfigureMigrationJobRequest();
request.setMigrationJobId(MigrationJobId);
request.setMigrationJobName(MigrationJobName);
request.setSourceEndpointRegion(SourceEndpoint_Region);
request.setSourceEndpointInstanceType(SourceEndpoint_InstanceType);
request.setSourceEndpointInstanceID(SourceEndpoint_InstanceID);
request.setSourceEndpointUserName(SourceEndpoint_UserName);
request.setSourceEndpointPassword(SourceEndpoint_Password);
request.setDestinationEndpointInstanceType(DestinationEndpoint_InstanceType);
request.setDestinationEndpointInstanceID(DestinationEndpoint_InstanceID);
request.setDestinationEndpointUserName(DestinationEndpoint_UserName);
request.setDestinationEndpointPassword(DestinationEndpoint_Password);
request.setMigrationModeStructureInitialization(MigrationMode_StructureInitialization);
);
request.setMigrationModeDataInitialization(MigrationMode_DataInitialization);
request.setMigrationModeDataSynchronization(MigrationMode_DataSynchronization);
);
request.setMigrationObject(MigrationObject);
try {
    ConfigureMigrationJobResponse response = client.getAcsResponse(request);
    System.out.println("Configure "+ MigrationJobId+ " Succeed");
} catch (Exception e) {
    // TODO: handle exception
    System.out.println("Configure "+MigrationJobId + " Failed!");
    System.out.println(e.toString());
}
}

```

2.12.1.2.2 CreateMigrationJob

2.12.1.2.2.1 Overview

You can call this operation to purchase a database migration instance. After the purchase, you need to call the `ConfigureMigrationJob` operation to configure a migration task.

2.12.1.2.2.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>CreateMigrationJob</code> .

Name	Type	Required	Description
Region	String	Yes	The region of the migration instance. Valid values: - cn-hangzhou: Alibaba Cloud in Hangzhou - cn-shanghai: Alibaba Cloud in Shanghai - cn-qingdao: Alibaba Cloud in Qingdao - cn-beijing: Alibaba Cloud in Beijing - cn-zhangbei: Alibaba Cloud in Zhangbei - cn-shenzhen: Alibaba Cloud in Shenzhen - cn-hongkong: Alibaba Cloud in Hong Kong - us-west-1: Alibaba Cloud in Western US - us-east-1: Alibaba Cloud in Eastern US - ap-southeast-1: Alibaba Cloud in Singapore - cn-hangzhou-finance-1: Finance Cloud in Hangzhou - cn-qingdao-finance-1: Finance Cloud in Qingdao - cn-shanghai-finance-1: Finance Cloud in Shanghai - cn-shenzhen-finance-1: Finance Cloud in Shenzhen - me-east-1: Alibaba Cloud in Dubai - en-central-1: Alibaba Cloud in Frankfurt
MigrationJobClass	String	Yes	The migration task type. Valid values: small, medium, and large. For the testing performance of each instance type, see Data migration types .
ClientToken	String	No	The token used to ensure the idempotence of the request. It can be any string.
OwnerId	String	No	If a RAM user is used to call this operation, the value of OwnerID is the UID of the Apsara Stack tenant account to which this RAM user belongs.

2.12.1.2.2.3 Response parameters

Name	Type	Description
MigrationJobId	String	The migration task ID.

2.12.1.2.2.4 Examples

The following code provides an example of how to use the Java SDK to purchase a migration instance.

```
private static String createMigrationJob(String region,String migrationJobClass) {
    CreateMigrationJobRequest request=new CreateMigrationJobRequest();
    request.setRegion("cn-hangzhou");
    request.setMigrationJobClass("small");
    try {
        CreateMigrationJobResponse response = client.getAcsResponse(request);
        String MigrationJobId = response.getMigrationJobId();
        System.out.println("Create Migration Job succeed. The Migration Job Id is "+
MigrationJobId);
        return MigrationJobId;
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Create Migration Job failed!" +e.toString());
        return null;
    }
}
```

2.12.1.2.3 DeletetMigrationJob

2.12.1.2.3.1 Overview

You can call this operation to delete a migration task regardless of its status. After a migration task is deleted, you cannot query or manage it through OpenAPI or the console.

2.12.1.2.3.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DeletetMigrationJob.
MigrationJobId	String	Yes	The migration task ID .

2.12.1.2.3.3 Response parameters

Name	Type	Description
Common response parameters	-	The request ID.

2.12.1.2.3.4 Examples

The following code provides an example of how to use the Java SDK to delete a migration task.

```
private static void deleteMigrationJob(String MigrationJobId) {
    DeleteMigrationJobRequest request = new DeleteMigrationJobRequest();
    DeleteMigrationJobResponse response = new DeleteMigrationJobResponse();
    request.setMigrationJobId(MigrationJobId);
    try {
        response = client.getAcsResponse(request);
        System.out.println("Delete Migration Job "+MigrationJobId+" Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Delete Migration Job "+MigrationJobId+" Failed!");
        System.out.println(e.toString());
    }
}
```

2.12.1.2.4 DescribeMigrationJobDetail

2.12.1.2.4.1 Overview

When a migration task is in the Migrating, MigrationFailed, Suspending, or Finished status, you can call this operation to query data migration details, including the migration status and progress of each object.

2.12.1.2.4.2 Request parameters

Description	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeMigrationJobDetail.
MigrationJobId	String	Yes	The migration task ID .
MigrationMode. StructureInitialization	Boolean	No	The schema migration details.
MigrationMode. DataInitialization	Boolean	No	The full data migration details.
MigrationMode. DataSynchronization	Boolean	No	The incremental data migration details.

Description	Type	Required	Description
PageSize	Integer	No	• The number of records on each page. Valid values : 30, 50, and 100. Default value: 30. • This parameter is required when only one of these three parameters is set to true : MigrationMode.StructureInitialization, MigrationMode.DataInitialization, and MigrationMode.DataSynchronization.
PageNum	Integer	No	• The page number . It must be greater than 0 and smaller than or equal to the maximum value of Integer. Default value: 1. • This parameter is required when only one of these three parameters is set to true : MigrationMode.StructureInitialization, MigrationMode.DataInitialization, and MigrationMode.DataSynchronization.

2.12.1.2.4.3 Response parameters

Name	Type	Description
StructureInitializationDetails	List	The schema migration details. For more information, see StructureInitializationDetail parameter definitions.
DataInitializationDetails	List	The full data migration details. For more information, see DataInitializationDetail parameter definitions.
DataSynchronizationDetails	List	The incremental data migration details. For more information, see DataSynchronizationDetail parameter definitions.

2.12.1.2.4.4 StructureInitializationDetail parameter definitions

Name	Type	Description
ObjectName	String	The name of the object to be migrated.
ObjectType	String	The type of the object to be migrated. Valid values : Table, Constraint, Index, View, MaterializeView, Type, Synonym, Trigger, Function, Procedure, Package, Default , Rule, and Plan Guide.
SourceOwnerDBName	String	The name of the source database from which the object is to be migrated.
DestinationOwnerDBName	String	The schema of the destination database to which the object is to be migrated.
Status	String	The migration status of the object to be migrated.
ErrorMessage	String	The reason why the object failed to be migrated.

Name	Type	Description
ObjectDefinition	String	The schema definition of the object to be migrated.
Constraints	List	Constraints in which the object to be migrated participates. Constraints are active only when the object to be migrated is a table. The list of constraints includes indexes and foreign keys.

2.12.1.2.4.5 DataInitializationDetail parameter definitions

Name	Type	Description
TableName	String	The name of the table to be migrated.
SourceOwnerDBName	String	The name of the source database from which the table is to be migrated.
DestinationOwnerDBName	String	The name of the destination database to which the table is to be migrated.
Status	String	The migration status of the table.
ErrorMessage	String	The reason why the table failed to be migrated.
TotalRowNum	String	The total number of records to be migrated in the table.
FinishRowNum	String	The number of records that have been migrated in the table.
UsedTime	String	The time that has been spent on migrating the table. Unit : second.

2.12.1.2.4.6 DataSynchronizationDetail parameter definitions

Name	Type	Description
TableName	String	The name of the table to be migrated.
SourceOwnerDBName	String	The name of the source database from which the table is to be migrated.
DestinationOwnerDBName	String	The name of the destination database to which the table is to be migrated.
Status	String	The migration status of the table to be migrated.
ErrorMessage	String	The reason why the table failed to be migrated.

2.12.1.2.4.7 Examples

The following code provides an example of how to use the Java SDK to query migration task details.

```
private static void describeMigrationJobDetail(String MigrationJobId) {
    DescribeMigrationJobDetailRequest request = new DescribeMigrationJobDetailRequest();
    request.setMigrationJobId(MigrationJobId);
    request.setMigrationModeStructureInitialization(true);
    request.setMigrationModeDataInitialization(true);
    request.setMigrationModeDataSynchronization(true);
    try {
        DescribeMigrationJobDetailResponse response = client.getAcsResponse(request);
        System.out.println("Get Migration Detail of Migration Job " + MigrationJobId + " Succeed!");
        List<StructureInitializationDetail> struInitDetails = response.getStructureInitializationDetailList();
        System.out.println("Structure Initialization Detail:");
        for (int i = 0; i < struInitDetails.size(); i++) {
            String objectName = struInitDetails.get(i).getObjectName();
            String SrcDBName = struInitDetails.get(i).getSourceOwnerDBName();
            String DestDBName = struInitDetails.get(i).getDestinationOwnerDBName();
            String Status = struInitDetails.get(i).getStatus();
            String errorMsg = struInitDetails.get(i).getErrorMessage();
            System.out.println("ObjectName:" + objectName + "; SRCDBName:" + SrcDBName + "; DESTDBName:" + DestDBName + "; Status:" + Status + "errorMsg:" + errorMsg);
        }
        List<DataInitializationDetail> dataInitDetails = response.getDataInitializationDetailList();
        System.out.println("Data Initialization Detail:");
        for (int i = 0; i < dataInitDetails.size(); i++) {
            String tblName = dataInitDetails.get(i).getTableName();
            String tbl_srcDBName = dataInitDetails.get(i).getSourceOwnerDBName();
        }
    } catch (Exception e) {
        e.printStackTrace();
    }
}
```

```

        String tbl_destDBName=dataInitDetails.get(i).getDestinationOwnerDBName();
        String dataInitStatus=dataInitDetails.get(i).getStatus();
        String dataInitSumRows=dataInitDetails.get(i).getTotalRowNum();
        String dataInitFinishRows=dataInitDetails.get(i).getFinishRowNum();
        String dataUsedTime=dataInitDetails.get(i).getMigrationTime();
        String dataInitErrMsg = dataInitDetails.get(i).getErrorMessage();
        System.out.println("TableName:"+tblName+"; SRCDBName:"+tbl_srcDBName
            +"; DESTDBName:"+tbl_destDBName+"; SumRows:"+dataInitSumRows+";
FinishRows"
            +"; UsedTime:"+dataUsedTime+"; ErrorMSG:"+dataInitErrMsg);
    }
    List<DataSynchronizationDetail> dataSyncDetails = response.getDataSynchronizati
onDetailList();
    System.out.println("Data Synchronization Detail");
    for (int i = 0; i < dataSyncDetails.size(); i++) {
        String dataSyncTblName=dataSyncDetails.get(i).getTableName();
        String dataSyncSRCDBName=dataSyncDetails.get(i).getSourceOwnerDBName();
        String dataSyncDESTDBName = dataSyncDetails.get(i).getDestinationOwnerD
BName();
        String dataSyncStatus = dataSyncDetails.get(i).getStatus();
        String dataSyncErrMsg = dataSyncDetails.get(i).getErrorMessage();
        System.out.println("TableName:"+dataSyncTblName+"; SRCDBName:"+
dataSyncSRCDBName
            +"; DESTDBName:"+dataSyncDESTDBName+"; Status:"+dataSyncStatus+";
ErrorMSG:"+dataSyncErrMsg);
    }
} catch (Exception e) {
    // TODO: handle exception
    System.out.println("Get Migration Detail of Migration Job " +MigrationJobId+" Failed
!");
    System.out.println(e.toString());
}
}

```

2.12.1.2.5 DescribeMigrationJobStatus

2.12.1.2.5.1 Overview

You can call this operation to query the data migration status regardless of the migration task status. You can query the overall migration status of the task, the migration status of each migration stage (schema migration, full data migration, and incremental data migration), and the precheck status.

2.12.1.2.5.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeMigrationJobStatus.
MigrationJobId	String	Yes	The migration task ID .

2.12.1.2.5.3 Response parameters

Name	Type	Description
MigrationJobId	String	The ID of the migration task.
MigrationJobName	String	The name of the migration task.
PayType	String	The billing method.
MigrationJobClass	String	The type of the migration instance.
SourceEndpoint	Endpoint	The IP address for connecting to the source instance. For more information, see the parameter definition in section 1.2.5.4.
DestinationEndpoint	Endpoint	The IP address for connecting to the destination instance. For more information, see the parameter definition in section 1.2.5.4.
MigrationMode	MigrationMode	The migration type. For more information, see the parameter definition in section 1.2.5.5.
MigrationObjects	List	The objects to be migrated.

Name	Type	Description
MigrationJobStatus	String	The status of the migration task. Valid values: • NotStarted: The migration task is not started. • Prechecking: The migration task is being prechecked. • PrecheckFailed: The precheck fails. • Migrating: Data is being migrated. • Suspending: The migration task is suspended. • MigrationFailed: The migration task fails. • Finished: The migration task is complete.
PrecheckStatus	PrecheckStatus	The precheck status including the check progress and the specific state. For more information, see the parameter definition in section 1.2.5.6.
StructureInitializationStatus	StructureInitializationStatus	The status of schema migration including the migration progress and the specific state. For more information, see the parameter definition in section 1.2.5.8.
DataInitializationStatus	DataInitializationStatus	The status of full data migration including the migration progress and the specific state. For more information, see the parameter definition in section 1.2.5.9.

Name	Type	Description
DataSynchronizationStatus	DataSynchronizationStatus	The status of incremental data migration including the migration progress and the specific state. For more information, see the parameter definition in section 1.2.5.10.

2.12.1.2.5.4 Endpoint parameter definitions

Name	Type	Description
InstanceType	String	The instance type.
Region	String	The region of the source instance.
InstanceId	String	The instance ID.
EngineName	String	The database type.
IP	String	The database connection address.
Port	String	The listening port of the database.
UserName	String	The username to access the database.
OracleSID	String	The Oracle SID.
DatabaseName	String	The database name.

2.12.1.2.5.5 MigrationMode parameter definitions

Name	Type	Description
StructureInitialization	String	Indicates whether to perform schema migration.
DataInitialization	String	Indicates whether to perform full data migration.
DataSynchronization	String	Indicates whether to perform incremental data migration.

2.12.1.2.5.6 PrecheckStatus parameter definitions

Name	Type	Description
Status	String	The precheck status.
Percent	String	The precheck progress. Unit : %.
Detail	List	The check details of each precheck item. For more information, see CheckItem parameter definitions.

2.12.1.2.5.7 CheckItem parameter definitions

Name	Type	Description
ItemName	String	The check item name.
CheckStatus	String	The check status. Valid values: • NotStarted • Checking • Failed • Finished
ErrorMessage	String	The cause of the error.
RepairMethod	String	The repair method.

2.12.1.2.5.8 StructureInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.

Name	Type	Description
Progress	String	The number of tables that have been migrated.

2.12.1.2.5.9 DataInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.2.5.10 DataSynchronizationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Delay	String	The migration latency.

2.12.1.2.5.11 Examples

The following code provides an example of how to use the Java SDK to query the status of a migration task.

```
private static void describeMigrationJobStatus(String MigrationJobId){
    DescribeMigrationJobStatusRequest request = new DescribeMigrationJobStatusRequest();
    request.setMigrationJobId(MigrationJobId);
    try {
        DescribeMigrationJobStatusResponse response = client.getAcsResponse(request);
        System.out.println("Get Status of Migration Job "+MigrationJobId+" Succeed!");
        String JobStatus=response.getMigrationJobStatus();
        /*Get the basic information of the migration job*/
        System.out.println("MigrationJobName:"+response.getMigrationJobName()
            +"MigrationJobId:"+response.getMigrationJobId()
            +"MigrationObjects:"+response.getMigrationObject()

2.12.1.2.6 StartMigrationJob

2.12.1.2.6.1 Overview

You can call this operation to start a migration task. When a migration task is in the NotStarted or MigrationFailed status, you can call this operation to start or restart it.

2.12.1.2.6.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to StartMigrationJob.
MigrationJobId	String	Yes	The migration task ID .

2.12.1.2.6.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.2.6.4 Examples

The following code provides an example of how to use the Java SDK to start a migration task.

```
private static void startMigrationJob(String MigrationJobId){
    StartMigrationJobRequest request = new StartMigrationJobRequest();
    request.setMigrationJobId(MigrationJobId);
    try {
        StartMigrationJobResponse response = client.getAcsResponse(request);
        System.out.println("Start "+MigrationJobId+" Succeed");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Start "+MigrationJobId + " Failed");
        System.out.println(e.toString());
    }
}
```

}

2.12.1.2.7 StopMigrationJob

2.12.1.2.7.1 Overview

You can call this operation to stop a migration task when it is in the **Migrating** status.

Note:

You cannot start a task that has been stopped.

2.12.1.2.7.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to StopMigrationJob.
MigrationJobId	String	Yes	The migration task ID .

2.12.1.2.7.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.2.7.4 Examples

The following code provides an example of how to use the Java SDK to stop a migration task.

```
private static void stopMigrationJob(String MigrationJobId) {
    StopMigrationJobRequest request = new StopMigrationJobRequest();
    try {
        request.setMigrationJobId(MigrationJobId);
        StopMigrationJobResponse response = client.getAcsResponse(request);
        System.out.println("Stop Migration Job "+MigrationJobId+" Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Stop Migration Job "+MigrationJobId+" Failed!");
        System.out.println(e.toString());
    }
}
```

2.12.1.2.8 SuspendMigrationJob

2.12.1.2.8.1 Overview

You can call this operation to suspend a migration task when it is in the Migrating status.

Note that if a task has been suspended for more than 6 hours after it enters the incremental data migration stage, you may fail to restart it through the StartMigrationJob operation.

2.12.1.2.8.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to SuspendMigrationJob .
MigrationJobId	String	Yes	The migration task ID .

2.12.1.2.8.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.2.8.4 Examples

The following code provides an example of how to use the Java SDK to suspend a migration task.

```
private static void suspendMigrationJob(String MigrationJobId){
    SuspendMigrationJobRequest request = new SuspendMigrationJobRequest();
    request.setMigrationJobId(MigrationJobId);
    try {
        SuspendMigrationJobResponse response = client.getAcsResponse(request);
        System.out.println("Suspend "+ MigrationJobId + " Succeed");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Suspend "+MigrationJobId +"Failed");
        System.out.println(e.toString());
    }
}
```

2.12.1.3 Data subscription APIs

2.12.1.3.1 ConfigureSubscriptionInstance

2.12.1.3.1.1 Overview

You can call this operation to modify the configurations of a change tracking task, such as instance connection details and objects for change tracking. You can call this operation multiple times to modify the configurations of a task before the task is started. Only the changes of RDS for MySQL instances can be tracked.

2.12.1.3.1.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ConfigureSubscriptionInstance</code> .
SubscriptionInstanceId	String	Yes	The ID of the subscription channel to be configured.
SubscriptionInstanceName	String	No	The name of a subscription channel that can distinguish it from other subscription channels.
SourceEndpoint.InstanceType	String	No	The type of the subscription instance . Valid value: <code>RDS</code> . Default value: <code>RDS</code> .
SourceEndpoint.InstanceId	String	Yes	The RDS instance ID.
SubscriptionDataType.DDL	Boolean	Yes	Indicates whether to subscribe to schema updates made through DDL. Valid values: <code>true</code> (yes) and <code>false</code> (no). Default value: <code>true</code> .
SubscriptionDataType.DML	Boolean	Yes	Indicates whether to subscribe to data updates made through DML. Valid values: <code>true</code> (yes) and <code>false</code> (no). Default value: <code>true</code> .

Name	Type	Required	Description
SubscriptionObjects	List	Yes	The listening port of the source instance . This parameter is required when the source instance is a user-created database . For more information, see SubscriptionObject parameter definitions.

2.12.1.3.1.3 SubscriptionObject parameter definitions

The SubscriptionObject parameters are defined as JSON strings. Certain regular expressions can be used in the object configuration.

The SubscriptionObject parameter definitions are as follows:

```
SubscriptionObject:{
  DBName:"The name of the database to be subscribed",
  TableIncludes:[{
    TableName: "The name of the table to be migrated"
  }]
}
```

SubscriptionObject indicates the whitelist of objects to be subscribed.

You can use the following regular expressions to define different object names:

- A period (.) matches any single character except '\r\n'.
- An asterisk (*) matches zero or more occurrences of a subexpression which occurs before . h.*llo matches strings such as hllo and heeeello.
- A question mark (?) matches zero or one occurrence of a subexpression which occurs before. h.? llo matches hllo and hello, but not haello.
- The [characters] character set matches any character included in the braces. For example , h[aello] matches hallo and hello.
- The [^characters] negative character set does not match any character included in the braces. For example, h[^ae]llo matches hcllo and hdllo, but not hallo or hello.
- The [character1-character2] character range matches any character included in the range from character1 to character2, such as [0-9] and [a-z].

2.12.1.3.1.4 Response parameters

Name	Type	Description
RequestId	String	The GUID of the request.
Success	String	Indicates whether the request is successful. Valid values: true and false.
ErrCode	String	The error code.
ErrorMessage	String	The detailed error message.

2.12.1.3.1.5 Example

This topic describes how to use the Java SDK to configure a migration task.

```
private static void configureSbeJob(String MigrationJobId){
    String MigrationJobName="jiangliutest";
    /*Source Endpoint*/
    String SourceEndpoint_InstanceId="rm-xxxxxxxxxxxxxxxxxx";
    String SourceEndpoint_InstanceType="rds";
    Boolean MigrationMode_SubscriptionDataTypeDML=true;
    Boolean MigrationMode_SubscriptionDataTypeDDL=true;
    String MigrationObjects="{\"DBName\": \"jiangliutest\",
        + \"TableIncludes\": [{\"TableName\": \"t1\"}]}";
    ConfigureSubscriptionInstanceRequest request = new ConfigureSubscriptio
nInstanceRequest();
    request.setMigrationJobId(MigrationJobId);
    request.setMigrationJobName(MigrationJobName);
    request.setSubscriptionInstanceId(jobId);
    request.setSubscriptionDataTypeDDL(MigrationMode_SubscriptionDataTypeDDL);
    request.setSubscriptionDataTypeDML(MigrationMode_SubscriptionDataTypeDML);
    request.setSourceEndpointInstanceType(SourceEndpoint_InstanceType);
    request.setSourceEndpointInstanceId(SourceEndpoint_InstanceId);
    request.setMigrationObject(MigrationObjects);
    try {
        ConfigureSubscriptionInstanceResponse response = client.getAcResponse(
request);
        System.out.println("Configure "+ MigrationJobId+ " Succeed");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Configure "+MigrationJobId + " Failed!");
        System.out.println(e.toString());
    }
}
```

2.12.1.3.2 CreateSubscriptionInstance

2.12.1.3.2.1 Overview

You can call this operation to purchase a database incremental subscription instance. After the purchase, you need to call the `ConfigureSubscriptionInstance` operation to configure a subscription task.

2.12.1.3.2.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateSubscriptionInstance.
Region	String	Yes	The region of the subscription instance. Valid values: - cn-hangzhou: Alibaba Cloud in Hangzhou - cn-shanghai: Alibaba Cloud in Shanghai - cn-qingdao: Alibaba Cloud in Qingdao - cn-beijing: Alibaba Cloud in Beijing - cn-zhangbei: Alibaba Cloud in Zhangbei - cn-shenzhen: Alibaba Cloud in Shenzhen - cn-hongkong: Alibaba Cloud in Hong Kong - us-west-1: Alibaba Cloud in Western US - us-east-1: Alibaba Cloud in Eastern US - ap-southeast-1: Alibaba Cloud in Singapore - cn-hangzhou-finance-1: Finance Cloud in Hangzhou - cn-qingdao-finance-1: Finance Cloud in Qingdao - cn-shanghai-finance-1: Finance Cloud in Shanghai - cn-shenzhen-finance-1: Finance Cloud in Shenzhen - me-east-1: Alibaba Cloud in Dubai - en-central-1: Alibaba Cloud in Frankfurt
ClientToken	String	No	The token used to ensure the idempotence of the request. It can be any string.
OwnerID	String	No	If a RAM user is used to call this operation , the value of OwnerID is the UID of the Apsara Stack tenant account to which this RAM user belongs.

2.12.1.3.2.3 Response parameters

Name	Type	Description
SubscriptionInstanceId	String	The subscription channel ID. This is the GUID of a subscription channel.

2.12.1.3.2.4 Examples

The following code provides an example of how to use the Java SDK to purchase a migration instance.

```
private String create() throws Exception {
    CreateSubscriptionInstanceRequest request = new CreateSubscriptionInstanceRequest();
    request.setRegion("cn-hangzhou");
    request.setPayType("postpaid");
    CreateSubscriptionInstanceResponse response = client.getAcsResponse(request);
    if(response == null){
        throw new Exception("create fail");
    }
    System.out.println("CreateSubscriptionInstanceRequest, result :"+response.
getSubscriptionInstanceId());
    return response.getSubscriptionInstanceId();
}
```

2.12.1.3.3 DeleteSubscriptionInstance

2.12.1.3.3.1 Overview

You can call this operation to delete a subscription channel regardless of its status. After a subscription task is deleted, you cannot query or manage it through OpenAPI or the console.

2.12.1.3.3.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DeleteSubscriptionInstance.
SubscriptionInstanceId	String	Yes	The ID of the subscription channel to be released.

2.12.1.3.3 Response parameters

Name	Type	Description
RequestId	String	The GUID of the request.
Success	String	Indicates whether the request is successful. Valid values: true and false.
ErrCode	String	The error code.
ErrorMessage	String	The detailed error message.

2.12.1.3.3.4 Examples

The following code provides an example of how to use the Java SDK to delete a subscription task.

```
private static void deleteMigrationJob(String MigrationJobId) {
    DeleteMigrationJobRequest request = new DeleteMigrationJobRequest();
    DeleteMigrationJobResponse response = new DeleteMigrationJobResponse();
    request.setMigrationJobId(MigrationJobId);
    try {
        response = client.getAcsResponse(request);
        System.out.println("Delete Migration Job "+MigrationJobId+" Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Delete Migration Job "+MigrationJobId+" Failed!");
        System.out.println(e.toString());
    }
}
```

2.12.1.3.4 DescribeSubscriptionInstances

2.12.1.3.4.1 Overview

You can call this operation to query the list of subscription channels that your Apsara Stack tenant account has access to. Data subscription channels in any status are returned.

2.12.1.3.4.2 Request parameters

Description	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeSubscriptionInstances.

Description	Type	Required	Description
PageSize	Integer	No	The number of records on each page. Valid values : 30, 50, and 100. Default value: 30.
PageNum	Integer	No	The page number. It must be greater than 0 and smaller than or equal to the maximum value of Integer. Default value: 1.

2.12.1.3.4.3 Response parameters

Name	Type	Description
SubscriptionInstances	List	The subscription channel details. For more information, see DescribeSubscriptionInstancesStatus .
PageNumber	Integer	The page number.
TotalRecrodCount	Integer	The total number of records.
PageRecordCount	Integer	The number of records on the page.

2.12.1.3.4.4 Examples

The following code provides an example of how to use the Java SDK to query the list of subscription instances.

```
public List<SubscriptionInstance> list(String jobName) throws ClientException {
    DescribeSubscriptionInstancesRequest request = new DescribeSubscription
InstancesRequest();
    request.setPageNum(1);
    request.setPageSize(20);
    if(jobName!=null) {
        request.setSubscriptionInstanceName(jobName);
    }
    DescribeSubscriptionInstancesResponse response = client.getAcsResponse(request);
    System.out.println("page no: "+response.getPageNumber());
    System.out.println("page size: "+response.getPageRecordCount());
    System.out.println("size: "+ response.getSubscriptionInstances().size());
    return response.getSubscriptionInstances();
}
```

```
}
```

2.12.1.3.5 DescribeSubscriptionInstanceStatus

2.12.1.3.5.1 Overview

You can call this operation to query the status of a subscription channel regardless of the subscription task status. You can query the channel configuration information, channel status, and downstream consumption status.

2.12.1.3.5.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DescribeSubscriptionInstanceStatus.
SubscriptionInstanceId	String	Yes	The subscription channel ID.

2.12.1.3.5.3 Response parameters

Name	Type	Description
SubscriptionInstanceId	String	The subscription channel ID.
SubscriptionInstanceName	String	The subscription channel name.
PayType	String	The billing method.
SourceEndpoint	Endpoint	The endpoint to access the source instance specified in the subscription task. For more information, see Endpoint parameter definitions.
SubscriptionDataType.DDL	Boolean	Indicates whether the data to be subscribed contains schema updates made through DDL. Valid values: true (yes) and false (no).
SubscriptionDataType.DML	Boolean	Indicates whether the data to be subscribed contains data updates made through DML. Valid values: true (yes) and false (no).

Name	Type	Description
SubscriptionObjects	List	The objects to be subscribed, listed in a SubscriptionObject array. For more information, see SubscriptionObject parameter definitions.
Status	String	The subscription channel status. Valid values: NotStarted, Prechecking, PrecheckFailed, Starting, Normal, and Abnormal.
ErrorMessage	String	The cause of the channel error.
ConsumptionCheckpoint	String	The consumption checkpoint of the downstream SDK connected to the subscription channel. The date format follows the ISO8601 standard. It is in the UTC format of YYYY-MM-DDThh:mm:ssZ. For example, 2017-08-15T12:00:00Z (or 20:00:00, August 15, 2017, China Standard Time).
BeginTimestamp	String	The start time of the timestamp range of the data stored in the subscription channel. The date format follows the ISO8601 standard. It is in the UTC format of YYYY-MM-DDThh:mm:ssZ. For example, 2017-08-15T12:00:00Z (or 20:00:00, August 15, 2017, China Standard Time).
EndTimestamp	String	The end time of the timestamp range of the data stored in the subscription channel. The date format follows the ISO8601 standard. It is in the UTC format of YYYY-MM-DDThh:mm:ssZ. For example, 2017-08-15T12:00:00Z (or 20:00:00, August 15, 2017, China Standard Time).
ConsumptionClient	String	The downstream client information, in the following format: IP address of the downstream client:Random ID generated by DTS.

2.12.1.3.5.4 Endpoint parameter definitions

Name	Type	Description
InstanceType	String	The instance type.
Region	String	The region of the source instance.
InstanceId	String	The instance ID.
EngineName	String	The database type.
IP	String	The connection address of the database.
Port	String	The listening port of the database.
UserName	String	The username to access the database.
OracleSID	String	The Oracle SID.
DatabaseName	String	The database name.

2.12.1.3.5.5 SubscriptionObject parameter definitions

Name	Type	Description
databaseName	String	The name of the database from which the list of objects are to be subscribed.
tableList	List	The names of the tables to be subscribed.
wholeDatabase	Boolean	Indicates whether to subscribe to the whole database.

2.12.1.3.5.6 Examples

The following code provides an example of how to use the Java SDK to query the status of a subscription channel.

```
private void describe(String jobId) throws ClientException {
    DescribeSubscriptionInstanceStatusRequest request = new DescribeSubscription
InstanceStatusRequest();
    request.setSubscriptionInstanceId(jobId);
    DescribeSubscriptionInstanceStatusResponse response = client.getAccsResponse(
        request);
    System.out.println(response.getStatus());
    System.out.println(response.getBeginTimestamp());
    System.out.println(response.getEndTimestamp());
}
```

```
    System.out.println(response.getConsumptionCheckpoint());  
}
```

2.12.1.3.6 ModifyComsumptionTimestamp

2.12.1.3.6.1 Overview

You can call this operation to modify the consumption checkpoint only when the subscription channel is in the Normal status and the consumption client is stopped.

2.12.1.3.6.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyComsumptionTimestamp.
SubscriptionInstanceId	String	Yes	The ID of the subscription channel for which the consumption checkpoint needs to be modified.
ConsumptionTimestamp	String	Yes	The timestamp of the modified consumption checkpoint. The timestamp format follows the ISO8601 standard. The UTC time is used. Format: yyyy-MM-ddTHH:mm:ssZ. For example, 2013-08-15T12:00:00Z indicates 20:00:00 on Tuesday, August 15, 2013 (Beijing Time).

2.12.1.3.6.3 Response parameters

Name	Type	Description
RequestId	String	The GUID of the request.
Success	String	Indicates whether the request is successful. Valid values: true and false.
ErrCode	String	The error code.
ErrorMessage	String	The detailed error message.

2.12.1.3.6.4 Examples

The following code provides an example of how to use the Java SDK to modify the consumption checkpoint.

```
private void modifyTimestamp(String jobId,String ts) throws ClientException {
    ModifyConsumptionTimestampRequest request = new ModifyConsumptionTim
estampRequest();
    request.setSubscriptionInstanceId(jobId);
    //ts
    request.setConsumptionTimestamp(ts);
    ModifyConsumptionTimestampResponse response = client.getAcResponse(request
);
    System.out.println("modify timestamp ,result:" + response.getSuccess());
}
```

2.12.1.3.7 ModifySubscriptionObject

2.12.1.3.7.1 Overview

When the subscription channel is in the NotStarted, Failed, Normal or Abnormal status, you can call this operation to modify the list of objects to be subscribed.

- If the subscription channel is in the Normal status, you call this operation to modify the list of objects to be subscribed. After that, DTS calls the StartSubscriptionInstance operation directly to start the subscription channel.
- If the subscription channel is in the NotStarted, Failed, or Abnormal status, you call this operation to modify the list of objects to be subscribed. After that, you need to call the StartSubscriptionInstance operation to start the subscription channel if you want to.

2.12.1.3.7.2 Request parameters

Description	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifySubscriptionObject.
SubscriptionInstanceId	String	Yes	The ID of the subscription channel for the list of objects to be modified.
SubscriptionObjects	List	Yes	The new list of objects to be subscribed after the modification. For more information, see SubscriptionObject parameter definitions.

2.12.1.3.7.3 SubscriptionObject parameter definitions

The SubscriptionObject parameters are defined as JSON strings. Certain regular expressions can be used in the object configuration.

The SubscriptionObject parameter definitions are as follows:

```
SubscriptionObject:{
  DBName:"The name of the database to be subscribed",
  TableIncludes:[{
    TableName: "The name of the table to be migrated"
  }]
}
```

SubscriptionObject indicates the whitelist of objects to be subscribed.

You can use the following regular expressions to define different object names:

- A period (.) matches any single character except '\r\n'.
- An asterisk (*) matches zero or more occurrences of a subexpression which occurs before. h.*llo matches strings such as hllo and heeeello.
- A question mark (?) matches zero or one occurrence of a subexpression which occurs before. h.? llo matches hllo and hello, but not haello.
- The [characters] character set matches any character included in the braces. For example, h[aello] matches hallo and hello.
- The [^characters] negative character set does not match any character included in the braces. For example, h[^ae]llo matches hcllo and hdllo, but not hallo or hello.
- The [character1-character2] character range matches any character included in the range from character1 to character2, such as [0-9] and [a-z].

2.12.1.3.7.4 Response parameters

Name	Type	Description
RequestId	String	The GUID of the request.
Success	String	Indicates whether the request is successful. Valid values: true and false.
ErrCode	String	The error code.
ErrorMessage	String	The detailed error message.

2.12.1.3.7.5 Examples

The following code provides an example of how to use the Java SDK to modify the list of objects to be subscribed.

```
private void modifyObject(String jobId) throws ClientException {
    ModifySubscriptionObjectRequest request = new ModifySubscriptionObjectRequest();
    request.setSubscriptionInstanceId(jobId);
    String sbeObject = "[{\n"
        + "\"DBName\": \"miyuntest\", \"\n"
        + "\"TableIncludes\": [\n"
        + "\"TableName\": \"t1\", \"\n"
        + "\"TableName\": \"t2\", \"\n"
        + "\"TableName\": \"t3\", \"\n"
        + "]"
        + "]}]";
    request.setSubscriptionObject(sbeObject);
    ModifySubscriptionObjectResponse response = client.getAcResponse(request);
    System.out.println(response.getSuccess());
}
```

2.12.1.3.8 StartSubscriptionInstance

2.12.1.3.8.1 Overview

You can call this operation to start a subscription channel only when the channel is in the NotStarted, Failed, or Suspending status.

2.12.1.3.8.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to StartSubscriptionInstance.
SubscriptionInstanceId	String	Yes	The ID of the subscription channel to be started.

2.12.1.3.8.3 Response parameters

Name	Type	Description
RequestId	String	The GUID of the request.
Success	String	Indicates whether the request is successful. Valid values: true and false.

Name	Type	Description
ErrCode	String	The error code.
ErrorMessage	String	The detailed error message.

2.12.1.3.8.4 Examples

The following code provides an example of how to use the Java SDK to start a subscription task.

```
private static void startSbeJob(String MigrationJobId){
    StartSubscriptionInstanceRequest request = new StartSubscriptionInstanceRequest();
    request.setSubscriptionInstanceId(jobId);
    try {
        StartSubscriptionInstanceResponse response = client.getAcsResponse(request);
        System.out.println("Start "+MigrationJobId+" Succeed");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Start "+MigrationJobId + " Failed");
        System.out.println(e.toString());
    }
}
```

2.12.1.4 Data synchronization APIs

2.12.1.4.1 ConfigureSynchronizationJob

2.12.1.4.1.1 Overview

After you call the CreateSynchronizationJob operation to purchase a synchronization instance, you can call this operation to configure a synchronization task, provided that the synchronization task is not configured.

2.12.1.4.1.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ConfigureSynchronizationJob.
SynchronizationJobId	String	Yes	The ID of the synchronization job.
SynchronizationJobName	String	No	The name of the synchronization task.
SourceEndpoint.InstanceId	String	Yes	The ID of the source synchronization instance.

Name	Type	Required	Description
Synchroniz ationDirec tion	String	No	The synchronization direction. This parameter is used only when two-way synchronization is configured for the instance. Valid values: Forward and Reverse. Default value: Forward.
SourceEndp oint. OwnerID	String	No	The GUID generated by Alibaba Cloud for the request. This parameter is used when source and destination instances do not belong to the same Alibaba Cloud account.
SourceEndp oint.Role	String	No	The role that the source instance grants to the destination instance. This parameter is used when the source and destination instances do not belong to the same Alibaba Cloud account. For more information about role permissions and how to grant a role, see Migrate or synchronize an instance across accounts .
Destinatio nEndpoint. InstanceId	String	Yes	The ID of the destination instance. If the destination instance is a MaxCompute or DataHub instance, the parameter indicates the corresponding project.
Synchroniz ationObjects	List	Yes	The objects to be synchronized.
StructureI nitialization	Boolean	No	Whether initial schema synchronization is performed before the synchronization task starts. Valid values: - true: Initial schema synchronization is performed. - false: Initial schema synchronization is not performed. - Default value: true.
DataInitia lization	Boolean	No	Whether initial full data synchronization is performed before the synchronization task starts. Valid values: - true: Initial full data synchronization is performed. - false: Initial full data synchronization is not performed. - Default value: true.

Name	Type	Required	Description
PartitionKey .ModifyTime _Year	Boolean	No	The definition of the partitioned key in the incremental log table when the destination instance is a MaxCompute instance. Valid values: • true: The primary partition of the incremental log table is a yearly partition. • false: The incremental log table does not support yearly partitions. • Default value: true.
PartitionKey .ModifyTime _Month	Boolean	No	The definition of the partitioned key in the incremental data table when the destination instance is a MaxCompute instance. Valid values: • true: The incremental data table supports monthly partitions. • false: The incremental data table does not support monthly partitions. • Default value: true.
PartitionKey .ModifyTime _Day	Boolean	No	The definition of the partitioned key in the incremental data table when the destination instance is a MaxCompute instance. Valid values: • true: The incremental data table supports daily partitions. • false: The incremental data table does not support daily partitions. • Default value: true.
PartitionKey .ModifyTime _Hour	Boolean	No	The definition of the partitioned key in the incremental data table when the destination instance is a MaxCompute instance. Valid values: • true: The incremental data table supports hourly partitions. • false: The incremental data table does not support hourly partitions. • Default value: true.

Name	Type	Required	Description
PartitionKey .ModifyTime _Minute	Boolean	No	The definition of the partitioned key in the incremental data table when the destination instance is a MaxCompute instance. Valid values: - true: The incremental data table supports minute partitions. - false: The incremental data table does not support minute partitions. A minute partition is generated every 15 minutes.

2.12.1.4.1.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.4.1.4 Example

This topic describes how to use the Java SDK to configure a synchronization task.

```
public void configureSyncJobRDS2RDS(String SyncJobId,DefaultAcsClient client) {
    ConfigureSynchronizationJobRequest request = new ConfigureSynchronizationJobRequest();
    request.setSynchronizationJobId(SyncJobId);
    request.setSynchronizationJobName("jiangliu_test_rds2rds_sync");
    request.setSourceEndpointInstanceId("rm-axxxxxxxxxxxxxxxxxx");
    request.setDestinationEndpointInstanceId("rm-bxxxxxxxxxxxxxxxxx");
    request.setStructureInitialization(true);
    request.setDataInitialization(true);
    String SyncObject="{\"DBName\": \"jiangliutest\", \"NewDBName\": \"jiangliutest\", \"TableIncludes\": [{\"TableName\": \"t1\", \"NewTableName\": \"t1\"}]}";
    request.setSynchronizationObjects(SyncObject);
    ConfigureSynchronizationJobResponse response = new ConfigureSynchronizationJobResponse();
    try {
        response = client.getAcsResponse(request);
        System.out.println("Configure Sync Job Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Configure Sync Job Failed");
        System.out.println(e.toString());
    }
}
```

2.12.1.4.2 CreateSynchronizationJob

2.12.1.4.2.1 Overview

You can call this operation to purchase a data synchronization instance. After the purchase, you need to call the `ConfigureSynchronizationJob` operation to configure the instance.

If your synchronization instance adopts the Pay-As-You-Go billing method, you will be charged only when you have called the `ConfigureSynchronizationJob` operation and started the synchronization task.

2.12.1.4.2.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>CreateSynchronizationJob</code> .
SourceRegion	String	Yes	The region of the source instance specified in the synchronization task. Valid values: - cn-hangzhou: Alibaba Cloud in Hangzhou - cn-shanghai: Alibaba Cloud in Shanghai - cn-qingdao: Alibaba Cloud in Qingdao - cn-beijing: Alibaba Cloud in Beijing - cn-zhangbei: Alibaba Cloud in Zhangbei - cn-shenzhen: Alibaba Cloud in Shenzhen - cn-hongkong: Alibaba Cloud in Hong Kong - us-west-1: Alibaba Cloud in Western US - us-east-1: Alibaba Cloud in Eastern US - ap-southeast-1: Alibaba Cloud in Singapore - cn-hangzhou-finance-1: Finance Cloud in Hangzhou - cn-qingdao-finance-1: Finance Cloud in Qingdao - cn-shanghai-finance-1: Finance Cloud in Shanghai - cn-shenzhen-finance-1: Finance Cloud in Shenzhen - me-east-1: Alibaba Cloud in Dubai - en-central-1: Alibaba Cloud in Frankfurt
SourceEndpoint. InstanceType	String	No	The type of the source instance specified in the synchronization task. Valid value: <code>RDS</code> . Default value: <code>RDS</code> .

Name	Type	Required	Description
DestinationEndpoint. InstanceType	String	No	The type of the destination instance specified in the synchronization task. Valid values: RDS, MaxCompute, and DataHub. Default value: RDS.
SourceRegion	String	Yes	The region of the destination instance specified in the synchronization task. Valid values: - cn-hangzhou: Alibaba Cloud in Hangzhou - cn-shanghai: Alibaba Cloud in Shanghai - cn-qingdao: Alibaba Cloud in Qingdao - cn-beijing: Alibaba Cloud in Beijing - cn-zhangbei: Alibaba Cloud in Zhangbei - cn-shenzhen: Alibaba Cloud in Shenzhen - cn-hongkong: Alibaba Cloud in Hong Kong - us-west-1: Alibaba Cloud in Western US - us-east-1: Alibaba Cloud in Eastern US - ap-southeast-1: Alibaba Cloud in Singapore - cn-hangzhou-finance-1: Finance Cloud in Hangzhou - cn-qingdao-finance-1: Finance Cloud in Qingdao - cn-shanghai-finance-1: Finance Cloud in Shanghai - cn-shenzhen-finance-1: Finance Cloud in Shenzhen - me-east-1: Alibaba Cloud in Dubai - en-central-1: Alibaba Cloud in Frankfurt
NetworkType	String	No	The type of the data transmission network used for cross-region synchronization. Valid values: Internet and Intranet. Default value : Internet.
SynchronizationJobClass	String	No	The synchronization task type. Valid values : micro, small, medium, and large. Default value: small.
PayType	String	Yes	The billing method. Valid values: Postpaid and Prepaid.

Name	Type	Required	Description
Period	String	No	Indicates whether to subscribe to the instance on a yearly or monthly basis. This parameter is required when PayType is set to Prepaid. Valid values: Year and Month.
UsedTime	String	No	The duration of the subscription, in months . This parameter is required when Period is set to Month. Set the value to an integer greater than 0.
ClientToken	String	No	The token used to ensure the idempotence of the request. It can be any string.

2.12.1.4.2.3 Response parameters

Name	Type	Description
SynchronizationJobId	String	The GUID of the synchronization task.

2.12.1.4.2.4 Examples

The following code provides an example of how to use the Java SDK to purchase a synchronization instance.

```
public class DataSyncTest {
    public String createSyncJob(DefaultAcsClient client) {
        CreateSynchronizationJobRequest request = new CreateSynchronizationJobRequest
        ();
        request.setSourceRegion("cn-hangzhou");
        request.setDestRegion("cn-hangzhou");
        request.setSynchronizationJobClass("micro");
        request.setPayType("Postpaid");
        request.setClientToken("createsyncjob_1");
        CreateSynchronizationJobResponse response = new CreateSynchronizatio
nJobResponse();
        try {
            response = client.getAcsResponse(request);
            String DataSyncId = response.getSynchronizationJobId();
            System.out.println("Create Synchronization Job Succeed! Synchronization Job Id is
"+DataSyncId);
            return DataSyncId;
        } catch (Exception e) {
            // TODO: handle exception
            System.out.println("Create Synchronization Job Failed!");
            return null;
        }
    }
}
```

2.12.1.4.3 DeleteSynchronizationJob

2.12.1.4.3.1 Overview

You can call this operation to delete a synchronization task regardless of the synchronization task status. After a synchronization task is released, you cannot query or manage it through OpenAPI or the console.

2.12.1.4.3.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to DeleteSynchronizationJob.
SynchronizationJobId	String	Yes	The synchronization task ID.

2.12.1.4.3.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.4.3.4 Examples

The following code provides an example of how to use the Java SDK to delete a synchronization task.

```
public void deleteSyncJob(String SyncJobId,DefaultAcsClient client) {
    DeleteSynchronizationJobRequest request = new DeleteSynchronizationJobRequest();
    request.setSynchronizationJobId(SyncJobId);
    DeleteSynchronizationJobResponse response = new DeleteSynchronizationJobResponse();
    try {
        response = client.getAcsResponse(request);
        System.out.println("Delete Sync Job "+SyncJobId+ " Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Delete Sync Job "+SyncJobId+ " Failed!");
    }
}
```

2.12.1.4.4 DescribeDataLoadStatus

2.12.1.4.4.1 Overview

You can call this operation to query initial synchronization details regardless of the synchronization task status.

2.12.1.4.4.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDataLoadStatus.
SynchronizationJobId	String	Yes	The synchronization task ID.
StructureInitialization	Boolean	No	The schema initialization details.
DataInitialization	Boolean	No	The full data initialization details.
DataSynchronization	Boolean	No	The incremental data initialization details.
PageSize	Integer	No	The number of records on each page. Valid values : 30, 50, and 100. Default value: 30 . This parameter is required when only one of these three parameters is set to true: StructureInitialization , DataInitialization , and DataSynchronization.

Name	Type	Required	Description
PageNum	Integer	No	The page number. It must be greater than 0 and smaller than or equal to the maximum value of Integer. Default value: 1. This parameter is required when only one of these three parameters is set to true: StructureInitialization, DataInitialization, and DataSynchronization.

2.12.1.4.4.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.4.4.4 Examples

The following code provides an example of how to use the Java SDK to query the initial synchronization details.

```
public void descInitStatus(String SyncJobId, DefaultAcsClient client) {
    DescribeInitializationStatusRequest request = new DescribeInitializationStatusRequest();
    request.setSynchronizationJobId(SyncJobId);
    DescribeInitializationStatusResponse response = new DescribeInitializationStatusResponse();
    try {
        response = client.getAcsResponse(request);
        System.out.println("Describe Initialization Detail of Synchronization Job "+ SyncJobId+" Succeed!");
        List<StructureInitializationDetail> strucInitDetails = response.getStructureInitializationDetails();
        List<DataInitializationDetail> dataInitDetails = response.getDataInitializationDetails();
        List<com.aliyuncs.dts.model.v20160801. DescribeInitializationStatusResponse.DataSynchronizationDetail> dataSynchronizationDetails = response.getDataSynchronizationDetails();
        System.out.println("Structure Initialization Detail:");
        for (int i = 0; i < strucInitDetails.size(); i++) {
            System.out.println("ObjectName:"+strucInitDetails.get(i).getObjectName()+
                "; ObjectType:"+strucInitDetails.get(i).getObjectType()+
                "; SRCDBName:"+strucInitDetails.get(i).getSourceOwnerDBName());
        }
    } catch (Exception e) {
        e.printStackTrace();
    }
}
```

```

        +"; DESTDBName:"+strucInitDetails.get(i).getDestinationOwnerDBName()
        +"; Status:"+strucInitDetails.get(i).getStatus()
        +"; ErrMSG:"+strucInitDetails.get(i).getErrorMessage());
    }
    System.out.println("Data Initialization Detail:");
    for (int i = 0; i < dataInitDetails.size(); i++) {
        System.out.println("TableName:"+dataInitDetails.get(i).getTableName()
            +"; SRCDBName:"+dataInitDetails.get(i).getSourceOwnerDBName()
            +"; DESTDBName:"+dataInitDetails.get(i).getDestinationOwnerDBName()
            +"; Status:"+dataInitDetails.get(i).getStatus()
            +"; TotalRows:"+dataInitDetails.get(i).getTotalRowNum()
            +"; FinishedRows:"+dataInitDetails.get(i).getFinishRowNum()
            +"; UsedTime:"+dataInitDetails.get(i).getUsedTime()
            +"; ErroMSG:"+dataInitDetails.get(i).getErrorMessage());
    }
    System.out.println("Data Synchronization Detail:");
    for (int i = 0; i < dataSynchronizationDetails.size(); i++) {
        System.out.println("TableName:"+dataSynchronizationDetails.get(i).getTableNa
me()
            +"; SRCDBName:"+dataSynchronizationDetails.get(i).getSourceO
wnerDBName()
            +"; DESTDBName:"+dataSynchronizationDetails.get(i).getDestina
tionOwnerDBName()
            +"; Status:"+dataSynchronizationDetails.get(i).getStatus()
            +"; ErrMSG:"+dataSynchronizationDetails.get(i).getErrorMessage());
    }
} catch (Exception e) {
    // TODO: handle exception
    System.out.println("Describe Initialization Status of Synchronization Job "+
SyncJobId+" Failed!");
    System.out.println(e.toString());
}
}

```

2.12.1.4.5 DescribeSynchronizationJobStatus

2.12.1.4.5.1 Overview

You can call this operation to query the status and running details of a synchronization task regardless of its status.

2.12.1.4.5.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSynchronizationJobStatus.
SynchronizationJobId	String	Yes	The ID of the synchronization instance.

Name	Type	Required	Description
SynchronizationDirection	String	No	The synchronization direction. Valid values: Forward and Reverse. Default value: Forward.

2.12.1.4.5.3 Response parameters

Name	Type	Description
SynchronizationJobId	String	The synchronization task ID.
SynchronizationJobName	String	The synchronization task name.
SynchronizationJobClass	String	The synchronization task type.
PayType	String	The billing method.
ExpireTime	String	The expiration time, in the format of YYYY-MM-DDT hh:mm:ssZ, such as 2011-06-09T 12:11:11Z.
SourceEndpoint	SourceEndpoint	The endpoint to access the source instance specified in the synchronization task.
DestinationEndpoint	DestinationEndpoint	The endpoint to access the destination instance specified in the synchronization task.
SynchronizationObjects	List	The objects to be synchronized.
StructureInitialization	String	Indicates whether to perform schema initialization.
DataInitialization	String	Indicates whether to perform full data initialization.
Status	String	The synchronization task status . Valid values: NotStarted, Prechecking, PrecheckFailed, Initializing, InitializeFailed, Synchronizing, Failed, Suspending, Modifying, and Finished.
ErrorMessage	String	The cause of the synchronization error.

Name	Type	Description
PrecheckStatus	PrecheckStatus	The precheck status. For more information, see PrecheckStatus parameter definitions.
StructureInitializationStatus	StructureInitializationStatus	The schema initialization status . For more information, see StructureInitializationStatus parameter definitions.
DataInitializationStatus	DataInitializationStatus	The full data initialization status . For more information, see DataInitializationStatus parameter definitions.
DataSynchronizationStatus	DataSynchronizationStatus	The incremental data initialization status. For more information , see DataSynchronizationStatus parameter definitions.
Delay	String	The synchronization latency. Unit: second.
Performance	String	The synchronization performance. For more information, see Performance parameter definitions.

2.12.1.4.5.4 PrecheckStatus parameter definitions

Name	Type	Description
Status	String	The precheck status.
Percent	String	The precheck progress. Unit : %.
Detail	List	The check details of each precheck item. For more information, see CheckItem parameter definitions.

2.12.1.4.5.5 CheckItem parameter definitions

Name	Type	Description
ItemName	String	The check item name.

Name	Type	Description
CheckStatus	String	The check status. Valid values: • NotStarted • Checking • Failed • Finished
ErrorMessage	String	The cause of the error.
RepairMethod	String	The repair method.

2.12.1.4.5.6 StructureInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.4.5.7 DataInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.

Name	Type	Description
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.4.5.8 DataSynchronizationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: - NotStarted - Migrating - Failed - Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Delay	String	The migration latency. Unit: second.

2.12.1.4.5.9 Performance parameter definitions

Name	Type	Description
TPS	String	The number of records that are synchronized per second .
Flow	String	The data traffic that is synchronized per second. Unit: Mbit/s.

2.12.1.4.5.10 Examples

The following code provides an example of how to use the Java SDK to query the status of a synchronization task.

```
public void descSyncJobStatus(String SyncJobId,DefaultAcsClient client) {
    DescribeSynchronizationJobStatusRequest request = new DescribeSynchronizat
ionJobStatusRequest();
    request.setSynchronizationJobId(SyncJobId);
}
```

```

DescribeSynchronizationJobStatusResponse response = new DescribeSynchronizat
ionJobStatusResponse();
try {
    response = client.getAcsResponse(request);
    /*Get Sync Configure of the Sync Job*/
    System.out.println("SyncJobId:"+response.getSynchronizationJobId()
        +"SyncJobName:"+response.getSynchronizationJobName()
        +"; PayType:"+response.getPayType()+"; ExpireTime:"+response.getExpireTime
    ()
        +"; SyncClass:"+response.getSynchronizationJobClass()
        +"; StrucInit:"+response.getStructureInitialization()
        +"; DataInit:"+response.getDataInitialization()+"; Status:"+response.getStatus
    ()
        +"; Delay:"+response.getDelay()
        +"; ErrMSG:"+response.getErrorMessage());
    /*Get Sync Objects of the Sync Job*/
    System.out.println("Sync Objects:");
    List<SynchronizationObject> syncObjects = response.getSynchronizationObjects();
    /*Get the Source Endpoint of the synchronization job*/
    SourceEndpoint sourceEndpoint = response.getSourceEndpoint();
    System.out.println("InstanceType:"+sourceEndpoint.getInstanceType()
        +"Instanceld:"+sourceEndpoint.getInstanceId());
    /*Get the Destination Endpoint of the synchronization job*/
    DestinationEndpoint destinationEndpoint = new DestinationEndpoint();
    System.out.println("Instance Type:"+destinationEndpoint.getInstanceType()
        +destinationEndpoint.getInstanceId());
    // Get Sync Object of the synchronization job
    System.out.println("SyncObject:"+org.json.JSONObject.toString(syncObjects
));
    // Get Precheck Status of the synchronization job
    try {
        com.aliyuncs.dts.model.v20160801. DescribeSynchronizationJobStatusResponse
.PrecheckStatus precheckStatus = response.getPrecheckStatus();
        System.out.println("Get Precheck Status for Sync Job Succeed");
        System.out.println("Precheck Status:"+response.getPrecheckStatus().getStatus()
            +"; Precheck Percent:"+response.getPrecheckStatus().getPercent());
        List<com.aliyuncs.dts.model.v20160801. DescribeSynchronizationJobStat
usResponse.PrecheckStatus.CheckItem> precheckDetails= precheckStatus.getDetail();
        for (int i = 0; i < response.getPrecheckStatus().getDetail().size(); i++) {
            System.out.println("CheckItem:"+response.getPrecheckStatus().getDetail().get
(i).getCheckStatus()
                +"; ErrorMessage:"+response.getPrecheckStatus().getDetail().get(i).getErrorMe
ssage()
                +"; RepairMethod:"+response.getPrecheckStatus().getDetail().get(i).
getRepairMethod());
        }
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Get Precheck Status for Sync Job Failed");
    }
    // Get Structure Initialization Status of the synchronization job
    try {
        System.out.println("Get Structure Initialization Status Succeed!");
        System.out.println("Structure Init Status:"+response.getStructureInitializationStat
us().getStatus()
            +"; Percent:"+response.getStructureInitializationStatus().getPercent()
            +"; Progress:"+response.getStructureInitializationStatus().getProgress()
            +"; ErrMSG:"+response.getStructureInitializationStatus().getErrorMessage());
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Get Structure Init Status Failed!");
    }
    // Get Data Initialization Status of the synchronization job
    try {

```

```

        System.out.println("Get Data Initialization Status Succeed!") ;
        System.out.println("Data Init Status:"+response.getDataInitializationStatus().
getStatus()
        +"; Percent:"+response.getDataInitializationStatus().getPercent()
        +"; Progress:"+response.getDataInitializationStatus().getProgress()
        +"; ErrMSG:"+response.getDataInitializationStatus().getErrorMessage());
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Get Data Init Status Failed!") ;
        System.out.println(e.toString());
    }
    //Get Data Sync Status
    try {
        com.aliyuncs.dts.model.v20160801. DescribeSynchronizationJobStatusResponse
.DataSynchronizationStatus dataSyncStatus = response.getDataSynchronizationStatus();
        System.out.println("Get Data Synchronization Status Succeed!") ;
        System.out.println("Data Sync Status:"+response.getDataSynchronizationStatus
().getStatus()
        +"; Percent:"+response.getDataSynchronizationStatus().getPercent()
        +"; Delay:"+response.getDataSynchronizationStatus().getDelay()
        +"; ErrMSG:"+response.getDataSynchronizationStatus().getErrorMessage());
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Get Data Sync Status Failed!") ;
        System.out.println(e.toString());
    }
    //Get Performance
    System.out.println("TPS:"+response.getPerformance().getRPS()
        +"Flow:"+response.getPerformance().getRPS());
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Describe Status of Data Sync Job "+ SyncJobId + "Failed");
        System.out.println(e.toString());
    }
}
}

```

2.12.1.4.6 DescribeSynchronizationJobs

2.12.1.4.6.1 Overview

You can call this operation to query the status and details of all synchronization tasks under the current account.

2.12.1.4.6.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSynchronizationJobs.

Name	Type	Required	Description
PageSize	Integer	No	The number of records on each page. Valid values : 30, 50, and 100. Default value: 30.
PageNum	Integer	No	The page number. It must be greater than 0 and smaller than or equal to the maximum value of Integer. Default value: 1.

2.12.1.4.6.3 Response parameters

Name	Type	Description
PageNumber	Integer	The page number.
TotalRecordCount	Integer	The total number of records.
PageRecordCount	Integer	The number of records on the page.
SynchronizationInstances	List	The synchronization task status. For more information, see SynchronizationInstance parameter definitions.

2.12.1.4.6.4 SynchronizationInstance parameter definitions

Name	Type	Description
SynchronizationJobId	String	The synchronization task ID.
SynchronizationJobName	String	The synchronization task name.
SynchronizationJobClass	String	The synchronization task type.
PayType	String	The billing method.

Name	Type	Description
ExpireTime	String	The expiration time, in the format of YYYY-MM-DDT hh:mm:ssZ, such as 2011-06-09T 12:11:11Z.
SourceEndpoint	SourceEndpoint	The endpoint to access the source instance specified in the synchronization task.
DestinationEndpoint	DestinationEndpoint	The endpoint to access the destination instance specified in the synchronization task.
SynchronizationObjects	List	The objects to be synchronized.
StructureInitialization	String	Indicates whether to perform schema initialization.
DataInitialization	String	Indicates whether to perform full data initialization.
Status	String	The synchronization task status. Valid values: • NotStarted • Prechecking • PrecheckFailed • Initializing • InitializeFailed • Synchronizing • Failed • Suspending • Modifying • Finished
ErrorMessage	String	The cause of the synchronization error.
PrecheckStatus	PrecheckStatus	The precheck status. For more information, see PrecheckStatus parameter definitions.

Name	Type	Description
StructureInitializationStatus	StructureInitializationStatus	The schema initialization status. For more information, see StructureInitializationStatus parameter definitions.
DataInitializationStatus	DataInitializationStatus	The full data initialization status. For more information, see DataInitializationStatus parameter definitions.
DataSynchronizationStatus	DataSynchronizationStatus	The incremental data initialization status. For more information, see DataSynchronizationStatus parameter definitions.
Delay	String	The synchronization latency. Unit: second.
Performance	String	The synchronization performance. For more information, see Performance parameter definitions.

2.12.1.4.6.5 PrecheckStatus parameter definitions

Name	Type	Description
Status	String	The precheck status.
Percent	String	The precheck progress. Unit : %.
Detail	List	The check details of each precheck item. For more information, see CheckItem parameter definitions.

2.12.1.4.6.6 CheckItem parameter definitions

Name	Type	Description
ItemName	String	The check item name.

Name	Type	Description
CheckStatus	String	The check status. Valid values: • NotStarted • Checking • Failed • Finished
ErrorMessage	String	The cause of the error.
RepairMethod	String	The repair method.

2.12.1.4.6.7 StructureInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.4.6.8 DataInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.

Name	Type	Description
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.4.6.9 DataSynchronizationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: - NotStarted - Migrating - Failed - Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Delay	String	The migration latency. Unit: second.

2.12.1.4.6.10 Performance parameter definitions

Name	Type	Description
TPS	String	The number of records that are synchronized per second .
Flow	String	The data traffic that is synchronized per second. Unit: Mbit/s.

2.12.1.4.6.11 Examples

The following code provides an example of how to use the Java SDK to query the list of synchronization tasks.

```
public void descSyncJobs(DefaultAcsClient client) {
    DescribeSynchronizationJobsRequest request = new DescribeSynchronizationJobsRequest();
}
```

```

DescribeSynchronizationJobsResponse response = new DescribeSynchronizat
ionJobsResponse();
try {
    response = client.getAcsResponse(request);
    System.out.println("Describe all Synchronization Jobs Succeed!");
    List<SynchronizationInstance> syncInstances=response.getSynchronizationIn
stances();
    System.out.println("Total num of Synchronization Jobs:"+syncInstances.size());
    for (SynchronizationInstance syncInstance : syncInstances) {
        System.out.println("SyncJobId:"+syncInstance.getSynchronizationJobId()
        +"; SyncJobName:"+syncInstance.getSynchronizationJobName()
        +"; PayType:"+syncInstance.getPayType()
        +"; InstanceClass:"+syncInstance.getSynchronizationJobClass()
        +"; StructInit:"+syncInstance.getStructureInitialization()
        +"; DataInit:"+syncInstance.getDataInitialization()
        +"; Status:"+syncInstance.getStatus()
        +"; ErrMSG:"+syncInstance.getErrorMessage()
        +"; Delay:"+syncInstance.getDelay());
        System.out.println("SourceEndpointInstanceType:"+syncInstance.getSourceE
ndpoint().getInstanceType()
        +"SourceEndpointInstanceId:"+syncInstance.getSourceEndpoint().getInstanc
eld());
        System.out.println("DestEndpointInstanceType:"+syncInstance.getDestina
tionEndpoint().getInstanceType()
        +"DestEndpointInstanceId:"+syncInstance.getDestinationEndpoint().
getInstanceId());
        // Get Precheck Status
        try {
            com.aliyuncs.dts.model.v20160801.DescribeSynchronizationJobsResponse
.SynchronizationInstance.PrecheckStatus precheckStatus = syncInstance.getPrechec
kStatus();
            System.out.println("Get Precheck Status for Sync Job Succeed");
            System.out.println("Precheck Status:"+syncInstance.getPrecheckStatus().
getStatus()
            +"Precheck Percent:"+syncInstance.getPrecheckStatus().getPercent());
            for (int j = 0; j < syncInstance.getPrecheckStatus().getDetail().size(); j++) {
                System.out.println("CheckItem:"+syncInstance.getPrecheckStatus().
getDetail().get(j).getCheckStatus()
                +"; ErrorMessage:"+syncInstance.getPrecheckStatus().getDetail().get(j).
getErrorMessage()
                +"; RepairMethod:"+syncInstance.getPrecheckStatus().getDetail().get(j).
getRepairMethod());
            }
        } catch (Exception e) {
            // TODO: handle exception
            System.out.println("Get Precheck Status for Sync Job Failed");
        }
        // Get Structure Initialization Status
        try {
            System.out.println("Get Structure Initialization Status Succeed!");
            System.out.println("Structure Init Status:"+syncInstance.getStructureIniti
alizationStatus().getStatus()
            +"; Percent:"+syncInstance.getStructureInitializationStatus().getPercent()
            +"; Progress:"+syncInstance.getStructureInitializationStatus().getProgress
()
            +"; ErrMSG:"+syncInstance.getStructureInitializationStatus().getErrorMe
ssage());
        } catch (Exception e) {
            // TODO: handle exception
            System.out.println("Get Structure Initialization Status Failed!");
        }
        // Get Data Initialization Status
        try {
            System.out.println("Get Data Init Status Succeed!");

```

```

        System.out.println("Data Init Status:"+syncInstance.getDataInitializationStatus
().getStatus()
        +"; Percent:"+syncInstance.getDataInitializationStatus().getPercent()
        +"; Progress:"+syncInstance.getDataInitializationStatus().getProgress()
        +"; ErrMSG:"+syncInstance.getDataInitializationStatus().getErrorMessage
());
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Get Data Init Status Failed!");
        System.out.println(e.toString());
    }
    //Get Data Synchronization Status
    try {
        System.out.println("Get Data Synchronization Status Succeed!");
        System.out.println("Data Sync Status:"+syncInstance.getDataSynchronizati
onStatus().getStatus()
        +"; Percent:"+syncInstance.getDataSynchronizationStatus().getPercent()
        +"; Delay:"+syncInstance.getDataSynchronizationStatus().getDelay()
        +"; ErrMSG:"+syncInstance.getDataSynchronizationStatus().getErrorMe
ssage());
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Get Data Sync Status Failed!");
        System.out.println(e.toString());
    }
} catch (Exception e) {
    // TODO: handle exception
    System.out.println("Desc all Sync Jobs Failed!");
    System.out.println(e.toString());
}
}

```

2.12.1.4.7 DescribeObjectModifyStatus

2.12.1.4.7.1 Overview

After you call the ModifySynchronizationObject operation to modify the list of objects to be synchronized, you can call this operation to query the modification status and progress.

2.12.1.4.7.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeObjectModifyStatus.

Name	Type	Required	Description
TaskId	String	Yes	The ID of the task for modifying the list of objects to be synchronized. It is the response parameter of the ModifySynchronizationObject operation.

2.12.1.4.7.3 Response parameters

Name	Type	Description
Status	String	The modification status of the list of objects to be synchronized. Valid values: - NotStarted - Prechecking - PrecheckFailed - Migrating - Failed - Finished
ErrorMessage	String	The reason why the list of objects to be synchronized failed to be modified.
PrecheckStatus	PrecheckStatus	The precheck status. For more information, see PrecheckStatus parameter definitions.
StructureInitializationStatus	StructureInitializationStatus	The schema initialization status. For more information, see StructureInitializationStatus parameter definitions.
DataInitializationStatus	DataInitializationStatus	The full data initialization status. For more information, see DataInitializationStatus parameter definitions.
DataSynchronizationStatus	DataSynchronizationStatus	The incremental data initialization status. For more information, see DataSynchronizationStatus parameter definitions.

2.12.1.4.7.4 PrecheckStatus parameter definitions

Name	Type	Description
Status	String	The precheck status.

Name	Type	Description
Percent	String	The precheck progress. Unit : %.
Detail	List	The check details of each precheck item. For more information, see CheckItem parameter definitions.

2.12.1.4.7.5 CheckItem parameter definitions

Name	Type	Description
ItemName	String	The check item name.
CheckStatus	String	The check status. Valid values: • NotStarted • Checking • Failed • Finished
ErrorMessage	String	The cause of the error.
RepairMethod	String	The repair method.

2.12.1.4.7.6 StructureInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.4.7.7 DataInitializationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Progress	String	The number of tables that have been migrated.

2.12.1.4.7.8 DataSynchronizationStatus parameter definitions

Name	Type	Description
Status	String	The migration status. Valid values: • NotStarted • Migrating • Failed • Finished
ErrorMessage	String	The cause of the migration error.
Percent	String	The migration progress. Unit : %.
Delay	String	The migration latency.

2.12.1.4.7.9 Examples

The following code provides an example of how to use the Java SDK to query the status of a task for modifying the list of objects to be synchronized.

```
public void descObjectModifyStatus(String SyncJobId,String TaskId,DefaultAcsClient client)
{
    DescribeSynchronizationObjectModifyStatusRequest request = new DescribeSynchronizationObjectModifyStatusRequest();
    request.setTaskId(TaskId);
}
```

```

DescribeSynchronizationObjectModifyStatusResponse response = new DescribeSynchronizationObjectModifyStatusResponse();
try {
    response = client.getAcsResponse(request);
    System.out.println("Describe Sync Object Modify Status Succeed!");
    String status=response.getStatus();
    PrecheckStatus precheckStatus = response.getPrecheckStatus();
    StructureInitializationStatus strucInitStatus=response.getStructureInitializationStatus();
    DataInitializationStatus dataInitStatus=response.getDataInitializationStatus();
    DataSynchronizationStatus dataSyncStatus = response.getDataSynchronizationStatus();
    String errorMsg=response.getErrorMessage();
    //Get Precheck Status
    System.out.println("The precheck status of SYNC Job "+SyncJobId);
    String precheck_status=precheckStatus.getStatus();
    String precheck_percent=precheckStatus.getPercent();
    System.out.println("Precheck Status:"+precheckStatus.getStatus()+"
    +"; Precheck Percent:"+precheckStatus.getPercent());
    System.out.println("Precheck Detail:");
    for (int i = 0; i < precheckStatus.getDetail().size(); i++) {
        String ItemName=precheckStatus.getDetail().get(i).getItemName();
        String CheckStatus=precheckStatus.getDetail().get(i).getCheckStatus();
        String CheckErrorMsg=precheckStatus.getDetail().get(i).getErrorMessage();
        String RepairMethod = precheckStatus.getDetail().get(i).getRepairMethod();
        System.out.println("CheckItem:"+ItemName+"; Status:"+CheckStatus+"
        ErrorMSG:"+CheckErrorMsg
        +"; RepairMethod:"+RepairMethod);
    }
    // Get the status of the structure Initialization
    String strucInit_Status=strucInitStatus.getStatus();
    String strucInit_percent=strucInitStatus.getPercent();
    String strucInit_progress=strucInitStatus.getProgress();
    String strucInit_ErrMsg=strucInitStatus.getErrorMessage();
    System.out.println("The Structure Init Status of SYNC Job "+SyncJobId);
    System.out.println("Status:"+strucInit_Status+"; Percent:"+strucInit_percent
    +"; Progress:"+strucInit_progress+"; ErrMSG:"+strucInit_ErrMsg);
    // Get the status of the data Initialization
    String dataInit_Status=dataInitStatus.getStatus();
    String dataInit_Percent = dataInitStatus.getPercent();
    String dataInit_Progress = dataInitStatus.getProgress();
    String dataInit_ErrMSG = dataInitStatus.getErrorMessage();
    System.out.println("The data Init Status of SYNC Job "+SyncJobId);
    System.out.println("Status:"+dataInit_Status+"; Percent:"+dataInit_Percent
    +"; Progress:"+dataInit_Progress+"; ErrMSG:"+dataInit_ErrMSG);
    // Get the status of the data synchronization
    String dataSync_Status=dataSyncStatus.getStatus();
    String dataSync_Percent=dataSyncStatus.getPercent();
    String dataSync_Delay=dataSyncStatus.getDelay();
    String dataSync_ErrMSG=dataSyncStatus.getErrorMessage();
    System.out.println("The data Init Status of SYNC Job "+SyncJobId);
    System.out.println("Status:"+dataSync_Status+"; Percent:"+dataSync_Percent
    +"; Delay:"+dataSync_Delay+"; ErrMSG:"+dataSync_ErrMSG);
} catch (Exception e) {
    // TODO: handle exception
    System.out.println("Describe Synchronization Objects Modify Status Failed");
    System.out.println(e.toString());
}
}

```

2.12.1.4.8 ModifySynchronizationObject

2.12.1.4.8.1 Overview

When a synchronization task is in the NotStarted, Synchronizing, Failed, or Suspending status, you can call this operation to modify the list of objects to be synchronized. After that , you can call the DescribeObjectModifyStatus operation to query the detailed modification status of the list of objects to be synchronized.

2.12.1.4.8.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifySynchronizationObject.
SynchronizationJobId	String	Yes	The ID of the synchronization task.
SynchronizationObjects	List	Yes	The list of modified objects to be synchronized.

2.12.1.4.8.3 Response parameters

Name	Type	Description
TaskId	String	The ID of the task for modifying the list of objects to be synchronized. You can call the DescribeObjectModifyStatus operation based on this ID to query the modification status.

2.12.1.4.8.4 Examples

The following code provides an example of how to use the Java SDK to modify the list of objects to be synchronized.

```
public String modifySyncObjects(String SyncJobId,DefaultAcsClient client) {
    String SyncObject="[{"DBName\":\"jiangliutest\", \"NewDBName\":\"jiangliutest\",
        + \"TableIncludes\":[{"TableName\":\"t2\", \"NewTableName\":\"t2\"}]]";
    ModifySynchronizationObjectRequest request = new ModifySynchronizationObjectRequest();
    request.setSynchronizationJobId(SyncJobId);
    request.setSynchronizationObjects(SyncObject);
    ModifySynchronizationObjectResponse response = new ModifySynchronizationObjectResponse();
}
```

```

try {
    response = client.getAcsResponse(request);
    String TaskId=response.getTaskId();
    System.out.println("Modify Sync Job "+SyncJobId+" Succeed! Modify task Id:"+
TaskId);
    return TaskId;
} catch (Exception e) {
    // TODO: handle exception
    System.out.println("Modify Sync Job " + SyncJobId + " Failed!");
    System.out.println(e.toString());
    return null;
}
}

```

2.12.1.4.9 StartSynchronizationJob

2.12.1.4.9.1 Overview

When a synchronization task is in the NotStarted, Failed, or Suspending status, you can call this operation to start the synchronization task.

2.12.1.4.9.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform . Set the value to StartSynchronizationJob.
SynchronizationJobId	String	Yes	The synchronization task ID.

2.12.1.4.9.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.4.9.4 Examples

The following code provides an example of how to use the Java SDK to start a synchronization task.

```

public void startSyncJob(String SyncJobId,DefaultAcsClient client) {
    StartSynchronizationJobRequest request = new StartSynchronizationJobRequest();
    request.setSynchronizationJobId(SyncJobId);
    StartSynchronizationJobResponse response = new StartSynchronizationJobResponse
();
    try {
        response = client.getAcsResponse(request);
    }
}

```

```

        System.out.println("Start Sync Job "+SyncJobId+" Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Start Sync Job "+SyncJobId+" Failed");
        System.out.println(e.toString());
    }
}

```

2.12.1.4.10 SuspendSynchronizationJob

2.12.1.4.10.1 Overview

When a synchronization task is in the Synchronizing status, you can call this operation to suspend the synchronization task. If a synchronization task has been suspended for over 6 hours, it may fail to be started.

2.12.1.4.10.2 Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to SuspendSynchronizationJob.
SynchronizationJobId	String	Yes	The synchronization task ID.

2.12.1.4.10.3 Response parameters

Name	Type	Description
<Common response parameters>	-	The request ID.

2.12.1.4.10.4 Examples

The following code provides an example of how to use the Java SDK to suspend a synchronization task.

```

public void suspendSyncJob(String SyncJobId,DefaultAcsClient client) {
    SuspendSynchronizationJobRequest request = new SuspendSynchronizati
onJobRequest();
    request.setSynchronizationJobId(SyncJobId);
    SuspendSynchronizationJobResponse response = new SuspendSynchronizati
onJobResponse();
    try {
        response = client.getAcsResponse(request);
        System.out.println("Suspend Sync Job "+SyncJobId+" Succeed!");
    } catch (Exception e) {
        // TODO: handle exception
        System.out.println("Suspend Sync Job "+SyncJobId+" Failed");
    }
}

```

```
        System.out.println(e.toString());
    }
}
```

2.12.2 Call the Java SDK

2.12.2.1 Quick start

This topic describes how to obtain and call the DTS Java SDK.

Install the Apsara Stack Java SDK

If you use Apache Maven to manage Java projects, you only need to import the JAR file to pom.xml of the project.

To use the development kit of Alibaba Cloud products, you must install the SDK core library and the product SDK.

The SDK core library version is 3.2.8, and the DTS SDK version is 2.0.3.

```
<dependency>
  <groupId>com.aliyun</groupId>
  <artifactId>aliyun-java-sdk-core</artifactId>
  <version>3.2.8</version>
</dependency>
<dependency>
  <groupId>com.aliyun</groupId>
  <artifactId>aliyun-java-sdk-dts</artifactId>
  <version>2.0.3-SNAPSHOT</version>
</dependency>
```

Use the Java SDK

The DTS SDK includes two core kits: aliyun-java-sdk-core-inner and aliyun-java-sdk-dts.

The aliyun-java-sdk-core-inner kit automatically routes requests to the DTS endpoint. The aliyun-java-sdk-dts kit includes the related classes of all DTS functions.

The following uses CreateMigrationJob, the method that uses the DTS Java SDK to create a data migration task, to describe the complete process of using the SDK. The aliyun-java-sdk-dts kit includes all classes used.

1. Create an object of `IClientProfile` named `profile`. This object stores the Access Key ID, Access Key Secret, and default region information.

```
IClientProfile profile = DefaultProfile.getProfile("cn-hangzhou", accessKeyId, accessSecret);
```

2. Create the `DefaultAcsClient` object. All subsequent responses are obtained from `DefaultAcsClient`.

```
client = new DefaultAcsClient(profile);
```

3. Create a request for the corresponding method. The request class is named in the format of API method name + `Request`. For example, the name of the API method used to create a migration task is `CreateMigrationJob`, so the corresponding request class name is `CreateMigrationJobRequest`. You can use a constructor to create a default class.

```
CreateMigrationJobRequest request=new CreateMigrationJobRequest();
```

4. Use the `setXxx` method of the request class to configure information that must be provided in API parameters. For example, configure the region and specification of a migration task.

```
request.setRegion("cn-hangzhou");  
request.setMigrationJobClass("small");
```

5. Use the `DefaultAcsClient` object to obtain a response to the corresponding request.

```
ConfigureMigrationJobResponse response = client.getAcsResponse(request);
```

6. Call the `getXxx` method in the response to obtain a returned parameter value, such as the migration task ID.

```
String MigrationJobId = response.getMigrationJobId();
```

7. The call process is now completed.

2.12.2.2 User manual

2.12.2.2.1 Install the Java SDK

This topic describes how to install and use the DTS Java SDK.

The Apsara Stack Java SDK supports JDK V1.6 and later. You can install the latest JDK version by importing the JAR file.

You can click [here](#) to download the DTS JAR file.

If you are using Eclipse or IntelliJ, you can install the DTS Java SDK directly by importing the JAR file.

The installation method is as follows:

- In Eclipse

To install the DTS Java SDK in Eclipse, follow these steps:

1. Copy the downloaded `aliyun-java-sdk-dts-2.0.3.jar` file to your project folder.
2. In Eclipse, right click the project, and then select **Properties**.
3. In the dialog box that appears, choose **Java Build Path > Libraries > Add JARs** to add the downloaded JAR files.
4. Click **Apply and Close**.

- In IntelliJ

To install the DTS Java SDK in IntelliJ, follow these steps:

1. Copy the downloaded `aliyun-java-sdk-dts-2.0.3.jar` file to your project folder.
2. Open your project in IntelliJ, and choose **File > Project Structure**.
3. Click **Apply** and then **OK**.

2.12.2.2.2 Configure identity verification credentials

When using the Apsara Stack SDK to access Apsara Stack services, you must provide an authorized account for identity verification.

Currently, the Java SDK supports identity verification based on the AccessKey.

When an Access Key is used as the access credential, you need to configure the credential during client initialization.

Notice:

Do not disclose any code that may contain your AccessKey. For example, do not commit the code to public GitHub projects. Otherwise, your Apsara Stack tenant account may be compromised.

```
DefaultProfile profile = DefaultProfile.getProfile(
    "<your-region-id>", // The region ID.
    "<your-access-key-id>", // The AccessKey ID of the authorized account.
    "<your-access-key-secret>"); // The AccessKey Secret of the authorized account.
```

2.12.2.2.3 Initiate a call

This topic describes how to use the DTS Java SDK to initiate a request.

Procedure

1. Create an AcsClient instance.

```
IAcsClient client = new DefaultAcsClient(profile);
```

2. Create a request.

A request class name is in the format of `${apiName}Request`, where **`${apiName}`** indicates the API name, such as `CreateMigrationJobRequest`.

When the SDKs of multiple services are used, different requests may have the same name. Distinguish the requests by service package.

```
CreateMigrationJobRequest request=new CreateMigrationJobRequest();
```

3. Initiate a call and handle the response.

```
try {  
    ConfigureMigrationJobResponse response = client.getAcsResponse(  
request);  
    System.out.println("Configure "+ MigrationJobId+ " Succeed");  
} catch (Exception e) {  
    // TODO: handle exception  
    System.out.println("Configure "+MigrationJobId + " Failed!");  
    System.out.println(e.toString());  
}
```

In normal cases, all response fields are deserialized into the response. You can directly call `response.getXXX()` to obtain the response fields.

However, if an exception occurs or you want to obtain the original HTTP response, you can use the `doAction()` method to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.12.2.2.4 Troubleshooting

The Java SDK returns corresponding errors when errors occur on the server side or the SDK side. These errors contain detailed error information, including the error code and the error message.

In normal cases, you do not need to solve the errors returned by the Java SDK. You only need to handle the errors returned by the server.

- `ServerException` is the error returned by the server.
- `ClientException` is the error returned by the SDK side.

For example, when the following error occurs, you have to modify the AccessKey ID based on the error message.

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified access key is not found.
```

If you want to handle the errors returned by the Java SDK, refer to the following example to write your code:

```
try {
    FooResponse response = client.getAcsResponse(request);
    // The following code is used to solve returned errors:
    // ...
} catch (ServerException e) {
    // You can add your own error handling logic here
    // For example, display the error message
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If you cannot solve the error, submit a ticket and provide the request ID to Alibaba
    technical support personnel.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {
    // You can add your own error handling logic here.
    // For example, display the error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
}
```

}

2.12.2.2.5 Errors and troubleshooting

The following are some common errors you may experience when using the Apsara Stack SDK.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot automatically obtain the endpoint of the called product in the specified region.	Check whether the provided region ID and endpoint are correct. After obtaining the correct endpoint, run the following code to set the endpoint: <pre>DefaultProfile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response	SDK response deserialization fails. In most cases, it is because the response structure received by the SDK does not conform to the API metadata. For example, the fields do not match or the format is incorrect.	You can use the <code>client.doAction(request)</code> method to obtain the original HTTP response.
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The request has timed out and all retry attempts have failed.	In scenarios such as low network quality, we recommend that you increase the timeout value or the allowed number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError : InvalidProtocol .NeedSsl	Your request is denied as lack of ssl protect .Recommend :https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol .NeedSsl&source=PopGw	The operation only accepts HTTPS requests but not HTTP requests.	Add the following code before sending a request: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.13 Server Load Balancer (SLB)

2.13.1 API reference

2.13.1.1 List of operations by function

Instance operations

Operation	Description
CreateLoadBalancer	Creates an SLB instance.
DeleteLoadBalancer	Deletes an SLB instance.
SetLoadBalancerStatus	Sets the status of an SLB instance.
SetLoadBalancerName	Modifies the name of an SLB instance.
DescribeLoadBalancers	Queries created SLB instances.
DescribeLoadBalancerAttribute	Queries detailed information of a specified SLB instance.
DescribeRegions	Queries available regions.
DescribeZones	Queries the zone information of a specified region.

Listener operations

Operation	Description
TCP listeners	
CreateLoadBalancerTCPListener	Creates a TCP listener.

Operation	Description
SetLoadBalancerTCPListenerAttribute	Modifies the configurations of a TCP listener.
DescribeLoadBalancerTCPListenerAttribute	Queries the configurations of a TCP listener.
UDP listeners	
CreateLoadBalancerUDPListener	Creates a UDP listener.
SetLoadBalancerUDPListenerAttribute	Modifies the configurations of a UDP listener.
DescribeLoadBalancerUDPListenerAttribute	Queries the configurations of a UDP listener.
HTTP listeners	
CreateLoadBalancerHTTPListener	Creates an HTTP listener.
SetLoadBalancerHTTPListenerAttribute	Modifies the configurations of an HTTP listener.
DescribeLoadBalancerHTTPListenerAttribute	Queries the configurations of an HTTP listener.
HTTPS listeners	
CreateLoadBalancerHTTPSListener	Creates an HTTPS listener.
SetLoadBalancerHTTPSListenerAttribute	Modifies the configurations of an HTTPS listener.
DescribeLoadBalancerHTTPSListenerAttribute	Queries the configurations of an HTTPS listener.
General listener operations	
StartLoadBalancerListener	Enables a listener.
DeleteLoadBalancerListener	Deletes a listener.
StopLoadBalancerListener	Disables a listener.
Access control	
SetListenerAccessControlStatus	Enables or disables access control for a specified listener.
DescribeListenerAccessControlAttribute	Queries the access control configurations of a specified listener.

Operation	Description
AddListenerWhiteListItem	Adds an IP address to the whitelist of a specified listener.
RemoveListenerWhiteListItem	Removes an IP address from the whitelist of a specified listener.
Forwarding rules	
CreateRules	Adds forwarding rules to a specified HTTP or HTTPS listener.
DeleteRules	Deletes forwarding rules.
DescribeRules	Queries the configured forwarding rules of a specified listener.
SetRule	Modifies the target VServer group of a specified forwarding rule.
DescribeRuleAttribute	Queries detailed information of a specified forwarding rule.

Back-end server operations

Operation	Description
AddBackendServers	Adds back-end servers.
RemoveBackendServers	Removes back-end servers.
SetBackendServers	Sets the weights of back-end servers.
VServer groups	
CreateVServerGroup	Creates a VServer group and adds back-end servers to the VServer group.
SetVServerGroupAttribute	Modifies the configurations of a VServer group.
AddVServerGroupBackendServers	Adds back-end servers to a specified VServer group.
RemoveVServerGroupBackendServers	Removes back-end servers from a specified VServer group.
ModifyVServerGroupBackendServers	Replaces back-end servers in a specified VServer group.
DeleteVServerGroup	Deletes a specified VServer group.

Operation	Description
DescribeVServerGroups	Queries created VServer groups.
DescribeVServerGroupAttribute	Queries detailed information of a specified VServer group.
Primary/secondary server groups	
CreateMasterSlaveServerGroup	Creates a primary/secondary server group.
DeleteMasterSlaveServerGroup	Deletes a primary/secondary server group.
DescribeMasterSlaveServerGroupAttribute	Queries detailed information of a specified primary/secondary server group.
DescribeMasterSlaveServerGroups	Queries created primary/secondary server groups.

Tag operations

Operation	Description
AddTags	Adds tags to a specified SLB instance.
DescribeTags	Queries created tags.
RemoveTags	Removes tags from a specified SLB instance.

2.13.1.2 Make API requests

When you call an SLB API, an HTTP GET request is sent to the endpoint of the SLB API. You must add corresponding request parameters to the request based on the API description. After the API is called, the system returns the processing result. Requests and responses are encoded using UTF-8.

Request structure

RPC applies to SLB APIs. You can call SLB APIs by sending HTTP GET requests.

The request structure is as follows:

```
http://Endpoint/?Action=xx&Parameters
```

In the request,

- **Endpoint:** The endpoint for SLB APIs is `slb.example.com`.

**Note:**

`example.com` is a custom domain name. Contact the system administrator to obtain the domain name. For more information, see [Obtain an endpoint](#).

- **Action:** The operation that you want to perform. For example, call **DescribeLoadBalancers** to query all created SLB instances.
- **Version:** The version of the APIs that you want to use. The current SLB API version is 2014-05-15.
- **Parameters:** Request parameters that are separated with ampersands (&).

Request parameters consist of common parameters and custom API parameters. Common parameters include the API version number and identity verification information. For more information, see [Common parameters](#).

The following code provides an example of how to call **DescribeLoadBalancers** to query SLB instances that have been created.

**Note:**

The API request is displayed in the following format:

```
https://slb.example.com/?Action=DescribeLoadBalancers
&Format=xml
&Version=2014-05-15
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&TimeStamp=2016-02-23T12:46:24Z
...
```

API authorization

To keep your account secure, we recommend that you call SLB APIs as a RAM user. Before calling SLB APIs as a RAM user, you must create a RAM user and assign corresponding permissions to it.

For more information about SLB resources and APIs that you can assign permissions to, see [RAM authentication](#).

Add a signature to an API request

To secure your API, you must add signature information to the API request. SLB uses the signature in the request to verify the identity of the caller.

SLB implements symmetric encryption through an AccessKey ID and an AccessKey Secret to authenticate the request sender. The AccessKey is an identity credential issued to Apsara Stack tenant accounts and RAM users (similar to the login password). The AccessKey ID is used to identify the user. The AccessKey Secret is used to encrypt the signature string on the client side and to verify the signature string on the server side. The AccessKey Secret must be kept strictly confidential. For more information, see [Obtain an AccessKey pair](#).

For an RPC API, you must add the signature to the API request in the following format:

```
https://endpoint/?SignatureVersion=1.0&SignatureMethod=HMAC-SHA1&Signature=
CT9X0VtwR86fNWSnsc6v8YGOjuE%3D&SignatureNonce=3ee8c1b8-83d3-44af-a94f-
4e0ad82fd6cf
```

Take **DescribeLoadBalancers** as an example. If the AccessKey ID is `testid`, and the AccessKey Secret is `testsecret`, the pre-signed request URL is as follows:

```
http://slb.example.com/?Action=DescribeLoadBalancers
&TimeStamp=2016-02-23T12:46:24Z
&Format=XML
&AccessKeyId=testid
&SignatureMethod=HMAC-SHA1
&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf
&Version=2014-05-26
&SignatureVersion=1.0
```

To calculate the signature, perform the following operations:

1. Use the request parameters to create a query string for the signature.

```
GET&%2F&AccessKeyId%3Dtestid&Action%3DDescribeLoadBalancers&Format%3DXML
&SignatureMethod%3DHMAC-SHA1&SignatureNonce%3D3ee8c1b8-83d3-44af-a94f-
-4e0ad82fd6cf&SignatureVersion%3D1.0&TimeStamp%3D2016-02-23T12%253A46%
253A24Z&Version%3D2014-05-15
```

2. Calculate the HMAC value of the string you want to sign.

Add an ampersand (&) to the AccessKey Secret and use the new string as the key to calculate the HMAC value. In this example, the key is `testsecret&`.

```
CT9X0VtwR86fNWSnsc6v8YGOjuE=
```

3. Add the signature to the request parameters:

```
http://slb.example.com/?Action=DescribeLoadBalancers
&TimeStamp=2016-02-23T12:46:24Z
&Format=XML
&AccessKeyId=testid
&SignatureMethod=HMAC-SHA1
&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf
```

```
&Version=2014-05-26
&SignatureVersion=1.0
&Signature=CT9X0VtwR86fNWSnsc6v8YGOjuE%3D
```

2.13.1.3 RAM authentication

Before calling an SLB API as a RAM user, you must use an Alibaba Cloud account to create an authorization policy to assign permissions to the RAM user. In the authorization policy, you must use an Alibaba Cloud Resource Name (ARN) as the unique identifier of the resource.

Available SLB resources

The following table describes the ARN format for different types of SLB resources.

Resource type	ARN format
LoadBalancer	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:slb:\$regionid:\$accountid:loadbalancer/*
	acs:slb:*\$accountid:loadbalancer/*
	acs:slb:*:*:loadbalancer/*
Certificate	acs:slb:\$regionid:\$accountid:certificate/\$servercertificateid
	acs:slb:\$regionid:\$accountid:certificate/*

\$regionid/accountid/servercertificateid is the resource ID. * indicates the corresponding resources.

SLB APIs

The following table lists the APIs that can be authorized and their corresponding ARN formats.

API	ARN format
CreateLoadBalancer	acs:slb:\$regionid:\$accountid:loadbalancer/*
ModifyLoadBalancerInternetSpec	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DeleteLoadBalancer	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
SetLoadBalancerStatus	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
SetLoadBalancerName	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid

API	ARN format
DescribeLoadBalancers	acs:slb:\$regionid:\$accountid:loadbalancer/*
DescribeLoadBalancerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DescribeRegions	acs:slb:*\$accountid:*
UploadServerCertificate	acs:slb:%s:%s:certificate/*
DeleteServerCertificate	acs:slb:%s:%s:certificate/%
DescribeServerCertificate	acs:slb:%s:%s:certificate/%
SetServerCertificateName	acs:slb:%s:%s:certificate/%
DescribeServerCertificates	acs:slb:%s:%s:certificate/*
CreateLoadBalancerHTTPListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
CreateLoadBalancerHTTPTLSListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:slb:%s:%s:certificate/%
CreateLoadBalancerTCPListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
CreateLoadBalancerUDPListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DeleteLoadBalancerListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
StartLoadBalancerListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
StopLoadBalancerListener	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
SetLoadBalancerHTTPListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
SetLoadBalancerHTTPSListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:slb:%s:%s:certificate/%
SetLoadBalancerTCPListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
SetLoadBalancerUDPListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid

API	ARN format
DescribeLoadBalancer HTTPListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DescribeLoadBalancer HTTPSListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DescribeLoadBalancer TCPListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DescribeLoadBalancer UDPListenerAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
AddBackendServers	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid
RemoveBackendServers	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid
SetBackendServers	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid
DescribeHealthStatus	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
CreateVServerGroup	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid
SetVServerGroupAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DeleteVServerGroup	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DescribeVServerGroups	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
DescribeVServerGroupAttribute	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
AddVServerGroupBackendServers	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid

API	ARN format
RemoveVServerGroupBackendServers	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid
ModifyVServerGroupBackendServers	acs:slb:\$regionid:\$accountid:loadbalancer/\$loadbalancerid
	acs:ecs:\$regionid:\$accountid:instance/\$instanceid

2.13.1.4 Common parameters

Common request parameters

Common request parameters are request parameters that you must use when you call any API.

Table 2-412: Common request parameters

Name	Type	Required	Description
Format	String	No	The format of the response. Valid values: JSON (default) XML
Version	String	Yes	The API version in the format of YYYY-MM-DD. Valid values: 2014-05-15
AccessKeyId	String	Yes	The AccessKey ID that is used to access a service.
Signature	String	Yes	The signature result string.
SignatureMethod	String	Yes	The algorithm used to create the request signature. Valid values: HMAC-SHA1
Timestamp	String	Yes	The request timestamp. The timestamp uses UTC and it complies with the ISO 8601 standard. The timestamp format is YYYY-MM-DDThh:mm:ssZ. For example, 20:00:00 on January 1st, 2013 in China Standard Time (UTC +8) would be written as 2013-01-10T12:00:00Z.

Name	Type	Required	Description
SignatureVersion	String	Yes	The signature algorithm version. Valid value: 1.0
SignatureNonce	String	Yes	A unique random number that is used to prevent network replay attacks. You must use different random numbers for different requests.

Example

```
http://slb.example.com/?Action=DescribeLoadBalancers
&TimeStamp=2014-05-19T10%3A33%3A56Z
&Format=xml
&AccessKeyId=testid
&Action=DescribeLoadBalancerAttribute
&SignatureMethod=Hmac-SHA1
&LoadBalancerId=loadBalancerID
&SignatureNonce=NwDAxvLU6tFE0DVb
&Version=2014-05-15
&SignatureVersion=1.0
&Signature=Signature
```

Common response parameters

API responses use a unified format. The 2xx HTTP status code indicates a successful invocation. The 4xx or 5xx HTTP status code indicates a failed invocation. The responses can be returned in JSON or XML format. The XML format is used by default. You can specify the format when calling an API.

Each time a request is sent to call an API, the system returns a unique identifier **RequestId**, regardless of whether the invocation is successful.

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<!--Result root node-->
<API name+Response>
  <!--Returned request tag-->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!--Returned result-->
</API name+Response>
```

- JSON format

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /*Returned result*/
}
```

}

2.13.1.5 Obtain an AccessKey pair

You can obtain the AccessKey pair on the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.13.1.6 Obtain an endpoint

You can obtain the product endpoint in Apsara Stack Operations.

Procedure

1. Log on to Apsara Stack Operations.
For how to log on to Apsara Stack Operations, see **Operations of basic platforms > Apsara Stack Operations > Log on to Apsara Stack Operations** in Operations Guide .
2. Click **Products** in the left-side navigation pane.
3. Choose **Apsara Infrastructure Management Framework** in the product list to go to the Apsara Infrastructure Management Framework page.

4. Choose **Operations > Machine Operations**. The **Machine Operations** page appears.

5. Select a machine and then click **Terminal** to log on to the machine.

Machine Operations											
Search Allows fuzzy or batch search. Separate multiple machines with commas or space.				Reset	Exact Match		Machine Bucket Change	Machine Online/Offline	Refresh

```

2.13.1.7 SLB instance

2.13.1.7.1 CreateLoadBalancer

You can call this operation to create an SLB instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateLoadBalancer.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.

Parameter	Type	Required	Description
LoadBalancerName	String	No	The name of the SLB instance. The name must be 2 to 128 characters in length. It must start with a letter and can contain letters, digits, periods (.), underscores (_), and hyphens (-).
AddressType	String	No	The network type of the SLB instance. Valid values : - internet: After an Internet SLB instance is created, the system allocates a public IP address to it so that the instance can forward requests from the Internet. - intranet: After an intranet SLB instance is created, the system allocates a private IP address to it so that the instance can only forward intranet requests.
VSwitchId	String	No	The ID of the VSwitch to which the intranet SLB instance belongs.  Note: When this parameter is specified, the AddressType parameter is automatically set to intranet.
ClientToken	String	No	The client token that is used to guarantee the idempotency of the request. The value of this parameter is generated by the client and must be unique among different requests. The maximum length is 64 ASCII characters.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Parameter	Type	Description
LoadBalancerId	String	The ID of the SLB instance.
Address	String	The IP address of the SLB instance.
VpcId	String	The ID of the VPC to which the SLB instance belongs.
VSwitchId	String	The ID of the VSwitch to which the SLB instance belongs.
LoadBalancerName	String	The name of the SLB instance.

Examples

Sample requests

```
https://slb.example.com/  
&Action=CreateLoadBalancer  
&RegionId=cn-east-hangzhou-01  
&LoadBalancerName=abc**  
&AddressType=internet  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<CreateLoadBalancerResponse>  
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>  
  <LoadBalancerId>139a0*****</LoadBalancerId>  
  <Address>42. **. **. **</Address>  
  <NetworkType>classic</NetworkType>  
  <LoadBalancerName>abc</LoadBalancerName>  
</CreateLoadBalancerResponse>
```

- JSON format

```
{  
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",  
  "LoadBalancerId": "139a0*****",  
  "Address": "42. **. **. **",  
  "NetworkType": "classic",  
  "LoadBalancerName": "abc*****"  
}
```

2.13.1.7.2 DeleteLoadBalancer

You can call this operation to delete an SLB instance.

Note:

The listeners and tags configured for the SLB instance will also be deleted.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteLoadBalancer.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/  
&Action=DeleteLoadBalancer  
&LoadBalancerId=lb-t4nj5vuz8*****  
&RegionId=ap-southeast-1  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<DeleteLoadBalancerResponse>  
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>  
</DeleteLoadBalancerResponse>
```

- JSON format

```
{  
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
```

}

2.13.1.7.3 SetLoadBalancerStatus

You can call this operation to set the status of an SLB instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetLoadBalancerStatus.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
LoadBalancerStatus	String	Yes	The status of the SLB instance. Valid values: - active When an SLB instance is in the active state, listeners in the instance forward the received traffic based on rules. By default, an SLB instance is in the active state after it is created. - inactive When an SLB instance is in the inactive state, listeners in the SLB instance do not forward the received traffic.  Note: If all listeners in an SLB instance are deleted, the SLB instance automatically enters the inactive state.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/  
&Action=SetLoadBalancerStatus  
&LoadBalancerId=lb-t4nj5vu*****  
&LoadBalancerStatus=active  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<SetLoadBalancerStatusResponse>  
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>  
</SetLoadBalancerStatusResponse>
```

- JSON format

```
{  
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"  
}
```

2.13.1.7.4 SetLoadBalancerName

You can call this operation to modify the name of an SLB instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetLoadBalancerName.
RegionId	String	No	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Parameter	Type	Required	Description
LoadBalancerName	String	Yes	The name of the SLB instance. The name must be 2 to 128 characters in length. It must start with a letter and can contain letters, digits, periods (.), underscores (_), and hyphens (-).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/  
&Action=SetLoadBalancerName  
&LoadBalancerId=lb-t4nj5vuz8*****  
&LoadBalancerName=abc  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<SetLoadBalancerNameResponse>  
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>  
</SetLoadBalancerNameResponse>
```

- JSON format

```
{  
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"  
}
```

2.13.1.7.5 DescribeLoadBalancers

You can call this operation to query created SLB instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeLoadBalancers.

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	No	The ID of the SLB instance. A maximum of 10 IDs can be queried each time . The entered values must be separated with commas (,).
LoadBalancerName	String	No	The name of the SLB instance. A maximum of 10 names can be queried each time. The entered values must be separated with commas (,).
AddressType	String	No	The network type of the SLB instance. Valid values: intranet internet
NetworkType	String	No	The network type of the intranet SLB instance. Valid values: - vpc - classic
VpcId	String	No	The ID of the VPC to which the SLB instance belongs.
VswitchId	String	No	The ID of the VSwitch to which the SLB instance belongs.
Address	String	No	The IP address of the SLB instance.
ServerIntranetAddress	String	No	The internal IP address of the attached back-end server. Multiple IP addresses can be queried each time . The entered values must be separated with commas (,).
ServerId	String	No	The ID of the attached back-end server.

Parameter	Type	Required	Description
MasterZoneId	String	No	The ID of the primary zone where the SLB instance resides.
SlaveZoneId	String	No	The ID of the secondary zone where the SLB instance resides.
Tags	JSON string	No	The tags bound to the SLB instance to query. A maximum of 10 tags can be specified.
tags elements			
TagKey	String	No	The key of the tag bound to the SLB instance to query.  Note: If you set the Tags parameter, you must also set this parameter.
TagValue	String	No	The key value of the tag bound to the SLB instance to query. The value cannot start with aliyun.  Note: If you set the Tags parameter, you must also set this parameter.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
LoadBalancers	JSON string	The list of SLB instances that were queried.
LoadBalancer elements		
LoadBalancerId	String	The ID of the SLB instance.
LoadBalancerName	String	The name of the SLB instance.

Parameter	Type	Description
LoadBalancerStatus	String	The status of the SLB instance. - inactive: The listeners of the SLB instance in the inactive state do not forward traffic. - active: After the SLB instance is created, it is in the active state by default. - locked: The SLB instance is locked.
Address	String	The IP address of the SLB instance.
RegionId	String	The ID of the region where the SLB instance resides.
RegionIdAlias	String	The alias of the region to which the SLB instance belongs.
AddressType	String	The network type of the SLB instance.
VSwitchId	String	The ID of the VSwitch to which the intranet SLB instance belongs.
VpcId	String	The ID of the VPC to which the intranet SLB instance belongs.
NetworkType	String	The network type of the intranet SLB instance. Valid values: - vpc - classic
CreateTime	String	The time when the SLB instance was created.
CreateTimeStamp	Integer	The timestamp generated when the SLB instance was created.
MasterZoneId	String	The ID of the primary zone where the SLB instance resides.
SlaveZoneId	String	The ID of the secondary zone where the SLB instance resides.

Examples

Sample requests

```
https://slb.example.com/
```

```
&Action=DescribeLoadBalancers
&RegionId=cn-hangzhou
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeLoadBalancersResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>

```

2.13.1.7.6 DescribeLoadBalancerAttribute

You can call this operation to query the details of a specified SLB instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeLoadBalancerAttribute.
LoadBalancerId	String	Yes	The ID of the SLB instance.
RegionId	String	No	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
LoadBalancerId	String	The ID of the SLB instance.
RegionId	String	The ID of the region where the SLB instance resides.
RegionIdAlias	String	The alias of the region where the SLB instance resides.
LoadBalancerName	String	The name of the SLB instance.

Parameter	Type	Description
LoadBalancerStatus	String	The status of the SLB instance. Valid values: - inactive: The listeners of the SLB instance in the inactive state do not forward traffic. - active: After the SLB instance is created, it is in the active state by default. - locked: The SLB instance is locked.
Address	String	The IP address of the SLB instance.
AddressType	String	The network type of the SLB instance.
NetworkType	String	The network type of the intranet SLB instance .
VpcId	String	The ID of the VPC to which the intranet SLB instance belongs.
VswitchId	String	The ID of the VSwitch to which the intranet SLB instance belongs.
CreateTimeStamp	Integer	The timestamp generated when the SLB instance was created.
CreateTime	String	The time when the SLB instance was created.
ListenerPorts	JSON string	The list of front-end port numbers used by the SLB instance.
ListenerPortsAndProtocol	JSON string	The list of front-end port numbers and protocols used by the SLB instance.
BackendServers	JSON string	The list of back-end servers for the SLB instance.
MasterZoneId	String	The ID of the primary zone to which the SLB instance belongs.
SlaveZoneId	String	The ID of the secondary zone to which the SLB instance belongs.
ListenerPortsAndProtocol elements		
ListenerPort	String	The front-end port number used by the SLB instance.
ListenerProtocol	Integer	The front-end listener protocol used by the SLB instance.
BackendServers elements		

Parameter	Type	Description
ServerId	String	The ID of the ECS instance.
Weight	Integer	The weight of the back-end server.

Examples

Sample requests

```
https://slb.example.com/
&Action=DescribeLoadBalancerAttribute
&LoadBalancerId=lb-t4nj5vuz8ish9emfk1f20
&Common request parameters
```

Sample responses

- XML format

```

2.13.1.7.7 DescribeRegions

This topic describes how to query available regions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRegions.

Response parameters

Name	Type	Description
RequestId	string	The request ID.
Regions	JSON string	The list of regions.
Region elements		
RegionId	String	The region ID.
LocalName	String	The region name.

Examples

Sample requests

```
https://slb.example.com/
&Action=DescribeRegions
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeRegionsResponse>
  <RequestId>1651FBB6-4FBF-49FF-A9F5-DF5D696C7EC6</RequestId>
  <Regions>
    <Region>
      <RegionId>cn-east-hangzhou-01</RegionId>
      <LocalName>Hangzhou</LocalName>
    </Region>
    <Region>
      <RegionId>cn-beijing</RegionId>
      <LocalName>Beijing</LocalName>
    </Region>
  </Regions>
</DescribeRegionsResponse>
```

- JSON format

```
{
  "RequestId": "1651FBB6-4FBF-49FF-A9F5-DF5D696C7EC6",
  "Regions": {
    "Region": [
      {
        "RegionId": "cn-hangzhou",
        "LocalName": "Qingdao"
      },
      {
        "RegionId": "cn-beijing",
        "LocalName": "Beijing"
      }
    ]
  }
}
```

2.13.1.7.8 DescribeZones

This topic describes how to query the zone information in a specified region.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeZones.
RegionId	String	Yes	The ID of the region.

Response parameters

Name	Type	Description
RequestId	String	The request ID.
Zones	JSON string	The list of zones.
Zone elements		
Zoneld	String	The zone ID.
LocalName	String	The name of the zone.
SlaveZones	JSON string	The list of secondary zones.
SlaveZone elements		
Zoneld	String	The ID of the secondary zone.
LocalName	String	The name of the secondary zone.

Examples

Sample requests

```
https://slb.example.com/  
&Action=DescribeZones  
&RegionId=cn-beijing  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >  
<RequestId>A48D35FF-440A-4BC0-A4A2-A9BF69B7E43A</RequestId>  
<Zones>  
  <Zone>  
    <SlaveZones></SlaveZones>  
    <Zoneld>cn-beijing-b</Zoneld>  
    <LocalName>Beijing Zone B</LocalName>  
  </Zone>  
</Zones>
```

- JSON format

```
{  
  "RequestId": "1FF3C0EC-588C-4872-8F86-8D88A652D1E4",  
  "Zones": {  
    "Zone": [  
      {  
        "Zoneld": "cn-beijing-b",  
        "LocalName": "Beijing Zone B",  
        "SlaveZones": {  
          "SlaveZone": []  
        }  
      }  
    ]  
  }  
}
```

```
}
}
```

2.13.1.8 Listener

2.13.1.8.1 TCP listener

2.13.1.8.1.1 CreateLoadBalancerTCPListener

You can call this operation to create a TCP listener.

Note:

The status of a newly created TCP listener is stopped. After a TCP listener is created, you must call **StartLoadBalancerListener** to enable the listener to forward traffic.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to <code>CreateLoadBalancerTCPListener</code> .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.

Parameter	Type	Required	Description
MasterSlaveServerGroupID	String	No	The ID of the primary/secondary server group.  Note: You can only specify either VServerGroupID or MasterSlaveServerGroupID.
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: -1: The peak bandwidth is unlimited. [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: - wrr: Back-end servers with higher weights receive more requests than those with lower weights. - wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. - rr: Requests are sequentially distributed to back-end servers.
PersistenceTimeout	Integer	No	The timeout period of the session persistence. Unit: seconds. Valid values: 0 to 3600 The default value is 0. When the default value is used, the session persistence function is disabled.

Parameter	Type	Required	Description
EstablishedTimeout	Integer	No	The connection timeout period. Unit: seconds. Valid values: 10 to 900
HealthCheckType	String	No	The health check type. Valid values: tcp and http. Default value: tcp.
HealthCheckDomain	String	No	The domain name used for health checks. Valid values: <code>\$_ip</code>: the private IP address of the back-end server. If you do not specify a value for <code>HealthCheckDomain</code> or you set the value to <code>\$_ip</code>, the SLB instance uses the <code>\$_ip</code> value as the domain name for health checks. <code>domain</code>: The domain name must be 1 to 80 characters in length. It can only contain letters, digits, periods (.), and hyphens (-).  Note: This parameter is not required when <code>HealthCheckType</code> is set to tcp.
HealthCheckURI	String	No	The URI used for health checks.  Note: This parameter is not required when <code>HealthCheckType</code> is set to tcp.
HealthCheckConnectPort	Integer	No	The port number used for health checks.
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10

Parameter	Type	Required	Description
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that the health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=CreateLoadBalancerTCPListener
&LoadBalancerId=lb-t4nj5vuz8i*****
&ListenerPort=443
&BackendServerPort=443
&Bandwidth=-1
&VServerGroupId=vsp-cig*****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateLoadBalancerTCPListenerResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</CreateLoadBalancerTCPListenerResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.8.1.2 SetLoadBalancerTCPListenerAttribute

You can call this operation to modify the configurations of a TCP listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetLoadBalancerTCPListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Parameter	Type	Required	Description
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
MasterSlaveServerGroupId	String	No	The ID of the primary/secondary server group.  Note: You can only specify either VServerGroupId or MasterSlaveServerGroupId.
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: -1: The peak bandwidth is unlimited. [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.

Parameter	Type	Required	Description
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: - wrr: Back-end servers with higher weights receive more requests than those with lower weights. - wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. - rr: Requests are sequentially distributed to back-end servers.
PersistenceTimeout	Integer	No	The timeout period of the session persistence. Unit: seconds. Valid values: 0 to 3600 The default value is 0. When the default value is used, the session persistence function is disabled.
EstablishedTimeout	Integer	No	The connection timeout period. Unit: seconds. Valid values: 10 to 900
HealthCheckType	String	No	The health check type. Valid values: tcp and http. Default value: tcp.

Parameter	Type	Required	Description
HealthCheckDomain	String	No	The domain name used for health checks. Valid values: <code>\$_ip</code>: the private IP address of the back-end server. If you do not specify a value for <code>HealthCheckDomain</code> or you set the value to <code>\$_ip</code>, the SLB instance uses the <code>\$_ip</code> value as the domain name for health checks. <code>domain</code>: The domain name must be 1 to 80 characters in length. It can only contain letters, digits, periods (.), and hyphens (-).  Note: This parameter is not required when <code>HealthCheckType</code> is set to <code>tcp</code>.
HealthCheckURI	String	No	The URI used for health checks.  Note: This parameter is not required when <code>HealthCheckType</code> is set to <code>tcp</code>.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: 1 to 65535
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from <code>fail</code> to <code>success</code>). Valid values: 2 to 10
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from <code>success</code> to <code>fail</code>). Valid values: 2 to 10

Parameter	Type	Required	Description
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that the health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetLoadBalancerTCPListenerAttribute
&LoadBalancerId=lb-t4nj5vuz8i****8
&ListenerPort=443
&BackendServerPort=443
&Bandwidth=-1
&VServerGroupId=vsp-cige****
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<SetLoadBalancerTCPListenerAttributeResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</SetLoadBalancerTCPListenerAttributeResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.8.1.3 DescribeLoadBalancerTCPListenerAttribute

You can call this operation to query configurations of a TCP listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeLoadBalancerTCPListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ListenerPort	Integer	The front-end port number used by the SLB instance.
BackendServerPort	Integer	The back-end port number used by the SLB instance.
Bandwidth	Integer	The peak bandwidth of the listener.

Parameter	Type	Description
Status	String	The status of the listener. Valid values: starting, running, configuring, stopping, and stopped
Scheduler	String	The scheduling algorithm.
VServerGroupId	String	The ID of the VServer group.
MasterSlaveServerGroup upId	String	The ID of the primary/secondary server group.
PersistenceTimeout	String	Indicates whether session persistence was enabled. If the value is 0, session persistence is disabled.
EstablishedTimeout	String	The connection timeout period. Unit: seconds.
HealthCheckType	String	The health check method used by the TCP listener.
HealthCheck	String	Indicates whether the health check function was enabled.
HealthyThreshold	Integer	The healthy threshold.
UnhealthyThreshold	Integer	The unhealthy threshold.
HealthCheckTimeout	Integer	The health check timeout period. Unit: seconds.
HealthCheckConnectTi meout	Integer	The health check timeout period. Unit: seconds.
HealthCheckInterval	Integer	The interval between two consecutive health checks . Unit: seconds.
HealthCheckDomain	String	The domain name used for health checks.
HealthCheckURI	String	The URI used for health checks.
HealthCheckHttpCode	String	The HTTP status code indicating that the health check is successful.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeLoadBalancerTCPListenerAttribute
&LoadBalancerId=lb-t4nj5vuz8*****
&ListenerPort=80
```

2.13.1.8.2 UDP listener**2.13.1.8.2.1 CreateLoadBalancerUDPListener**

You can call this operation to create a UDP listener.

**Note:**

The status of a newly created UDP listener is stopped. After the listener is created, you must call **StartLoadBalancerListener** to enable the listener to forward traffic.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to <code>CreateLoadBalancerUDPLListener</code> .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535.  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
MasterSlaveServerGroupId	String	No	The ID of the primary/secondary server group.  Note: You can only specify either VServerGroupId or MasterSlaveServerGroupId .

Parameter	Type	Required	Description
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: • -1: The peak bandwidth is unlimited. • [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: • wrr: Back-end servers with higher weights receive more requests than those with lower weights. • wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. • rr: Requests are sequentially distributed to back-end servers.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: 1 to 65535
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10

Parameter	Type	Required	Description
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that the health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.
HealthCheckReq	String	No	The request string for UDP listener health checks . It must be 1 to 500 characters in length. It can contain only letters and digits.
HealthCheckExp	String	No	The response string for UDP listener health checks . It must be 1 to 500 characters in length. It can contain only letters and digits.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=CreateLoadBalancerTCPListener
&LoadBalancerId=lb-t4nj5vuz8ish9*****
&ListenerPort=443
&BackendServerPort=443
&Bandwidth=-1
&VServerGroupId=vsp-cig*****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateLoadBalancerTCPListenerResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</CreateLoadBalancerTCPListenerResponse>
```

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.8.2.2 SetLoadBalancerUDPListenerAttribute

You can call this operation to modify the configurations of a UDP listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to <code>SetLoadBalancerUDPListenerAttribute</code> .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Parameter	Type	Required	Description
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
MasterSlaveServerGroupId	String	No	The ID of the primary/secondary server group.  Note: You can only specify either VServerGroupId or MasterSlaveServerGroupId .
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: • -1: The peak bandwidth is unlimited. • [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.

Parameter	Type	Required	Description
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: • wrr: Back-end servers with higher weights receive more requests than those with lower weights. • wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. • rr: Requests are sequentially distributed to back-end servers.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: 1 to 65535.
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10

Parameter	Type	Required	Description
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that the health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.
HealthCheckReq	String	No	The request string for UDP listener health checks . It must be 1 to 500 characters in length. It can contain only letters and digits.
HealthCheckExp	String	No	The response string for UDP listener health checks . It must be 1 to 500 characters in length. It can contain only letters and digits.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetLoadBalancerUDPListenerAttribute
&LoadBalancerId=lb-t4nj5vuz8is*****
&ListenerPort=443
&BackendServerPort=443

```

2.13.1.8.2.3 DescribeLoadBalancerUDPListenerAttribute

You can call this operation to query the configurations of a UDP listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeLoadBalancerUDPListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ListenerPort	Integer	The front-end port number used by the SLB instance.
BackendServerPort	Integer	The back-end port number used by the SLB instance.
Bandwidth	Integer	The peak bandwidth of the listener.
Status	String	The status of the listener. Valid values: starting, running, configuring, stopping, and stopped
Scheduler	String	The scheduling algorithm.
VServerGroupId	String	The ID of the VServer group.
MasterSlaveServerGroupUpId	String	The ID of the primary/secondary server group.
HealthCheck	String	Indicates whether the health check function was enabled.
HealthyThreshold	Integer	The healthy threshold.
UnhealthyThreshold	Integer	The unhealthy threshold.
HealthCheckTimeout	Integer	The health check timeout period. Unit: seconds.
HealthCheckConnectTimeout	Integer	The health check timeout period. Unit: seconds.
HealthCheckInterval	Integer	The interval between two consecutive health checks . Unit: seconds.
HealthCheckHttpCode	String	The HTTP status code indicating that the health check is successful.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeLoadBalancerUDPLListenerAttribute
&LoadBalancerId=lb-t4nj5vuz****8
&ListenerPort=80
&Common request parameters
```

Sample responses

```

2.13.1.8.3 HTTP listener

2.13.1.8.3.1 CreateLoadBalancerHTTPListener

You can call this operation to create an HTTP listener.

Note:

The status of a newly created listener is stopped. After the listener is created, you must call the **StartLoadBalancerListener** operation to enable the listener to forward traffic.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to <code>CreateLoadBalancerHTTPListener</code> .

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: -1: The peak bandwidth is unlimited. [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.
XForwardedFor	String	No	Specifies whether to use the X-Forwarded-For header to obtain the real IP address of the client. Default value: on. Valid values: on and off

Parameter	Type	Required	Description
XForwardedFor_SLBIP	String	No	Specifies whether to use the SLB-IP header to obtain the real IP address of the client. Default value: off. Valid values: on and off
XForwardedFor_SLBID	String	No	Specifies whether to use the SLB-ID header to obtain the ID of the SLB instance. Default value: off. Valid values: on and off
XForwardedFor_proto	String	No	Specifies whether to use the X-Forwarded-Proto header to obtain the listener protocol of the SLB instance. Default value: off. Valid values: on and off
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: • wrr: Back-end servers with higher weights receive more requests than those with lower weights. • wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. • rr: Requests are sequentially distributed to back-end servers.
StickySession	String	Yes	Specifies whether to enable session persistence. Valid values: on and off

Parameter	Type	Required	Description
StickySessionType	String	No	The method for processing cookies. Valid values: - insert: inserts a cookie. The SLB instance inserts the server ID as the cookie into the first HTTP or HTTPS response . When receiving another request containing the cookie from the client, the SLB instance distributes the request to the back-end server specified by the cookie. - server: rewrites a cookie. When detecting that a new cookie is set, the SLB instance uses it to overwrite the original cookie. When receiving another request containing the new cookie from the client, the SLB instance distributes the request to the back-end server specified by the new cookie.  Note: If StickySession is set to on, you must specify a value for this parameter.
CookieTimeout	Integer	No	The cookie timeout period. Unit: seconds. Valid values: 1 to 86400  Note: If StickySession is set to on and StickySessionType is set to insert, you must specify a value for this parameter.

Parameter	Type	Required	Description
Cookie	String	No	The cookie configured on the back-end server. The cookie must be 1 to 200 characters in length . It can only contain ASCII letters and digits. It cannot contain commas (,), semicolons (;), or spaces. It cannot start with a dollar sign (\$). If StickySession is set to on and StickySessionType is set to server, you must specify a value for this parameter.
HealthCheck	String	Yes	Specifies whether to enable the health check function. Valid values: on and off
HealthCheckDomain	String	No	The domain name used for health checks. Valid values: • <code>\$_ip</code>: the private IP address of the back-end server. If you do not specify a value for <code>HealthCheckDomain</code> or you set the value to <code>\$_ip</code>, the SLB instance uses the <code>\$_ip</code> value as the domain name for health checks. • <code>domain</code>: The domain name must be 1 to 80 characters in length. It can only contain letters, digits, periods (.), and hyphens (-).
HealthCheckURI	String	No	The URI used for health checks.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: • <code>-520</code>: The back-end port number configured for the listener is used for health checks. • <code>1-65535</code>: The back-end port number is used for health checks.

Parameter	Type	Required	Description
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that a health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.

Parameter	Type	Required	Description
Gzip	String	No	Specifies whether to enable gzip compression to compress files of a specific type. Valid values: on and off. Default value: on.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=CreateLoadBalancerHTTPListener
&LoadBalancerId=lb-t4nj5vuz8ish*****
&ListenerPort=80
&BackendServerPort=80
&Bandwidth=-1
&HealthCheck=on
&HealthCheckDomain=$_ip

```

}

2.13.1.8.3.2 SetLoadBalancerHTTPListenerAttribute

You can call this operation to modify the configurations of an HTTP listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetLoadBalancerHTTPListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: -1: The peak bandwidth is unlimited. [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.

Parameter	Type	Required	Description
XForwardedFor	String	No	Specifies whether to use the X-Forwarded-For header to obtain the real IP address of the client. Default value: on. Valid values: on and off
XForwardedFor_SLBIP	String	No	Specifies whether to use the SLB-IP header to obtain the real IP address of the client. Default value: off. Valid values: on and off
XForwardedFor_SLBID	String	No	Specifies whether to use the SLB-ID header to obtain the ID of the SLB instance. Default value: off. Valid values: on and off
XForwardedFor_proto	String	No	Specifies whether to use the X-Forwarded-Proto header to obtain the listener protocol of the SLB instance. Default value: off. Valid values: on and off
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: • wrr: Back-end servers with higher weights receive more requests than those with lower weights. • wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. • rr: Requests are sequentially distributed to back-end servers.

Parameter	Type	Required	Description
StickySession	String	Yes	Specifies whether to enable session persistence. Valid values: on and off
StickySessionType	String	No	The method for processing cookies. Valid values: - insert: inserts a cookie. The SLB instance inserts the server ID as the cookie into the first HTTP or HTTPS response . When receiving another request containing the cookie from the client, the SLB instance distributes the request to the back-end server specified by the cookie. - server: rewrites a cookie. When detecting that a new cookie is set, the SLB instance uses it to overwrite the original cookie. When receiving another request containing the new cookie from the client, the SLB instance distributes the request to the back-end server specified by the new cookie.  Note: If StickySession is set to on, you must specify a value for this parameter.
CookieTimeout	Integer	No	The cookie timeout period. Unit: seconds. Valid values: 1 to 86400  Note: If StickySession is set to on and StickySessionType is set to insert, you must specify a value for this parameter.

Parameter	Type	Required	Description
Cookie	String	No	The cookie configured on the back-end server. The cookie must be 1 to 200 characters in length . It can only contain ASCII letters and digits. It cannot contain commas (,), semicolons (;), or spaces. It cannot start with a dollar sign (\$). If StickySession is set to on and StickySessionType is set to server, you must specify a value for this parameter.
HealthCheck	String	Yes	Specifies whether to enable the health check function. Valid values: on and off
HealthCheckDomain	String	No	The domain name used for health checks. Valid values: • <code>\$_ip</code>: the private IP address of the back-end server. If you do not specify a value for <code>HealthCheckDomain</code> or you set the value to <code>\$_ip</code>, the SLB instance uses the <code>\$_ip</code> value as the domain name for health checks. • <code>domain</code>: The domain name must be 1 to 80 characters in length. It can only contain letters, digits, periods (.), and hyphens (-).
HealthCheckURI	String	No	The URI used for health checks.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: • <code>-520</code>: The back-end port number configured for the listener is used for health checks. • <code>1-65535</code>: The back-end port number is used for health checks.

Parameter	Type	Required	Description
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that a health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.

Parameter	Type	Required	Description
Gzip	String	No	Specifies whether to enable gzip compression to compress files of a specific type. Valid values: on and off. Default value: on.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetLoadBalancerHTTPListenerAttribute
&LoadBalancerId=lb-t4nj5vuz8is*****
&ListenerPort=80
&BackendServerPort=80
&Bandwidth=-1
&HealthCheck=on
&HealthCheckDomain=$_ip
&HealthCheckURI=/test/index.html
&HealthCheckConnectPort=8080
&HealthyThreshold=4
&UnhealthyThreshold=4
&HealthCheckTimeout=3
&HealthCheckInterval=5
&VServerGroupId=vsp-cige6j****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<SetLoadBalancerHTTPListenerAttributeResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</SetLoadBalancerHTTPListenerAttributeResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
```

}

2.13.1.8.3 DescribeLoadBalancerHTTPListenerAttribute

You can call this operation to query the configurations of an HTTP listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeLoadBalancerHTTPListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ListenerPort	Integer	The front-end port number used by the SLB instance.
Bandwidth	Integer	The peak bandwidth of the listener.
Status	String	The status of the listener. Valid values: starting, running, configuring, stopping, and stopped
XForwardedFor	String	Specifies whether to use the X-Forwarded-For header to obtain the real IP address of the client.
XForwardedFor_SLBIP	String	Specifies whether to use the SLB-IP header to obtain the real IP address of the client.

Parameter	Type	Description
XForwardedFor_SLBID	String	Specifies whether to use the SLB-ID header to obtain the ID of the SLB instance.
XForwardedFor_proto	String	Specifies whether to use the X-Forwarded-Proto header to obtain the listener protocol of the SLB instance.
Scheduler	String	The scheduling algorithm.
StickySession	String	Specifies whether to enable session persistence.
StickySessionType	String	The method used for processing cookies.
CookieTimeout	Integer	The cookie timeout period. Unit: seconds.
Cookie	String	The cookie configured on the back-end server.
HealthCheck	String	Specifies whether to enable the health check function .
HealthCheckDomain	String	The domain name used for health checks.
HealthCheckURI	String	The URI used for health checks.
HealthyThreshold	Integer	The healthy threshold.
UnhealthyThreshold	Integer	The unhealthy threshold.
HealthCheckTimeout	Integer	The health check timeout period. Unit: seconds.
HealthCheckInterval	Integer	The interval between two consecutive health checks. Unit: seconds.
HealthCheckHttpCode	String	The HTTP status code indicating that the health check is successful.
HealthCheckConnectPort	Integer	The port number used for health checks.
VServerGroupId	String	The ID of the VServer group.
Gzip	String	Specifies whether to enable gzip compression.

Examples

2.13.1.8.4 HTTPS listener

2.13.1.8.4.1 CreateLoadBalancerHTTPSListener

You can call this operation to create an HTTPS listener.

Note:

The status of a newly created listener is **stopped**. After a listener is created, you must call **StartLoadBalancerListener** to enable the listener to forward traffic.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateLoadBalancerHTTPSListener .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
ServerCertificateId	String	Yes	The ID of the server certificate.

Parameter	Type	Required	Description
CACertificateId	String	No	The ID of the CA certificate. If you upload both the CA certificate and the server certificate, two-way authentication is adopted. If you upload only the server certificate, one-way authentication is adopted.
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: -1: The peak bandwidth is unlimited. [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.
XForwardedFor	String	No	Specifies whether to use the X-Forwarded-For header to obtain the real IP address of the client. Default value: on. Valid values: on and off
XForwardedFor_SLBIP	String	No	Specifies whether to use the SLB-IP header to obtain the real IP address of the client. Default value: off. Valid values: on and off
XForwardedFor_SLBID	String	No	Specifies whether to use the SLB-ID header to obtain the ID of the SLB instance. Default value: off. Valid values: on and off
XForwardedFor_proto	String	No	Specifies whether to use the X-Forwarded-Proto header to obtain the listener protocol of the SLB instance. Default value: off. Valid values: on and off

Parameter	Type	Required	Description
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: • wrr: Back-end servers with higher weights receive more requests than those with lower weights. • wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. • rr: Requests are sequentially distributed to back-end servers.
StickySession	String	Yes	Specifies whether to enable session persistence. Valid values: on and off

Parameter	Type	Required	Description
StickySessionType	String	No	The method for processing cookies. Valid values: - insert: inserts a cookie. The SLB instance inserts the server ID as the cookie into the first HTTP or HTTPS response . When receiving another request containing the cookie from the client, the SLB instance distributes the request to the back-end server specified by the cookie. - server: rewrites a cookie. When detecting that a new cookie is set, the SLB instance uses it to overwrite the original cookie. When receiving another request containing the new cookie from the client, the SLB instance distributes the request to the back-end server specified by the new cookie.  Note: If StickySession is set to on, you must specify a value for this parameter.
CookieTimeout	Integer	No	The cookie timeout period. Unit: seconds. Valid values: 1 to 86400  Note: If StickySession is set to on and StickySessionType is set to insert, you must specify a value for this parameter.

Parameter	Type	Required	Description
Cookie	String	No	The cookie configured on the back-end server. The cookie must be 1 to 200 characters in length . It can only contain ASCII letters and digits. It cannot contain commas (,), semicolons (;), or spaces. It cannot start with a dollar sign (\$). If StickySession is set to on and StickySessionType is set to server, you must specify a value for this parameter.
HealthCheck	String	Yes	Specifies whether to enable the health check function. Valid values: on and off
HealthCheckDomain	String	No	The domain name used for health checks. Valid values: • <code>\$_ip</code>: the private IP address of the back-end server. If you do not specify a value for <code>HealthCheckDomain</code> or you set the value to <code>\$_ip</code>, the SLB instance uses the <code>\$_ip</code> value as the domain name for health checks. • <code>domain</code>: The domain name must be 1 to 80 characters in length. It can only contain letters, digits, periods (.), and hyphens (-).
HealthCheckURI	String	No	The URI used for health checks.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: • <code>-520</code>: The back-end port number configured for the listener is used for health checks. • <code>1-65535</code>: The back-end port number is used for health checks.

Parameter	Type	Required	Description
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that the health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.

Parameter	Type	Required	Description
Gzip	String	No	Specifies whether to enable gzip compression to compress files of a specific type. Valid values: on and off. Default value: on.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

2.13.1.8.4.2 SetLoadBalancerHTTPSListenerAttribute

You can call this operation to modify the configurations of an HTTPS listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetLoadBalancerHTTPSListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
BackendServerPort	Integer	Yes	The back-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If VServerGroupId is not specified, you must specify a value for this parameter.
VServerGroupId	String	No	The ID of the VServer group.
ServerCertificateId	String	Yes	The ID of the server certificate.
CACertificateId	String	No	The ID of the CA certificate. If you upload both the CA certificate and the server certificate, two-way authentication is adopted. If you upload only the server certificate, one-way authentication is adopted.

Parameter	Type	Required	Description
Bandwidth	Integer	Yes	The peak bandwidth of the listener. Unit: Mbit/s. Valid values: • -1: The peak bandwidth is unlimited. • [1-5000]: The peak bandwidth range of the listener. The total peak bandwidth of all listeners cannot exceed the peak bandwidth of the SLB instance.
XForwardedFor	String	No	Specifies whether to use the X-Forwarded-For header to obtain the real IP address of the client. Default value: on. Valid values: on and off
XForwardedFor_SLBIP	String	No	Specifies whether to use the SLB-IP header to obtain the real IP address of the client. Default value: off. Valid values: on and off
XForwardedFor_SLBID	String	No	Specifies whether to use the SLB-ID header to obtain the ID of the SLB instance. Default value: off. Valid values: on and off
XForwardedFor_proto	String	No	Specifies whether to use the X-Forwarded-Proto header to obtain the listener protocol of the SLB instance. Default value: off. Valid values: on and off

Parameter	Type	Required	Description
Scheduler	String	No	The scheduling algorithm. Default value: wrr. Valid values: • wrr: Back-end servers with higher weights receive more requests than those with lower weights. • wlc: Requests are forwarded based on the weight and load (the number of connections) of each back-end server. If the weights are the same, back-end servers with fewer connections receive more requests than those with more connections. • rr: Requests are sequentially distributed to back-end servers.
StickySession	String	Yes	Specifies whether to enable session persistence. Valid values: on and off

Parameter	Type	Required	Description
StickySessionType	String	No	The method used for processing cookies. Valid values: - insert: inserts a cookie. The SLB instance inserts the server ID as the cookie into the first HTTP or HTTPS response . When receiving another request containing the cookie from the client, the SLB instance distributes the request to the back-end server specified by the cookie. - server: rewrites a cookie. When detecting that a new cookie is set, the SLB instance uses it to overwrite the original cookie. When receiving another request containing the new cookie from the client, the SLB instance distributes the request to the back-end server specified by the new cookie.  Note: If StickySession is set to on, you must specify a value for this parameter.
CookieTimeout	Integer	No	The cookie timeout period. Unit: seconds. Valid values: 1 to 86400  Note: If StickySession is set to on and StickySessionType is set to insert, you must specify a value for this parameter.

Parameter	Type	Required	Description
Cookie	String	No	The cookie configured on the back-end server. The cookie must be 1 to 200 characters in length . It can only contain ASCII letters and digits. It cannot contain commas (,), semicolons (;), or spaces. It cannot start with a dollar sign (\$). If StickySession is set to on and StickySessionType is set to server, you must specify a value for this parameter.
HealthCheck	String	Yes	Specifies whether to enable the health check function. Valid values: on and off
HealthCheckDomain	String	No	The domain name used for health checks. Valid values: • <code>\$_ip</code>: the private IP address of the back-end server. If you do not specify a value for <code>HealthCheckDomain</code> or you set the value to <code>\$_ip</code>, the SLB instance uses the <code>\$_ip</code> value as the domain name for health checks. • <code>domain</code>: The domain name must be 1 to 80 characters in length. It can only contain letters, digits, periods (.), and hyphens (-).
HealthCheckURI	String	No	The URI used for health checks.
HealthCheckConnectPort	Integer	No	The port number used for health checks. Valid values: • <code>-520</code>: The back-end port number configured for the listener is used for health checks. • <code>1-65535</code>: The back-end port number is used for health checks.

Parameter	Type	Required	Description
HealthyThreshold	Integer	No	The number of consecutive health check successes before the back-end server is declared to be healthy (from fail to success). Valid values: 2 to 10
UnhealthyThreshold	Integer	No	The number of consecutive health check failures before the back-end server is declared to be unhealthy (from success to fail). Valid values: 2 to 10
HealthCheckTimeout	Integer	No	The health check timeout period. Unit: seconds. If the back-end server does not respond within a specified period of time, the server fails the health check. Valid values: 1 to 300  Note: If the HealthCheckTimeout value is smaller than the HealthCheckInterval value, the HealthCheckTimeout value is ignored and the HealthCheckInterval value is regarded as the timeout period.
HealthCheckInterval	Integer	No	The interval between two consecutive health checks. Unit: seconds. Valid values: 1 to 50
HealthCheckHttpCode	String	No	The HTTP status code indicating that the health check is successful. Multiple HTTP status codes are separated with commas (,). Valid values: http_2xx, http_3xx, http_4xx, and http_5xx. Default value: http_2xx.

Parameter	Type	Required	Description
Gzip	String	No	Specifies whether to enable gzip compression to compress files of a specific type. Valid values: on and off. Default value: on.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

2.13.1.8.4.3 DescribeLoadBalancerHTTPSListenerAttribute

You can call this operation to query the configurations of an HTTPS listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeLoadBalancerHTTPSListenerAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ListenerPort	Integer	The front-end port number used by the SLB instance.
Bandwidth	Integer	The peak bandwidth of the listener.
Status	String	The status of the listener. Valid values: starting, running, configuring, stopping, and stopped
XForwardedFor	String	Indicates whether the X-Forwarded-For header was used to obtain the real IP address of the client.
XForwardedFor_SLBIP	String	Indicates whether the SLB-IP header was used to obtain the real IP address of the client.

Parameter	Type	Description
XForwardedFor_SLBID	String	Indicates whether the SLB-ID header was used to obtain the ID of the SLB instance.
XForwardedFor_proto	String	Indicates whether the X-Forwarded-Proto header was used to obtain the listener protocol of the SLB instance.
Scheduler	String	The scheduling algorithm.
StickySession	String	Indicates whether session persistence was enabled.
StickySessionType	String	The method used for processing cookies.
CookieTimeout	Integer	The cookie timeout period. Unit: seconds.
Cookie	String	The cookie configured on the back-end server.
HealthCheck	String	Indicates whether the health check function was enabled.
HealthCheckDomain	String	The domain name used for health checks.
HealthCheckURI	String	The URI used for health checks.
HealthyThreshold	Integer	The healthy threshold.
UnhealthyThreshold	Integer	The unhealthy threshold.
HealthCheckTimeout	Integer	The health check timeout period. Unit: seconds.
HealthCheckInterval	Integer	The interval between two consecutive health checks. Unit: seconds.
HealthCheckHttpCode	String	The HTTP status code indicating that the health check is successful.
HealthCheckConnectPort	Integer	The port number used for health checks.
VServerGroupId	String	The ID of the VServer group.
ServerCertificateId	String	The ID of the server certificate.
CACertificateId	String	The ID of the CA certificate.

Parameter	Type	Description
Gzip	String	Indicates whether gzip compression was enabled.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeLoadBalancerHTTPSListenerAttribute
&LoadBalancerId=lb-t4nj5vuz8ish9emfk1f20
&ListenerPort=443
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >

2.13.1.8.5 Access control

2.13.1.8.5.1 SetListenerAccessControlStatus

You can call this operation to enable or disable the access control feature for a specified listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetListenerAccessControlStatus.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
AccessControlStatus	String	Yes	Specifies whether to enable access control. Valid values: - open_white_list: enables access control. - close: disables access control.  Note: When access control is enabled, you must configure a whitelist of IP addresses. Otherwise, no access is allowed.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetListenerAccessControlStatus
&LoadBalancerId=lb-t4nj5vuz8ish*****
&ListenerPort=80
&AccessControlStatus=open_white_list
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<SetListenerAccessControlStatusResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</SetListenerAccessControlStatusResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.8.5.2 DescribeListenerAccessControlAttribute

You can call this operation to query the access control configurations of a specified listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeListenerAccessControlAttribute.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AccessControlStatus	String	Indicates whether access control was enabled. Valid values: - open_white_list: indicates that access control was enabled. - close: indicates that access control was disabled.
SourceItems	String	The access control list.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeListenerAccessControlAttribute
&LoadBalancerId=lb-t4nj5vuz****
&ListenerPort=80
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeListenerAccessControlAttributeResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
  <AccessControlStatus>open_white_list</AccessControlStatus>
  <SourceItems>1. *. *. *. *,1. *. *. */21</SourceItems>
</DescribeListenerAccessControlAttributeResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",
  "AccessControlStatus": "open_white_list",
  "SourceItems": "1. *. *. *. *,1. *. *. */21"
}
```

2.13.1.8.5.3 AddListenerWhiteListItem

You can call this operation to add IP addresses to the access whitelist of a specified listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to AddListenerWhiteListItem.

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
SourceItems	String	Yes	The whitelist for access control. Only requests from IP addresses in the whitelist are forwarded. Multiple IP addresses or CIDR blocks are separated with commas (,). The IP address 0.0.0.0 or the CIDR block 0.0.0.0/0 is not allowed. To disable access control, call SetListenerAccessControlStatus and set the AccessControlStatus parameter to close.  Note: The listener works when AccessControlStatus is set to open_white_list.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples**Sample requests**

```
https://slb.example.com/?Action=AddListenerWhiteListItem
&LoadBalancerId=lb-t4nj5vuz8ish****
&ListenerPort=80
&SourceItems=10.**.**.**,10.**.**.**/24
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<AddListenerWhiteListItemResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</AddListenerWhiteListItemResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.8.5.4 RemoveListenerWhiteListItem

You can call this operation to remove IP addresses from a listener whitelist.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to RemoveListenerWhiteListItem.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Parameter	Type	Required	Description
SourceItems	String	Yes	The whitelist for access control. Only requests from IP addresses in the whitelist are forwarded. Multiple IP addresses or CIDR blocks are separated with commas (,). The IP address 0.0.0.0 or the CIDR block 0.0.0.0/0 is not allowed. To disable access control, call SetListenerAccessControlStatus and set the AccessControlStatus parameter to close.  Note: If all IP addresses are removed, the listener no longer forwards any requests.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action= RemoveListenerWhiteListItem
&LoadBalancerId=lb-t4nj5vuz8is***
&ListenerPort=80
&SourceItems=10. **. **. **/8
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<RemoveListenerWhiteListItemResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</RemoveListenerWhiteListItemResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
```

}

2.13.1.8.6 Forwarding rules

2.13.1.8.6.1 CreateRules

You can call this operation to add forwarding rules to a specified HTTP or HTTPS listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateRules .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	String	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535
Rules	JSON string	Yes	The forwarding rules that you want to add.  Note: A maximum of 10 forwarding rules can be added to a single request.
Rule elements			
RuleName	String	Yes	The name of the forwarding rule. The name must be 1 to 80 characters in length. It can only contain letters, digits, hyphens (-), forward slashes (/), periods (.), and underscores (_). Note: The names of forwarding rules in a listener must be unique.

Parameter	Type	Required	Description
Domain	String	No	The request domain name. The domain name can only contain letters, digits, hyphens (-), and periods (.).
Url	String	No	The request URL. The URL must be 1 to 80 characters in length. It can only contain letters, digits, hyphens (-), forward slashes (/), periods (.), percent signs (%), question marks (?), number signs (#), and ampersands (&). Note: You must specify a domain name, a URL, or both of them. The combination of the domain name and the URL must be unique in a listener.
VServerGroupId	String	Yes	The ID of the VServer group associated with the forwarding rule.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Rules	JSON string	The list of forwarding rules.
Rules elements		
RuleId	String	The ID of the forwarding rule.
RuleName	String	The name of the forwarding rule.

Examples

Sample requests

```
https://slb.example.com/?Action=CreateRules
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8is****
&ListenerPort=80
&Rules=[
  {"RuleName":"Rule1","Domain":"abcdefg.com","Url":"/image","VServerGroupId":"Group1"},
  {"RuleName":"Rule2","Domain":"abcdefg.com","Url":"/cache","VServerGroupId":"Group2"}
]
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<CreateRulesResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <Rules>
    <Rule>
      <RuleId>rule-3ejhkt****</RuleId>
      <RuleName>Rule1</RuleName>
    </Rule>
    <Rule>
      <RuleId>rule-tybqi6*****</RuleId>
      <RuleName>Rule2</RuleName>
    </Rule>
  </Rules>
</CreateRulesResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "Rules": {
    "Rule": [
      {
        "RuleId": "rule-3ejhkt**",
        "RuleName": "Rule1"
      },
      {
        "RuleId": "rule-tybq*****",
        "RuleName": "Rule2"
      }
    ]
  }
}
```

2.13.1.8.6.2 DeleteRules

You can call this operation to delete forwarding rules.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteRules.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.

Parameter	Type	Required	Description
RuleIds	JSON string	Yes	The list of forwarding rules that you want to delete.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=DeleteRules
&RegionId=cn-hangzhou
&RuleIds=[rule-tybqi6*****,rule-3ejh*****]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DeleteRules>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
</DeleteRules>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C"
}
```

2.13.1.8.6.3 SetRule

You can call this operation to modify the target VServer group of a specified forwarding rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetRule.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.

Parameter	Type	Required	Description
RuleId	String	Yes	The ID of the forwarding rule.
VServerGroupId	String	Yes	The ID of the target VServer group of the forwarding rule.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetRule
&RegionId=cn-hangzhou
&RuleId=[rule-3ejh***** &VServerGroupId=rsp-cige6*****]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<SetRuleResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
</SetRuleResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C"
}
```

2.13.1.8.6.4 DescribeRules

You can call this operation to query forwarding rules associated with a listener.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeRules.
RegionId	String	Yes	The ID of the region where the SLB instance resides.

Parameter	Type	Required	Description
LoadBalancerId	String	Yes	The ID of the SLB instance. You can call the DescribeRegions operation to obtain the region ID.
ListenerPort	String	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Rules	String	The list of rules.
Rule elements		
RuleId	String	The ID of the forwarding rule.
RuleName	String	The name of the forwarding rule.
Domain	String	The domain name.
Url	String	The request URL.
VServerGroupId	String	The ID of the target VServer group of the forwarding rule.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeRules
&RegionId=cn-hangzhou
&LoadBalancerId=lb-152a6*****
&ListenerPort=80
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DescribeRulesResponse>
  <RequestId>C9E4B5F7-1AA8-4578-9D59-8525C32BAD41</RequestId>
  <Rules>
    <Rule>
      <Url>/index</Url>
      <Domain>example.com</Domain>
      <VServerGroupId>rsp-bp1t8k*****</VServerGroupId>
      <RuleId>rule-bp1ixgml*****</RuleId>
```

```

    <RuleName>test</RuleName>
  </Rule>
  <Rule>
    <Url>/index</Url>
    <Domain>test.com</Domain>
    <VServerGroupId>rsp-bp1t8kf*****</VServerGroupId>
    <RuleId>rule-bp16ryrp****</RuleId>
    <RuleName>test2</RuleName>
  </Rule>
</Rules>
</DescribeRulesResponse>

```

- JSON format

```

{
  "RequestId": "C9E4B5F7-1AA8-4578-9D59-8525C32BAD41",
  "Rules": {
    "Rule": [
      {
        "Url": "/index",
        "Domain": "example.com",
        "VServerGroupId": "rsp-bp1t8k****",
        "RuleId": "rule-bp1ixgm*****",
        "RuleName": "test"
      },
      {
        "Url": "/index",
        "Domain": "test.com",
        "VServerGroupId": "rsp-bp1t8k*****",
        "RuleId": "rule-bp16ryrp*****",
        "RuleName": "test2"
      }
    ]
  }
}

```

2.13.1.8.6.5 DescribeRuleAttribute

You can call this operation to query the detailed configurations of a specified forwarding rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeRuleAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
RuleId	String	Yes	The ID of the forwarding rule.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
RuleName	String	The name of the forwarding rule.
LoadBalancerId	String	The ID of the SLB instance.
ListenerPort	Integer	The front-end port number used by the SLB instance.
Domain	String	The domain name configured in the forwarding rule.
Url	String	The URL configured in the forwarding rule.
VServerGroupId	String	The ID of the VServer group associated with the forwarding rule.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeRuleAttribute
&RegionId=cn-hangzhou
&RuleId=rule-3ejhk*****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DescribeRuleAttributeResponse>
  <RequestId>3E0FA650-1843-466E-8664-3E7D88E0DD5F</RequestId>
  <Domain>example.com</Domain>
  <Url>/index</Url>
  <VServerGroupId>rsp-bp1t8kk*****</VServerGroupId>
  <LoadBalancerId>lb-bp148m1ohj2juoh*****</LoadBalancerId>
  <RuleName>test</RuleName>
  <ListenerPort>8080</ListenerPort>
</DescribeRuleAttributeResponse>
```

- JSON format

```
{
  "RequestId": "3E0FA650-1843-466E-8664-3E7D88E0DD5F",
  "Domain": "example.com",
  "Url": "/index",
  "VServerGroupId": "rsp-bp1t8kkfa****",
  "LoadBalancerId": "lb-bp148m1ohj2juoh9u*****",
  "RuleName": "test",
  "ListenerPort": 8080
}
```

}}

2.13.1.8.7 DeleteLoadBalancerListener

You can call this operation to delete a listener.

**Note:**

A listener can be deleted only when it is in the stopped or running state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteLoadBalancerListener.
LoadBalancerId	String	Yes	The ID of the SLB instance. You can call the DescribeRegions operation to obtain the region ID.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=DeleteLoadBalancerListener
&LoadBalancerId=lb-t4nj5vuz8ish9e*****
&ListenerPort=80
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteLoadBalancerListenerResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
```

```
</DeleteLoadBalancerListenerResponse>
```

- JSON format

```
{  
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"  
}
```

2.13.1.8.8 StartLoadBalancerListener

You can call this operation to enable a listener.

Note:

When you call this operation, note the following items:

- You can call the operation only when the listener is in the stopped state.
- After the operation is called, the listener enters the starting state.
- You cannot call the operation when the SLB instance to which the listener belongs is in the locked state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to StartLoadBalancerListener.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action= StartLoadBalancerListener
&LoadBalancerId=lb-t4nj5vuz8ish9*****8
&ListenerPort=80
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<StartLoadBalancerListenerResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</StartLoadBalancerListenerResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.8.9 StopLoadBalancerListener

You can call this operation to stop a listener.

Note:

When you call this operation, note the following items:

- After the operation is called, the listener enters the stopped state.
- You cannot call the operation when the SLB instance to which the listener belongs is in the locked state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to StopLoadBalancerListener.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Parameter	Type	Required	Description
ListenerPort	Integer	Yes	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action= StopLoadBalancerListener
&LoadBalancerId=lb-t4nj5vuz8ish9*****8
&ListenerPort=80
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<StopLoadBalancerListenerResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</StopLoadBalancerListenerResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.9 Server certificate

2.13.1.9.1 UploadServerCertificate

You can call this operation to upload a server certificate.

Only one server certificate and a corresponding private key can be uploaded at a time . This API operation is transactional. Either both the certificate and the private key are uploaded, or neither are uploaded. After the certificate and the private key are uploaded, the fingerprints of all server certificates for your account are returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to UploadServerCertificate.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
ServerCertificate	String	No	The server certificate that you want to upload.
ServerCertificateName	String	No	The name of the server certificate that you want to upload.
PrivateKey	String	Yes	The private key that you want to upload.
ResourceGroupId	String	No	The ID of the enterprise resource group.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ServerCertificateId	String	The ID of the server certificate.
ServerCertificateName	String	The name of the server certificate.
Fingerprint	String	The fingerprint of the server certificate.

Examples

Sample requests

```
https://slb.example.com/?Action=UploadServerCertificate
&RegionId=cn-hangzhou-01
&ServerCertificate=test
&ServerCertificateName=mycert01
&PrivateKey=wmsa*****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<UploadServerCertificateResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
```

```
<ServerCertificateId>idkp-123-cn-*****-01</ServerCertificateId>
<ServerCertificateName>mycert01</ServerCertificateName>
<Fingerprint>01:DF:AB:CD</Fingerprint>
</UploadServerCertificateResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",
  "ServerCertificateId": "idkp-123-cn-****-01",
  "ServerCertificateName": "mycert01",
  "Fingerprint": "01:DF:AB:CD"
}
```

2.13.1.9.2 DeleteServerCertificate

You can call this operation to delete a server certificate.

Note:

You cannot delete a certificate that is in use.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteServerCertificate.
RegionId	String	No	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
ServerCertificateId	String	Yes	The ID of the server certificate.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=DeleteServerCertificate
&RegionId=cn-hangzhou
&ServerCertificateId=idkp-123-cn-****-01
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteServerCertificateResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</DeleteServerCertificateResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.9.3 DescribeServerCertificates

You can call this operation to query uploaded server certificates.

**Note:**

To guarantee certificate security, only the fingerprint and name of the certificate are returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeServerCertificates.
RegionId	String	No	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
ServerCertificateId	String	No	The ID of the server certificate.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ServerCertificates	JSON string	The list of the server certificates.
ServerCertificate elements		

Parameter	Type	Description
ServerCertificateId	String	The ID of the server certificate.
ServerCertificateName	String	The name of the server certificate.
RegionId	String	The region of the server certificate.
Fingerprint	String	The fingerprint of the server certificate.
CreateTime	String	The time when the server certificate was uploaded.
CreateTimeStamp	Long	The timestamp generated when the server certificate was uploaded.

Examples

Sample requests

<https://slb.example.com/?Action=DescribeServerCertificates>
&Common request parameters

Sample responses

- XML format

```

      }
    ]
  }
}
```

2.13.1.9.4 SetServerCertificateName

You can call this operation to configure a name for a server certificate.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetServerCertificateName.
ServerCertificateId	String	Yes	The ID of the server certificate.

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
ServerCertificateName	String	Yes	The name of the server certificate. The name must be 1 to 80 characters in length . It must start with letters. It can contain digits, periods (.), underscores (_), and hyphens (-).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetServerCertificateName
&RegionId=cn-hangzhou
&ServerCertificateId=139a00604ad-cn-east-****-01
&ServerCertificateName=abc
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<SetServerCertificateNameResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FE7BA984</RequestId>
</SetServerCertificateNameResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FE7BA984"
}
```

2.13.1.9.5 UploadCACertificate

You can call this operation to upload a CA certificate.

You can upload only one CA certificate at a time. After a certificate is uploaded, the ID, name, and fingerprint of the certificate are returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to UploadCACertificate.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
CACertificate	String	Yes	The CA certificate to upload.
CACertificateName	String	No	The name of the CA certificate.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CACertificateId	String	The ID of the CA certificate.
CACertificateName	String	The name of the CA certificate.
Fingerprint	String	The fingerprint of the CA certificate.
CreateTime	String	The time when the CA certificate was uploaded.
Fingerprint	Long	The timestamp generated when the CA certificate was uploaded.

Examples

Sample requests

```
https://slb.example.com/?Action=UploadCACertificate
&RegionId=cn-east-hangzhou-01
&CACertificate=test
&CACertificateName=mycacert01
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<UploadCACertificateResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
  <CACertificateId>idkp-234-cn-****-02</CACertificateId>
```

```
<CACertificateName>mycacert01</CACertificateName>
<Fingerprint>02:DF:AB:ED</Fingerprint>
</UploadCACertificateResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",
  "CACertificateId": "idkp-234-cn-****-02",
  "CACertificateName": "mycacert01",
  "Fingerprint": "02:DF:AB:ED"
}
```

2.13.1.9.6 DeleteCACertificate

You can call this operation to delete a CA certificate.

**Note:**

You cannot delete a CA certificate that is in use.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteCACertificate.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
CACertificateId	String	Yes	The ID of the CA certificate to delete.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=DeleteCACertificate
&RegionId=cn-hangzhou
&CACertificateId=idkp-234-cn-****-02
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteCACertificateResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FF7BA984</RequestId>
</DeleteCACertificateResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FF7BA984"
}
```

2.13.1.9.7 DescribeCACertificates

You can call this operation to query uploaded CA certificates.

**Note:**

To guarantee certificate security, only the fingerprint and name of the certificate are returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeCACertificates.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
CACertificateId	String	No	The ID of the CA certificate.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CACertificates	JSON string	The list of CA certificates.
CACertificate elements		
CACertificateId	String	The ID of the CA certificate.
CACertificateName	String	The name of the CA certificate.

Parameter	Type	Description
RegionId	String	The region of the CA certificate.
Fingerprint	String	The fingerprint of the CA certificate.
ResourceGroupId	String	The ID of the resource group.
CreateTimeStamp	Long	The timestamp generated when the CA certificate was uploaded.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeCACertificates
&RegionId=cn-hangzhou
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >

        "ResourceGroupId": "rg-acfmxyzb4*****",
        "RegionId": "cn-hangzhou",
        "CACertificateId": "1231579085529123_15c73d*****_-986300114_-2110544408",
        "Fingerprint": "0d:f6:9e:ed:c2:6d:df:06:ac:af:82:fb:17:1b:5b:08:39:b3:d9:d0"
      }
    ]
  }
}
```

```
}
```

2.13.1.9.8 SetCACertificateName

You can call this operation to configure the name of a CA certificate.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetCACertificateName.
CACertificateId	String	Yes	The ID of the CA certificate.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
CACertificateName	String	Yes	The name of the CA certificate. The name must be 1 to 80 characters in length. It must start with letters. It can contain letters, digits, periods (.), underscores (_), and hyphens (-).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetCACertificateName
&CACertificateId=139a00604ad-cn-east-*****-01
&CACertificateName=mycacert02
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<SetCACertificateNameResponse>
  <RequestId>CEF72CEB-54B6-4AE8-B225-F876FE7BA984</RequestId>
```

```
</SetCACertificateNameResponse>
```

- JSON format

```
{
  "RequestId": " CEF72CEB-54B6-4AE8-B225-F876FE7BA984"
}
```

2.13.1.10 Backend server

2.13.1.10.1 AddBackendServers

You can call this operation to add back-end servers.

Note:

If the information of multiple identical ECS instances is contained in a request, only the first ECS instance is added and the other ECS instances are ignored.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to AddBackendServers.
LoadBalancerId	String	Yes	The ID of the SLB instance.
BackendServers	JSON string	Yes	The list of back-end servers to add.  Note: Only back-end servers in the running state can be added to the SLB instance. A maximum of 20 back-end servers can be added each time.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Weight	Integer	No	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
LoadBalancerId	String	The ID of the SLB instance.
BackendServers	JSON string	The list of back-end servers.
BackendServer elements		
ServerId	String	The ID of the ECS instance.
Weight	Integer	The weight of the back-end server.

Examples

Sample requests

```
https://slb.example.com/?Action=AddBackendServers
&LoadBalancerId=lb-t4nj5vuz8ish9e*****
&BackendServers=[
  {"ServerId":"vm-***","Weight":"100"},
  {"ServerId":"vm-***","Weight":"100"}]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<AddBackendServersResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
  <LoadBalancerId>139a00604ad-cn-east-hangzhou-01</LoadBalancerId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</AddBackendServersResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",
  "LoadBalancerId": "139a00604ad-cn-east-***-01",
  "BackendServers": {
    "BackendServer": [
      {
        "ServerId": "vm-***",
        "Weight": 100
      },
      {

```

```
"ServerId": "vm-***",  
"Weight": 100  
}  
]  
}
```

2.13.1.10.2 RemoveBackendServers

You can call this operation to remove back-end servers.

Note:

If the back-end servers are not included in the server list of the specified SLB instance, they cannot be deleted and no error is returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to RemoveBackendServers.
RegionId	String	Yes	The ID of the region where the SLB instance resides.
LoadBalancerId	String	Yes	The ID of the SLB instance.
BackendServers	JSON string	Yes	The list of back-end servers to remove.  Note: Up to 20 back-end servers can be removed at a time.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
LoadBalancerId	String	The ID of the SLB instance.
BackendServers	JSON string	The list of back-end servers.

Examples

Sample requests

```
https://slb.example.com/?Action=RemoveBackendServers  
&LoadBalancerId=lb-t4nj5vuz8is*****
```

```
&BackendServers=["i-bp143t8c5uralrxxxx","i-bp12zdi79965uxxxx"]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<RemoveBackendServersResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
  <LoadBalancerId>139a00604ad-cn-east-*****-01</LoadBalancerId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-2**1</ServerId>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-****</ServerId>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</RemoveBackendServersResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",
  "LoadBalancerId": "139a00604ad-cn-east-*****-01",
  "BackendServers": {
    "BackendServer": [
      {
        "ServerId": "vm-***",
        "Weight": 100
      },
      {
        "ServerId": "vm-***",
        "Weight": 100
      }
    ]
  }
}
```

2.13.1.10.3 SetBackendServers

You can call this operation to set weights for back-end servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetBackendServers.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Parameter	Type	Required	Description
BackendServers	JSON string	Yes	The list of back-end servers to add.  Note: Only back-end servers in the running state can be added to the SLB instance. A maximum of 20 back-end servers can be added each time.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Weight	Integer	No	The weight of the back-end server. Valid values: [0, 100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
LoadBalancerId	String	The ID of the SLB instance.
BackendServers	JSON string	The list of back-end servers.
BackendServer elements		
ServerId	String	The ID of the ECS instance.
Weight	Integer	The weight of the back-end server.

Examples

Sample requests

```
https://slb.example.com/?Action=SetBackendServers
&LoadBalancerId=lb-t4nj5vuz8ish9emfk1f20
&BackendServers=[{"ServerId":"vm-233","Weight":0}, {"ServerId":"vm-234","Weight":0}]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<SetBackendServersResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
  <LoadBalancerId>139a00604ad-cn-east-hangz*****hou-01</LoadBalancerId>
```

```
<BackendServers>
  <BackendServer>
    <ServerId>vm-***</ServerId>
    <Weight>0</Weight>
  </BackendServer>
  <BackendServer>
    <ServerId>vm-***</ServerId>
    <Weight>0</Weight>
  </BackendServer>
</BackendServers>
</SetBackendServersResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710",
  "LoadBalancerId": "139a00604ad-cn-east-****-01",
  "BackendServers": {
    "BackendServer": [
      {
        "ServerId": "vm-***",
        "Weight": 0
      },
      {
        "ServerId": "vm-***",
        "Weight": 0
      }
    ]
  }
}
```

2.13.1.10.4 DescribeHealthStatus

You can call this operation to query the health status of back-end servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeHealthStatus.
LoadBalancerId	String	Yes	The ID of the SLB instance.
ListenerPort	Integer	No	The front-end port number used by the SLB instance. Valid values: 1 to 65535  Note: If you do not specify this parameter, the health status of all ports is checked.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
BackendServers	List	The list of back-end servers.
BackendServer elements		
ServerId	String	The ID of the ECS instance.
ServerHealthStatus	String	The health status of the back-end server: - normal: The back-end server is healthy. - abnormal: The back-end server is unhealthy. - unavailable: The health check has not been completed.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeHealthStatus
&LoadBalancerId=lb-t4nj5vuz8i*****
&ListenerPort=80
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeHealthStatusResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <ServerHealthStatus>normal</ServerHealthStatus>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <ServerHealthStatus>abnormal</ServerHealthStatus>
    </BackendServer>
  </BackendServers>
</DescribeHealthStatusResponse>
```

- JSON format

```
{

```

2.13.1.10.5 AddNcServers

You can call this operation to add physical back-end servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to AddNcServers.
RegionId	String	Yes	The ID of the region where the SLB instance resides.
HostEcsInstancId	String	Yes	The ID of an ECS instance in the VPC.
LoadBalancerId	String	Yes	The ID of the SLB instance.
BackendServers	List	Yes	The list of physical back-end servers to add. You can add a maximum of 20 physical back-end servers.
BackendServer elements			
ServerId	String	Yes	The IP address of the physical back-end server.
Weight	Integer	No	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.
Type	String	Yes	The type of the back-end server. Set the value to nc.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=AddNcServers
&RegionId=cn-hangzhou
&LoadBalancerId=lb-bp1mbyphktev5qnfts3p4
&BackendServers=[
  {"ServerId":"192. **. **. **", "Weight":"50", "Type":"nc"},
  {"ServerId":"192. **. **. **", "Weight":"50", "Type":"nc"}]
&HostEcsInstanceId=i-bp1fiznm0sikg4q6****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<AddNcServersResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
</AddNcServersResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710"
}
```

2.13.1.10.6 RemoveNcServers

You can call this operation to delete physical back-end servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to RemoveNcServers.
RegionId	String	Yes	The ID of the region where the SLB instance resides.
LoadBalancerId	String	Yes	The ID of the SLB instance.
BackendServers	List	Yes	The list of physical back-end servers to remove.
HostEcsInstanceId	String	Yes	The ID of an ECS instance in the VPC.
BackendServer elements			
ServerId	String	Yes	The IP address of the physical back-end server.

Parameter	Type	Required	Description
Weight	Integer	No	The weight of the physical back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.
Type	String	Yes	The type of the back-end server. Set the value to nc.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=RemoveNcServers
&RegionId=cn-hangzhou
&LoadBalancerId=lb-bp1mbyphktev5qnfts3p4
&BackendServers=[
    {"ServerId":"192. **. **. **", "Weight":"50","Type":"nc"},
    {"ServerId":"192. **. **. **", "Weight":"50","Type":"nc"}]
&HostEcsInstanceId=i-bp1fiznm0sikg4q6xyrt
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<RemoveNcServersResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
</RemoveNcServersResponse>
```

- JSON format

```
{
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710"
```

}

2.13.1.10.7 SetNcServers

You can call this operation to set the weight of physical back-end servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetNcServers.
RegionId	String	Yes	The ID of the region where the SLB instance resides.
HostEcsInstancId	String	Yes	The ID of an ECS instance in the VPC.
LoadBalancerId	String	Yes	The ID of the SLB instance.
BackendServers	List	Yes	The list of physical back-end servers.
BackendServer elements			
ServerId	String	Yes	The IP address of the physical back-end server.
Weight	Integer	No	The weight of the physical back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.
Type	String	Yes	The type of the back-end server. Set this parameter to nc.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=SetNcServers
&RegionId=cn-hangzhou
&LoadBalancerId=lb-bp1mbyphktev5qnfts3p4
&BackendServers=[
```

```
{ "ServerId": "192. **. **. **", "Weight": "50", "Type": "nc"},  
{ "ServerId": "192. **. **. **", "Weight": "50", "Type": "nc"}  
&HostEcsInstanceId=i-bp1fiznm0sikg4*****  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<SetNcServersResponse>  
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>  
</SetNcServersResponse>
```

- JSON format

```
{  
  "RequestId": "365F4154-92F6-4AE4-92F8-7FF34B540710"  
}
```

2.13.1.11 VServer group

2.13.1.11.1 CreateVServerGroup

You can call this operation to create a VServer group and add back-end servers to the VServer group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateVServerGroup .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
VServerGroupName	String	No	The name of the VServer group.

Parameter	Type	Required	Description
BackendServers	JSON string	No	The list of back-end servers. A VServer group can contain a maximum of 20 back-end servers. If you do not specify this parameter, an empty VServer group is created.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Port	Integer	Yes	The port number used by the back-end server. Valid values: 1 to 65535
Weight	Integer	Yes	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
BackendServers	JSON string	The list of back-end servers.

Examples

Sample requests

```
https://slb.example.com/?Action=CreateVServerGroup
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9***
&VServerGroupName=Group1
&BackendServers=[
  {"ServerId":"vm-***","Port":"80","Weight":"100"},
  {"ServerId":"vm-***","Port":"90","Weight":"100"},
  {"ServerId":"vm-***","Port":"70","Weight":"100"}
]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<CreateVServerGroupResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <VServerGroupId>rsp-cige6j***</VServerGroupId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>90</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>70</Port>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</CreateVServerGroupResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "VServerGroupId": "rsp-cige6****",
  "BackendServers": {
    "BackendServer": [
      { "ServerId": "vm-***", "Port": "80", "Weight": "100" },
      { "ServerId": "vm-***", "Port": "90", "Weight": "100" },
      { "ServerId": "vm-***", "Port": "70", "Weight": "100" }
    ]
  }
}
```

2.13.1.11.2 SetVServerGroupAttribute

You can call this operation to modify a VServer group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to SetVServerGroupAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.

Parameter	Type	Required	Description
LoadBalancerId	String	Yes	The ID of the SLB instance.
VServerGroupName	String	No	The name of the VServer group.
BackendServers	JSON string	No	The list of back-end servers. A VServer group can contain a maximum of 20 back-end servers. If you do not specify this parameter, an empty VServer group is created.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Port	Integer	Yes	The port number used by the back-end server. Valid values: 1 to 65535
Weight	Integer	Yes	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
BackendServers	JSON string	The list of back-end servers.

Examples

Sample requests

```
https://slb.example.com/?Action=SetVServerGroupAttribute
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9em****
&VServerGroupName=Group1
&BackendServers=[
  {"ServerId":"vm-****","Port":"80","Weight":"100"},
  {"ServerId":"vm-****","Port":"90","Weight":"100"},
  {"ServerId":"vm-****","Port":"70","Weight":"100"}
]
```

] &Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<SetVServerGroupAttributeResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <VServerGroupId>rsp-cige6****</VServerGroupId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>90</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>70</Port>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</SetVServerGroupAttributeResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "VServerGroupId": "rsp-cige6****",
  "BackendServers": {
    "BackendServer": [
      { "ServerId": "vm-***", "Port": "80", "Weight": "100" },
      { "ServerId": "vm-***", "Port": "90", "Weight": "100" },
      { "ServerId": "vm-***", "Port": "70", "Weight": "100" }
    ]
  }
}
```

2.13.1.11.3 AddVServerGroupBackendServers

You can call this operation to add back-end servers to a specified VServer group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to AddVServerGroupBackendServers.

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
VServerGroupId	String	Yes	The ID of the VServer group.
BackendServers	JSON string	Yes	The list of back-end servers. A VServer group can contain a maximum of 20 back-end servers.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Port	Integer	Yes	The port number used by the back-end server. Valid values: 1 to 65535
Weight	Integer	Yes	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
BackendServers	JSON string	The list of back-end servers.

Examples

Sample requests

```
https://slb.example.com/?Action=AddVServerGroupBackendServers
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8is*****
&VServerGroupName=Group1
&BackendServers=[
  {"ServerId":"vm-****","Port":"80","Weight":"100"},
  {"ServerId":"vm-****","Port":"90","Weight":"100"},
```

```
{
  "ServerId": "vm-***", "Port": "70", "Weight": "100"
}
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<AddVServerGroupBackendServersResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <VServerGroupId>rsp-cige6j*****</VServerGroupId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>90</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>70</Port>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</AddVServerGroupBackendServersResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "VServerGroupId": "rsp-cige6j5e7p",
  "BackendServers": {
    "BackendServer": [
      {
        "ServerId": "vm-233", "Port": "80", "Weight": "100"
      },
      {
        "ServerId": "vm-232", "Port": "90", "Weight": "100"
      },
      {
        "ServerId": "vm-231", "Port": "70", "Weight": "100"
      }
    ]
  }
}
```

2.13.1.11.4 RemoveVServerGroupBackendServers

You can call this operation to remove back-end servers from a specified VServer group.

Note:

If the back-end servers specified in **BackendServers** do not exist in the VServer group, they cannot be deleted and no error is returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to <code>RemoveVServerGroupBackendServers</code> .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
VServerGroupId	String	Yes	The ID of the VServer group.
BackendServers	JSON string	Yes	The list of back-end servers. A VServer group can contain a maximum of 20 back-end servers.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Port	Integer	Yes	The port number used by the back-end server. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
BackendServers	JSON string	The list of back-end servers.

Examples

Sample requests

```
https://slb.example.com/?Action=RemoveVServerGroupBackendServers
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9*****
&VServerGroupName=Group1
&BackendServers=[
  {"ServerId":"vm-***","Port":"80","Weight":"100"},
  {"ServerId":"vm-***","Port":"90","Weight":"100"},
]
```

```
]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<RemoveVServerGroupBackendServersResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <VServerGroupId>rsp-cige6j***</VServerGroupId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>70</Port>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</RemoveVServerGroupBackendServersResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "VServerGroupId": "rsp-cige6****",
  "BackendServers": {
    "BackendServer": [
      {
        "ServerId": "vm-***",
        "Port": "80",
        "Weight": "100"
      },
      {
        "ServerId": "vm-***",
        "Port": "90",
        "Weight": "100"
      },
      {
        "ServerId": "vm-***",
        "Port": "70",
        "Weight": "100"
      }
    ]
  }
}
```

2.13.1.11.5 ModifyVServerGroupBackendServers

You can call this operation to replace back-end servers in a specified VServer group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to <code>ModifyVServerGroupBackendServers</code> .
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
VServerGroupId	String	Yes	The ID of the VServer group.

Parameter	Type	Required	Description
OldBackendServers	JSON string	Yes	Back-end servers to be removed.
NewBackendServers	JSON string	Yes	Back-end servers to be added. A VServer group can contain a maximum of 20 back-end servers.  Note: Make sure that the same number of back-end servers are listed in OldBackendServers and NewBackendServers.
BackendServer elements			
ServerId	String	Yes	The ID of the ECS instance.
Port	Integer	Yes	The port number used by the back-end server. Valid values: 1 to 65535
Weight	Integer	Yes	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
BackendServers	JSON string	The list of back-end servers.

Examples

Sample requests

```
https://slb.example.com/?Action=ModifyVServerGroupBackendServers
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9em*****
&VServerGroupName=Group1
&OldBackendServers=[{"ServerId":"vm-****","Port":"80","Weight":"100"},{"ServerId":"vm-****","Port":"90","Weight":"100"},]
```

```
&NewBackendServers=[{"ServerId":"vm-***","Port":"80","Weight":"100"},{"ServerId":"vm-***","Port":"90","Weight":"100"},]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<ModifyVServerGroupBackendServersResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <VServerGroupId>rsp-cige6j****</VServerGroupId>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
    </BackendServer>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>90</Port>
      <Weight>100</Weight>
    </BackendServer>
  </BackendServers>
</ModifyVServerGroupBackendServersResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "VServerGroupId": "rsp-cige6j****",
  "BackendServers": {
    "BackendServer": [
      {
        "ServerId": "vm-***",
        "Port": "80",
        "Weight": "100"
      },
      {
        "ServerId": "vm-***",
        "Port": "90",
        "Weight": "100"
      }
    ]
  }
}
```

2.13.1.11.6 DeleteVServerGroup

You can call this operation to delete a specified VServer group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteVServerGroup.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.

Parameter	Type	Required	Description
VServerGroupId	String	Yes	The ID of the VServer group to be deleted.  Note: You cannot delete a VServer group that is in use.

Parameter	Type	Description
RequestId	String	The ID of the request.

Response parameters

Examples

Sample requests

```
https://slb.example.com/?Action=DeleteVServerGroup
&RegionId=cn-hangzhou
&VServerGroupId=rsp-cige6****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DeleteVServerGroupResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
</DeleteVServerGroupResponse>
```

- JSON format

```
{ "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C" }
```

2.13.1.11.7 DescribeVServerGroups

You can call this operation to query all VServer groups created in a specified SLB instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeVServerGroups.

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
VServerGroupName	String	The name of the VServer group.
BackendServers	JSON string	The list of back-end servers.
BackendServer elements		
ServerId	String	The ID of the ECS instance.
Port	Integer	The port number used by the back-end server.
Weight	Integer	The weight of the back-end server.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeVServerGroups
&RegionId=cn--hangzhou
&LoadBalancerId=139a0***
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DescribeVServerGroupsResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <VServerGroupId>rsp-cige6****</VServerGroupId>
  <VServerGroupName>Group1</VServerGroupName>
  <BackendServers>
    <BackendServer>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
```

```

</BackendServer>
<BackendServer>
  <ServerId>vm-***</ServerId>
  <Port>90</Port>
  <Weight>100</Weight>
</BackendServer>
</BackendServers>
</DescribeVServerGroupsResponse>

```

- JSON format

```

{

2.13.1.11.8 DescribeVServerGroupAttribute

You can call this operation to query the details of a VServer group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeVServerGroupAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	No	The ID of the SLB instance.
ListenerPort	String	No	The front-end port number used by the SLB instance. Valid values: 1 to 65535

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VServerGroupId	String	The ID of the VServer group.
VServerGroupName	String	The name of the VServer group.
BackendServers	JSON string	The list of back-end servers.
BackendServers elements		
ServerId	String	The ID of the ECS instance.
Port	Integer	The port number used by the back-end server.
Weight	Integer	The weight of the back-end server.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeVServerGroupAttribute
&RegionId=cn-hangzhou
&VServerGroupId=rsp-cige6j5e7p
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DescribeVServerGroupAttributeResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>

      "Port": "90",
      "Weight": "100"
    }
  ]
}
}

```

2.13.1.12 Primary/secondary VServer group

2.13.1.12.1 CreateMasterSlaveServerGroup

You can call this operation to create a primary/secondary server group. A primary/secondary server group contains only two back-end servers: a primary back-end server and a secondary back-end server.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateMasterSlaveServerGroup.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.
MasterSlaveServerGroupName	String	No	The name of the primary/secondary server group.

Parameter	Type	Required	Description
MasterSlaveBackendServers	JSON string	No	The list of back-end servers in the primary/secondary server group. A primary/secondary server group can contain a maximum of two back-end servers. If you do not specify this parameter, an empty primary/secondary server group is created.
ServerId	String	Yes	The ID of the ECS instance.
Port	String	Yes	The port number used by the back-end server. Valid values: 1 to 65535
Weight	String	Yes	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.
ServerType	String	Yes	The role of the back-end server. Default value: Master. Valid values: Master and Slave

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
MasterSlaveServerGroupId	String	The ID of the primary/secondary server group.
MasterSlaveBackendServers	JSON string	The list of back-end servers in the primary/secondary server group.
MasterSlaveBackendServer elements		
ServerId	String	The ID of the ECS instance.
Port	String	The port number used by the back-end server. Valid values: 1 to 65535

Parameter	Type	Description
Weight	String	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to the back-end server.
ServerType	String	The role of the back-end server. Default value: Master. Valid values: Master and Slave

Examples

Sample requests

```
https://slb.example.com/?Action=CreateMasterSlaveServerGroup
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9emf*****
&MasterSlaveServerGroupName=Group1
&MasterSlaveBackendServers=[
  {"ServerId":"vm-***","Port":"80","Weight":"100","ServerType":"Master"},
  {"ServerId":"vm-***","Port":"90","Weight":"100","ServerType":"Slave"},
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<CreateMasterSlaveServerGroupResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <MasterSlaveServerGroupId>rsp-cige6*****</MasterSlaveServerGroupId>
  <MasterSlaveBackendServers>
    <MasterSlaveBackendServers>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
      <ServerType>Master</ServerType>
    </MasterSlaveBackendServers>
    <MasterSlaveBackendServers>
      <ServerId>vm-***</ServerId>
      <Port>90</Port>
      <Weight>100</Weight>
      <ServerType>Slave</ServerType>
    </MasterSlaveBackendServers>
  </MasterSlaveBackendServers>
</CreateMasterSlaveServerGroupResponse>
```

- JSON format

```
{
  "RequestId":"9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "MasterSlaveServerGroupId":"rsp-cige6j****",
  "MasterSlaveBackendServers":{
    "MasterSlaveBackendServers":[
```

```
{
  "ServerId": "vm-****", "Port": "80", "Weight": "100", "ServerType": "Master"},
  {"ServerId": "vm-****", "Port": "90", "Weight": "100", "ServerType": "Slave"},
}
```

2.13.1.12.2 DeleteMasterSlaveServerGroup

You can call this operation to delete a specified primary/secondary server group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteMasterSlaveServerGroup.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
MasterSlaveServerGroupId	String	Yes	The ID of the primary/secondary server group to delete.  Note: You cannot delete a primary/secondary server group that is in use.

Parameter	Type	Description
RequestId	String	The ID of the request.

Response parameters

Examples

Sample requests

```
https://slb.example.com/?Action=DeleteMasterSlaveServerGroup
&RegionId=cn-hangzhou
&MasterSlaveServerGroupId=rs-cige6j*****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DeleteMasterSlaveServerGroupResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
```

```
</DeleteMasterSlaveServerGroupResponse>
```

- JSON format

```
{"RequestId":"9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C"}
```

2.13.1.12.3 DescribeMasterSlaveServerGroupAttribute

You can call this operation to query the details of a primary/secondary server group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMasterSlaveServerGroupAttribute.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
MasterSlaveServerGroupId	String	Yes	The ID of the primary/secondary server group to query.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
MasterSlaveServerGroupId	String	The ID of the primary/secondary server group.
MasterSlaveBackendServers	JSON string	The list of back-end servers in the primary/secondary server group.
MasterSlaveBackendServer elements		
ServerId	String	The ID of the ECS instance.
Port	String	The port number used by the back-end server. Valid values: 1 to 65535

Parameter	Type	Description
Weight	String	The weight of the back-end server. Valid values: [0,100]. The default value is 100. If the value is 0, no requests are forwarded to this back-end server.
ServerType	String	The role of the back-end server. Default value: Master. Valid values: Master and Slave

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeMasterSlaveServerGroupAttribute
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9e*****
&MasterSlaveServerGroupName=Group1
&MasterSlaveBackendServers=[
  {"ServerId":"vm-***","Port":"80","Weight":"100","ServerType":"Master"},
  {"ServerId":"vm-***","Port":"90","Weight":"100","ServerType":"Slave"},
]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
<DescribeMasterSlaveServerGroupAttributeResponse>
  <RequestId>9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C</RequestId>
  <MasterSlaveServerGroupId>rsp-cige6j****</MasterSlaveServerGroupId>
  <MasterSlaveBackendServers>
    <MasterSlaveBackendServers>
      <ServerId>vm-***</ServerId>
      <Port>80</Port>
      <Weight>100</Weight>
      <ServerType>Master</ServerType>
    </MasterSlaveBackendServers>
    <MasterSlaveBackendServers>
      <ServerId>vm-***</ServerId>
      <Port>90</Port>
      <Weight>100</Weight>
      <ServerType>Slave</ServerType>
    </MasterSlaveBackendServers>
  </MasterSlaveBackendServers>
</DescribeMasterSlaveServerGroupAttributeResponse>
```

- JSON format

```
{
  "RequestId": "9DEC9C28-AB05-4DDF-9A78-6B08EC9CE18C",
  "MasterSlaveServerGroupId": "rsp-cige6j5e7p",
  "MasterSlaveBackendServers": {
    "MasterSlaveBackendServers": [
```

```
{
  "ServerId": "vm-233", "Port": "80", "Weight": "100", "ServerType": "Master",
  "ServerId": "vm-232", "Port": "90", "Weight": "100", "ServerType": "Slave",
}
```

2.13.1.12.4 DescribeMasterSlaveServerGroups

You can call this operation to query primary/secondary server groups you have created.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMasterSlaveServerGroups.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerId	String	Yes	The ID of the SLB instance.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
MasterSlaveServerGroupId	String	The ID of the primary/secondary server group.
MasterSlaveServerGroupName	String	The name of the primary/secondary server group.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeMasterSlaveServerGroups
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9em****
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
```

```
<DescribeMasterSlaveServerGroupsResponse>
  <RequestId>2631BB5E-B576-4925-BDED-07A66D23E5DE</RequestId>
  <MasterSlaveServerGroups>
    <MasterSlaveServerGroup>
      <MasterSlaveServerGroupId>rsp-bp1ro3****</MasterSlaveServerGroupId>
      <MasterSlaveServerGroupName>test</MasterSlaveServerGroupName>
    </MasterSlaveServerGroup>
  </MasterSlaveServerGroups>
</DescribeMasterSlaveServerGroupsResponse>
```

- JSON format

```
{
  "RequestId": "2631BB5E-B576-4925-BDED-07A66D23E5DE",
  "MasterSlaveServerGroups": {
    "MasterSlaveServerGroup": [
      {
        "MasterSlaveServerGroupId": "rsp-bp1ro3m****",
        "MasterSlaveServerGroupName": "test"
      }
    ]
  }
}
```

2.13.1.13 Tags

2.13.1.13.1 AddTags

You can call this operation to add tags to a specified SLB instance.

When you call this operation, note the following items:

- You can add up to 10 tags to an SLB instance.
- You can add a maximum of five tags at a time.
- All tags and keys added to an SLB instance must be unique.
- If you add a tag that has the same key as an existing tag but with a different value, the new tag overwrites the existing one.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to AddTags.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerID	String	Yes	The ID of the SLB instance.

Parameter	Type	Required	Description
Tags	JSON string	Yes	The list of tags to be added. A maximum of five tags can be specified.
Tag elements			
TagKey	String	Yes	The key value of the tag. The key value must be 1 to 64 characters in length. It cannot start with <code>aliyun</code> .
TagValue	String	No	The value of the tag. The value must be 1 to 128 characters in length. It cannot start with <code>aliyun</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=AddTags
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9emf*****
&Tags=[
  {"TagKey":"Key1","TagValue":"Value1"}
  {"TagKey":"Key2","TagValue":"Value2"}]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<AddTagsResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
</AddTagsResponse>
```

- JSON format

```
{
  "RequestId":"365F4154-92F6-4AE4-92F8-7FF34B540710",
```

}

2.13.1.13.2 DescribeTags

You can call this operation to query tags you have created.

When you call this operation, note the following items:

- You can query the tags by instance ID, tag key, or tag value.
- The specified conditions are of "and" relation. Only tags meeting all specified conditions are returned.
- If you specify a tag key without specifying a tag value, all tags associated with the key are returned.
- You must also specify **TagKey** if you have specified **TagValue**.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeTags.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerID	String	No	The ID of the SLB instance.
Tags	JSON string	No	The list of tags to query.
PageSize	Integer	No	The number of entries to return on each page. Valid values: [1, 50]. Default value: 10
PageNumber	Integer	No	The number of the page to return. Default value: 1.
Tag elements			
TagKey	String	Yes	The key value of the tag. The key value must be 1 to 64 characters in length. It cannot start with aliyun.

Parameter	Type	Required	Description
TagValue	String	No	The value of the tag. The value must be 1 to 128 characters in length. It cannot start with <code>aliyun</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TagSets	JSON string	The list of tags.
PageSize	Integer	The number of entries returned on each page.
PageNumber	Integer	The number of the returned page.
TotalCount	Integer	The total number of queried tags.
Tag elements		
TagKey	String	The key value of the tag.
TagValue	String	The value of the tag.
InstanceCount	Integer	The total number of instances bound to the tag.

Examples

Sample requests

```
https://slb.example.com/?Action=DescribeTags
&RegionId=cn-hangzhou
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeTagsResponse>
  <RequestId>87696689-7951-4206-B30F-79D35A95C904</RequestId>
  <TotalCount>3</TotalCount>
  <PageNumber>1</PageNumber>
  <PageSize>50</PageSize>
  <TagSets>
    <TagSet>
      <InstanceCount>1</InstanceCount>
      <TagKey>Protocol</TagKey>
      <TagValue>HTTPS</TagValue>
    </TagSet>
    <TagSet>
      <InstanceCount>1</InstanceCount>
      <TagKey>network</TagKey>
```

```

    <TagValue>classic</TagValue>
  </TagSet>
  <TagSet>
    <InstanceCount>1</InstanceCount>
    <TagKey>acs_cluster</TagKey>
    <TagValue>cb2f4d713ba634931bf5851f08c073256</TagValue>
  </TagSet>
</TagSets>
</DescribeTagsResponse>

```

- JSON format

```

{
  "PageNumber":1,
  "TotalCount":3,
  "PageSize":50,
  "RequestId":"87696689-7951-4206-B30F-79D35A95C904",
  "TagSets":{
    "TagSet":[

        "TagKey":"acs_cluster"
      }
    ]
  }
}

```

2.13.1.13.3 RemoveTags

You can call this operation to remove tags from a specified SLB instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to RemoveTags.
RegionId	String	Yes	The ID of the region where the SLB instance resides. You can call the DescribeRegions operation to obtain the region ID.
LoadBalancerID	String	Yes	The ID of the SLB instance.

Parameter	Type	Required	Description
Tags	JSON string	No	The list of tags to remove.
Tag elements			
TagKey	String	Yes	The key value of the tag. It must be 1 to 64 characters in length. It cannot start with aliyun.
TagValue	String	No	The value of the tag. The value must be 1 to 128 characters in length. It cannot start with aliyun.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://slb.example.com/?Action=RemoveTags
&RegionId=cn-hangzhou
&LoadBalancerId=lb-t4nj5vuz8ish9*****
&Tags=[
  {"TagKey":"Key1","TagValue":"Value1"}
  {"TagKey":"Key2","TagValue":"Value2"}]
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<RemoveTagsResponse>
  <RequestId>365F4154-92F6-4AE4-92F8-7FF34B540710</RequestId>
</RemoveTagsResponse>
```

- JSON format

```
{
  "RequestId":"365F4154-92F6-4AE4-92F8-7FF34B540710",
```

}

2.13.1.14 Error codes

Error code	Error message	HTTP status code	Description
CertificateAndPrivateKeyIsReferred	Certificate and PrivateKey Is Referred.	400	The error message returned when the certificate is already in use by other listeners.
CertificateNotMatchPrivateKey	Certificate and key does not match.	400	The error message returned when the certificate and private key do not match.
HealthCheckerNotFound	No health-checked Listener to the specified port of the Load Balancer.	404	The error message returned when the health check function has not been configured.
Forbidden.SubUser	User not authorized to operate on the specified resource as your account is created by another user.	403	The error message returned when you do not have permission to operate the resource.
Forbidden	User not authorized to operate on the specified resource .	403	The error message returned when you do not have permission to operate the resource.
IncorrectListenerAccessControlStatus	Current listener access control status does not support this operation.	500	The error message returned when the current access control status of the listener does not support this operation.
InternalServerError	The request processing has failed due to backend service exception.	400	The error message returned when an unknown internal error occurs.

Error code	Error message	HTTP status code	Description
InternalInvokeError	The request processing has failed due to some unknown error, exception or failure.	500	The error message returned when an unknown internal error occurs.
InvalidBackendServers.Inconsistent	Specified LoadBalancer instance's address type is private, so it is forbidden to add ECS VPC backend servers for now.	400	The error message returned when the network types of the backend server and the SLB instance do not match.
InvalidBackendServers.Inconsistent	All BackendServers on one Specified LoadBalancer have to be in the same VPC or all classic	400	The error message returned when the ECS instances acting as backend servers for the SLB are deployed in both a classic network and a VPC.
InvalidIdentity	The request identity was not allowed to operate.	400	The error message returned when you do not have permission to operate.
InvalidLoadBalancerId.NotFound	LoadBalancerId does not exist.	404	The error message returned when the specified SLB instance does not exist.
InvalidParameter	The specified parameter ServerCertificate format is error.	404	The error message returned when the format of the specified certificate is incorrect.
InvalidParameter	The specified parameter ServerCertificateId is empty.	404	The error message returned when the certificate value is not specified.

Error code	Error message	HTTP status code	Description
InvalidParameter	The specified parameter <code>ServerCertificateId</code> is not supported.	404	The error message returned when the specified server certificate ID is invalid.
InvalidParameter	The specified parameter <code>ServerCertificate</code> or <code>Key</code> is empty.	404	The error message returned when the values of the certificate and the private key are not specified.
InvalidParameter	The specified parameter key format is error.	404	The error message returned when the format of the specified private key is incorrect.
InvalidParameter	Specified region is not supported.	404	The error message returned when the specified region is not supported.
InvalidParameter	Port is not Integer.	400	The error message returned when the specified port number is not an integer or is not in the range of 1 to 65535.
InvalidParameter	The specified port is not valid.	400	The error message returned when the specified port number is not an integer or is not in the range of 1 to 65535.
InvalidParameter	The specified bandwidth is not valid.	400	The error message returned when the specified instance bandwidth is invalid.
InvalidParameter	Specified parameter <code>Check</code> is not valid.	400	The error message returned when the specified parameter is invalid.
InvalidParameter	The specified parameter <code>HealthCheckHttpCode</code> is not valid.	400	The error message returned when the specified value of HealthCheckHttpCode is invalid.

Error code	Error message	HTTP status code	Description
InvalidParameter	The specified parameter bandwidth is not valid, out of the instance total bandwidth.	400	The error message returned when the specified value of Bandwidth exceeds the total bandwidth and is therefore invalid.
InvalidParameter	The specified parameter bandwidth is not valid.	400	The error message returned when the specified value of Bandwidth is invalid.
InvalidParameter	The specified parameter HealthCheck is not valid.	400	The error message returned when the specified health check parameter is invalid.
InvalidParameter	The specified parameter SourceItem is not valid.	400	The error message returned when the specified value of SourceItem is invalid.
InvalidParameter	The specified protocol is not valid.	400	The error message returned when the specified protocol type is invalid.
InvalidParameter	RS Pool is empty.	400	The error message returned when there are no available backend servers.
InvalidParameter	RS Pool doesn't exist.	400	The error message returned when there are no available backend servers.
InvalidParameter	Illegal user ID.	400	The error message returned when the user ID is invalid.
InvalidParameter	User ID is null	400	The error message returned when the user ID field is empty.
InvalidParameter	The specified parameter lb_type is not valid.	400	The error message returned when the SLB instance type is invalid.
InvalidParameter	The specified parameter mode is not valid..	400	The error message returned when the specified value of Mode is invalid.

Error code	Error message	HTTP status code	Description
InvalidParameter	The specified parameter AccessControlStatus is not valid.	400	The error message returned when the specified value of AccessControlStatus is invalid.
InvalidParameter	The specified parameter SourceItems is not valid.	400	The error message returned when the specified value of SourceItem is invalid.
InvalidParameter	The specified parameter BackendServers is not valid.	404	The error message returned when the specified value of BackendServers is invalid.
InvalidParameter	Specified parameter is not valid.	400	The error message returned when the specified parameter is invalid.
InvalidParameter	The specified parameter Domain is not valid.	400	The error message returned when the specified value of Domain is invalid.
InvalidParameter	The specified parameter URI is not valid.	400	The error message returned when the specified value of URI is invalid.
InvalidParameter	The specified parameter Scheduler is not valid.	400	The error message returned when the specified value of Scheduler is invalid.
InvalidParameter	The specified parameter ListenerStatus is not valid.	400	The error message returned when the specified value of ListenerStatus is invalid.
InvalidParameter	The specified parameter PersistenceTimeout is not valid.	400	The error message returned when the specified value of PersistenceTimeout is invalid.

Error code	Error message	HTTP status code	Description
InvalidParameter	The specified parameter ConnectPort is not valid.	400	The error message returned when the specified value of ConnectPort is invalid.
InvalidParameter	The specified parameter ConnectTimeou is not valid.	400	The error message returned when the specified value of ConnectTimeout is invalid.
InvalidParameter	The specified parameter StickySessionType is not valid.	400	The error message returned when the specified value of StickySessionType is invalid.
InvalidParameter	The specified parameter HealthyThreshold is not valid.	400	The error message returned when the specified value of HealthyThreshold is invalid.
InvalidParameter	The specified parameter UnhealthyThreshhold is not valid.	400	The error message returned when the specified value of UnhealthyThreshold is invalid.
InvalidParameter	The specified parameter Interval is not valid.	400	The error message returned when the specified value of Interval is invalid.
InvalidParameter	The specified parameter XForwardedFor is not valid.	400	The error message returned when the specified value of XForwardedFor is invalid.
InvalidParameter	The specified parameter IsPublicAddress is not valid.	400	The error message returned when the specified value of IsPublicAddress is invalid.
InvalidRegionId. NotFound	Specified region does not exist.	404	The error message returned when the specified region does not exist.

Error code	Error message	HTTP status code	Description
InvalidServerId. Malformed	A specified server ID is not valid, flush control ip chain fail.	400	The error message returned when the specified backend server ID is invalid.
InvalidServerId. NotFound	The specified server is not found.	400	The error message returned when the specified backend server does not exist.
InvalidWeight. Malformed	A specified weight is not valid.	400	The error message returned when the specified value of weight is invalid.
IpNotAvailable	The specified parameter Address is not valid.	400	The error message returned when the specified value of Address is invalid.
ListenerAlreadyExists	There is already a listener bound to the port on the specified load balancer.	400	The error message returned when there is already a listener bound to the port on the specified SLB instance.
ListenerNotFound	No Listener to the specified port of the Load Balancer.	404	The error message returned when the specified listener does not exist.
MissingParameter	The input parameter Cookie that is mandatory for processing this request is not supplied.	400	The error message returned when the Cookie parameter is not specified.
MissingParameter	The input parameter BackendServerPort that is mandatory for processing this request is not supplied.	400	The error message returned when the BackendServerPort parameter is not specified.

Error code	Error message	HTTP status code	Description
MissingParameter	The input parameter LoadBalancerId that is mandatory for processing this request is not supplied.	400	The error message returned when the LoadBalancerId parameter is not specified.
MissingParameter	The input parameter RegionId that is mandatory for processing this request is not supplied.	400	The error message returned when the RegionId parameter is not specified.
MissingParameter	The combination of some parameters violates the spec.	400	The error message returned when a required parameter is not specified.
MissingParameter	The input parameter OwnerId , OwnerAccount that is mandatory for processing this request is not supplied.	403	The error message returned when OwnerAccount and OwnerId are not specified.
PrivateKeyEncryption	Key has Encrypted .	400	The error message returned when the private key is encrypted.
Processing SameRequest	The same request is being processed . Please try later.	400	The error message returned when the same request is being processed. You can try again later.
ServerCertificateId.NotFound	Specified ServerCertificateId does not exist.	404	The error message returned when the specified certificate does not exist.

Error code	Error message	HTTP status code	Description
ServiceUnavailable	The request has failed due to a temporary failure of the server.	503	The error message returned when the service is unavailable.
ServiceUnavailable	The specified loadbalancer name has been used.	503	The error message returned when the specified instance name is already being used.
TcpNotSupportForHybridLb	Hybrid type loadbalancer doesn't support TCP type listener.	400	The error message returned when a TCP listener cannot be created.
TooManyBackendServers	The total number of input real servers exceeds max supported number: 20.	400	The error message returned when you are trying to add more than 20 backend servers at a time.
TooManyBackendServers	The backend server parameter has too many entries.	400	The error message returned when the specified number of backend servers exceeds the limit.
UnsupportedOperation	The Loadbalancer doesn't support this function.	400	The error message returned when the SLB instance does not support the operation.
UnsupportedOperation	The specified action is not supported.	400	The error message returned when the specified operation is not supported.
UnsupportedOperationonfixedprotocolport	The specified port has been assigned one type of protocol, and this protocol doesn't support this operation.	400	The error message returned when the specified port does not support the operation.
UnsupportedParameter	The parameter is not supported.	400	The error message returned when the input parameter is not supported.

Error code	Error message	HTTP status code	Description
VipNotMatchRspool	The vip protocol is not match with Rspool.	400	The error message returned when the protocol type of the listener and the application protocol of the backend server do not match.
VipTooManyListeners	The total number of input listeners exceeds max supported number: 50.	400	The error message returned when you are trying to add more than 50 listeners at a time.
InvalidParameter	The specified resource does not exist.	400	The error message returned when the specified resource does not exist.
ServiceUnavailable	The specified loadbalancer is configuring, please retry later.	503	The error message returned when the specified instance is currently under configuration. You can try again later.
ServiceUnavailable	Obtain Ip Fail, please make sure the ECS exists and the status is running.	503	The error message returned when the IP address cannot be obtained. Verify that the ECS instance exists and that it is in the running state.
ServiceUnavailable	The specified region not support VPC.	503	The error message returned when the specified region does not support VPCs.
InvalidParameter	The specified vpc cloud instance has been deleted.	400	The error message returned when the specified VPC instance has been deleted.

2.13.2 SDK reference

2.13.2.1 Java SDK

2.13.2.1.1 Quick start

This topic describes how to install and use Alibaba Cloud Apsara Stack SLB Java SDK.

Preparation

- To use the SLB Java SDK, you must have an Apsara Stack tenant account as well as an AccessKey. See [Obtain an AccessKey pair](#) for more information about how to obtain and view your AccessKey in the Apsara Stack console.
- Obtain the SLB endpoint. For more information, see [Obtain an endpoint](#).
- The SLB Java SDK supports JDK V1.6 and later.

Installation

If you use Apache Maven to manage Java projects, you only need to import the JAR file to the pom.xml file of the project.

To use the SLB Java SDK, you must install both the SDK and the SDK core library.

The SDK core library version is 3.7.1, and the SLB Java SDK version is 1.0.

```
<dependencies>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-core</artifactId>
    <version>3.7.1</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-core-3.7.1.jar</systemPath>
  </dependency>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-ecs</artifactId>
    <version>3.5.0</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-slb-1.0.jar</systemPath>
  </dependency>
</dependencies>
```

Usage

The following code example shows the three main steps to use the SLB Java SDK:

1. Create and initialize a DefaultAcsClient instance.
2. Create an API request and set parameters.
3. Initiate the request and handle the response or exception.

```
package com.testprogram;
import com.aliyuncs.profile.DefaultProfile;
```

```

import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.ecs.model.v20140526.*;
public class Main {
    public static void main(String[] args) {
        //Create a DefaultAcsClient instance and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // Your region ID
            "<your-access-key-id>", // AccessKey ID of your Apsara Stack tenant account
            "<your-access-key-secret>"); // AccessKey Secret of your Apsara Stack tenant
        account
        // Set the service endpoint.
        profile.addEndpoint("your-region-id", "your-region-id", "product", "endpoint");
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and set parameters.
        DescribeInstancesRequest request = new DescribeInstancesRequest();
        request.setPageSize(10);
        // Initiate the request and handle the response or exception.
        DescribeInstancesResponse response;
        try {
            response = client.getAcsResponse(request);
            for (DescribeInstancesResponse.Instance instance:response.getInstances()) {
                System.out.println(instance.getPublicIpAddress());
            }
        } catch (ServerException e) {
            e.printStackTrace();
        } catch (ClientException e) {
            e.printStackTrace();
        }
    }
}

```

2.13.2.1.2 Use the SDK

2.13.2.1.2.1 Install Java SDK

This topic describes how to install and use Alibaba Cloud Apsara Stack SLB Java SDK.

The SLB Java SDK supports JDK V1.6 and later. You can install the latest JDK version by importing the JAR file.

You can click [here](#) to download SLB JAR files.

If you are using Eclipse or IntelliJ as the IDE, you can install the SLB Java SDK directly by importing JAR files.

The installation methods are as follows:

- In Eclipse

Complete the following steps to install the SLB Java SDK in Eclipse:

1. Copy the downloaded `aliyun-java-sdk-slb.jar` file to your project folder.
2. Open your project in Eclipse, right-click the project, and choose **Properties** from the shortcut menu.
3. In the dialog box that appears, click **Java Build Path** in the left-side navigation pane and then the **Libraries** tab. Click **Add JARs** to add the downloaded JAR files.
4. Click **Apply and Close**.

- In IntelliJ

Complete the following steps to install the SLB Java SDK in IntelliJ:

1. Copy the downloaded `aliyun-java-sdk-slb.jar` file to your project folder.
2. Open your project in IntelliJ, and choose **File** > **Project Structure**.
3. Click **Apply** and then **OK**.

2.13.2.1.2.2 Configure identity verification credentials

When using Alibaba Cloud Apsara Stack SDK to access Apsara Stack services, you must provide your Apsara Stack tenant account for identity verification.

Currently, the SLB Java SDK supports identity verification using AccessKeys. For details on how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

If you use an AccessKey as the access credential, you must configure your credential when initializing the client.

Notice:

Do not disclose any code containing your AccessKey (for example, do not commit the code to public GitHub projects). Otherwise, your Apsara Stack tenant account may be compromised.

```
DefaultProfile profile = DefaultProfile.getProfile(
    "<your-region-id>", // Your region ID
    "<your-access-key-id>", // AccessKey ID of your Apsara Stack tenant account
    "<your-access-key-secret>"); // AccessKey Secret of your Apsara Stack tenant account
```

2.13.2.1.2.3 Initiate a call

This topic describes how to use the SLB Java SDK to initiate a call.

Procedure

1. Create an AcsClient instance.

```
IAcsClient client = new DefaultAcsClient(profile);
```

2. Create a request.

The naming convention for requests is `${apiName}Request`, where **`${apiName}`** is the API name such as `DescribeLoadBalancers`.

When the SDKs of multiple services are used, different requests may have the same name. Differentiate the requests by SDK package.

```
DescribeLoadBalancersRequest request = new DescribeLoadBalancersRequest();
request.setPageSize(10);
```

3. Initiate a call and handle the response.

```
DescribeLoadBalancersResponse response;
try {
    response = client.getAcsResponse(request);
    for (DescribeLoadBalancersResponse.Instance instance:response.getInstances()) {
        System.out.println(instance.getPublicIpAddress());
    }
} catch (ServerException e) {
    e.printStackTrace();
} catch (ClientException e) {
    e.printStackTrace();
}
```

In normal cases, all returned fields are deserialized into the response. You can directly call `response.getXXX()` to obtain the response fields.

```
instanceStatus := response.getStatus()
```

If an exception occurs or you need the original HTTP response, use `doAction()` to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.13.2.1.2.4 Handle errors

Alibaba Cloud Apsara Stack SLB Java SDK returns error messages when errors occur on the server or SDK side. The messages contain error details, including error codes and error messages.

Among the errors returned by the SLB Java SDK, you do not need to handle the SDK errors, but must solve the server errors.

- `ServerException` indicates a server error.
- `ClientException` indicates an SDK error.

For example, when the following error occurs, you can modify the AccessKey ID based on the error message to solve the problem:

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified access key is not found.
```

If you want to handle the SDK errors returned by the SLB Java SDK, refer to the following example to write your code:

```
try {
    FooResponse response = client.getAcsResponse(request);
    // Handle the response.
    // ...
} catch (ServerException e) {
    // You can add your own error handling logic here.
    // For example, display the error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If you are unable to troubleshoot the problem, submit a ticket and provide RequestId
    // to Alibaba Cloud technical support personnel.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {
    // You can add your own error handling logic here.
    // For example, display the error message.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
}
```

}

2.13.2.1.2.5 Common errors

The following table lists some common errors you may experience when using the SDK, and describes their potential causes and solutions.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot automatically obtain the endpoint of the called service in the specified region.	Check whether the provided region ID and endpoint are correct. After obtaining the correct endpoint, use the following code to set the endpoint: <pre>DefaultProfile.addEndpoint("cn-hangzhou", "cn-hangzhou", "Ecs", "ecs.example.com");</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response	SDK response deserialization fails. In most cases, the cause is an inconsistency between the API metadata and the response structure received by the SDK, such as mismatched fields or an incorrect format.	You can use the <code>client.doAction(request)</code> method to obtain the original HTTP response.
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The request times out and all retry attempts fail.	In scenarios such as poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError : InvalidProtocol .NeedSsl	Your request is denied as lack of ssl protect .Recommend :https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API accepts only HTTPS requests, not HTTP requests.	Add the following code before sending a request: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.13.2.2 Python SDK

2.13.2.2.1 Quick start

This topic describes how to install and use Alibaba Cloud Apsara Stack SLB Python SDK.

Preparation

- To use the SLB Python SDK, you must have an Apsara Stack tenant account as well as an Accesskey. For more information about how to obtain and view your AccessKey in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- Obtain the SLB endpoint. For more information, see [Obtain an endpoint](#).

Installation

Complete the following steps to install the SLB Python SDK:

1. Install the SDK core library.

- For Python V2.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core
```

- For Python V3.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core-v3
```

2. Install the SLB Python SDK.

An example of the command used to install the SLB Python SDK is as follows:

```
pip install aliyun-python-sdk-slb
```

Usage

The following code example shows the three main steps to use the SLB Python SDK:

1. Create a client instance. When creating the client instance, you must specify the Region ID, AccessKey ID, and AccessKey Secret parameters.
2. Create an API request and set parameters.
3. Initiate the request and handle the response or exception.

```
#!/usr/bin/env python
#coding=utf-8

from aliyunsdkcore import client
from aliyunsdkslb.request.v20140515 import CreateLoadBalancerRequest
from aliyunsdkcore.profile import region_provider
#region_provider.modify_point('slb', '<regionId>', 'slb.<regionId>.aliyuncs.com')

clt = client.AcsClient('<AccessKey ID>', '<AccessKey Secret>', 'Region ID')

# Set parameters.
request = CreateLoadBalancerRequest.CreateLoadBalancerRequest()
request.set_accept_format('json')

# Initiate a request.
response = clt.do_action(request)

print response
```

2.13.2.2.2 Use the SDK

2.13.2.2.2.1 Install Python SDK

This topic describes how to install and use Alibaba Cloud Apsara Stack SLB Python SDK.

The SLB Python SDK supports Python V2.6.x, V2.7.x, V3.x and later. You can install the SLB Python SDK by using one of the following methods:

- Use pip (recommended)

Run the following commands to install the SLB Python SDK by using pip:

```
pip install aliyun-python-sdk-core # Install the SDK core library.
pip install aliyun-python-sdk-rds # Install SLB Python SDK.
```

Note:

For Python V3.x, replace `pip install aliyun-python-sdk-core` with `pip install aliyun-python-sdk-core-v3`.

- Use GitHub

Run the following commands to install the SLB Python SDK by using GitHub:

```
git clone https://github.com/aliyun/aliyun-openapi-python-sdk.git
# Install the SDK core library.
cd aliyun-python-sdk-core
```

```
python setup.py install
# Install the SLB Python SDK.
cd aliyun-python-sdk-slb
python setup.py install
```

- Use source code
 1. [Download the SDK package](#) and decompress it.
 2. Use one of the following methods to install the SLB Python SDK:
 - Modify sys.path to add the directory in which the SDK package is decompressed.
- Example:

```
>>> import sys
>>> sys.path.append('/Users/michael/my_py_scripts')
```

**Note:**

This modification is in effect only when the ECS instance is running.

- Set environment variable PYTHONPATH and add the directory in which the SDK package is decompressed. The content of this environment variable is automatically added to the module search directory.

The method of setting PYTHONPATH is similar to that of setting environment variable Path.

- Place the decompressed SDK package in the project. You can then use the SDK directly in the project.

2.13.2.2.2 Configure identity verification credentials

When using Alibaba Cloud Apsara Stack SDK to access Apsara Stack services, you must provide your Apsara Stack tenant account for identity verification.

Currently, the SLB Python SDK supports identity verification using AccessKeys. For details about how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

If you use an AccessKey as the access credential, you must configure your credential when initializing the client.

**Notice:**

Do not disclose any code containing your AccessKey (for example, do not commit the code to public GitHub projects). Otherwise, your Apsara Stack tenant account may be compromised.

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

2.13.2.2.2.3 Initiate a call

This topic describes how to use the SLB Python SDK to initiate a call.

Procedure

1. Import the SLB Python SDK.

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.acs_exception.exceptions import ClientException
from aliyunsdkcore.acs_exception.exceptions import ServerException
from aliyunsdkslb.request.v20140515 import CreateLoadBalancerRe
quest
```

2. Create an AcsClient instance.

```
client = AcsClient(
    "<your-access-key-id>",
    "<your-access-key-secret>",
    "<your-region-id>" );
```

3. Create a Request object.

```
request = CreateLoadBalancerRequest.CreateLoadBalancerRequest()
request.set_LoadBalancerName('MyLoadBalancer')
request.set_AddressType('internet')
request.set_InternetChargeType('paybytraffic')
```

4. Initiate a call and handle the response.

```
response = client.do_action_with_exception(request)
print response
```

2.13.2.2.2.4 Set HTTPS requests

Alibaba Cloud Apsara Stack Python SDK allows you to initiate API requests over HTTP and HTTPS.

You can specify a protocol (HTTP or HTTPS) for a specific request, or set a global default protocol.

Note:

The default protocol of the service takes precedence over the global default protocol.

Add OpenSSL support

The HTTPS protocol support of Alibaba Cloud Apsara Stack Python SDK is based on the OpenSSL support in Python. To use Alibaba Cloud Apsara Stack Python SDK to send HTTP requests, you must add OpenSSL support in Python.

Run the `python -c "import ssl"` command to check whether OpenSSL is supported in Python. If `ImportError: No module named ssl` is not displayed in the command output, OpenSSL is already supported.

If OpenSSL is not supported, run the following command to install it:

```
pip install pyopenssl
```

Set the protocol to HTTP or HTTPS for a request

The following code example shows how to set the protocol to HTTPS for a request:

```
request = CreateLoadBalancerRequest.CreateLoadBalancerRequest()
request.set_protocol_type("https")
# Valid value: https or http
```

Set a global default protocol

The following code example shows how to set a global default protocol:

```
import aliyunsdkcore.request
aliyun sdkcore.request.set_default_protocol_type("https")
# Create a request and call client.do_action_with_exception() to send the request.
```

2.13.2.2.2.5 Handle errors

If an error occurs on the server side or SDK side when you use the Python SDK, the Python SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Generally, you are not required to handle the errors returned by the Python SDK. You are only required to handle the errors on the server side according to the error message.

- `ServerException` is the error message on the server side.
- `ClientException` is the error message on the SDK side.

For example, if the following error occurs, modify the ID of AccessKey according to the detailed error message.

```
aliyun sdkcore.acs\_exception.exceptions.ServerException: HTTP Status: 404 Error: InvalidAccessKeyId.NotFound Specified access key is not found.
```

To handle the errors returned by the Python SDK, see the following code example for reference:

```
try:
    response = client.do_action_with_exception(request)
except ServerException as e:
    # Add your own error handling logic here.
    # For example, print the detailed error message.
    print e.get_http_status()
    print e.get_error_code()
    print e.get_error_msg()
```

2.13.2.2.2.6 Common errors

This topic describes the common errors when you use the Python SDK. Troubleshoot the problems based on the corresponding causes and solutions.

Error code	Error message	Cause	Solution
SDK.InvalidRegionId	Can not find endpoint to access.	SDK cannot automatically obtain the endpoint (domain name) of the called product in the specified region.	Check if the provided region ID and endpoint are correct. Obtain the endpoint and then use the following code to configure the endpoint: <pre>from aliyunsdkcore.profile import region_provider region_provider.modify_point('product_name', 'region_id', 'endpoint')</pre>
SDK.TimeoutError	—	The request times out and all retries fail.	If the network quality is low, we recommend that you extend the timeout or increase the maximum number of retries.

Error code	Error message	Cause	Solution
SDK. ServerError :InvalidProtocol. NeedSsl	Your request is denied as lack of ssl protect. Recommend: https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	This API only accepts HTTPS requests, instead of HTTP requests.	Before sending a request, add the following code: <pre>request.set_protocol_type('https')</pre>

2.13.2.3 PHP SDK

2.13.2.3.1 Quick start

Alibaba Cloud Apsara Stack SLB PHP SDK allows you to access SLB without performing complicated programming operations. This topic describes how to install and use the SLB PHP SDK.

Preparation

- To use the SLB PHP SDK, you must have an Apsara Stack tenant account as well as an AccessKey. For more information about how to obtain and view your AccessKey in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- Obtain the SLB endpoint. For more information, see [Obtain an endpoint](#).
- The SLB PHP SDK supports PHP V5.3, V5.4, V5.5, V5.6, V7.0, and V7.1. (You can use the **php -v** command to obtain the current PHP version number.)

Installation

Complete the following steps to install the SLB PHP SDK:

1. Download the PHP SDK source code from the [Apsara Stack official website](#).

2. Add the PHP SDK reference to your code.

Assume that the PHP SDK source code is downloaded to the `/path/to/alibabacloud-openapi-php-sdk` directory, and run the following command to add the PHP SDK reference:

```
require_once '/path/to/alibabacloud-openapi-php-sdk/alibabacloud-php-sdk-core/Config.php';
```

Usage

The following code example shows the three main steps to use the SLB PHP SDK:

1. Create and initialize a DefaultAcsClient instance.

When creating and initializing the DefaultAcsClient instance, you must specify the **Region ID**, **AccessKey ID**, and **AccessKey Secret** parameters.

2. Create an API request and set parameters.

3. Initiate the request and handle the response or exception.

```
<? php

use Slb\Request\V20140515\DescribeLoadBalancersRequest;

// Create a DefaultAcsClient instance and initialize it.
$clientProfile = DefaultProfile::getProfile(
    "<your-region-id>",          # Your region ID
    "<your-access-key-id>",      # Your AccessKey ID
    "<your-access-key-secret>"  # Your AccessKey Secret
);
$client = new DefaultAcsClient($clientProfile);

# Create an API request and set parameters.
$request = new DescribeLoadBalancersRequest();
$request->setPageSize(10);

# Initiate the request and handle the response.
try {
    $response = $client->getAcsResponse($request);
    print_r($response);
} catch (ServerException $e) {
    print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
} catch (ClientException $e) {
    print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
}
```

? >

2.13.2.4 Go SDK

2.13.2.4.1 Quick start

Alibaba Cloud Apsara Stack SLB Go SDK allows your to access SLB without performing complicated programming operations. This topic describes how to obtain and use the SLB Go SDK.

Preparation

- To use the SLB Go SDK, you must have an Apsara Stack tenant account as well as an AccessKey. For more information about how to obtain and view your AccessKey in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- Obtain the SLB endpoint. For more information, see [Obtain an endpoint](#).

Installation

1. Download the Go SDK source code from the [Apsara Stack official website](#).
2. Decompress the source code to the directory specified by GO_PATH.

Usage

The following code example shows the three main steps to use the SLB Go SDK:

1. Create a client instance.
2. Create an API request and set parameters.
3. Initiate the request and handle the response or exception.

```
package main

import (
    "github.com/aliyun/alibaba-cloud-sdk-go/services/slb"
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"
    "fmt"
)

func main() {
    // Create an slbClient instance.
    slbClient, err := slb.NewClientWithAccessKey(
        "<your-region-id>", // Your region ID
        "<your-access-key-id>", // Your AccessKey ID
        "<your-access-key-secret>") // Your AccessKey Secret
    if err != nil {
        // Handle the exception.
        panic(err)
    }
    // Create an API request and set parameters.
    request := slb.CreateDescribeLoadBalancersRequest()
    // Set request.PageSize to 10.
    request.PageSize = requests.NewInteger(10)
    // Initiate the request and handle the exception.
```

```

response, err := slbClient.DescribeLoadBalancers(request)
if err != nil {
    // Handle the exception.
    panic(err)
}
fmt.Println(response)
}

```

2.13.2.4.2 Use the SDK

2.13.2.4.2.1 Install Go SDK

This topic describes how to install Alibaba Cloud Apsara Stack SLB Go SDK.

Context

The SLB Go SDK supports Go V1.7 and later. You can install the SLB Go SDK by using the following methods:

Procedure

1. Download the Go SDK source code from the [Apsara Stack official website](#).
2. Decompress the source code to the directory specified by GO_PATH.

2.13.2.4.2.2 Configure identity verification credentials

When using Alibaba Cloud Apsara Stack SDK to access Apsara Stack services, you must provide your Apsara Stack tenant account for identity verification.

Currently, the SLB Go SDK supports identity verification using AccessKeys. For details on how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

If you use an AccessKey as the access credential, you must configure your credential when initializing the client.

Notice:

Do not disclose any code containing your AccessKey (for example, do not commit the code to public GitHub projects). Otherwise, your Apsara Stack tenant account may be compromised.

```

// Create an slbClient instance.
client, err := slb.NewClientWithAccessKey(
    "<your-region-id>", // Your region ID
    "<your-access-key-id>", // Your AccessKey ID

```

```
"<your-access-key-secret>") // Your AccessKey Secret
```

If you want to use the custom Config or credentials other than AccessKeys, you must first create a Credential object to store the credentials, and then submit the Credential object when initializing the client.

```
// Customize configurations.
config := NewConfig()
// Create a Credential object.
credential := &credentials.BaseCredential{
    AccessKeyId:  "<your-access-key-id>",
    AccessKeySecret: "<your-access-key-secret>",
}
// Initialize the client.
client, err := NewClientWithOptions("cn-hangzhou", config, credential)
```

2.13.2.4.2.3 Initiate a call

This topic describes how to use the SLB Go SDK to initiate a call.

Procedure

1. Import the SLB Go SDK.

```
import github.com/aliyun/alibaba-cloud-sdk-go/services/slb
```

2. Create an slbClient instance that contains all the SLB APIs.

```
slbClient := slb.NewClientWithAccessKey(
    "<your-region-id>",
    "<your-access-key-id>",
    "<your-access-key-secret>")
```

3. Use the xxx.CreateXXXRequest method to create a request.

The naming convention for the method is `${service}.Create${apiName}Request`, where

- **\${service}** is a service name in lowercase letters such as slb.
- **\${apiName}** is an API name such as DescribeLoadBalancers.

```
request := slb.CreateDescribeLoadBalancersRequest()
```

```
request.InstanceId = ""
```

4. Initiate a call.

```
response, err := slbClient.DescribeLoadBalancers(request)
```

5. Handle the response.

In normal cases, all returned fields are deserialized into the response. You can directly call `response.getXXX()` to obtain the response fields.

```
instanceStatus := response.Status
```

If an error (`err != nil`) occurs or you need the original HTTP response, you can use the following methods to obtain the original data:

```
// Obtain the original HTTP response. The response type is *http.Response.
httpResponse := response.GetOriginHttpResponse()

// Obtain the status code of the original HTTP response. The response type is int.
statusCode := response.GetHttpStatus()

// Obtain the header of the original HTTP response. The response type is map[string][]string.
headers := response.GetHttpHeaders()

// Obtain the content of the original HTTP response. The response type is []byte.
contentBytes := response.GetHttpContentBytes()

// Obtain the original HTTP response content and convert the content to a UTF-8 string. The response type is string.
contentString := response.GetHttpContentString()
```

2.13.2.4.2.4 Handle errors

Alibaba Cloud Apsara Stack SLB Go SDK returns error messages when errors occur on either the server or SDK side. The messages contain error details, that is, `ClientError` and `ServerError` in `sdk.errors`. The errors conform to the standard Go error interface, so they can be handled in a similar way as standard Go errors.

ClientError

When an error occurs to any call in the SLB Go SDK and cannot be handled automatically, the SLB Go SDK returns a `ClientError`.

You can use the following code to determine and obtain error information from the `ClientError`:

```
response, err := slbClient.DescribeLoadBalancers(request)
if clientError, ok := err.(*errors.ClientError); ok {
    // Obtain the error code.
    clientError.ErrorCode()
    // Obtain the error description.
```

```

clientError.Message()
// Obtain the original error, which may be nil.
clientError.OriginError()
}

```

ServerError

When a server returns an error response, the SLB Go SDK encapsulates the error response into a `ServerError` and returns it.

Note:

In this case, you can still obtain the original HTTP response from the encapsulated response.

You can execute the following code to determine and obtain error information from `ServerError` and `Response`:

```

response, err := slbClient.DescribeLoadBalancers(request)
if serverError, ok := err.(*errors.ServerError); ok {
    // Obtain the error code.
    serverError.ErrorCode()
    // Obtain the error description.
    serverError.Message()
    // Obtain the original HTTP response.
    response.GetOriginHttpResponse()
}

```

2.13.2.4.2.5 Customize configurations

The topic lists the custom configurations supported by Alibaba Cloud Apsara Stack SLB Go SDK.

Method

You can use the config module of the SLB Go SDK to customize configurations.

```

config := NewConfig().
    WithEnableAsync(true).
    WithGoRoutinePoolSize(5).
    WithMaxTaskQueueSize(1000)
client, err := slb.NewClientWithOptions("<region-id>", config, credential)

```

Note:

Currently, the config module of the SLB Go SDK does not support the following calling method:

```
config := &Config{EnableAsync: true,}
```

Supported custom configurations

The following table shows the supported custom configurations currently.

Configuration	Default value	Description
AutoRetry	true	Whether to enable the automatic retry
MaxRetryTime	3	The maximum number of retries With the automatic retry enabled, the maximum time consumption for a single call is Timeout (MaxRetryTime + 1).
Timeout	10time.Second	Timeout value. Full-link timeout value, containing establishing connection, redirecting, and reading response If the value is 0, no timeout occurs.
HttpTransport	nil	Enable the configuration of the underlying net/http client You can configure the original http.client of Go with this configuration, such as persistent connection.
EnableAsync	false	Whether to enable the asynchronous feature
MaxTaskQueueSize	1000	The length of the asynchronous queue, which takes effect only when EnableAsync=true If the queue is full, new calls are congested.
GoRoutinePoolSize	5	The maximum number of concurrent connections, which takes effect only when EnableAsync=true

2.13.2.4.2.6 Asynchronous calls

With the concurrent characteristic of the Go language, we recommend that you control the concurrent requests of SDK on the application layer. For your convenience, the Alibaba

Cloud Go SDK provides the concurrent calling method that can be directly used. The related concurrency control is achieved within SDK.

Enable the concurrent function for a client

In the following example, the `Credential` object is used to set up user credentials.

```
// The maximum number of concurrent connections.
poolSize := 10

// The maximum number of cacheable requests.
maxTaskQueueSize := 10000

// Enable the asynchronous feature when creating a client.
config := sdk.NewConfig().
    WithEnableAsync(true).
    WithGoRoutinePoolSize(poolSize).      // Optional. Default value: 5.
    WithMaxTaskQueueSize(maxTaskQueueSize) // Optional. Default value: 1000

// Use the custom configuration to initialize the client.
slbClient, err := slb.NewClientWithOptions("<your-region-id>", config, credential)

// Alternatively, enable the asynchronous feature after initializing the client.
client.EnableAsync(poolSize, maxTaskQueueSize)
```

Initiate asynchronous calls

The Alibaba Cloud Go SDK supports two methods of initiating asynchronous calls as follows :

- Use channel as the returned value.

```
// this will not block
responseChannel, errChannel := client.FooWithChan(request)
// this will block
response := <-responseChannel
err = <-errChanne
```

- Use callback to control the response.

```
// this will not block
blocker := client.FooWithCallback(request, func(response *FooResponse, err error) {
    // handle the response and err
})
// The blocker is (chan int) and is used to control the synchronization. If the returned
value is 1, the action succeeds. If the returned value is 0, the action fails.
// If <-blocker returns 0 and the action fails, the error message is transmitted to
callback by means of err.
// this will block
```

```
result := <-blocker
```

2.13.2.4.2.7 Use CommonRequest

If the product API that you want to call does not have the corresponding SDK, you can use the generic calling method (CommonRequest) to call the product APIs. By using the CommonRequest calling method, you can call any APIs.

Example: Call a RESTful API

The following code example shows how to use CommonRequest to call the API that lists all the Container Service cluster instances:

```
package main

import (
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk"
    "fmt"
)

func main() {
    client, err := sdk.NewClientWithAccessKey("{your_region_id}", "{your_access_key_id}", "{your_access_key_id}")
    if err != nil {
        panic(err)
    }

    request := requests.NewCommonRequest()
    request.Domain = "cs.aliyuncs.com"
    request.Version = "2015-12-15"
    // Because the API is a RESTful API, you must specify the value of the PathPattern field.
    request.PathPattern = "/clusters"
    response, err := client.ProcessCommonRequest(request)
    if err != nil {
        panic(err)
    }
    fmt.Print(response.GetHttpContentString())
}
```

}

2.13.2.4.2.8 Common errors

This topic describes the common errors when you use the Go SDK. Troubleshoot the problems based on the corresponding causes and solutions.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot automatically obtain the endpoint of the called service in the specified region.	Check whether the specified region ID and endpoint are correct. After obtaining the correct endpoint, use the following code to set the endpoint: <code>request.Domain = "<endpoint>"</code>
SDK.JsonUnmarshalError	Failed to unmarshal response, but you can get the data via response.StatusCode() and response.HttpContentString()	SDK response deserialization fails. In most cases, the cause is an inconsistency between the API metadata and the response structure received by the SDK, such as mismatched fields or an incorrect format.	For more information, see Response parsing .
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The request times out and all retry attempts fail.	- In scenarios such as cross-region calls or poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries. - If the problem persists and there are no issues with the network quality, we recommend that you submit a ticket.

Error code	Error message	Cause	Solution
SDK.AsyncFunctionNotEnabled	Async function is not enabled in client, please invoke 'client.EnableAsync()' function	An asynchronous API is called when the asynchronous request switch is not turned on.	Enable the asynchronous feature. For more information, see Asynchronous calls .

Response parsing

Ignore SDK deserialization failures and obtain the response attributes by extracting the original HTTP response.

Note:

Alibaba Cloud Apsara Stack Go SDK depends on JMESPath. Therefore, if the response content is in JSON format, you can directly use JMESPath to parse the response.

```
response, err := client.CreateInstance(request)
if err != nil {
    // Handle the exception.
    if clientErr, isClientErr := err.(*errors.ClientError); isClientErr {
        if clientErr.ErrorCode() == errors.JsonUnmarshalErrorCode {
            // You can obtain the original response data through our encapsulation
            methods.
            // The HTTP status code in the response. Type: int.
            statusCode := response.GetHttpStatus()
            // The HTTP header in the response. Type: map[string][]string.
            responseHeader := response.GetHttpHeaders()
            // The packet content in the response. Type: []byte.
            responseBytes := response.GetHttpContentBytes()
            // The packet content in the response. Type: string, equivalent to string(
            response.GetHttpContentBytes())`.
            responseContent := response.GetHttpContentString()
            // You can also directly obtain the original response. Type: net/http.Response.
            httpResponse := response.GetOriginHttpResponse()
        }
    }
}
```

```
}
```

2.13.2.5 .NET SDK

2.13.2.5.1 Quick start

Alibaba Cloud Apsara Stack SLB .NET SDK allows your to access SLB without performing complicated programming operations. This topic describes how to install and use the SLB .NET SDK.

Preparation

- To use the SLB .NET SDK, you must have an Apsara Stack tenant account as well as an AccessKey. For more information about how to obtain and view your AccessKey in the Apsara Stack console, see [Obtain an AccessKey pair](#).
- Obtain the SLB endpoint. For more information, see [Obtain an endpoint](#).
- The SLB .Net SDK applies to .NET Framework V4.0 and later.

Install SLB .NET SDK

To use the SDK of a service, you must install both the SDK and SDK core library. For example, to use the SLB .NET SDK, you must install both the SDK and the SDK core library. Install the SLB .NET SDK by using either of the following methods:

- Add DLL reference
 1. Download the DLL package from [.NET SDK](#), and decompress it to get the DLL files.
 2. Right-click your project in the Solution Explorer of Visual Studio and click **Reference**.
 3. In the menu that appears, click **Add Reference**.
 4. In the dialog box that appears, click **Browse**. Then select the downloaded DLL file and click **Confirm**.

- Add project reference
 1. Download the .NET SDK source code from the [Apsara Stack official website](#) .
 2. You can find a aliyun-net-openapi-XXX folder in the folder of the downloaded source code, and then locate a *.csproj file, which is the .NET project file. For example, find the aliyun-net-openapi-slb folder and then the aliyun-net-sdk-slb.csproj file.
 3. In Visual Studio, right-click your solution.
 4. Choose **Add > Existing Project**.
 5. In the dialog box that appears, select the .NET project file such as aliyun-net-sdk-slb.csproj and click **Open**.
 6. Right-click your project and choose **Reference > Add Reference** from the shortcut menu.

Usage

The following code example shows the three main steps to use the SLB .NET SDK:

1. Create and initialize a DefaultAcsClient instance.
2. Create an API request and set parameters.
3. Initiate the request and handle the response or exception.

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Profile;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.Slb.Model.V20140526;

class TestProgram
{
    static void Main(string[] args)
    {
        // Construct a client for initiating requests.
        IClientProfile profile = DefaultProfile.GetProfile(
            "<your-region-id>",
            "<your-access-key-id>",
            "<your-access-key-secret>");
        DefaultAcsClient client = new DefaultAcsClient(profile);
        try
        {
            // Construct a request.
            DescribeLoadBalancersRequest request = new DescribeLoadBalancersRequest
        (
            );
            request.PageSize = 10;
            // Initiate the request and obtain a response.
            DescribeLoadBalancersResponse response = client.GetAcsResponse(request);
            System.Console.WriteLine(response.TotalCount);
        }
        catch (ServerException ex)
        {
            System.Console.WriteLine(ex.ToString());
        }
        catch (ClientException ex)
        {
        }
    }
}
```

```
        System.Console.WriteLine(ex.ToString());  
    }  
}
```

2.13.2.5.2 Use the SDK

2.13.2.5.2.1 Install .NET SDK

This topic describes how to install Alibaba Cloud Apsara Stack SLB .NET SDK.

You can install the SLB .NET SDK by using either of the following methods:

- Add DLL reference
 1. Download the package containing the DLL file from [.NET SDK](#) and then extract the package to obtain the DLL file.
 2. In the Solution Explorer of Visual Studio, right-click your project and then select **Reference**.
 3. In the displayed menu, click **Add Reference**.
 4. In the displayed dialog box, click **Browse**. Select the downloaded DLL file and click **Confirm**.
- Add project reference
 1. Download the .NET SDK source code from the [Apsara Stack official website](#) .
 2. You can find an aliyun-net-openapi-XXX folder in the folder of the downloaded source code and then locate a *.csproj file, which is the .NET project file in the folder. For example, find the `aliyun-net-openapi-slb` folder and then the `aliyun-net-sdk-slb.csproj` file.
 3. In Visual Studio, right-click your solution.
 4. Choose **Add > Existing Project**.
 5. In the displayed dialog box, select the .NET project file such as the `aliyun-net-sdk-slb.csproj` file, and click **Open**.
 6. Right-click your project and choose **Reference > Add Reference** from the shortcut menu.

2.13.2.5.2.2 Configure identity verification credentials

When using the Alibaba Cloud .NET SDK to access Alibaba Cloud Apsara Stack services, you must provide an Alibaba Cloud account for authentication.

Currently, the SLB .NET SDK supports identity verification using AccessKeys. For details about how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

If you use an AccessKey as the access credential, you must configure your credential when initializing the client.

**Notice:**

Do not disclose any code containing your AccessKey (for example, do not commit the code to public GitHub projects). Otherwise, your Apsara Stack tenant account may be compromised.

```
IClientProfile clientProfile = DefaultProfile.GetProfile(
    "<your-region-id>", // Your region ID
    "<your-access-key-id>", // AccessKey ID of your Apsara Stack tenant account
    "<your-access-key-secret>"); // AccessKey Secret of your Apsara Stack tenant account
```

2.13.2.5.2.3 Initiate a call

This topic describes how to use the SLB .NET SDK to initiate a call.

1. Create a DefaultAcsClient instance.

```
DefaultAcsClient client = new DefaultAcsClient(clientProfile);
```

2. Create a request.

The naming convention for requests is `${apiName}Request`, where **`${apiName}`** is the API name such as `DescribeLoadBalancers`.

When the SDKs of multiple services are used, different requests may have the same name. Differentiate the requests by SDK package.

```
DescribeLoadBalancersRequest request = new DescribeLoadBalancersRequest();
```

```
request.PageSize = 10;
```

3. Initiate a call and handle the response.

```
DescribeLoadBalancersResponse response = client.GetAcsResponse(request);
```

In normal cases, all returned fields are deserialized into the response. You can directly call `response.getXXX()` to obtain the response fields.

```
System.Console.WriteLine(response.TotalCount);
```

2.13.2.5.2.4 Handle errors

If an error occurs on the server side or SDK side when you use Alibaba Cloud .NET SDK, the .NET SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Generally, you are not required to handle the errors returned by the Alibaba Cloud .NET SDK. You are only required to handle the errors on the server side according to the error message.

- `ServerException` is the error message on the server side.
- `ClientException` is the error message on the SDK side.

For example, if the following error occurs, modify the ID of AccessKey according to the detailed error message.

```
InvalidAccessKeyId.NotFound : Specified access key is not found.
```

To handle the errors returned by the .NET SDK, see the following code example for reference:

```
try
{
    CreateInstanceResponse response = client.GetAcsResponse(request);
    // Handle the response.
    // ...
}
catch (ServerException e)
{
    // Add your own error handling logic here.
    // For example, print the detailed error message.
    Console.WriteLine("ErrorCode=" + e.ErrorCode);
    Console.WriteLine("ErrorMessage=" + e.ErrorMessage);
    // If the problem is tricky, open a ticket and provide the RequestId for us.
    Console.WriteLine("ErrorCode=" + e.RequestId);
}
catch (ClientException e)
{
    // Add your own error handling logic here.
    // For example, print the detailed error message.
    Console.WriteLine("ErrorCode=" + e.ErrorCode);
    Console.WriteLine("ErrorMessage=" + e.ErrorMessage);
}
```

}

2.13.2.5.2.5 Use CommonRequest

If the product API that you want to call does not have the corresponding SDK, you can use the generic calling method (CommonRequest) to call the product APIs. By using the CommonRequest calling method, you can call any APIs.

Characteristics of CommonRequest calling

The CommonRequest calling method has the following characteristics:

- Light weight: You only need the core package to initiate the call, without downloading or installing the SDK of each product.
- Easy and convenient: You can call the latest API without updating the SDK.
- Fast iteration

Call an API by using CommonRequest

To make a CommonRequest request, you must specify the following parameters. You can obtain the values of these parameters from the API documents.

- Domain: specifies the service endpoint.
- Version: specifies the API version, in the format of YYYY-MM-DD.

You can get the API version from the common parameters in the API documents.

- Action: specifies the name of the API to be called.

You must obtain the **Action** parameter value and specify the API name in the form of `request.ApiName = "<Action>"`.

For example, to call the **RunInstances** API, initiate a CommonRequest request with `request.ApiName = "RunInstances"`.

Example: Call a RESTful API

The following code example shows how to use CommonRequest to call the API that lists all the Container Service cluster instances:

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.Core.Profile;

class Sample
{
    static void Main(string[] args)
    {
        // Construct a client instance for initiating requests.
        IClientProfile profile = DefaultProfile.GetProfile(
```

```
"<your-region-id>",
"<your-access-key-id>",
"<your-access-key-secret>");
DefaultAcsClient client = new DefaultAcsClient(profile);

try
{
    // Construct a request.
    CommonRequest request = new CommonRequest();
    request.Domain = "cs.aliyuncs.com";
    request.Version = "2015-12-15";

    // Because the API is a RESTful API, you must specify the value of the UriPattern
field. request.UriPattern = "/clusters";

    // Initiate the request and obtain a response.
    CommonResponse response = client.GetCommonResponse(request);
    System.Console.WriteLine(response.Data);
}
catch (ServerException ex)
{
    System.Console.WriteLine(ex.ToString());
}
catch (ClientException ex)
{
    System.Console.WriteLine(ex.ToString());
}
}
```

2.13.2.5.2.6 Common errors

This topic describes the common errors when you use the .NET SDK. Troubleshoot the problems based on the corresponding causes and solutions.

Error code	Cause	Solution
SDK.InvalidRegionId	SDK cannot automatically obtain the endpoint of the called product in the specified region.	Check if your endpoint is correct.
InvalidAccessKeyId. NotFound	The configured AccessKey ID is invalid.	Check if your AccessKey ID is correct.
SDK.ConnectionReset	The endpoint cannot be connected when you initiate a request.	Check if your network is available.

Error code	Cause	Solution
SDK.InvalidProfile	The DefaultProfile parameter that you provided when initializing DefaultAcsClient is invalid.	Make sure that the provided DefaultProfile parameter object is properly initialized and configured with corresponding parameters.
SDK.SessionTokenExpired	The DefaultProfile parameter that you provided when initializing DefaultAcsClient is invalid.	Make sure that the provided SessionToken parameter is in the validity period, which is generally one hour.
SignatureDoesNotMatch	The provided SessionToken is invalid or has expired.	Make sure that the provided DefaultProfile parameter object is properly initialized and configured with corresponding parameters.
SDK.InvalidProfile	The AccessKey Secret does not match the AccessKey ID.	Make sure that the provided AccessKey Secret is valid.

2.13.2.6 Obtain an AccessKey pair

You can obtain an AccessKey pair in the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center** >

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.13.2.7 Obtain an endpoint

You can obtain an endpoint of SLB in Apsara Stack Operations.

Procedure

1. Log on to Apsara Stack Operations.

For how to log on to Apsara Stack Operations, see **Operations of basic platforms > Apsara Stack Operations > Log on to Apsara Stack Operations** in Operations Guide .

2. Click **Products** in the left-side navigation pane.
3. Choose **Apsara Infrastructure Management Framework** in the product list to go to the Apsara Infrastructure Management Framework page.
4. Choose **Operations > Machine Operations**. The **Machine Operations** page appears.
5. Select a machine and then click **Terminal** to log on to the machine.

Machine Operations									
Search Allows fuzzy or batch search. Separate multiple machines with commas or space.				Reset	Exact Match		Machine Bucket Change	Machine Online/Offline	Refresh
Hostname	IP	Cluster	Project	IDC	Room	Rack	Warranty	Status	Actions
vm010012016112		tianji-A-3788	tianji	amtest72				GOOD	Terminal Machine Operation
a50e05101.cloud.e08.amtest72		tianji-A-3788	tianji	amtest72	A5-8	E08		GOOD	Terminal Machine Operation
a50e07101.cloud.e08.amtest72		tianji-A-3788	tianji	amtest72	A5-8	E08		GOOD	Terminal Machine Operation
a50e09001.cloud.e09.amtest72		tianji-A-3788	tianji	amtest72	A5-8	E09		GOOD	Terminal Machine Operation
vm010012016020		tianji-A-3788	tianji	amtest72				GOOD	Terminal Machine Operation

  \"c.sr.service_registration\": \"{\\\"ots.cluster_admin_dns_port\\\":\\\"9090\\\",\\\"ots.cluster_admin_dns_src_port\\\":\\\"21069\\\",\\\"ots.cluster_dns\\\":\\\"i.cn-qiandao-hu-sg-amtest85001-a.ots.env6.shuguang-ops.com\\\",\\\"ots.cluster_dns_port\\\":\\\"80\\\",\\\"ots.cluster_dns_src_port\\\":\\\"21038\\\",\\\"ots.cluster_name\\\":\\\"tianji-A-4423\\\",\\\"ots.cluster_rep_dns\\\":\\\"ir.cn-qiandao-hu-sg-amtest85001-a.ots.env6.shuguang-ops.com\\\",\\\"ots.cluster_rep_dns_port\\\":\\\"8080\\\",\\\"ots.cluster_rep_dns_src_port\\\":\\\"21054\\\",\\\"ots.data_file_max_copy\\\":\\\"3\\\",\\\"ots.data_file_min_copy\\\":\\\"3\\\",\\\"ots.endpoint_suffix\\\":\\\"cn-qiandao-hu-sg-d01.ots.env6.shuguang-ops.com\\\",\\\"ots.ha_smoketest_dns\\\":\\\"otsinnerha.cn-qiandao-hu-sg-d01.ots.env6.shuguang-ops.com\\\",\\\"ots.ha_smoketest_instance_id\\\":\\\"otsinnerhai\\\",\\\"ots.ha_smoketest_instance_name\\\":\\\"otsinnerha\\\",\\\"ots.link_file_max_copy\\\":\\\"3\\\",\\\"ots.link_file_min_copy\\\":\\\"3\\\",\\\"ots.monitor_accessid\\\":\\\"f6veRVcC07CYhM7w\\\",\\\"ots.\"
```

2.14 Virtual Private Cloud (VPC)

2.14.1 API reference

2.14.1.1 List of operations by function

The following tables list API operations available for use in a VPC.

Table 2-413: VPC operations

Operation	Description
CreateVpc	Creates a VPC.
DeleteVpc	Deletes a VPC.
DescribeVpcs	Queries created VPCs.
ModifyVpcAttribute	Modifies the name and description of a VPC.

Table 2-414: VSwitch operations

Operation	Description
CreateVSwitch	Creates a VSwitch.
DeleteVSwitch	Deletes a VSwitch.
ModifyVSwitchAttribute	Modifies the name and description of a VSwitch.
DescribeVSwitches	Queries created VSwitches.

Table 2-415: VRouter operations

Operation	Description
ModifyVRouterAttribute	Modifies the name and description of a VRouter.
DescribeVRouters	Queries VRouters in a specified region.
CreateRouteEntry	Creates a custom route entry on a VRouter or VBR.
DeleteRouteEntry	Deletes a route entry in the routing table of a VRouter or VBR.
DescribeRouteTables	Queries route entries in a routing table.

Table 2-416: EIP operations

Operation	Description
AllocateEipAddress	Creates an Elastic IP address (EIP).

Operation	Description
AssociateEipAddress	Binds an EIP to a VPC instance in the same region.
UnassociateEipAddress	Unbinds an EIP from a VPC instance.
ModifyEipAddressAttribute	Modifies the name, description, and peak bandwidth of an EIP.
ReleaseEipAddress	Releases a specified EIP.
DescribeEipAddresses	Queries created EIPs.

Table 2-417: Router interface operations

Operation	Description
CreateRouterInterface	Creates a router interface.
ConnectRouterInterface	The initiator router interface initiates a connection to the receiver router interface.
DeactivateRouterInterface	Deactivates a router interface.
ModifyRouterInterfaceSpec	Modifies the specifications of a router interface.
DeleteRouterInterface	Deletes a router interface.
DescribeRouterInterfaces	Queries router interfaces in a specified region.
ActivateRouterInterface	Activates an inactive router interface.
ModifyRouterInterfaceAttribute	Modifies the configurations of a router interface.

Table 2-418: Physical connection operations

Operation	Description
CreatePhysicalConnection	Creates a physical connection.
CancelPhysicalConnection	Cancels a physical connection before it is enabled. After you cancel the physical connection, it enters the Canceled state.
DeletePhysicalConnection	Deletes a physical connection.
ModifyPhysicalConnectionAttribute	Modifies the configurations of a physical connection.

Operation	Description
DescribePhysicalConnections	Queries physical connections in a specified region.
TerminatePhysicalConnection	Terminates a physical connection after it is enabled.
EnablePhysicalConnection	Enables a physical connection that is in the Confirmed state. After you have enabled the physical connection, it enters the Enabled state.

Table 2-419: VBR operations

Operation	Description
CreateVirtualBorderRouter	Creates a virtual border router (VBR).
DeleteVirtualBorderRouter	Deletes a VBR.
DescribeVirtualBorderRouters	Queries created VBRs.
DescribeVirtualBorderRoutersForPhysicalConnection	Queries the VBRs created for a physical connection , including VBRs that belong to the physical connection owner and other accounts.
ModifyVirtualBorderRouterAttribute	Modifies the configurations of a VBR.
TerminateVirtualBorderRouter	Terminates a VBR.
RecoverVirtualBorderRouter	Recovers a terminated VBR.

Table 2-420: NAT Gateway operations

Operation	Description
CreateNatGateway	Creates a NAT Gateway.
DeleteNatGateway	Deletes a NAT specified Gateway.
ModifyNatGatewaySpec	Modifies the type of a NAT Gateway.
ModifyNatGatewayAttribute	Modifies the configurations of a NAT Gateway.

Operation	Description
DescribeNatGateways	Queries created NAT Gateways.
CreateBandwidthPackage	Creates a NAT service plan.
ModifyBandwidthPackageSpec	Modifies the bandwidth of a specified NAT service plan.
DescribeBandwidthPackages	Queries NAT service plans in a specified region.
ModifyBandwidthPackageAttribute	Modifies the name and description of a specified NAT service plan.
DeleteBandwidthPackage	Deletes a specified NAT service plan.
AddBandwidthPackageIps	Adds public IP addresses to a NAT service plan.
RemoveBandwidthPackageIps	Removes public IP addresses from a NAT service plan.
CreateForwardEntry	Adds DNAT entries to a DNAT table.
DeleteForwardEntry	Deletes a specified DNAT entry.
ModifyForwardEntry	Modifies a specified DNAT entry.
DescribeForwardTableEntries	Queries DNAT entries in a specified DNAT table.
CreateSnatEntry	Adds SNAT entries to a SNAT table.
DeleteSnatEntry	Deletes a specified SNAT entry.
ModifySnatEntry	Modifies the SNATed IP address (public IP address) in a specified SNAT entry.
DescribeSnatTableEntries	Queries SNAT entries in a specified SNAT table.

2.14.1.2 Call VPC APIs

2.14.1.2.1 Request structure

When you call a VPC operation, an HTTP GET request is sent to the endpoint of the VPC operation. You must add the relevant request parameters to the request based on the operation description. After the operation is called, the system returns the processing result. Requests and responses are encoded in UTF-8.

VPC uses the RPC API. You can call VPC API operations by sending HTTP GET requests.

The request structure is as follows:

```
http://Endpoint/?Action=xx&Parameters
```

In the request,

- **Endpoint:** The endpoint for the VPC API is `vpc.example.com`.

Note:

`example.com` is a custom domain name. You can obtain endpoints in Apsara Stack Operations console. For more information, see [Obtain an endpoint](#).

- **Action:** The operation that you want to perform. For example, you can call **DescribeVpcs** to query all created VPC instances.
- **Version:** The version of the API that you want to use. The current VPC API version is 2016-04-28.
- **Parameters:** Request parameters that are separated with ampersands (&).

Request parameters consist of common parameters and custom API parameters.

Common parameters include the API version and authentication information. For more information, see [Common parameters](#).

The following code provides an example of how to call the **DescribeVpcs** operation to query the created VPCs.

Note:

To improve readability, the API request is displayed in the following format:

```
https://vpc.example.com/?Action=DescribeVpcs
&Format=xml
&Version=2014-05-15
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2012-06-01T12:00:00Z
```

2.14.1.2.2 API authorization

To ensure the security of your account, we recommend that you call VPC APIs as a RAM user. Before you can use a RAM account to call a VPC API, you must create a RAM account and assign corresponding permissions to it.

For more information about VPC resources and APIs you can assign permissions on, see [RAM authentication](#).

2.14.1.2.3 Request signature

To ensure the security of your API, you must sign the API request. Apsara Stack uses the signature in the request for identity verification.

Apsara Stack implements symmetric encryption through an AccessKey pair (AccessKey ID and AccessKey Secret) to authenticate the request sender. AccessKey pairs are an identity credential issued to Apsara Stack tenant accounts and RAM users (similar to the login password). The AccessKey ID is used to identify the user. The AccessKey Secret is used to encrypt the signature string on the client side and to verify the signature string on the server side. The AccessKey Secret must be kept strictly confidential. For more information about how to create an AccessKey pair, see [Obtain an AccessKey pair](#).

For an RPC API, you must add the signature to the API request in the following format:

```
https://endpoint/?SignatureVersion=1.0&SignatureMethod=HMAC-SHA1&Signature=xxxx%  
xxxx%3D&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf
```

Take **DescribeVpcs** as an example. If the AccessKey ID is `testid` and the AccessKey Secret is `testsecret`, the original request URL is as follows:

```
http://vpc.example.com/?Action=DescribeVpcs  
&Timestamp=2016-02-23T12:46:24Z  
&Format=XML  
&AccessKeyId=testid  
&SignatureMethod=HMAC-SHA1  
&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf  
&Version=2016-04-28  
&SignatureVersion=1.0
```

Follow these steps to calculate the signature:

1. Use the request parameters to create the string to be signed.

```
GET&%2F&AccessKeyId%3Dtestid&Action%3DDescribeVpcs&Format%3DXML&  
SignatureMethod%3DHMAC-SHA1&SignatureNonce%3D3ee8c1b8-83d3-44af-a94f-  
4e0ad82fd6cf&SignatureVersion%3D1.0&TimeStamp%3D2016-02-23T12%253A46%  
253A24Z&Version%3D2014-05-15
```

2. Calculate the HMAC value of the string to be signed.

Append an ampersand (&) to the AccessKey Secret, which will be used as the key to calculate the HMAC value. In this example, the key is `testsecret&`.

```
CT9X0VtwR86fNWSnsc6v8YGOjuE=
```

3. Add the signature to the request parameters:

```
http://vpc.example.com/?Action=DescribeVpcs  
&Timestamp=2016-02-23T12:46:24Z  
&Format=XML
```

```
&AccessKeyId=testid
&SignatureMethod=HMAC-SHA1
&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf
&Version=2016-04-28
&SignatureVersion=1.0
&Signature=xxxx%xxxx%3D
```

2.14.1.2.4 Obtain an AccessKey pair

You can obtain an AccessKey pair in the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.14.1.2.5 Obtain an endpoint

You can obtain the endpoint of a VPC in Apsara Stack Operations.

Procedure

1. Log on to Apsara Stack Operations.

For how to log on to Apsara Stack Operations, see **Operations of basic platforms >**

Apsara Stack Operations > Log on to Apsara Stack Operations in Operations Guide .

2. Click **Products** in the left-side navigation pane.

3. Choose **Apsara Infrastructure Management Framework** in the product list to go to the Apsara Infrastructure Management Framework page.
4. Choose **Operations > Machine Operations**. The **Machine Operations** page appears.
5. Select a machine and then click **Terminal** to log on to the machine.

Machine Operations											
Search Allows fuzzy or batch search. Separate multiple machines with commas or space. Reset ☐ Exact Match Machine Bucket Change Machine Online/Offline Refresh											
Hostname	IP	Cluster	Project	IDC	Room	Rack	Warranty	Status	Actions	Terminal	Machine Operation
vm010012016112		tianji-A-3788	tianji	amtest72				GOOD		Terminal	Machine Operation
a50e05101.cloud.e08.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E08		GOOD		Terminal	Machine Operation
a50e07101.cloud.e08.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E08		GOOD		Terminal	Machine Operation
a50e09001.cloud.e08.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E09		GOOD		Terminal	Machine Operation
vm010012016020		tianji-A-3788	tianji	amtest72				GOOD		Terminal	Machine Operation
a50f11014.cloud.f11.amtest72		tianji-A-3788	tianji	amtest72	A5-6	F11		GOOD		Terminal	Machine Operation
a50e09106.cloud.e10.amtest72		tianji-A-3788	tianji	amtest72	A5-6	E10		GOOD		Terminal	Machine Operation

6. Run the following command to obtain the JSON data:

```
curl -l "http://127.0.0.1:7070/api/v3/column/c.sr.service_registration,c.sr.id?c.sr.service_registration"
```

```
{
  "c.sr.id": "vpc-controller",
  "c.sr.service_registration": "{\n\"db.vpcregiondb.name\": \"vpcregiondb\", \"db.vpcregiondb.passwd\": \"caMjyyf1cGhpt63k\", \"db.vpcregiondb.port\": \"3098\", \"db.vpcregiondb.url\": \"vpcregiondb.mysql.minirds.env12.ops.shuguang.com\", \"db.vpcregiondb.user\": \"vpcregiondb\", \"mvss.dns\": \"mvss.env12.ops.shuguang.com\", \"mvss.ips\": \"\", \"mvss.vips\": \"\", \"vpcmaster.dns\": \"virtualmaster.env12.ops.shuguang.com\", \"vpcmaster.ips\": \"\", \"vpcmaster.vips\": \"\", \"vpcmaster.vips\": \"9627:9627\"}",
},
{
  "c.sr.id": "vpc-xnet",
  "c.sr.service_registration": "{\n\"db.xnet.name\": \"xnet\", \"db.xnet.passwd\": \"5Ljqr4nddwoaWisd\", \"db.xnet.port\": \"3096\", \"db.xnet.url\": \"xnet.mysql.minirds.env12.ops.shuguang.com\", \"db.xnet.user\": \"xnet\", \"xnet.dns\": \"xnet.env12.ops.shuguang.com\", \"xnet.ips\": \"10.12.16.208\", \"xnet.vips\": \"\", \"xnet.vips\": \"8000,8001,10152,9997,8087:80,8000,8001,10152,9997,8087\"}",
},
{
  "c.sr.id": "vpc-yaochi",
  "c.sr.service_registration": "{\n\"vbs.ips\": \"10.12.16.208,10.12.16.209\", \"vpc-inner.openapi.endpoint\": \"vpc-inner.env12.ops.shuguang.com\", \"vpc-internal.openapi.endpoint\": \"vpc-internal.env12.shuguang.com\", \"vpc.base.endpoint\": \"vbs.env12.ops.shuguang.com\", \"vpc.driver.endpoint\": \"vpcdriver.env12.ops.shuguang.com\", \"vpc.openapi.endpoint\": \"vpc.env12.shuguang.com\", \"vpcyaochidb.db.host\": \"vpcyaochidb.mysql.minirds.env12.ops.shuguang.com\", \"vpcyaochidb.db.name\": \"vpcyaochidb\", \"vpcyaochidb.db.password\": \"bzobaj1qrNNhm5za\", \"vpcyaochidb.db.port\": \"3095\", \"vpcyaochidb.db.user\": \"vpcyaochidb\"}",
}
}
```

7. Obtain the endpoint of a VPC based on the ID (vpc-yaochi) and the key value (vpc.openapi.endpoint) of the VPC service.

2.14.1.3 RAM authentication

Before calling a VPC API using a RAM user, you must use an Apsara Stack tenant account to create an authorization policy to assign permissions to the RAM user. In the authorization

policy, an Alibaba Cloud Resource Name (ARN) is used as the unique identifier of the resource to authorize.

VPC resources

The following table lists the VPC resources that can be authorized and their corresponding ARN formats.

Resource type	ARN format
Virtual Private Cloud (VPC)	acs:vpc:\$regionid:\$accountid:vpc/\$vpcid
	acs:vpc:\$regionid:\$accountid:vpc/*
	acs:vpc:*\$accountid:vpc/*
VRouter	acs:vpc:\$regionid:\$accountid:vrouter/\$vrouterid
	acs:vpc:\$regionid:\$accountid:vrouter/*
	acs:vpc:*\$accountid:vrouter/*
VSwitch	acs:vpc:\$regionid:\$accountid:vswitch/\$vswitchid
	acs:vpc:\$regionid:\$accountid:vswitch/*
	acs:vpc:*\$accountid:vswitch/*
Routing table	acs:vpc:\$regionid:\$accountid:routetable/\$routetableid
	acs:vpc:\$regionid:\$accountid:routetable/*
	acs:vpc:*\$accountid:routetable/*
Elastic IP Address (EIP)	acs:vpc:\$regionid:\$accountid:eip/\$allocationid
	acs:vpc:\$regionid:\$accountid:eip/*
	acs:vpc:*\$accountid:eip/*
NAT Gateway	acs:vpc:\$regionid:\$accountid:natgateway/\$natgatewayid
	acs:vpc:\$regionid:\$accountid:natgateway/*
	acs:vpc:*\$accountid:vpc/*
NAT Gateway service plan	acs:vpc:\$regionid:\$accountid:bandwidthpackage/\$bandwidthpackageid
	acs:vpc:\$regionid:\$accountid:bandwidthpackage/*
	acs:vpc:*\$accountid:vpc/*
Forwarding table	acs:vpc:\$regionid:\$accountid:forwardtable/\$forwardtableid
	acs:vpc:\$regionid:\$accountid:forwardtable/*
	acs:vpc:*\$accountid:vpc/*

Resource type	ARN format
SNAT table	acs:vpc:\$regionid:\$accountid:snattable/\$snattableid
	acs:vpc:\$regionid:\$accountid:snattable/*
	acs:vpc:*\$accountid:vpc/*
General resource	acs:vpc:\$regionid:\$accountid:*
	acs:vpc:*\$accountid:*

\$regionid/\$accountid/\$vrouterid are IDs of the specific resources, * represents all resources.

VPC API operations

The following table lists the API operations that can be authorized and their corresponding ARN formats.

Operation	ARN format
vpc:CreateVpc	acs:vpc:\$regionid:\$accountid:vpc/*
vpc>DeleteVpc	acs:vpc:\$regionid:\$accountid:vpc/\$vpcid
vpc:DescribeVpcs	vpc:\$regionid:\$accountid:vpc/*
vpc:ModifyVpcAttribute	acs:vpc:\$regionid:\$accountid:vpc/\$vpcid
vpc:DescribeVRouters	acs:vpc:\$regionid:\$accountid:vrouter/*
	The VRouter ID is specified: "vpc:Vpc":"acs:vpc:\$regionid:\$accountid:vpc/\$vpcid"
	The VRouter ID is not specified: "vpc:Vpc":"acs:vpc:\$regionid:\$accountid:vpc/*"
vpc:ModifyVRouterAttribute	acs:vpc:\$regionid:\$accountid:vrouter/\$vrouterid
vpc:CreateVSwitch	acs:vpc:\$regionid:\$accountid:vswitch/*

2.14.1.4 Common parameters

Common request parameters

Common request parameters are request parameters that you must use when you call each API.

Table 2-421: Common request parameters

Name	Type	Required	Description
Format	String	No	The format of the response. Valid values: JSON (default) XML

Name	Type	Required	Description
Version	String	Yes	The API version in the format of YYYY-MM-DD. Valid value: 2016-04-28
AccessKeyId	String	Yes	The AccessKey ID that you use to call an API.
Signature	String	Yes	The signature result string.
SignatureMethod	String	Yes	The algorithm used to create the request signature. Valid value: HMAC-SHA1
Timestamp	String	Yes	The timestamp of the request. The timestamp uses UTC and it complies with the ISO 8601 standard. Its format is YYYY-MM-DDThh:mm:ssZ. For example, 20:00:00 on January 10, 2013 in China Standard Time (UTC +8) is written as 2013-01-10T12:00:00Z.
SignatureVersion	String	Yes	The version of the signature algorithm. Valid value: 1.0
SignatureNonce	String	Yes	A unique random number that is used to prevent network replay attacks. You must use different random numbers for different requests.

Example

```
http://vpc.example.com/?Action=DescribeVpcs
&Timestamp=2016-02-23T12:46:24Z
&Format=XML
&AccessKeyId=testid
&SignatureMethod=HMAC-SHA1
&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf
&Version=2016-04-28
&SignatureVersion=1.0
```

Common response parameters

API responses use a unified format. 2xx HTTP status codes indicate a successful invocation . 4xx or 5xx HTTP status codes indicate a failed invocation. The responses can be returned

in JSON or XML format. The XML format is used by default. You can specify the format when calling an API.

Each time you send a request to call an API, the system returns a unique identifier

RequestId, regardless of whether the invocation is successful or not.

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
  <!--Result root node-->
  <API name+Response>
    <!--Returned request tag-->
    <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
    <!--Returned results-->
  </API name+Response>
```

- JSON format

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /*Returned results*/
}
```

2.14.1.5 VPC

2.14.1.5.1 CreateVpc

You can call this operation to create a VPC in a specified region.

When you call this operation, take note of the following items:

- You must specify the IP address range of the VPC in the form of a CIDR block. You can use the standard private IP address ranges and their subsets as the IP address range of the VPC. The standard IP address ranges include 10.0.0.0/8, 172.16.0.0/12, and 192.168.0.0/16. The allowed block size is between a /24 netmask and a /8 netmask. The default IP address range is 172.16.0.0/12.
- The CIDR block cannot be modified after the VPC is created.
- Each VPC can contain a maximum of 15,000 cloud instances.
- A VRouter and a routing table are automatically created after a VPC is created.
- A maximum of three client-side CIDR blocks can be added to a VPC. If a client-side CIDR block is a subset of another client-side CIDR block, the one with the shorter netmask takes effect. For example, if there are two CIDR blocks 10.0.0.0/8 and 10.1.0.0/16, only 10.0.0.0/8 takes effect.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>CreateVpc</code> .
RegionId	String	Yes	The region ID of the VPC. You can call the DescribeRegions operation to query the latest region list.
CidrBlock	String	No	The IP address range of the VPC in CIDR block form. The following IP address ranges and their subsets can be used: • 10.0.0.0/8 • 172.16.0.0/12 (default) • 192.168.0.0/16
VpcName	String	No	The name of the VPC. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the VPC. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Parameter	Type	Required	Description
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.
UserCidr	String	No	The client-side CIDR block. Separate multiple CIDR blocks with commas (.). You can configure a maximum of three CIDR blocks.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VpcId	String	The ID of the VPC.
VRouterId	String	The ID of the VRouter.
RouteTableId	String	The ID of the routing table.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateVpc
&RegionId=cn-hangzhou
&CidrBlock=10.10.0.0/24
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateVpcResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
  <RouteTableId>vtb-bp145q7glnuzdxxxxxxx</RouteTableId>
  <VRouterId>vrt-bp1lhl0taikrtxxxxxxx</VRouterId>
  <VpcId>vpc-bp15zckdt37xxxxxxx</VpcId>
```

```
</CreateVpcResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0",
  "RouteTableId": "vtb-bp145q7glnuzdxxxxxxx",
  "VRouterId": "vrt-bp1lhl0taikrtxxxxxxx",
  "VpcId": "vpc-bp15zckdt37pqxxxxxxx"
}
```

2.14.1.5.2 DeleteVpc

You can call this operation to delete a VPC.

When you call this operation, make sure that the following requirements are met:

- Before you delete a VPC, ensure that you have released or removed all resources in the VPC, such as VSwitches, cloud instances, and router interfaces.
- Only VPCs in the Available state can be deleted.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteVpc.
VpcId	String	Yes	The ID of the VPC to delete.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteVpc
&VpcId=vpc-25eq58pl3xxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteVpcResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
```

```
</DeleteVpcResponse>
```

- JSON format

```
{  
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"  
}
```

2.14.1.5.3 DescribeVpcs

You can call this operation to query created VPCs in a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVpcs.
RegionId	String	No	The region ID of the VPC. You can call the DescribeRegions operation to query the latest region list.
VpcId	String	No	The ID of the VPC. A maximum of 20 VPC IDs can be specified. You can separate multiple VPC IDs with commas (,).
IsDefault	Boolean	No	Specifies whether to query the default VPC in the specified region. Valid values: • true: (default) All VPCs in the specified region are queried. • false: The default VPC is not queried.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
Vpcs	List	The details about the VPC. For more information, see the Vpcs list.

Table 2-422: Vpcs list

Parameter	Type	Description
VpcId	String	The ID of the VPC.
RegionId	String	The region ID of the VPC.
Status	String	The status of the VPC. Valid values: - Pending: The VPC is being configured. - Available: The VPC is available.
VpcName	String	The name of the VPC.
VSwitchIds	String	The list of VSwitches in the VPC.
CidrBlock	String	The CIDR block of the VPC.
VRouterId	String	The ID of the VRouter.
Description	String	The description of the VPC.
CreationTime	String	The time when the VPC was created.
IsDefault	Boolean	Indicates whether the VPC is the default VPC in the region.
UserCidrs	String	The list of client-side CIDR blocks.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeVpcs
&RegionId=cn-hangzhou
&CidrBlock=10.10.0.0/24
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >

```

2.14.1.5.4 ModifyVpcAttribute

You can call this operation to modify the name and description of a VPC.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVpcAttribute.
VpcId	String	Yes	The ID of the VPC.
VpcName	String	No	The name of the VPC. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the VPC. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyVpcAttribute
&VpcId=vpc-257gq642nxxxxxxxxx
&VpcName=Vpc02
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyVpcAttributeResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ModifyVpcAttributeResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.5.5 DescribeVpcAttribute

You can call this operation to query the configurations of a VPC.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVpcAttribute.
VpcId	String	Yes	The ID of the VPC to query.
RegionId	String	Yes	The region ID of the VPC.
IsDefault	Boolean	No	Specifies whether the VPC is the default VPC. Valid values: - false: The VPC is not the default VPC. - true: The VPC is the default VPC.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VpcName	String	The name of the VPC.
Description	String	The description of the VPC.
IsDefault	Boolean	Indicates whether the VPC is the default VPC.
VRouterId	String	The ID of the VRouter.

Parameter	Type	Description
VpcId	String	The ID of the VPC.
CidrBlock	String	The CIDR block of the VPC.
VSwitchIds	List	The list of VSwitches in the VPC.
Status	String	The status of the VPC.
CreationTime	String	The time when the VPC was created.
CloudResources	List	The list of resources in the VPC.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeVpcAttribute
&VpcId=vpc-bp13cwaie5zzbxxxxxxx
&RegionId=cn-hangzhou
&CommonParameters
```

Sample responses

2.14.1.6 VRouter

2.14.1.6.1 DescribeVRouters

You can call this operation to query VRouters in a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVRouters.
RegionId	String	No	The region ID of the VPC. You can call the DescribeRegions operation to query the latest region list.
VRouterId	String	No	The ID of the VRouter.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
VRouters	JSON string	The details about the VRouter.
Vpcs elements		
VRouterId	String	The ID of the VRouter.
RegionId	String	The region ID of the VPC.
VpcId	String	The ID of the VPC to which the VRouter belongs.

Parameter	Type	Description
RouteTableIds	String	The ID of the routing table for the VRouter.
VRouterName	String	The name of the VRouter.
Description	String	The description of the VRouter.
CreationTime	String	The time when the VRouter was created.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeVRouters
&RegionId=us-west-1
&Common request parameters
```

Sample responses

2.14.1.6.2 ModifyVRouterAttribute

You can call this operation to modify the name and description of a VRouter.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVRouterAttribute.
VRouterId	String	Yes	The ID of the VRouter.
VRouterName	String	No	The name of the VRouter. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with http:// or https://.
Description	String	No	The description of the VRouter. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with http:// or https://.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyVRouterAttribute
```

```
&VRouterId=vrt-25bezxxxxxxx
&VRouterName=VRouter2
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyVRouterAttributeResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ModifyVRouterAttributeResponse>
```

- JSON format

```
{

  "RouteTableId": "vtb-bp145q7gluzdxxxxxxx",
  "VRouterId": "vrt-bp1lhl0taikrtxxxxxxx",
  "VpcId": "vpc-bp15zckdt37pqxxxxxxx"
}
```

2.14.1.7 VSwitch

2.14.1.7.1 CreateVSwitch

You can call this operation to create a VSwitch in a VPC.

When you call this operation, take note of the following items:

- A maximum of 24 VSwitches can be created in a VPC.
- The first IP address and last three IP addresses of each VSwitch are reserved. For example, if the CIDR block of a VSwitch is 192.168.1.0/24, IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved.
- The number of cloud instances under a VSwitch cannot exceed the remaining capacity of the VPC. The remaining capacity is the difference between 15,000 and the current number of cloud instances.
- A cloud instance can belong to only one VSwitch.
- VSwitches do not support broadcasting or multicasting. After a VSwitch is created, its CIDR block cannot be modified.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>CreateVSwitch</code> .
ZoneId	String	Yes	The ID of the zone to which the VSwitch belongs. You can call the DescribeZones operation to query the latest zone list.
CidrBlock	String	Yes	The CIDR block of the VSwitch. It must meet the following requirements: • The CIDR block size of a VSwitch must be between a /29 netmask and a /16 netmask. • The CIDR block of a VSwitch must be within the range of the CIDR block of the VPC to which the VSwitch belongs. • The CIDR block of a VSwitch cannot be the same as the destination CIDR block in the route entry of the VPC. However, it can be a subset of the destination CIDR block. • If the CIDR blocks of your VSwitch and VPC are the same, only one VSwitch can be created for the VPC.
VpcId	String	Yes	The ID of the VPC to which the VSwitch belongs.
VSwitchName	String	No	The name of the VSwitch. The name must be 2 to 128 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Parameter	Type	Required	Description
Description	String	No	The description of the VSwitch. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VSwitchId	String	The ID of the VSwitch.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateVSwitch
&CidrBlock=172.16.1.0/24
&VpcId=vpc-257gq64xxxxxxxxx
&ZoneId=cn-beijing-a
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateVSwitchResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
  <VSwitchId>vsw-25nauexxxxxxxx
</VSwitchId>
</CreateVSwitchResponse>
```

- JSON format

```
{
```

```
"RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0",  
"VSwitchId": "vsw-25naue4xxxxxxxxx"  
}
```

2.14.1.7.2 DeleteVSwitch

You can call this operation to delete a VSwitch.

When you call this operation, make sure that the following requirements are met:

- Before you delete a VSwitch, ensure that you have released or removed all resources in the VSwitch, such as cloud instances and router interfaces.
- Only VSwitches in the Available state can be deleted.
- You cannot delete a VSwitch from a VPC in which a VSwitch or route entry is being created or deleted.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteVSwitch.
VSwitchId	String	Yes	The ID of the VSwitch to delete.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteVSwitch  
&VSwitchId=vsw-25naue4xxxxxxxxx  
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >  
<DeleteVSwitchResponse>  
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
```

```
</DeleteVSwitchResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.7.3 ModifyVSwitchAttribute

You can call this operation to modify the name and description of a VSwitch.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVSwitchAttribute.
VSwitchId	String	Yes	The ID of the VSwitch.
VSwitchName	String	No	The name of the VSwitch. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the VSwitch. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyVSwitchAttribute
&VSwitchId=vsw-25nauexxxxxxxx
&VSwitchName=VS02
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyVSwitchAttributeResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ModifyVSwitchAttributeResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.7.4 DescribeVSwitches

You can call this operation to query created VSwitches.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVSwitches.
RegionId	String	Yes	The region ID of the VPC to which the VSwitch belongs. You can call the DescribeRegions operation to query the latest region list.
VpcId	String	No	The ID of the VPC.
ZoneId	String	No	The ID of the zone to which the VSwitch belongs. You can call the DescribeZones operation to query the latest zone list.
VSwitchId	String	No	The ID of the VSwitch.

Parameter	Type	Required	Description
IsDefault	Boolean	No	Specifies whether to query the default VSwitch in the specified region. Valid values: • true: (default) All VSwitches in the specified region are queried. • false: The default VSwitch is not queried.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
VSwitches	JSON string	The details about the VSwitch.
VSwitches elements		
VpcId	String	The ID of the VPC to which the VSwitch belongs.
VSwitchId	String	The ID of the VSwitch.
Status	String	The status of the VSwitch. Valid values: • Pending: The VSwitch is being configured. • Available: The VSwitch is available.
CidrBlock	String	The CIDR block of the VSwitch.
ZoneId	String	The zone to which the VSwitch belongs.
AvailableIpAddressCount	Integer	The number of available IP addresses in the VSwitch.
VSwitchName	String	The name of the VSwitch.
Description	String	The description of the VSwitch.

Parameter	Type	Description
CreationTime	String	The time when the VSwitch was created.
IsDefault	Boolean	Indicates whether the VSwitch is the default VSwitch in the zone.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeVSwitches
&VSwitchId=vsw-25eq58xxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DescribeVSwitchesResponse>

}
```

2.14.1.7.5 DescribeVSwitchAttributes

You can call this operation to query the configurations of a VSwitch.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVSwitchAttributes.
VSwitchId	String	Yes	The ID of the VSwitch to query.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
RouteTable	List	The routing table information of the VSwitch.
Description	String	The description of the VSwitch.
IsDefault	Boolean	Indicates whether the VSwitch is the default VSwitch .
ZoneId	String	The zone to which the VSwitch belongs.
AvailableIpAddressCount	Integer	The number of available IP addresses.
VSwitchId	String	The ID of the VSwitch.
VpcId	String	The ID of the VPC to which the VSwitch belongs.
CidrBlock	String	The CIDR block of the VSwitch.
Status	String	The status of the VSwitch.
VSwitchName	String	The name of the VSwitch.
CreationTime	String	The time when the VSwitch was created.
CloudResources	String	The cloud resources under the VSwitch.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeVSwitchAttributes

```

2.14.1.8 Routing table**2.14.1.8.1 CreateRouteEntry**

You can call this operation to create route entries in a VRouter or VBR.

When you call this operation to create route entries in a VRouter, make sure that the following requirements are met:

- A routing table can contain a maximum of 48 custom route entries.
- The destination CIDR block (**DestinationCidrBlock**) of a custom route entry and the CIDR block of a VSwitch in the VPC cannot be the same as each other nor a subset of each other.
- The destination CIDR block (**DestinationCidrBlock**) of a custom route entry cannot be 100.64.0.0/10 or a subset of 100.64.0.0/10.
- The destination CIDR blocks (**DestinationCidrBlock**) of route entries in the same routing table cannot be the same.
- If the specified destination CIDR block (**DestinationCidrBlock**) is an IP address, the /32 netmask is used.
- Multiple custom route entries can be destined for the same next hop (**NextHopId**).
- The next hop (**NextHopId**) of the custom route entry must belong to the same VPC as the routing table.
- ECMP route entries can be configured through the **NextHopList** parameter.
 - When adding a normal custom route entry (non-ECMP route entry), you must specify **DestinationCidrBlock**, **NextHopType**, and **NextHopId**, and you cannot specify **NextHopList**.
 - When adding an ECMP route entry, you must specify **DestinationCidrBlock** and **NextHopList**, and you cannot specify **NextHopType** and **NextHopId**.

When you call this operation to create route entries in a VBR, make sure that the following requirements are met:

- A routing table can contain a maximum of 48 custom route entries.
- The **NextHopList** parameter is not supported.
- The destination CIDR block (**DestinationCidrBlock**) of a custom route entry cannot be 100.64.0.0/10 or a subset of 100.64.0.0/10.
- The destination CIDR blocks (**DestinationCidrBlock**) of route entries in the same routing table cannot be the same.
- If the specified destination CIDR block (**DestinationCidrBlock**) is an IP address, the /32 netmask is used.
- Multiple custom route entries can be destined for the same next hop (**NextHopId**).
- The next hop (**NextHopId**) of a custom route entry must be a router interface associated with the VBR.

- Route entries can be created only when the VBR is in the Active state and the physical connection corresponding to the VBR is in the Enabled state. Route entries cannot be created if the physical connection has overdue payments.
- When adding a normal custom route entry (non-ECMP route entry), you must specify **DestinationCidrBlock**, **NextHopType**, and **NextHopId**, and you cannot specify **NEXTHopList**.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateRouteEntry.
RouteTableId	String	Yes	The ID of the routing table.
DestinationCidrBlock	String	Yes	The destination CIDR block of the custom route entry, which must meet the following requirements: • The destination CIDR block of a route entry cannot be 100.64.0.0/10 or a subset of 100.64.0.0/10. • The destination CIDR blocks of route entries in the same routing table cannot be the same. • If the specified destination CIDR block is an IP address, the /32 netmask is used.
NextHopType	String	No	The type of the next hop. Valid values: • Instance: (default) The next hop is an ECS instance. • RouterInterface: The next hop is a router interface.  Note: You must specify this parameter when creating normal route entries (non-ECMP route entries).

Parameter	Type	Required	Description
NextHopId	String	No	The ID of the next-hop instance. The next-hop instance must be in the VPC or VBR to which the routing table belongs.  Note: You must specify this parameter when creating normal route entries (non-ECMP route entries).
NextHopList	String	No	The list of next hops. The next hops must meet the following requirements: • ECMP route entries are only supported for the VPC routing table. • The number of next hops must be 2, 3, or 4. • The next hops must be VRouter interfaces that are destined for VBRs.  Note: You must specify this parameter when creating ECMP route entries.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.
NextHopList elements			
 Note: You must specify this parameter when creating ECMP route entries.			

Parameter	Type	Required	Description
NextHopType	String	No	The type of the next hop. Valid values: - Instance: (default) The next hop is an ECS instance. - RouterInterface: The next hop is a router interface.
NextHopId	String	No	The ID of the next-hop instance.
Enabled	Integer	No	Specifies whether the next-hop is available. 1: The next hop is available. 0: The next hop is unavailable.
Weight	Integer	No	The routing weight of the next hop.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateRouteEntry
&VpcId=vpc-257gq6xxxxxxxxx
&RouteTableId=vrt-5citwfxxxxxxxxxx
&DestinationCidrBlock=0.0.0.0/0
&NextHopId=i-25sktxxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateRouteEntryResponse>
  <RequestId>12D086F6-8F31-4658-84C1-006DED011A85</RequestId>
</CreateRouteEntryResponse>
```

- JSON format

```
{
  "RequestId": "12D086F6-8F31-4658-84C1-006DED011A85"
```

}

2.14.1.8.2 DeleteRouteEntry

You can call this operation to delete route entries from the routing table of a VRouter or VBR.

When you call this operation, make sure that the following requirements are met:

- Only route entries in the Available state can be deleted.
- You cannot delete route entries from a VPC in which a VSwitch or route entry is being created or deleted.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteRouteEntry.
RouteTableId	String	Yes	The ID of the routing table to which the route entry belongs.
DestinationCidrBlock	String	Yes	The destination CIDR block of the route entry.
NextHopId	String	No	The ID of the next-hop instance. You must specify this parameter when deleting normal route entries (non-ECMP route entries).
NextHopList	String	No	The list of next hops. You must specify this parameter when deleting ECMP route entries.

Table 2-423: NextHopList list

Parameter	Type	Required	Description
NextHopType	String	No	The type of the next hop. Valid values: • Instance: (default) The next hop is an ECS instance. • RouterInterface: The next hop is a router interface.
NextHopId	String	No	The ID of the next-hop instance.

Parameter	Type	Required	Description
Enabled	Integer	No	Specifies whether the next-hop is available. 1: The next hop is available. 0: The next hop is unavailable.
Weight	Integer	No	The routing weight of the next hop.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteRouteEntry
&RouterTableId=vtb-25vtxlxxxxxxx
&DestinationCidrBlock=192.168.1.0/24
&NextHopId=i-25skttxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteRouteEntryResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</DeleteRouteEntryResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.8.3 DescribeRouteTables

You can call this operation to query route entries in a routing table.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRouteTables.

Parameter	Type	Required	Description
RouterType	String	No	The type of the router to which the routing table belongs. Valid values: • VRouter • VBR
RouterId	String	No	The ID of the VRouter or VBR to which the routing table belongs.
VRouterId	String	No	The ID of the VRouter to which the routing table belongs. The value of the RouterType parameter is set to VRouter automatically when this parameter is specified.
RouteTableId	String	No	The ID of the routing table.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
RouteTables	List	The details about the routing table. For more information, see the RouteTables list.

Table 2-424: RouteTables list

Parameter	Type	Description
RouterType	String	The type of the router to which the routing table belongs. Valid values: • VRouter • VBR
RouterId	String	The ID of the VRouter or VBR to which the routing table belongs.
VRouterId	String	The ID of the VRouter.
RouteTableId	String	The ID of the routing table.
RouteTableType	String	The type of the routing table.
CreationTime	String	The time when the routing table was created.
RouteEntrys	List	The details about the route entry. For more information, see the RouteEntrys list.

Table 2-425: RouteEntrys list

Parameter	Type	Description
Type	String	The type of the route entry. Valid value: • Custom: custom route entry
RouteTableId	String	The ID of the routing table to which the route entry belongs.
DestinationCidrBlock	String	The destination CIDR block of the route entry.
NextHopType	String	The type of the next hop.
InstanceId	String	The ID of the next-hop instance.
Status	String	The status of the route entry. Valid values: • Pending: The route entry is being configured. • Available: The route entry is available. • Modifying: The route entry is being modified.
RouterId	String	The ID of the VRouter or VBR to which the routing table belongs.

Parameter	Type	Description
NextHops	List	The next-hop list of ECMP routes. For more information, see the NextHops list.

Table 2-426: NextHops list

Parameter	Type	Description
NextHopType	String	The type of the next hop. Valid values: - Instance: (default) The next hop is an ECS instance. - RouterInterface: The next hop is a router interface.
NextHopId	String	The ID of the next-hop instance.
Enabled	Integer	Indicates whether the next-hop is available. 1: The next hop is available. 0: The next hop is unavailable.
Weight	Integer	The routing weight of the next hop.

2.14.1.9 Elastic IP Address (EIP)

2.14.1.9.1 AllocateEipAddress

You can call this operation to create an Elastic IP address (EIP).

An EIP in the Available state is randomly allocated in the specified region after this operation is called. EIP supports only ICMP, TCP, and UDP at the transport layer.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>AllocateEipAddress</code> .
RegionId	String	Yes	The region ID of the EIP. You can call the DescribeRegions operation to query the latest region list.
Bandwidth	String	No	The peak bandwidth of the EIP. Unit: Mbit/s. Default value: 5.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
EipAddress	String	The allocated EIP.
AllocationId	String	The ID of the EIP.

Examples

Sample requests

```
https://vpc.example.com/?Action=AllocateEipAddress
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
```

```
<AllocateEipAddressResponse>
  <AllocationId>eip-25877c7xxxxxxx</AllocationId>
  <EipAddress>123.xx.xx. 206</EipAddress>
  <RequestId>B6B9F518-60F8-4D81-9242-1207B356754D</RequestId>
</AllocateEipAddressResponse>
```

- JSON format

```
{
  "AllocationId": "eip-25877c70x",
  "EipAddress": "123.xx.xx. 206",
  "RequestId": "B6B9F518-60F8-4D81-9242-1207B356754D"
}
```

2.14.1.9.2 AssociateEipAddress

You can call this operation to bind an EIP to a cloud instance in the same region.

When you call this operation, make sure that the following requirements are met:

- Only EIPs in the Available state can be bound.
- An EIP can only be bound to one cloud instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AssociateEipAddress.
AllocationId	String	Yes	The ID of the EIP.
InstanceType	String	No	The type of the cloud instance to bind. Valid value: • EcsInstance: (default) an ECS instance of the VPC network Only the ECS instance in the running or stopped state can be bound. After the EIP is bound, the SLB instance can forward requests from the public network.
InstanceId	String	Yes	The ID of the cloud instance to bind.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=AssociateEipAddress
&AllocationId=eip-25877cxxxxxxx
&InstanceId=i-25skktxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<AssociateEipAddressResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</AssociateEipAddressResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.9.3 UnassociateEipAddress

You can call this operation to unbind an EIP from a cloud instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to UnassociateEipAddress.
AllocationId	String	Yes	The ID of the EIP.
InstanceType	String	No	The type of the cloud instance to unbind. Valid value: EcsInstance: (default) an ECS instance of the VPC network
InstanceId	String	Yes	The ID of the cloud instance to unbind.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=UnassociateEipAddress
&AllocationId=eip-25877c7xxxxxxx
&InstanceId=i-25skktxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<UnassociateEipAddressResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</UnassociateEipAddressResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.9.4 ModifyEipAddressAttribute

You can call this operation to modify the name, description, and peak bandwidth of an EIP.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyEipAddressAttribute.
AllocationId	String	Yes	The ID of the EIP.
Bandwidth	String	No	The peak bandwidth of the EIP. Unit: Mbit/s.

Parameter	Type	Required	Description
Name	String	No	The name of the EIP. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the EIP. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyEipAddressAttribute
&AllocationId=eip-25877c7xxxxxxx
&Name=eip1
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyEipAddressAttributeResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ModifyEipAddressAttributeResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
```

```
}
```

2.14.1.9.5 ReleaseEipAddress

You can call this operation to release an EIP.

When you call this operation, make sure that the following requirements are met:

- Only EIPs in the Available state can be released.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ReleaseEipAddress.
AllocationId	String	Yes	The ID of the EIP.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ReleaseEipAddress
&AllocationId=eip-25877c7xxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ReleaseEipAddressResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ReleaseEipAddressResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
```

}

2.14.1.9.6 DescribeEipAddresses

You can call this operation to query the EIPs that have been created for the specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEipAddresses.
RegionId	String	Yes	The region ID of the EIP. You can call the DescribeRegions operation to query the latest region list.
Status	String	No	The status of the EIP. Valid values: • Associating: The EIP is being bound to a cloud instance. • Unassociating: The EIP is being unbound from a cloud instance. • InUse: The EIP has been bound to a cloud instance. • Available: The EIP is not bound to any cloud instances.
AllocationId	String	No	The ID of the EIP.
Associated InstanceType	String	No	The type of the cloud instance to bind. Valid value: EcsInstance: (default) an ECS instance of the VPC network
Associated InstanceId	String	No	The ID of the cloud instance to bind.
PageNumber	Integer	No	The number of the page to return. Default value: 1.

Parameter	Type	Required	Description
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
EipAddresses	List	The details about the queried EIPs.

Table 2-427: EipAddresses list

Parameter	Type	Description
RegionId	String	The region ID of the EIP.
IpAddress	String	The address of the EIP.
AllocationId	String	The ID of the EIP.
Status	String	The status of the EIP. Valid values: • Associating: The EIP is being bound to a cloud instance. • Unassociating: The EIP is being unbound from a cloud instance. • InUse: The EIP has been bound to a cloud instance. • Available: The EIP is not bound to any cloud instances.
InstanceType	String	The type of the cloud instance that the EIP is bound.
InstanceId	String	The ID of the cloud instance that the EIP is bound.
Bandwidth	String	The peak bandwidth of the EIP. Unit: Mbit/s.
InternetChargeType	String	The billing method of the EIP.

Parameter	Type	Description
AllocationTime	String	The time when the EIP was created.
OperationLocks	String	The reason why the EIP is locked. Valid values: financial: The EIP is locked due to overdue payments. security: The EIP is locked due to security reasons.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeEipAddresses
&RegionId=cn-hangzhou-1
&Common request parameters
```

Sample responses

```

2.14.1.10 Router interface

2.14.1.10.1 ConnectRouterInterface

You can call this operation to connect the initiator router interface to the receiver router interface.

After this operation is called, the router interface enters the Connecting state. When the connection is established, the router interface enters the Active state.

When you call this operation, make sure that the following requirements are met:

- Only an initiator router interface in the Idle state can initiate a connection.
- A maximum of one pair of interconnected router interfaces can be created between any two routers.
- You cannot initiate a connection if your account contains any router interface that has overdue payments.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ConnectRouterInterface.
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.
RouterInterfaceId	String	Yes	The ID of the initiator router interface.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ConnectRouterInterface
&RegionId=cn-hangzhou
&RouterInterfaceId=ri-sf3rxxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ConnectRouterInterfaceResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ConnectRouterInterfaceResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
```

}

2.14.1.10.2 DeactivateRouterInterface

You can call this operation to deactivate a router interface.

After the operation is called, the router interface enters the Deactivating state. Once deactivated, the router interface enters the Inactive state.

**Note:**

You cannot deactivate a router interface that has overdue payments.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeactivateRouterInterface.
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.
RouterInterfaceId	String	Yes	The ID of the router interface.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeactivateRouterInterface
&RegionId=cn-hangzhou
&RouterInterfaceId=ri-sf3rxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeactivateRouterInterfaceResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
```

```
</DeactivateRouterInterfaceResponse>
```

- JSON format

```
{  
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"  
}
```

2.14.1.10.3 ModifyRouterInterfaceSpec

You can call this operation to modify the specification of a router interface.

After the operation is called, the router interface enters the Activating state. Once activated, the router interface enters the Active state.

**Note:**

You cannot modify the specification of a router interface that has overdue payments.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyRouterInterfaceSpec</code> .
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.
RouterInterfaceId	String	Yes	The ID of the router interface.
Spec	String	Yes	The specification of the router interface.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Spec	String	The specification of the router interface.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyRouterInterfaceSpec
&RegionId=cn-hangzhou
&Spec=Middle. 2
&RouterInterfaceId=ri-2ze7fbuohm7pcxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyRouterInterfaceSpecResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
  <Spec>Middle. 2</Spec>
</ModifyRouterInterfaceSpecResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0",
  "Spec": "Middle. 2"
}
```

2.14.1.10.4 DeleteRouterInterface

You can call this operation to delete a router interface.

When you call this operation, make sure that the following requirements are met:

- You can only delete a router interface that is in the Idle or Inactive state.
- Before deleting a router interface, you must delete all custom route entries destined for the router interface.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteRouterInterface.

Parameter	Type	Required	Description
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.
RouterInterfaceId	String	Yes	The ID of the router interface.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteRouterInterface
&RegionId=cn-hangzhou
&RouterInterfaceId=ri-sf3rxxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteRouterInterfaceResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</DeleteRouterInterfaceResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
```

```
}
```

2.14.1.10.5 DescribeRouterInterfaces

You can call this operation to query router interfaces in a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRouterInterfaces.
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
Filter.n.Key	String	No	Specifies filter condition n. You can specify a maximum of five filter conditions. Valid values of n: 1 to 5. You can specify multiple values for each filter condition. If you use "or" to separate multiple values, the system returns results that match at least one of the filter conditions. If you use "and" to separate multiple values, the system returns results that match all filter conditions. The following filter conditions are available: - RouterInterfaceId: the ID of the router interface. RouterId: the ID of the VRouter or VBR. - RouterType: the type of the router associated with the router interface. - RouterInterfaceOwnerId: the account ID of the router interface. - OppositeInterfaceId: the ID of the peer router interface. - OppositeRouterType: the type of the router associated with the peer router interface. - OppositeRouterId: the ID of the peer router (VRouter or VBR). - OppositeInterfaceOwnerId: the account ID of the peer router interface. - Status: the status of the router interface. - Name: the name of the router interface.
Filter.n.Value.m	String	No	Specifies value m of filter condition n. Valid values of m: 1 to 5.

Parameter	Type	Required	Description
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
RouterInterfaceSet	List	The details about the router interface. For more information, see the RouterInterfaceType list.

Table 2-428: RouterInterfaceType list

Parameter	Type	Description
RouterType	String	The type of the router to which the routing table belongs. Valid values: • VRouter • VBR
RouterInterfaceId	String	The ID of the router interface.
RouterId	String	The ID of the router to which the routing table belongs.
VRouterId	String	The ID of the VRouter.
Spec	String	The specification of the router interface.
Role	String	The role of the router interface: connection initiator or connection receiver.
CreationTime	String	The time when the router interface was created.
OppositeInterfaceOwnerId	String	The account ID of the owner of the peer router interface.

Parameter	Type	Description
OppositeRouterType	String	The type of the router associated with the peer router interface.
OppositeRouterId	String	The ID of the router associated with the peer router interface.
OppositeInterfaceId	String	The ID of the peer router interface.
VpcInstanceId	String	The ID of the instance of the VPC network to connect to.
InstanceId	String	The ID of the next-hop instance.
Status	String	The status of the router interface.

2.14.1.10.6 ActivateRouterInterface

You can call this operation to activate an inactive router interface.

After the operation is called, the router interface enters the Activating state. Once activated, the router interface enters the Active state.

Note:

You cannot activate a router interface that has overdue payments.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ActivateRouterInterface</code> .
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.
RouterInterfaceId	String	Yes	The ID of the router interface.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ActivateRouterInterface
&RegionId=cn-hangzhou
&RouterInterfaceId=ri-sf3rxsfxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ActivateRouterInterfaceResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</ActivateRouterInterfaceResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.10.7 ModifyRouterInterfaceAttribute

You can call this operation to modify the configurations of a router interface.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyRouterInterfaceAttribute</code> .
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.
RouterInterfaceId	String	Yes	The ID of the router interface.

Parameter	Type	Required	Description
AccessPointId	String	No	The ID of the access point to which the VBR belongs. You can call the DescribeAccessPoints operation to query the latest access point list.  Note: You must specify this parameter in the scenario of physical connection access.
RouterId	String	Yes	The ID of the router associated with the router interface.
DeleteHealthCheckIp	Boolean	No	Specifies whether to delete the IP address for health check configured on the router interface. Valid values: true: deletes the IP address for health check. false: (default) does not delete the IP address for health check.
OppositeRouterId	String	No	The ID of the peer router.
OppositeInterfaceId	String	No	The ID of the peer router interface.
OppositeInterfaceOwnerId	String	No	The ID of the owner of the peer router interface.
HealthCheckSourceIp	String	No	The source IP address used to perform health check on the physical connection. It must be an unused IP address within the VPC.  Note: You can specify this parameter in the scenario of physical connection access.

Parameter	Type	Required	Description
HealthCheckTargetIp	String	No	The destination IP address used to perform health check on the physical connection.  Note: This parameter is required when the HealthCheckSourceIp parameter is specified.
Name	String	No	The name of the router interface. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code>.
Description	String	No	The description of the router interface. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code>.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyRouterInterfaceAttribute
&Name=test
&RouterInterfaceId=ri-2ze7fbuohm7pc3xxxxxxx
&RegionId=cn-hangzhou
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyRouterInterfaceAttributeResponse>
  <RequestId>980960B0-2969-40BF-8542-EBB34FD358AB</RequestId>
```

```
</ModifyRouterInterfaceAttributeResponse>
```

- JSON format

```
{
  "RequestId": "980960B0-2969-40BF-8542-EBB34FD358AB"
}
```

2.14.1.10.8 CreateRouterInterface

You can call this operation to create a router interface.

When you call this operation, make sure that the following requirements are met:

- A maximum of one pair of interconnected router interfaces can be created between two routers.
- A maximum of five router interfaces can be created for a router.
- If your account contains any router interface that has overdue payments, you cannot create new router interfaces.
- The destination CIDR blocks (**DestinationCidrBlock**) of route entries in the same routing table cannot be the same.
- The router interface created for a virtual border router (VBR) must act as the connection initiator.
- If you want to create a router interface for a VBR, the VBR must be in the Active state.

Note:

A router interface created by using the API operation is billed on a daily basis.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>CreateRouterInterface</code> .
RegionId	String	Yes	The region ID of the router interface. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
RouterType	String	Yes	The type of the router associated with the router interface. Valid values: • VRouter • VBR
AccessPointId	String	No	The ID of the access point to which the VBR belongs. You can call the DescribeAccessPoints operation to query the latest access point list.  Note: You must specify this parameter in the scenario of physical connection access.
RouterId	String	Yes	The ID of the router associated with the router interface.
Role	String	Yes	The role of the router interface. Valid values: • InitiatingSide: connection initiator • AcceptingSide: connection receiver
Spec	String	Yes	The specification of the router interface. The available specifications and the corresponding bandwidths are as follows: • Mini.2: 2 Mbit/s • Mini.5: 5 Mbit/s • Small.1: 10 Mbit/s • Small.2: 20 Mbit/s • Small.5: 50 Mbit/s • Middle.1: 100 Mbit/s • Middle.2: 200 Mbit/s • Middle.5: 500 Mbit/s • Large.1: 1,000 Mbit/s • Large.2: 2,000 Mbit/s • Large.5: 5,000 Mbit/s • Xlarge.1: 10,000 Mbit/s

Parameter	Type	Required	Description
OppositeRegionId	String	Yes	The region ID of the connection receiver.
OppositeAccessPointId	String	No	The ID of the access point of the peer router interface.  Note: This parameter must be specified when the peer router interface is on a VBR and cannot be modified after the router interface is created.
OppositeRouterType	String	No	The type of the router associated with the peer router interface. Valid values: • VRouter • VBR
OppositeRouterId	String	No	The ID of the peer router.
OppositeInterfaceId	String	No	The ID of the peer router interface.
OppositeInterfaceOwnerId	String	No	The ID of the owner of the peer router interface.
HealthCheckSourceIp	String	No	The source IP address used to perform health check on the physical connection. It must be an unused IP address within the VPC.  Note: You can specify this parameter in the scenario of physical connection access.
HealthCheckTargetIp	String	No	The destination IP address used to perform health check on the physical connection.  Note: This parameter is required when the HealthCheckSourceIp parameter is specified.

Parameter	Type	Required	Description
Name	String	No	The name of the router interface. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the router interface. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
RouterInterfaceId	String	The ID of the router interface.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateRouterInterface
&RegionId=cn-beijing
&Role=InitiatingSide
&OppositeRegionId=cn-beijing
&Spec=Mini.5
&RouterType=VRouter
&RouterId=vrt-2zepuy8qbrq6yxxxxxxxxx
&OppositeRouterId=vrt-2zefso23vmuxxxxxxxxxx
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateRouterInterfaceResponse>
  <RequestId>980960B0-2969-40BF-8542-EBB34FD358AB</RequestId>
  <RouterInterfaceId>ri-2ze7fbuohmxxxxxx</RouterInterfaceId>
</CreateRouterInterfaceResponse>
```

- JSON format

```
{
  "RequestId": "980960B0-2969-40BF-8542-EBB34FD358AB"
  "RouterInterfaceId": "ri-2ze7fbuohmxxxxxx"
}
```

2.14.1.11 Physical connection

2.14.1.11.1 CreatePhysicalConnection

You can call this operation to create a physical connection.

After the physical connection enters the Initial state, contact the carrier to begin construction.

When you call this operation, make sure that the following requirements are met:

- The number of physical connections that are not in the Enabled state cannot exceed five.
- If your account contains any physical connection that has overdue payments, you cannot create new physical connections.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreatePhysicalConnection.
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
AccessPointId	String	Yes	The ID of the access point that is associated with the physical connection. You can call the DescribeAccessPoints operation to query the latest access point list.
CircuitCode	String	No	The circuit code provided by the carrier for the physical connection.
LineOperator	String	Yes	The carrier that provides the physical connection. Valid values: - CT: China Telecom - CU: China Unicom - CM: China Mobile - CO: Other providers in China - Equinix: Equinix - Other: Other providers outside China
PeerLocation	String	Yes	The geographical location of the on-premise IDC.
Bandwidth	String	No	The bandwidth of the NAT service plan. Unit: Mbit/s. Valid values: 2 to 10240. Default value: 100.
PortType	String	No	The access port type of the physical connection. Valid values: 100Base-T: 100M electrical port 1000Base-T: (default) 1 GE electrical port 1000Base-LX: 1 GE single-mode optical port (10 km) 10GBase-T: 10 GE electrical port 10GBase-LR: 10 GE single-mode optical port (10 km)

Parameter	Type	Required	Description
RedundantPhysicalConnectionId	String	No	The ID of the redundant physical connection. The redundant physical connection must be in the Allocated, Confirmed, or Enabled state.
Name	String	No	The name of the physical connection. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the physical connection. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
PhysicalConnectionId	String	The ID of the VPC.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreatePhysicalConnection
&RegionId=cn-beijing
&AccessPointId=ap-cn-beijing-ft-A
```

```
&LineOperator=CT
&PeerLocation=XXX
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreatePhysicalConnectionResponse>
  <RequestId>8A6A5EC5-6F6C-4906-9689-56ACE58A13E0</RequestId>
  <PhysicalConnectionId>pc-*****</PhysicalConnectionId>
</CreatePhysicalConnectionResponse>
```

- JSON format

```
{
  "PhysicalConnectionId": "pc-*****",
  "RequestId": "8A6A5EC5-6F6C-4906-9689-56ACE58A13E0"
}
```

2.14.1.11.2 CancelPhysicalConnection

You can call this operation to cancel a physical connection before it is enabled. After you cancel the physical connection, it enters the Canceled state.

You can only cancel a physical connection that is in the Initial, Approved, Allocated, or Confirmed state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>CancelPhysicalConnection</code> .
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
PhysicalConnectionId	String	Yes	The ID of the physical connection.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=CancelPhysicalConnection
&PhysicalConnectionId=pc-2zeoaxkq3xxxx
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CancelPhysicalConnectionResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</CancelPhysicalConnectionResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.11.3 DeletePhysicalConnection

You can call this operation to delete a physical connection.

You can only delete a physical connection that is in the Rejected, Canceled, AllocationFailed, or Terminated state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeletePhysicalConnection.
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
PhysicalConnectionId	String	Yes	The ID of the physical connection.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeletePhysicalConnection
&PhysicalConnectionId=pc-2zeoaxkq3xxxx
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeletePhysicalConnectionResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</DeletePhysicalConnectionResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.11.4 ModifyPhysicalConnectionAttribute

You can call this operation to modify the configurations of a physical connection.

When you call this operation, make sure that the following requirements are met:

- If you want to modify the specification or the redundant physical connection ID, the corresponding physical connection must be in the Initial or Rejected state.
- You cannot modify the attributes of the physical connection that is in the Canceled, Allocating, AllocationFailed, or Terminated state.
- After modification, the physical connection in the Rejected state will enter the Initial state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyPhysicalConnectionAttribute</code> .
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
PhysicalConnectionId	String	Yes	The ID of the physical connection.
LineOperator	String	No	The carrier that provides the physical connection. Valid values: - CT: China Telecom - CU: China Unicom - CM: China Mobile - CO: Other providers in China - Equinix: Equinix - Other: Other providers outside China
CircuitCode	String	No	The circuit code provided by the carrier for the physical connection.
PeerLocation	String	No	The geographical location of the local IDC.
Bandwidth	String	No	The bandwidth of the physical connection. Unit: Mbit/s. Valid values: 2 to 10240. Default value: 100.
PortType	String	No	The access port type of the physical connection. Valid values: 100Base-T: 100M electrical port 1000Base-T: (default) 1 GE electrical port 1000Base-LX: 1 GE single-mode optical port (10 km) 10GBase-T: 10 GE electrical port 10GBase-LR: 10 GE single-mode optical port (10 km)
RedundantPhysicalConnectionId	String	No	The ID of the redundant physical connection. The redundant physical connection must be in the Allocated, Confirmed, or Enabled state.

Parameter	Type	Required	Description
Name	String	No	The name of the physical connection. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the physical connection. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyPhysicalConnectionAttribute
&PhysicalConnectionId=pc-2zeoaxkq3xxxxx
&RegionId=cn-beijing
&Name=test3
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<ModifyPhysicalConnectionAttributeResponse>
  <RequestId>8A6A5EC5-6F6C-4906-9689-56ACE58A13E0</RequestId>
</ModifyPhysicalConnectionAttributeResponse>
```

- JSON format

```
{
  "RequestId": "8A6A5EC5-6F6C-4906-9689-56ACE58A13E0"
}
```

2.14.1.11.5 DescribePhysicalConnections

You can call this operation to query physical connections in a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePhysicalConnections.
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
Filter.n.Key	String	No	Specifies filter condition n. You can specify a maximum of five filter conditions. Valid values of n: 1 to 5. You can specify multiple values for each filter condition. If you use "or" to separate multiple values, the system returns results that match at least one of the filter conditions. If you use "and" to separate multiple values, the system returns results that match all filter conditions. The following filter conditions are available: - PhysicalConnectionId: The ID of the physical connection. AccessPointId: The ID of the access point. - Type: The type of the physical connection. Default value: VPC. - LineOperator: The carrier of the physical connection. - Status: The status of the physical connection. - Spec: The specification of the physical connection. - Name: The name of the physical connection.
Filter.n.Value.m	String	No	Specifies value m of filter condition n. Valid values of m: 1 to 5.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
PhysicalConnectionSet	List	The details about the physical connection. For more information, see the PhysicalConnectionSet list.

Table 2-429: PhysicalConnectionSet list

Parameter	Type	Description
PhysicalConnectionId	String	The ID of the physical connection.
AccessPointId	String	The ID of the access point that is associated with the physical connection.
Status	String	The status of the physical connection. Valid values: • Initial: application in progress • Approved: approved • Allocating: resource allocation in progress • Allocated: under construction • Confirmed: pending user confirmation • Enabled: enabled • Rejected: rejected • Canceled: canceled • Allocation Failed: resource allocation failed • Terminated: terminated
BusinessStatus	String	The payment status of the physical connection. Valid values: • Normal: The payment status is normal. • FinancialLocked: The physical connection is locked due to overdue payments. • SecurityLocked: The physical connection is locked due to security reasons.
CreationTime	String	The time when the physical connection was created.

Parameter	Type	Description
EnabledTime	String	The time when the physical connection was enabled .
LineOperator	String	The carrier that provides the physical connection. Valid values: - CT: China Telecom - CU: China Unicom - CM: China Mobile - CO: Other providers in China - Equinix: Equinix - Other: Other providers outside China
Spec	String	The specification of the physical connection.
PeerLocation	String	The geographical location of the local IDC.
PortType	String	The access port type of the physical connection. Valid values: 100Base-T: 100M electrical port 1000Base-T: (default) 1 GE electrical port 1000Base-LX: 1 GE single-mode optical port (10 km) 10GBase-T: 10 GE electrical port 10GBase-LR: 10 GE single-mode optical port (10 km)
RedundantPhysicalConnectionId	String	The ID of the redundant physical connection.
Name	String	The name of the physical connection.
Description	String	The description of the physical connection.
ADLocation	String	The location of the physical access device.
PortNumber	String	The port number of the physical access device.
CircuitCode	String	The circuit code provided by the carrier for the physical connection.
Bandwidth	String	The bandwidth of the physical connection.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribePhysicalConnections
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

2.14.1.11.6 TerminatePhysicalConnection

You can call this operation to terminate a physical connection after it is enabled.

The physical connection enters the Terminating state after the operation is called. The connection enters the Terminated state when the process is completed.

When you call this operation, make sure that the following requirements are met:

- You can only terminate a physical connection in the Enabled state.
- Before terminating a physical connection, you must delete the virtual border routers (VBRs) associated with the physical connection.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>TerminatePhysicalConnection</code> .
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
PhysicalConnectionId	String	Yes	The ID of the physical connection.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=TerminatePhysicalConnection
&PhysicalConnectionId=pc-2zeoaxkq3xxxxx
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<TerminatePhysicalConnectionResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</TerminatePhysicalConnectionResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.11.7 EnablePhysicalConnection

You can call this operation to enable a physical connection that is in the Confirmed state.

After you have enabled the physical connection, it enters the Enabled state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to EnablePhysicalConnection.
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
PhysicalConnectionId	String	Yes	The ID of the physical connection.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=EnablePhysicalConnection
&PhysicalConnectionId=pc-2zeoaxkq3xxxxx
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<EnablePhysicalConnectionResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</EnablePhysicalConnectionResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.12 Virtual border router

2.14.1.12.1 CreateVirtualBorderRouter

You can call this operation to create a virtual border router (VBR).

Each physical connection can associate with two VBRs. One belongs to your own account and the other belongs to a different account. If you create a VBR by using your account, the VBR is in the Enabled state after the operation is called. If you create a VBR by using another account, the VBR is in the Unconfirmed state after the operation is called.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateVirtualBorderRouter.
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
PhysicalConnectionId	String	Yes	The ID of the physical connection.

Parameter	Type	Required	Description
VbrOwnerId	String	No	The account ID of the VBR owner. The default value is the account ID of the user who is calling the operation.
VlanId	String	Yes	The VLAN ID of the VBR. Valid values: 1 to 2999.  Note: Only the owner of the physical connection can specify this parameter. The VLAN IDs of the two VBRs that are associated with the same physical connection must be different.
CircuitCode	String	Yes	The circuit code provided by the carrier for the physical connection.  Note: Only the owner of the physical connection can specify this parameter.
LocalGatewayIp	String	Yes	The IP address of the Alibaba Cloud-side gateway. The IP address is configured for the VBR to interconnect your VPC and your on-premises data center.
PeerGatewayIps	String	Yes	The IP address of your on-premises gateway . The IP address is configured for the VBR to interconnect your VPC and your on-premises data center.
PeeringSubnetMask	String	No	The netmask for the Alibaba Cloud-side IP address and the on-premises IP address. The two IP addresses must be located in the same subnet.

Parameter	Type	Required	Description
Name	String	No	The name of the VBR. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the VBR. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
VbrId	String	The ID of the VBR.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateVirtualBorderRouter
&PhysicalConnectionId=pc-2zeoaxkq3jotxxxxxxx
&RegionId=cn-hangzhou
&VlanId=10
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<CreateRouterInterfaceResponse>
  <RequestId>980960B0-2969-40BF-8542-EBB34FD358AB</RequestId>
  <VbrId>vbr-2zecmmvg5gvu8xxxxxxx</VbrId>
</CreateRouterInterfaceResponse>
```

- JSON format

```
{
  "RequestId": "980960B0-2969-40BF-8542-EBB34FD358AB"
  "VbrId": "vbr-2zecmmvg5gvu8xxxxxxx"
}
```

2.14.1.12.2 DeleteVirtualBorderRouter

You can call this operation to delete a VBR.

Before you call this operation, make sure that the following requirements are met:

- Before deleting a VBR, you must delete all router interfaces on the VBR.
- You can only delete a VBR that is in the Unconfirmed, Enabled, or Terminated state.
- If the owner of a physical connection wants to delete a VBR under another account, the VBR must be in the Unconfirmed state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteVirtualBorderRouter.
RegionId	String	Yes	The region ID of the VBR. You can call the DescribeRegions operation to query the latest region list.
VbrId	String	Yes	The ID of the VBR.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteVirtualBorderRouter
&VbrId=pc-2zeoaxkq3xxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteVirtualBorderRouterResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</DeleteVirtualBorderRouterResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.12.3 DescribeVirtualBorderRouters

You can call this operation to query created VBRs.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVirtualBorderRouters.
RegionId	String	Yes	The region ID of the VBR. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
Filter.n.Key	String	No	Specifies filter condition n. You can specify a maximum of five filter conditions. Valid values of n: 1 to 5. You can specify multiple values for each filter condition. If you use "or" to separate multiple values, the system returns results that match at least one of the filter conditions. If you use "and" to separate multiple values, the system returns results that match all filter conditions. The following filter conditions are available: - PhysicalConnectionId: The ID of the physical connection. VbrId: The ID of the VBR. - Status: The status of the VBR. - AccessPointId: The ID of the access point that is associated with the physical connection. - Name: The name of the VBR.
Filter.n.Value.m	String	No	Specifies value m of filter condition n. Valid values of m: 1 to 5.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.

Parameter	Type	Description
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
VirtualBorderRouterSet	List	The list of VBRs. For more information, see the VirtualBorderRouterType list.

Table 2-430: VirtualBorderRouterType list

Parameter	Type	Description
VbrId	String	The ID of the VBR.
VbrOwnerId	String	The account ID of the VBR owner. When the VBR owner and the owner of the physical connection are the same, this parameter is empty.
CreationTime	Integer	The time when the VBR was created.
ActivationTime	String	The time when the VBR was activated for the first time.
TerminationTime	String	The last time when the VBR was terminated.
RecoveryTime	String	The last time when the VBR was recovered from the Terminated state to the Active state.
Status	String	The status of the VBR.
VlanId	String	The VLAN ID of the VBR.
CircuitCode	String	The circuit code provided by the carrier for the physical connection.
RouteTableId	String	The ID of the routing table of the VBR.
VlanInterfaceId	String	The ID of the router interface of the VBR.
LocalGatewayIp	String	The Alibaba Cloud-side IP address The IP address of the Alibaba Cloud-side gateway. The IP address is configured for the VBR to interconnect your VPC and your on-premises data center.
PeerGatewayIp	String	The IP address of your on-premises gateway. The IP address is configured for the VBR to interconnect your VPC and your on-premises data center.
PeeringSubnetMask	String	The netmask for the Alibaba Cloud-side IP address and the on-premises IP address.
Name	String	The name of the VBR.
Description	String	The description of the VBR.

Parameter	Type	Description
PhysicalConnectionId	String	The ID of the physical connection that the VBR connects to.
AccessPointId	String	The ID of the access point that is associated with the physical connection.
Status	String	The status of the physical connection. Valid values: - Initial: application in progress - Approved: approved - Allocating: resource allocation in progress - Allocated: under construction - Confirmed: pending user confirmation - Enabled: enabled - Rejected: rejected - Canceled: canceled - Allocation Failed: resource allocation failed - Terminated: terminated
BusinessStatus	String	The payment status of the physical connection. Valid values: - Normal: The payment status is normal. - FinancialLocked: The physical connection is locked due to overdue payments. - SecurityLocked: The physical connection is locked due to security reasons.

Examples

Sample requests

```

2.14.1.12.4

DescribeVirtualBorderRoutersForPhysicalConnection

You can call this operation to query the VBRs connected to a specified physical connection, including VBRs that belong to the physical connection owner and other accounts.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>DescribeVirtualBorderRoutersForPhysicalConnection</code> .
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
PhysicalConnectionId	String	No	The ID of the physical connection.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
VirtualBorderRouterForPhysicalConnectionSet	List	The list of VBRs. For more information, see the VirtualBorderRouterForPhysicalConnectionType list.

Table 2-431: VirtualBorderRouterForPhysicalConnectionType list

Parameter	Type	Description
VbrId	String	The ID of the VBR.
VbrOwnerId	String	The account ID of the VBR owner. When the VBR owner and the owner of the physical connection are the same, this parameter is empty.
CreationTime	Integer	The time when the VBR was created.
ActivationTime	String	The time when the VBR was activated for the first time.
TerminationTime	String	The last time when the VBR was terminated.
RecoveryTime	String	The last time when the VBR was recovered from the Terminated state to the Active state.
VlanId	String	The VLAN ID of the VBR.
CircuitCode	String	The circuit code provided by the carrier for the physical connection.

}
```

2.14.1.12.5 ModifyVirtualBorderRouterAttribute

You can call this operation to modify the configurations of a VBR.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVirtualBorderRouterAttribute.

Parameter	Type	Required	Description
RegionId	String	Yes	The region ID of the physical connection. You can call the DescribeRegions operation to query the latest region list.
VbrId	String	Yes	The ID of the VBR.
VlanId	String	Yes	The VLAN ID of the VBR. Valid values: 1 to 2999.  Note: Only the owner of the physical connection can specify this parameter. The VLAN IDs of two VBRs of the same physical connection must be different.
CircuitCode	String	Yes	The circuit code provided by the carrier for the physical connection.  Note: Only the owner of the physical connection can specify this parameter.
LocalGatewayIp	String	Yes	The IP address of the Alibaba Cloud-side gateway. The IP address is configured for the VBR to interconnect your VPC and your on-premises data center.
PeerGatewayIps	String	Yes	The IP address of your on-premises gateway . The IP address is configured for the VBR to interconnect your VPC and your on-premises data center.
PeeringSubnetMask	String	No	The netmask for the Alibaba Cloud-side IP address and the on-premises IP address. The two IP addresses must be located in the same subnet.

Parameter	Type	Required	Description
Name	String	No	The name of the VBR. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the VBR. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyVirtualBorderRouterAttribute
&VbrId=vbr-2zee2e2cwtetxxxxxxxxx
&Name=test
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >

  <RequestId>980960B0-2969-40BF-8542-EBB34FD358AB</RequestId>
</ModifyVirtualBorderRouterAttributeResponse>
```

- JSON format

```
{
  "RequestId": "980960B0-2969-40BF-8542-EBB34FD358AB"
```

```
}
```

2.14.1.12.6 TerminateVirtualBorderRouter

You can call this operation to terminate a VBR.

After the operation is called, the state of the VBR will be changed from Enabled to Terminated. Before you call this operation, make sure that the following requirements are met:

- Only the owner of the physical connection that the VBR connects to can call this operation.
- If the VBR has been in the Terminated state for seven days or longer, its VLAN ID can be occupied by other VBRs.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to TerminateVirtualBorderRouter.
RegionId	String	Yes	The region ID of the VBR. You can call the DescribeRegions operation to query the latest region list.
VbrId	String	Yes	The ID of the VBR.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=TerminateVirtualBorderRouter
&VbrId=pc-2zeoaxkq3xxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<TerminateVirtualBorderRouterResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</TerminateVirtualBorderRouterResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.12.7 RecoverVirtualBorderRouter

You can call this operation to recover a terminated VBR.

After the operation is called, the state of the VBR will be changed from Terminated to Recovering. When the operation is completed, the VBR status will be changed to the Enabled state. Before you call this operation, make sure that the following requirements are met:

- Only the owner of the physical connection that the VBR connects to can call this operation.
- The physical connection that the VBR connects to must be in the Enabled state.
- If the VBR has been in the Terminated state for seven days or longer, its VLAN ID can be occupied by other VBRs. In this case, the recover fails.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RecoverVirtualBorderRouter.
RegionId	String	Yes	The region ID of the VBR. You can call the DescribeRegions operation to query the latest region list.
VbrId	String	Yes	The ID of the VBR.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=RecoverVirtualBorderRouter
&VbrId=pc-2zeoaxkq3xxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<RecoverVirtualBorderRouterResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</RecoverVirtualBorderRouterResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.13 NAT Gateway

2.14.1.13.1 CreateNatGateway

You can call this operation to create a NAT Gateway.

When you call this operation, make sure that the following requirements are met:

- A NAT Gateway and a self-built SNAT Gateway (by using an ECS instance as the SNAT Gateway) cannot coexist in a VPC.
- After you have created a NAT Gateway, a route entry is automatically added to the routing table of the VPC. The destination CIDR block is 0.0.0.0/0 and the next-hop is the NAT Gateway. The route entry ensures that traffic is routed to the NAT Gateway.
- If the VPC routing table already contains a route entry with a destination CIDR block of 0.0.0.0/0, delete this route entry. Otherwise, you cannot create a NAT Gateway.

Types of NAT Gateway

You can specify the type of a NAT Gateway as needed. The type of a NAT Gateway determines its SNAT performance (maximum connections and the number of new connections per second), but does not affect the data throughput.

The relationships between NAT Gateway types and SNAT performance metrics are as follows.

Type	Maximum connection	New connection per second
Small	10,000	1,000
Middle	50,000	5,000
Large	200,000	10,000

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateNatGateway.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
VpcId	String	Yes	The ID of the VPC.
Spec	String	No	The type of the NAT Gateway. Valid values: - Small (default) - Middle - Large
BandwidthPackage.n.IpCount	String	No	The number of public IP addresses in the NAT service plan n. Valid values: 1 to 50. n indicates the sequence of the service plan. Valid values: 1 to 4.  Note: This parameter can only be specified if the NAT service plan is included in your account before November 3, 2017. If the NAT service plan is not included in your account before November 3, 2017, bind an EIP.

Parameter	Type	Required	Description
BandwidthPackage.n.Bandwidth	String	No	The bandwidth of the NAT service plan n. Valid values: 5 to 5000. You can use the client to generate this value, but you must ensure that it is unique among different requests. The bandwidth can contain only ASCII characters, and cannot exceed 64 characters in length.  Note: This parameter can only be specified if the NAT service plan is included in your account before November 3, 2017. If the NAT service plan is not included in your account before November 3, 2017, bind an EIP.
BandwidthPackage.n.Zone	String	No	The zone to which the NAT service plan n belongs. If you do not specify this parameter, the bandwidth package is randomly allocated to a zone. Connectivity is not affected when the IP addresses of the NAT service plan and the back-end ECS instance belong to different zones. However, if the IP addresses belong to the same zone, the latency can be shortened.  Note: This parameter can only be specified if the NAT service plan is included in your account before November 3, 2017. If the NAT service plan is not included in your account before November 3, 2017, bind an EIP.

Parameter	Type	Required	Description
Name	String	No	The name of the NAT Gateway. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the NAT Gateway. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
NatGatewayId	String	The ID of the NAT Gateway.
SnatTableIds	List	The SNAT table of the NAT Gateway.
ForwardTableIds	List	The DNAT table of the NAT Gateway.
BandwidthPackageId	String	The NAT service plan of the NAT Gateway.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateNatGateway
&VpcId=vpc-11af8xxxxxxx
```

```
&Name=MyNatGW
&BandwidthPackage.1.IpCount=5
&RegionId=cn-shanghai
&BandwidthPackage.1.Bandwidth=150
&BandwidthPackage.1.Zone=cn-shanghai-a
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<CreateNatGatewayResponse>
  <BandwidthPackageIds></BandwidthPackageIds>

  </SnatTableIds>
  <ForwardTableIds>
    <ForwardTableId>ftb-2ze49kghsvq8lxxxxxxxx</ForwardTableId>
  </ForwardTableIds>
  <NatGatewayId>ngw-2zeo05qre24nhxxxxxxxx</NatGatewayId>
</CreateNatGatewayResponse>
```

- JSON format

```
{
  "BandwidthPackageIds": {
    "BandwidthPackageId": [ ]
  },
  "RequestId": "C44F62BE-9CE7-4277-B117-69243F3988BF",
  "SnatTableIds": {
    "SnatTableId": [
      "stb-2zeal45my4svyxxxxxxxx"
    ]
  },
  "ForwardTableIds": {
    "ForwardTableId": [
      "ftb-2ze49kghsvq8lxxxxxxxx"
    ]
  },
  "NatGatewayId": "ngw-2zeo05qre24nhxxxxxxxx"
}
```

2.14.1.13.2 DeleteNatGateway

You can call this operation to delete a NAT Gateway.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteNatGateway.

Parameter	Type	Required	Description
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
NatGatewayId	String	Yes	The ID of the NAT Gateway.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteNatGateway
&RegionId=cn-beijing
&NatGatewayId=ngw-112za3xxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteNatGatewayResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</DeleteNatGatewayResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.13.3 ModifyNatGatewaySpec

You can call this operation to modify the type of a NAT Gateway.

A NAT Gateway is billed based on the type of the highest specifications that have been used .

You can specify the type of a NAT Gateway as needed. The type of a NAT Gateway determines its SNAT performance (maximum connections and the number of new connections per second), but does not affect the data throughput.

The relationships between NAT Gateway types and SNAT performance metrics are as follows.

Type	Maximum connection	New connection per second
Small	10,000	1,000
Middle	50,000	5,000
Large	200,000	10,000

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyNatGatewaySpec</code> .
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
NatGatewayId	String	Yes	The ID of the NAT Gateway.
Spec	String	No	The type of the NAT Gateway. Valid values: - Small (default) - Middle - Large
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyNatGatewaySpec
&NatGatewayId=ngw-112za33xxxxxxx
&Spec=Large
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<ModifyNatGatewaySpecResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</ModifyNatGatewaySpecResponse>
```

- JSON format

```
{
  "RequestId": "2315DEB7-5E92-423A-91F7-4C1EC9AD97C3"
}
```

2.14.1.13.4 ModifyNatGatewayAttribute

You can call this operation to modify the configurations of a NAT Gateway.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyNatGatewayAttribute</code> .
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
NatGatewayId	String	Yes	The ID of the NAT Gateway.

Parameter	Type	Required	Description
Name	String	No	The name of the NAT Gateway. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the NAT Gateway. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyNatGatewayAttribute
&NatGatewayId=ngw-112za3xxxxxxx
&Spec=Large
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<ModifyNatGatewayAttributeResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</ModifyNatGatewayAttributeResponse>
```

- JSON format

```
{
  "RequestId": "2315DEB7-5E92-423A-91F7-4C1EC9AD97C3"
```

}

2.14.1.13.5 DescribeNatGateways

You can call this operation to query created NAT Gateways in a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeNatGateways.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
NatGatewayId	String	No	The ID of the NAT Gateway.
VpcId	String	No	The ID of the VPC.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
NatGateways	List	The details about the NAT Gateway. For more information, see the NatGateway list.

Table 2-432: NatGateway list

Parameter	Type	Description
NatGatewayId	String	The region ID of the NAT Gateway.
RegionId	String	The ID of the NAT Gateway.
Description	Integer	The description of the NAT Gateway.
Spec	String	The type of the NAT Gateway.
Status	String	The status of the NAT Gateway. Valid values: • Initiating: The NAT Gateway is being initialized. • Available: The NAT Gateway is available. • Pending: The NAT Gateway is being configured.
ForwardTableIds	List	The DNAT table.
BandwidthPackageIds	List	The NAT bandwidth package list.
SnatTableIds	List	The SNAT table.
BusinessStatus	String	The payment status of the NAT Gateway. Valid values: • Normal: The payment status is normal. • FinancialLocked: The NAT Gateway is locked due to overdue payments. • SecurityLocked: The NAT Gateway is locked due to security reasons.
CreationTime	String	The time when the NAT Gateway was created.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeNatGateways
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

```

2.14.1.13.6 CreateBandwidthPackage

You can call this operation to create a NAT bandwidth package.

The public IP address and bandwidth of the NAT Gateway are encapsulated into a NAT bandwidth package. You can create a maximum of four NAT bandwidth packages for a NAT Gateway.

A NAT bandwidth package includes:

- A shared bandwidth
- A group of public IP addresses

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateBandwidthPackage.

Parameter	Type	Required	Description
RegionId	String	Yes	The region ID of the NAT bandwidth package. You can call the DescribeRegions operation to query the latest region list.
NatGatewayId	String	Yes	The ID of the NAT Gateway.
IpCount	Integer	Yes	The number of public IP addresses in the NAT bandwidth package. Valid values: 1 to 50.
Bandwidth	Integer	Yes	The bandwidth of the NAT bandwidth package. Valid values: 5 to 1000.
Zone	String	No	The zone to which the NAT bandwidth package belongs. If you do not specify this parameter, the bandwidth package is randomly allocated to a zone.  Note: Connectivity is not affected when the IP addresses of the NAT bandwidth package and the back-end ECS instance belong to different zones. However, when the IP addresses belong to the same zone, the latency can be shortened.
Name	String	No	The name of the NAT bandwidth package. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code>.

Parameter	Type	Required	Description
Description	String	No	The description of the NAT bandwidth package. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
BandwidthPackageId	String	The ID of the NAT bandwidth package.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateBandwidthPackage
&NatGatewayId=ngw-7mwb327xxxxxxx
&RegionId=cn-shanghai
&Bandwidth=5
&ZoneId=cn-shanghai-a
&IpCount=1
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<CreateBandwidthPackageResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
  <BandwidthPackageId>bwp-s6lmtmxmxxxxxxx</BandwidthPackageId>
```

```
</CreateBandwidthPackageResponse>
```

- JSON format

```
{
  "BandwidthPackageId": "bwp-s6lmtmxxxxxxx",
  "RequestId": "54ED4074-3F89-4F11-B166-837DD3E20FE3"
}
```

2.14.1.13.7 ModifyBandwidthPackageSpec

You can call this operation to modify the bandwidth of a NAT bandwidth package.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyBandwidthPackageSpec</code> .
RegionId	String	Yes	The region ID of the NAT bandwidth package. You can call the DescribeRegions operation to query the latest region list.
BandwidthPackageId	String	Yes	The ID of the NAT bandwidth package.
Bandwidth	Integer	Yes	The bandwidth of the NAT bandwidth package. Valid values: 5 to 1000.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyBandwidthPackageSpec
&BandwidthPackageId=bwp-11odxu2xxxxxxx
&RegionId=cn-shanghai
&Bandwidth=200
&IpCount=1
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<ModifyBandwidthPackageSpecResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</ModifyBandwidthPackageSpecResponse>
```

- JSON format

```
{
  "RequestId": "54ED4074-3F89-4F11-B166-837DD3E20FE3"
}
```

2.14.1.13.8 DescribeBandwidthPackages

You can call this operation to query NAT bandwidth packages in a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBandwidthPackages.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
NatGatewayId	String	No	The ID of the NAT Gateway.
BandwidthPackageId	String	No	The ID of the NAT bandwidth package.
PageNumber	Integer	No	The number of the page to return. Default value: 1.

Parameter	Type	Required	Description
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
BandwidthPackage	List	The details about the NAT bandwidth package. For more information, see the BandwidthPackage list.

Table 2-433: BandwidthPackage list

Parameter	Type	Description
BandwidthPackageId	String	The ID of the NAT bandwidth package.
RegionId	String	The region ID of the NAT bandwidth package.
Description	Integer	The description of the NAT bandwidth package.
Name	String	The name of the NAT bandwidth package.
ZoneId	String	The zone to which the NAT bandwidth package belongs.
GatewayId	String	The ID of the NAT Gateway.
Bandwidth	String	The bandwidth of the NAT bandwidth package. Unit : Mbit/s.
SnatTableIds	List	The SNAT table.
InternetChargeType	String	The billing method of the NAT bandwidth package. Valid value: PayByBandwidth.

Parameter	Type	Description
CreationTime	String	The time when the NAT bandwidth package was created.
ISP	String	The carrier type of the NAT bandwidth package. Valid value: BGP.
PublicIpAddresses	String	The public IP address list of the NAT bandwidth package. For more information, see the PublicIpAdresse list.
CreationTime	String	The time when the NAT bandwidth package was created.

Table 2-434: BandwidthPackage

Parameter	Type	Description
BandwidthPackageId	String	The ID of the NAT bandwidth package.
RegionId	String	The region ID of the NAT bandwidth package.
Description	Integer	The description of the NAT bandwidth package.
Name	String	The name of the NAT bandwidth package.
ZoneId	String	The zone to which the NAT bandwidth package belongs.
GatewayId	String	The ID of the NAT Gateway.
Bandwidth	String	The bandwidth of the NAT bandwidth package. Unit : Mbit/s.
SnatTableIds	List	The SNAT table.
CreationTime	String	The time when the NAT bandwidth package was created.

Parameter	Type	Description
ISP	String	The carrier type of the NAT bandwidth package. Valid value: BGP.
PublicIpAddresses	String	The public IP address list of the NAT bandwidth package.
CreationTime	String	The time when the NAT bandwidth package was created.

Table 2-435: PublicIpAddress list

Parameter	Type	Description
AllocationId	String	The ID of the public IP address.
IpAddress	String	The public IP address.

2.14.1.13.9 ModifyBandwidthPackageAttribute

You can call this operation to modify the name and description of a NAT bandwidth package.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyBandwidthPackageAttribute</code> .
RegionId	String	Yes	The region ID of the NAT bandwidth package. You can call the DescribeRegions operation to query the latest region list.
BandwidthPackageId	String	Yes	The ID of the NAT bandwidth package.
Name	String	No	The name of the NAT bandwidth package. The name must be 2 to 128 characters in length. It can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .
Description	String	No	The description of the NAT bandwidth package. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with <code>http://</code> or <code>https://</code> .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com?Action=ModifyBandwidthPackageAttribute
&BandwidthPackageId=bwp-s6lmtmxxxxxxx
&Name=modified
&RegionId=cn-shanghai
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<ModifyBandwidthPackageAttributeResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</ModifyBandwidthPackageAttributeResponse>
```

- JSON format

```
{
  "RequestId": "54ED4074-3F89-4F11-B166-837DD3E20FE3"
}
```

2.14.1.13.10 DeleteBandwidthPackage

You can call this operation to delete a NAT bandwidth package.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteBandwidthPackage.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
BandwidthPackageId	String	Yes	The ID of the NAT bandwidth package.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteBandwidthPackage
&BandwidthPackageId=bwp-11odxu2xxxxxxx
&RegionId=cn-shanghai
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<DeleteBandwidthPackageResponse>
  <RequestId>0ED8D006-F706-4D23-88ED-E11ED28DCAC0</RequestId>
</DeleteBandwidthPackageResponse>
```

- JSON format

```
{
  "RequestId": "0ED8D006-F706-4D23-88ED-E11ED28DCAC0"
}
```

2.14.1.13.11 AddBandwidthPackageIps

You can call this operation to add public IP addresses to a NAT bandwidth package.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AddBandwidthPackageIps.
RegionId	String	Yes	The region ID of the NAT bandwidth package. You can call the DescribeRegions operation to query the latest region list.
BandwidthPackageId	String	Yes	The ID of the NAT bandwidth package.
IpCount	String	No	The number of public IP addresses in the NAT bandwidth package. Valid values: 1 to 50.

Parameter	Type	Required	Description
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=AddBandwidthPackageIps
&BandwidthPackageId=bwp-11odxu2xxxxxxx
&RegionId=cn-shanghai
&IpCount=6
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<AddBandwidthPackageIpsResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</AddBandwidthPackageIpsResponse>
```

- JSON format

```
{
  "RequestId": "2315DEB7-5E92-423A-91F7-4C1EC9AD97C3"
}
```

2.14.1.13.12 RemoveBandwidthPackageIps

You can call this operation to remove public IP addresses from a NAT bandwidth package.

When you call this operation, make sure that the following requirements are met:

- You cannot remove all public IP addresses from the NAT bandwidth package.

- You cannot remove any IP addresses that are not included in the NAT bandwidth package.
- You cannot remove any IP addresses listed in the DNAT table or the SNAT table.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>RemoveBandwidthPackageIps</code> .
RegionId	String	Yes	The region ID of the NAT bandwidth package. You can call the DescribeRegions operation to query the latest region list.
BandwidthPackageId	String	Yes	The ID of the NAT bandwidth package.
RemovedIpAddresses.n	String	No	The ID of the public IP address <i>n</i> to be removed. Valid values of <i>n</i> : 1 to 20.
ClientToken	String	No	The client token that is used to ensure the idempotence of the request. You can use the client to generate this value, but you must ensure that it is unique among different requests. The token can contain only ASCII characters, and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=RemoveBandwidthPackageIps
&RemovedIpAddresses.1=nateip-1110a2lxxxxxxx
&RemovedIpAddresses.2=nateip-11s2jemxxxxxxx
&BandwidthPackageId=bwp-11odxu2kxxxxxxx
&RegionId=cn-shanghai
```

&Common request parameters**Sample responses**

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<RemoveBandwidthPackageResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</RemoveBandwidthPackageResponse>
```

- JSON format

```
{
  "RequestId": "2315DEB7-5E92-423A-91F7-4C1EC9AD97C3"
}
```

2.14.1.13.13 CreateForwardEntry

You can call this topic to add DNAT entries to a DNAT table.

Each DNAT entry consists of five elements: ExternalIp, ExternalPort, Protocol, InternalIp, and InternalPort.

After a DNAT entry is added, the NAT Gateway forwards packets of the specified protocol received from [ExternalIp: ExternalPort] to [InternalIp: InternalPort], and sends the response back through the same route.

When you call this operation, make sure that the following requirements are met:

- A NAT Gateway and a user-created SNAT Gateway (using an ECS instance as the SNAT Gateway) cannot coexist in a VPC.
- After you have created a NAT Gateway, a route entry is automatically added to the routing table of the VPC. The destination CIDR block is 0.0.0.0/0 and the next-hop is the NAT Gateway. The entry ensures that traffic is routed to the NAT Gateway.
- If the VPC routing table already contains an entry with a destination CIDR block of 0.0.0.0/0, delete this entry. Otherwise, you cannot create a NAT Gateway.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateForwardEntry.

Parameter	Type	Required	Description
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
ForwardTableId	String	Yes	The ID of the DNAT table.
ExternalIp	String	Yes	The public IP address.
IpProtocol	String	Yes	The protocol type. Valid values: - TCP - UDP - Any
ExternalPort	String	No	The public port. Valid values: 1 to 65535.
InternalIp	String	Yes	The destination private IP address.
InternalPort	String	No	The destination private port. Valid values: 1 to 65535.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ForwardEntryId	String	The ID of the DNAT entry.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateForwardEntry
&ExternalIp=139.xx.xx.107
&RegionId=cn-shanghai
&ExternalPort=Any
&InternalIp=192.xx.xx.1
&ForwardTableId=ftb-11tc6xgmxxxxxxx
&IpProtocol=Any
&InternalPort=Any
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<CreateForwardEntryResponse>
  <ForwardEntryId>fwd-119smwxxxxxxxx</ForwardEntryId>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</CreateForwardEntryResponse>
```

- JSON format

```
{
  "ForwardEntryId": "fwd-119smwxxxxxxxx",
  "RequestId": "2315DEB7-5E92-423A-91F7-4C1EC9AD97C3"
}
```

2.14.1.13.14 DeleteForwardEntry

You can call this operation to delete a DNAT entry.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteForwardEntry.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
ForwardTableId	String	Yes	The ID of the DNAT table.
ForwardEntryId	String	Yes	The ID of the DNAT entry.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteForwardEntry
&ForwardEntryId=dnat-bs5bexxxxxxxxx
&RegionId=cn-shanghai
&ForwardTableId=stb-244xxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<DeleteForwardEntryResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</DeleteForwardEntryResponse>
```

- JSON format

```
{
  "RequestId": "69B31D6E-9F34-4A5A-8DBC-230A3918E828"
}
```

2.14.1.13.15 ModifyForwardEntry

You can call this operation to modify a DNAT entry.

**Note:**

You cannot modify a DNAT entry if any DNAT entry in the DNAT table is in the Pending or Modifying state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyForwardEntry</code> .
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
ForwardTableId	String	Yes	The ID of the DNAT table.
ForwardEntryId	String	Yes	The ID of the DNAT entry.
ExternalIp	String	No	The public IP address.
IpProtocol	String	No	The protocol type. Valid values: • TCP • UDP • Any
ExternalPort	String	No	The public port. Valid values: 1 to 65535.

Parameter	Type	Required	Description
InternalIp	String	No	The destination private IP address.
InternalPort	String	No	The destination private port. Valid values: 1 to 65535.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
ForwardEntryId	String	The ID of the DNAT entry.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateForwardEntry
&ExternalIp=139.xx.xx.107
&RegionId=cn-shanghai
&ExternalPort=Any
&InternalIp=192.xx.xx.1
&ForwardTableId=ftb-11tc6xxxxxxxxx
&IpProtocol=Any
&InternalPort=Any
&Common request parameters
```

Sample responses

- XML format

```
<?xml version="1.0" encoding="UTF-8"?>
<CreateForwardEntryResponse>
  <ForwardEntryId>fwd-119smw5xxxxxxxx</ForwardEntryId>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</CreateForwardEntryResponse>
```

- JSON format

```
{
  "ForwardEntryId": "fwd-119smw5xxxxxxxx",
  "RequestId": "2315DEB7-5E92-423A-91F7-4C1EC9AD97C3"
```

}

2.14.1.13.16 DescribeForwardTableEntries

You can call this operation to query DNAT entries in a DNAT table.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeForwardTableEntries.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
ForwardTableId	String	No	The ID of the DNAT table.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
ForwardTableEntries	List	The details about the NAT Gateway. For more information, see the ForwardTableEntry list.

Table 2-436: ForwardTableEntry list

Parameter	Type	Description
ForwardTableId	String	The ID of the DNAT table that the DNAT entry belongs to.

Parameter	Type	Description
ForwardEntryId	String	The ID of the DNAT entry.
ExternalIp	String	The public IP address.
ExternalPort	String	The public port.
IpProtocol	String	The protocol type.
InternalIp	String	The private IP address.
InternalPort	String	The private port.
Status	String	The status of the DNAT entry. Valid values: - Pending: The DNAT entry is being configured. - Available: The DNAT entry is available. - Modifying: The DNAT entry is being modified.

Examples

Sample requests

```
https://vpc.example.com/?&Action=DescribeForwardTableEntries
&RegionId=cn-shanghai
&ForwardTableId=ftb-11tc6xxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<DescribeForwardTableEntriesResponse>
  <PageNumber>1</PageNumber>
  <TotalCount>1</TotalCount>
  <PageSize>10</PageSize>

      }
    ]
  }
}
```

2.14.1.13.17 CreateSnatEntry

You can call this operation to add SNAT entries to a SNAT table.

Each SNAT entry contains a VSwitch ID and a public IP address (SnatIp). After you have added a SNAT entry, ECS instances can access the public network through the public IP address.

When you call this operation, make sure that the VSwitch specified in the SNAT entry meet the following requirements:

- The VSwitch must belong to the same VPC as the NAT Gateway.
- Each VSwitch can belong to only one SNAT entry.
- A public IP address cannot be used by a DNAT entry and a SNAT entry at the same time.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateSnatEntry.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
SnatTableId	String	Yes	The ID of the SNAT table.
SourceVSwitchId	String	Yes	The ID of the VSwitch.
SourceCIDR	String	Yes	The CIDR block of the VSwitch, such as 10.1.1.0/24.  Note: You cannot specify this parameter and SourceVSwitchId at the same time.
SnatIp	String	No	The public IP address. You can separate multiple IP addresses with commas (,). Example: 47.XX.XX.98,47.XX.XX.99,47.XX.XX.241

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
SnatEntryId	String	The ID of the SNAT entry.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateSnatEntry
&RegionId=cn-shanghai
&SnatTableId=stb-gz3r3odxxxxxxxxx
&SnatIp=139.xx.xx.40
&SourceVSwitchId=vsw-yrv0wixxxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<CreateSnatEntryResponse>
  <SnatEntryId>snat-kmd6nvxxxxxxxxx</SnatEntryId>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
```

```
</CreateSnatEntryResponse>
```

- JSON format

```
{
  "RequestId": "69B31D6E-9F34-4A5A-8DBC-230A3918E828",
  "SnatEntryId": "snat-kmd6nvxxxxxxxx"
}
```

2.14.1.13.18 DeleteSnatEntry

You can call this operation to delete a SNAT entry.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteSnatEntry.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
SnatTableId	String	Yes	The ID of the SNAT table.
SnatEntryId	String	Yes	The ID of the SNAT entry.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteSnatEntry
&SnatEntryId=snat-bs5bezbxxxxxxxx
&RegionId=cn-shanghai
&SnatTableId=stb-244fxxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<DeleteSnatEntryResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
```

```
</DeleteSnatEntryResponse>
```

- JSON format

```
{
  "RequestId": "69B31D6E-9F34-4A5A-8DBC-230A3918E828"
}
```

2.14.1.13.19 ModifySnatEntry

You can call this operation to modify the SNATed IP address (public IP address) of a specified SNAT entry.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifySnatEntry</code> .
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
SnatTableId	String	Yes	The ID of the SNAT table.
SnatEntryId	String	Yes	The ID of the SNAT entry.
SnatIp	String	No	The public IP address. You can separate multiple IP addresses with commas (,). Example: 47.XX.XX.98,47.XX.XX.99,47.XX.XX.241

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifySnatEntry
&SnatEntryId=snat-bs5bezbmxxxxxxx
&RegionId=cn-shanghai
&SnatTableId=stb-gz3r3oxxxxxxx
&SnatIp=139.xx.xx.107
```

&Common request parameters

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<ModifySnatEntryResponse>
  <RequestId>2315DEB7-5E92-423A-91F7-4C1EC9AD97C3</RequestId>
</ModifySnatEntryResponse>
```

- JSON format

```
{
  "RequestId": "69B31D6E-9F34-4A5A-8DBC-230A3918E828"
}
```

2.14.1.13.20 DescribeSnatTableEntries

You can call this operation to query SNAT entries in a SNAT table.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSnatTableEntries.
RegionId	String	Yes	The region ID of the NAT Gateway. You can call the DescribeRegions operation to query the latest region list.
SnatTableId	String	Yes	The ID of the SNAT table.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.

Parameter	Type	Description
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
SnatTableEntries	List	The details about the SNAT entries.

Table 2-437: SnatEntry

Parameter	Type	Description
SnatTableId	String	The ID of the SNAT table to which the SNAT entries belong.
SnatEntryId	String	The ID of the SNAT entry.
SourceVSwitchId	String	The ID of the VSwitch that accesses the public network through SNAT.
SourceCIDR	String	The source CIDR block of the SNAT entry.
SnatIp	String	The public IP address of the SNAT entry.
Status	String	The status of the SNAT entry. Valid values: - Pending: The SNAT entry is being configured. - Available: The SNAT entry is available. - Modifying: The SNAT entry is being modified.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeSnatTableEntries
&RegionId=cn-shanghai
&SnatTableId=stb-gz3r3odxxxxxxx
&Common request parameters
```

2.14.1.14 High-Availability Virtual IP

2.14.1.14.1 CreateHaVip

You can call this operation to create a High-Availability Virtual IP (HaVip).

When you call this operation, make sure that the following requirements are met:

- You can create a maximum of five HaVips for a VPC.

- Before you delete a VPC, you must delete the HaVips that you have created for it.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateHaVip.
RegionId	String	Yes	The region ID of the HaVip instance. You can call the DescribeRegions operation to query the latest region list.
VSwitchId	String	Yes	The ID of the VSwitch to which the HaVip instance belongs.
IpAddress	String	No	The IP address of the HaVip instance. If this parameter is not specified, an idle IP address of the specified VSwitch is randomly allocated.
Description	String	No	The description of the HaVip instance. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with http:// or https://.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
HaVipId	String	The ID of the HaVip instance.

Error codes

Error code	Error message	HTTP status code	Description
InvalidRegionId.NotFound	The RegionId provided does not exist in our records.	404	The error message returned because the specified RegionId does not exist.

Error code	Error message	HTTP status code	Description
MissingParameter	The input parameter "\$ParameterName" that is mandatory for processing this request is not supplied.	400	The error message returned because a required parameter is missing.
InvalidVSwitchId.NotFound	The specified VSwitch does not exist in the specified region.	404	The error message returned because the specified VSwitchId does not exist.
InvalidIpAddress.Malformed	The specified IP address is wrongly formed.	400	The error message returned because the IP address format is incorrect.
InvalidIpAddress.OutOfRange	The specified IP address is out of VSwitch CIDR.	400	The error message returned because the specified IP address is outside the range of the VSwitch CIDR block.
InvalidIpAddress.NotAvailable	The specified IP address is not available because it is a system reserved IP address.	400	The error message returned because the specified IP address is a system reserved address and is therefore unavailable.
InvalidIpAddress.AlreadyUsed	The specified IP address is already used by other resource.	400	The error message returned because the specified IP address is already used by other resources.
InvalidDescription.Malformed	The specified Description is wrongly formed.	403	The error message returned because the format of the Description is invalid.
QuotaExceeded.HaVip	Living HaVip quota exceeded.	403	The error message returned because the number of HaVips for the account has exceeded the upper limit.
CountLimitExceed.HaVipInVpc	Specified Vpc exceeds the quota of max number of ha-vip count.	403	The error message returned because the number of HaVips within the VPC has reached the upper limit.

Examples

Sample requests

```
https://vpc.example.com/?Action=CreateHaVip
&VSwitchId=vsw-25b7pvxxxxxxxxx
&RegionId=cn-hangzhou
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<CreateHaVipResponse>
  <RequestId>C44F62BE-9CE7-4277-B117-69243F3988BF</RequestId>
  <HaVipId>hvip-2zeo05qre24nhrqpyxxxxxxxx</HaVipId>
</CreateHaVipResponse>
```

- JSON format

```
{
  "RequestId": "C44F62BE-9CE7-4277-B117-69243F3988BF",
  "HaVipId": "hvip-2zeo05qre24nhrqpyxxxxxxxx"
}
```

2.14.1.14.2 ModifyHaVipAttribute

You can call this operation to modify the description of a HaVip instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to <code>ModifyHaVipAttribute</code> .
RegionId	String	Yes	The region ID of the HaVip instance. You can call the DescribeRegions operation to query the latest region list.
HaVipId	String	Yes	The ID of the HaVip instance that you want to modify.
Description	String	No	The description of the HaVip instance.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Examples

Sample requests

```
https://vpc.example.com/?Action=ModifyHaVipAttribute
&HaVipId=havip-2zeo05qre24nhrqpyfdxxxxxxx
&RegionId=cn-shanghai
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<ModifyHaVipAttributeResponse>
  <RequestId>C44F62BE-9CE7-4277-B117-69243F3988BF</RequestId>
</ModifyHaVipAttributeResponse>
```

- JSON format

```
{
  "RequestId": "C44F62BE-9CE7-4277-B117-69243F3988BF"
}
```

2.14.1.14.3 DeleteHaVip

You can call this operation to delete a High-Availability Virtual IP (HaVip).

When you call this operation, make sure that the following requirements are met:

- You can only delete a HaVip in the Available state.
- Make sure that there is no route destined for the HaVip that you want to delete.
- Make sure that the HaVip that you want to delete is not bound to an EIP.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteHaVip.

Parameter	Type	Required	Description
RegionId	String	Yes	The region ID of the HaVip instance. You can call the DescribeRegions operation to query the latest region list.
HaVipId	String	Yes	The ID of the HaVip instance that you want to delete.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

Error code	Error message	HTTP status code	Description
InvalidRegionId.NotFound	The RegionId provided does not exist in our records.	404	The error message returned because the specified RegionId does not exist.
MissingParameter	The input parameter "\$ParameterName" that is mandatory for processing this request is not supplied.	400	The error message returned because a required parameter is missing.
InvalidHaVipId.NotFound	The specified HaVip does not exist in the specified region.	404	The error message returned because the specified HaVip does not exist.
IncorrectStatus	HaVip can be deleted only when it's status is Available.	400	The error message returned because the HaVip instance to be deleted is not in the Available state.
DependencyViolation.HaVipReferedByRouteEntry	HaVip cannot be deleted when it is referred by a route table entry as next hop.	400	The error message returned because the specified HaVip is specified as the next-hop for a route entry.

Error code	Error message	HTTP status code	Description
Dependency Violation. HaVipAssociatedWithEIP	HaVip cannot be deleted when it is associated with a EIP.	400	The error message returned because the specified HaVip is bound to an EIP.

Examples

Sample requests

```
https://vpc.example.com/?Action=DeleteHaVip
&HaVipId=havip-2zeo05qre24nhrqpyfds2
&RegionId=cn-shanghai
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<DeleteHaVipResponse>
  <RequestId>C44F62BE-9CE7-4277-B117-69243F3988BF</RequestId>
</DeleteHaVipResponse>
```

- JSON format

```
{
  "RequestId": "C44F62BE-9CE7-4277-B117-69243F3988BF"
}
```

2.14.1.14.4 AssociateHaVip

You can call this operation to bind a HaVip to an ECS instance of the VPC network.

When you call this operation, make sure that the following requirements are met:

- The HaVip takes effect immediately when it is bound to an ECS instance of the VPC network. You do not need to restart the ECS instance. However, you must configure the HaVip on the instance NIC.
- The HaVip and the ECS instances you want to bind must be managed by the same VSwitch.
- You can bind a HaVip to a maximum of two ECS instances.
- You can bind an ECS instance only when it is in the Running or Stopped state.
- You can bind a HaVip instance only when it is in the Available or InUse state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AssociateHaVip.
RegionId	String	Yes	The region ID of the HaVip instance. You can call the DescribeRegions operation to query the latest region list.
HaVipId	String	Yes	The ID of the HaVip instance.
InstanceId	String	Yes	The ID of the ECS instance that you want to bind.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
HaVipId	String	The ID of the HaVip instance.

Error codes

Error code	Error message	HTTP status code	Description
InvalidRegionId.NotFound	The RegionId provided does not exist in our records.	404	The error message returned because the specified RegionId does not exist.
MissingParameter	The input parameter "\$ParameterName" that is mandatory for processing this request is not supplied.	400	The error message returned because a required parameter is missing.
InvalidHaVipId.NotFound	The specified HaVip does not exist in the specified region.	404	The error message returned because the specified HaVip does not exist.
InvalidInstanceId.NotFound	The specified Instance does not exist in the specified region.	404	The error message returned because the specified ECS instance does not exist.

Error code	Error message	HTTP status code	Description
IncorrectHaVipStatus	HaVip can be operated by this action only when it's status is Available or InUse.	400	The error message returned because the HaVip instance that you want to bind is not in the Available or InUse state.
IncorrectInstanceStatus	ECS instance can be operated by this action only when it's status is Running or Stopped.	400	The error message returned because the ECS instance that you want to bind is not in the Running or Stopped state.
CountLimitExceeded. HaVipOnECSInstance	The amount of Instance associated with the specified HaVip reach its limits.	400	You can bind a HaVip to a maximum of two ECS instances . The error message returned because the number of ECS instances bound to the specified HaVip has exceeded the upper limit.
CountLimitExceed. HaVipOnInstance	The amount of HaVip associated with the specified Instance reach its limits.	400	The error message returned because the number of HaVips bound to the specified ECS instance has reached the upper limit.
NotBelongToSameVSwitch	The specified HaVip and ECSInstance do not belong to same VSwitch.	400	The error message returned because the specified HaVip and the ECS instance are not managed by the same VSwitch .

Examples

Sample requests

```
https://vpc.example.com/?Action=AssociateHaVip
&HaVipId=havip-2zeo05qre24nhrxxxxxxx
&RegionId=cn-shanghai
&InstanceId=i-faf344422ffsxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<AssociateHaVipResponse>
```

```
<RequestId>C44F62BE-9CE7-4277-B117-69243F3988BF</RequestId>
</AssociateHaVipResponse>
```

- JSON format

```
{
  "RequestId": "C44F62BE-9CE7-4277-B117-69243F3988BF"
}
```

2.14.1.14.5 UnassociateHaVip

You can call this operation to unbind a HaVip from an ECS instance of the VPC network.

When you call this operation, make sure that the following requirements are met:

- You can unbind an ECS instance when it is in the Running or Stopped state.
- A HaVip instance can only be unbound when it is in the Available or InUse state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to UnassociateHaVip.
RegionId	String	Yes	The region ID of the HaVip instance. You can call the DescribeRegions operation to query the latest region list.
HaVipId	String	Yes	The ID of the HaVip instance.
InstanceId	String	Yes	The ID of the ECS instance that you want to unbind.
Force	String	No	Specifies whether to force an unbinding operation. Valid values: True and False. Default value: False.  Note: You cannot unbind the primary instance if the parameter value is False.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

Error code	Error message	HTTP status code	Description
InvalidRegionId.NotFound	The RegionId provided does not exist in our records.	404	The error message returned because the specified RegionId does not exist.
InvalidHaVipId.NotFound	The specified HaVip does not exist in the specified region.	404	The error message returned because the specified HaVip does not exist.
InvalidInstanceId.NotFound	The specified Instance does not exist in the specified region.	404	The error message returned because the specified ECS instance does not exist.
IncorrectHaVipStatus	HaVip can be operated by this action only when it's status is Available or InUse.	400	The error message returned because the HaVip instance that you want to unbind is not in the Available or InUse state.
IncorrectInstanceStatus	ECS instance can be operated by this action only when it's status is Running or Stopped.	400	The error message returned because the ECS instance that you want to unbind is not in the Running or Stopped state.
Forbidden.UnassociateMaster	Unassociating a master instance is not allowed unless the parameter Force is True.	400	The error message returned because the primary instance cannot be unbound. You can unbind the primary instance only after you have set Force to True.
NotBelongToSameVSwitch	The specified HaVip and ECSInstance do not belong to same VSwitch.	400	The error message returned because the specified HaVip and the ECS instance are not managed by the same VSwitch.

Examples

Sample requests

```
https://vpc.example.com/?Action=UnassociateHaVip
&HaVipId=havip-2zeo05qre24nhrqxxxxxxx
&RegionId=cn-shanghai
&InstanceId=i-faf344422ffsxxxxxxx
&Common request parameters
```

Sample responses

- XML format

```
<? xml version="1.0" encoding="UTF-8" ? >
<UnassociateHaVipResponse>
  <RequestId>C44F62BE-9CE7-4277-B117-69243F3988BF</RequestId>
</UnassociateHaVipResponse>
```

- JSON format

```
{
  "RequestId": "C44F62BE-9CE7-4277-B117-69243F3988BF"
}
```

2.14.1.14.6 DescribeHaVips

You can call this operation to query HaVip instances within a specified region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeHaVips.
RegionId	String	Yes	The region ID of the HaVip instance. You can call the DescribeRegions operation to query the latest region list.

Parameter	Type	Required	Description
Filter.n.Key	String	Yes	Specifies filter condition n. You can specify a maximum of five filter conditions. Valid values of n: 1 to 5. You can specify multiple values for each filter condition. If you use "or" to separate multiple values, the system returns results that match at least one of the filter conditions. If you use "and" to separate multiple values, the system returns results that match all filter conditions. The following filter conditions are available: • VpcId: the ID of the VPC • VSwitchId: the ID of the VSwitch • Status: the status of the HaVip instance • HaVipId: the ID of the HaVip instance • HaVipAddress: the IP address of the HaVip instance
Filter.n.Value.m	String	Yes	Specifies value m of filter condition n. Valid values of m: 1 to 5.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.

Parameter	Type	Description
PageSize	String	The number of entries on each page.
HaVipItemType	List	The details about the HaVip.

Table 2-438: HaVipItemType

Parameter	Type	Description
HaVipId	String	The ID of the HaVip instance.
RegionId	String	The region ID of the HaVip instance.
VpcId	String	The ID of the VPC to which the HaVip instance belongs.
VSwitchId	String	The ID of the VSwitch to which the HaVip instance belongs.
IpAddress	String	The private IP address of the HaVip instance.
Status	String	The status of the HaVip instance.
Associated Instances	String	The ECS instances that are bound to the HaVip instance.
MasterInstanceId	String	The ID of the HaVip instance that has been bound to the private IP address.
Associated EipAddresses	String	The list of EIPs that are bound to the HaVip instance.
Description	String	The description of the HaVip instance.
CreationTime	String	The time when the HaVip instance was created.

Error codes

Error code	Error message	HTTP status code	Description
InvalidRegionId.NotFound	The RegionId provided does not exist in our records.	404	The error message returned because the specified RegionId does not exist.
MissingParameter	The input parameter "\$ParameterName" that is mandatory for processing this request is not supplied.	400	The error message returned because a required parameter is missing.

Error code	Error message	HTTP status code	Description
RepeatedParameter. \$ParameterName	Specified parameter \$ParameterName is repeated.	400	The error message returned because the specified parameter is repeated.
NonsequenceParameter.{xxx.n.yyy.m}	Specified parameter is not a continuous sequence.	400	The error message returned because the key or value of the Filter does not start from 1 or in a continuous sequence.
InvalidFilterKey.ValueNotSupported	Specified filter key is not supported: Filter.X.key	400	The error message returned because the specified filter condition is not supported.

Examples

Sample requests

2.14.1.15 DescribeRegions

This topic describes how to query available regions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRegions.

Response parameters

Name	Type	Description
RequestId	String	The request ID.
Regions	List	The list of available regions.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeRegions
```

&<Common request parameters>

Sample responses

XML format

```
<? xml version="1.0" encoding="utf-8"? >

      }
    ]
  }
}
```

2.14.1.16 DescribeZones

This topic describes how to query zones in a specific region.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeZones.
RegionId	String	Yes	The region ID. You can call DescribeRegions to obtain the region ID.

Response parameters

Name	Type	Description
RequestId	String	The request ID.
Zones	List	The list of zones.

Examples

Sample requests

```

2.14.1.17 DescribeAccessPoints

You can call this operation to query physical connection access points in a region.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccessPoints.
RegionId	String	Yes	The region ID of the access point. You can call the DescribeRegions operation to query the latest region list.
PageNumber	Integer	No	The number of the page to return. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	String	The total number of entries.
PageNumber	Integer	The current page number.
PageSize	String	The number of entries on each page.
AccessPointSet	List	A list of access points.

Examples

Sample requests

```
https://vpc.example.com/?Action=DescribeAccessPoints
&RegionId=cn-beijing
&Common request parameters
```

Sample responses

JSON format

```
{
  "AccessPointSet": {
    "AccessPointType": [
      {
        "Name": "Beijing-Fengtai-A",
        "Status": "recommended",
        "Description": "cn-beijing-ft-cxp32",
        "Type": "VPC",
        "Location": "",
        "HostOperator": "Haokuan",
        "AttachedRegionNo": "cn-beijing",
        "AccessPointId": "ap-cn-beijing-ft-A"
      }
    ]
  },
  "PageNumber": 1,

2.14.2 SDK reference

2.14.2.1 Call the SDK for Java

2.14.2.1.1 Quick start

This topic describes how to obtain and call the VPC Java SDK.

Environment preparation

- Before using the Java SDK, you must have an authorized account and an AccessKey pair that comprises an AccessKey ID and an AccessKey Secret. For more information about how to obtain and view your AccessKey in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).
- The Apsara Stack Java SDK requires JDK V1.6 and later.

Install the Apsara Stack Java SDK

If you use Apache Maven to manage Java projects, you need only to import the JAR file to pom.xml of the project.

To use the service development kit, you must install the SDK core library and the service SDK .

The version of the SDK core library is 3.7.1. The version of the VPC SDK is 1.0.

```

<dependencies>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-core</artifactId>
    <version>3.7.1</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-core-3.7.1.jar</systemPath>
  </dependency>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>aliyun-java-sdk-vpc</artifactId>
    <version>1.0</version>
    <scope>system</scope>
    <systemPath>${project.basedir}/lib/aliyun-java-sdk-vpc-1.0.jar</systemPath>
  </dependency>
</dependencies>

```

</dependencies>

Call the Java SDK

The following code provides an example of how to call the Apsara Stack Java SDK:

1. Create a DefaultAcsClient instance and initialize it.
2. Create an API request and set its parameters.
3. Initiate the request and handle the response or exceptions.

```
import java.util.UUID;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.profile.DefaultProfile;
import com.aliyuncs.vpc.model.v20160428.CreateVpcRequest;
import com.aliyuncs.vpc.model.v20160428.CreateVpcResponse;
public class Demo {
    public static void main(String[] args) {
        // Create a DefaultAcsClient instance and initialize it.
        DefaultProfile profile = DefaultProfile.getProfile(
            "<your-region-id>", // Your region ID.
            "<your-access-key-id>", // Your AccessKey ID.
            "<your-access-key-secret>"); // Your AccessKey Secret.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create an API request and set its parameters.
        CreateVpcRequest request = new CreateVpcRequest();
        request.setVpcName("MyVpc");
        request.setCidrBlock("192.168.0.0/16");
        request.setClientToken(UUID.randomUUID().toString());
        // Initiate the request and handle the response or exceptions.
        CreateVpcResponse response;
        try {
            response = client.getAcsResponse(request);
            String vpcId = response.getVpcId();
            System.out.println("Create vpc success, vpcId = " + vpcId);
        } catch (ServerException e) {
            e.printStackTrace();
        } catch (ClientException e) {
            e.printStackTrace();
        }
    }
}
```

2.14.2.1.2 Usage

2.14.2.1.2.1 Install the SDK for Java

This topic describes how to install and use the VPC SDK for Java.

The VPC SDK for Java supports JDK V1.6 and later. You can import the JAR file to install the JDK.

You can click [Here](#) to download the JAR file for VPC.

You can import the JAR file to install the VPC SDK for Java regardless of the IDE (Eclipse or IntelliJ).

The installation method is as follows:

- Use Eclipse

To install the VPC SDK for Java through Eclipse, perform the following operations:

1. Copy the downloaded `aliyun-java-sdk-vpc-1.0.jar` file to your project folder.
2. Open your project in Eclipse, right-click the project, and choose **Properties** from the shortcut menu.
3. In the dialog box that appears, choose **Java Build Path > Libraries > Add JARs** to add the downloaded JAR file.
4. Click **Apply and Close**.

- Use IntelliJ

To install the VPC SDK for Java through IntelliJ, perform the following operations:

1. Copy the downloaded `aliyun-java-sdk-vpc-1.0.jar` file to your project folder.
2. Open your project in IntelliJ, and choose **File > Project Structure** from the menu.
3. Click **Apply**, and then click **OK**.

2.14.2.1.2.2 Configure identity verification credentials

When using SDKs to access Apsara Stack resources, you must provide an authorized Apsara Stack tenant account to verify your identity.

The Java SDK supports the use of AccessKey pairs for identity verification. For more information about how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

To use AccessKey pairs as credentials, you must configure your credentials when initializing the client.

Notice:

Ensure that code containing your AccessKey is kept confidential and is not exposed (such as being uploaded to a public GitHub project). Otherwise, the information security of your Apsara Stack tenant account may become compromised.

```
DefaultProfile profile = DefaultProfile.getProfile(
    "<your-region-id>", // Your region ID.
    "<your-access-key-id>", // Your AccessKey ID.
```

```
"<your-access-key-secret>"); // Your AccessKey Secret.
```

2.14.2.1.2.3 Call a service

This topic describes how to use the VPC SDK for Java to initiate a request.

Procedure

1. Create an AcsClient instance.

```
IAcsClient client = new DefaultAcsClient(profile);
```

2. Create a request.

The naming convention for a request is `${apiName}Request`. In the code, `${apiName}` is the API name, such as `CreateVpc`.

When multiple SDKs are used, different requests may have the same name. Differentiate the requests based on the `PageSize` value.

```
CreateVpcRequest request = new CreateVpcRequest();  
request.setPageSize(10);
```

3. Make a call and handle the response.

```
DescribeInstancesResponse response;  
try {  
    response = client.getAcsResponse(request);  
    for (DescribeInstancesResponse.Instance instance:response.getInstances()) {  
        System.out.println(instance.getPublicIpAddress());  
    }  
} catch (ServerException e) {  
    e.printStackTrace();  
} catch (ClientException e) {  
    e.printStackTrace();  
}
```

```
}
```

All the returned fields are deserialized into the response. You can call `response.getXXX()` to obtain the response fields.

```
instanceStatus := response.getStatus()
```

However, if an exception occurs or you want to obtain the original HTTP response, use `doAction()` to obtain the original response.

```
HttpResponse response = client.doAction(request);
```

2.14.2.1.2.4 Handle exceptions

When you use the Apsara Stack SDK for Java, if the server or SDK encounters an exception, the corresponding exception information is returned. The exception information contains error details, such as error codes and error messages.

Typically, you do not need to handle the exceptions that the SDK for Java returns. You need only to handle exceptions related to the server.

- `ServerException` indicates the error message generated on the server side.
- `ClientException` indicates the error message for SDK exceptions.

For example, if the following exception occurs, you can modify the AccessKey ID based on the error message.

```
com.aliyuncs.exceptions.ClientException: InvalidAccessKeyId.NotFound : Specified access key is not found.
```

If you need to handle SDK exceptions, you can use the following example as a reference:

```
try {
    FooResponse response = client.getAcsResponse(request);
    // Handle the response.
    // ...
} catch (ServerException e) {
    // You can add your own exception handling logic here.
    // In this example, an error message is displayed when an exception occurs.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
    // If the problem persists, you can submit a ticket with the request ID included.
    System.out.println("ResponseId=" + e.getRequestId());
} catch (ClientException e) {
    // You can add your own exception handling logic here.
    // In this example, an error message is displayed when an exception occurs.
    System.out.println("ErrorCode=" + e.getErrCode());
    System.out.println("ErrorMessage=" + e.getErrMsg());
}
```

```
}
```

2.14.2.1.2.5 Common errors

This topic describes how to troubleshoot common errors you may encounter during the use of SDKs.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot obtain the region endpoint of the called service.	Check whether the provided region ID and endpoint are correct. After you obtain the correct endpoint, you can run the following code to set the endpoint: <pre>DefaultProfile.addEndpoint("cn-hangzhou", "cn-hangzhou", "Vpc", "vpc.example.com");</pre>
SDK.JsonUnmarshalError	Failed to unmarshal response	The SDK response fails to be deserialized. In most cases, it is because the structure of the response received by the SDK does not conform to the API metadata, such as mismatched fields or incorrect formatting.	You can use the <code>client.doAction(request)</code> method to obtain the original HTTP response.
SDK.TimeoutError	The request timed out 4 times (3 for retry), perhaps we should have the threshold raised a little?	The request has timed out and all retry attempts have failed.	In scenarios such as poor network quality, we recommend that you prolong the timeout period or increase the maximum number of retries.

Error code	Error message	Cause	Solution
SDK.ServerError: InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect Recommend : https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API only accepts HTTPS requests. It does not accept HTTP requests.	You can add the following code to the request before it is sent: <pre>request.setProtocol(ProtocolType.HTTPS)</pre>

2.14.2.2 Call the SDK for Python

2.14.2.2.1 Quick start

This topic describes how to obtain and call the VPC Python SDK.

Environment preparation

- Before using the Python SDK, you must have an authorized account and an AccessKey pair that comprises an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).

Install the Python SDK

To install the Python SDK, perform the following operations:

1. Install the SDK core library.

- If you are using Python V2.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core
```

- If you are using Python V3.x, run the following command to install the SDK core library:

```
pip install aliyun-python-sdk-core-v3
```

2. Install the SDK for the VPC.

The following command provides an example of how to install the VPC SDK:

```
pip install aliyun-python-sdk-cms
```

Call the Python SDK

The following example shows you how to call the Python SDK:

1. Create a client instance. When creating the client instance, you must obtain the Region ID, AccessKey ID, and AccessKey Secret.
2. Create an API request and set its parameters.
3. Initiate the request and handle the response or exceptions.

```
#!/usr/bin/env python
#coding=utf-8

from aliyunsdkcore import client
from aliyunsdkvpc.request.v20160428 import CreateVpcRequest
from aliyunsdkcore.profile import region_provider
#region_provider.modify_point('slb', '<regionId>', 'slb.<regionId>.aliyuncs.com')

clt = client.AcsClient('<AccessKey ID>','<AccessKey Secret>','Region ID')

# Set parameters.
request = CreateVpcRequest.CreateVpcRequest()
request.set_accept_format('json')
# Initiate the request.
response = clt.do_action(request)
```

```
print response
```

2.14.2.2.2 Usage

2.14.2.2.2.1 Install the SDK for Python

This topic describes how to install and call the VPC SDK for Python.

The SDK for Python supports Python V2.6.x, 2.7.x, 3.x, and later. You can use the following installation methods:

- Use pip (recommended)

Run the following commands to install the SDK for Python through pip:

```
pip install aliyun-python-sdk-core # Install the SDK core library.  
pip install aliyun-python-sdk-vpc # Install the VPC management library.
```

Note:

If you are using Python V3.x, use the `pip install aliyun-python-sdk-core-v3` command instead of the `pip install aliyun-python-sdk-core` command.

- Use GitHub

Run the following commands to install the SDK for Python through GitHub:

```
git clone https://github.com/aliyun/aliyun-openapi-python-sdk.git  
# Install the SDK core library.  
cd aliyun-python-sdk-core  
python setup.py install  
# Install the VPC SDK.  
cd aliyun-python-sdk-vpc  
python setup.py install
```

- Use the source code

1. [Download the SDK package](#) and decompress it.

2. You can use one of the following methods to install the SDK package:

- Modify the `sys.path` variable, and add the directory that you want to search for. It is the directory of the SDK package after it is decompressed. For example:

```
>>> import sys  
>>> sys.path.append('/Users/michael/ my_py_scripts')
```

Note:

This modification only takes effect during the running process.

- Configure the PYTHONPATH environment variable, and add the directory that you want to decompress the SDK package to. The content of this environment variable is automatically added to the module search directory.

You can configure the PYTHONPATH environment variable similar to how you configure the Path environment variable.

- Place the decompressed SDK package in the project. You can then use the SDK for Python in the project.

2.14.2.2.2.2 Configure identity verification credentials

When using SDKs to access Apsara Stack resources, you must provide an authorized Apsara Stack tenant account to verify your identity.

The Python SDK supports the use of AccessKey pairs for identity verification. For more information about how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

To use AccessKey pairs as credentials, you must configure your credentials when initializing the client.

Notice:

Ensure that code containing your AccessKey is kept confidential and is not exposed (such as being uploaded to a public GitHub project). Otherwise, the information security of your Apsara Stack tenant account may become compromised.

```
clt = client.AcsClient(secret_id, secret_key, region_id)
```

2.14.2.2.2.3 Call a service

This topic describes how to use the VPC SDK for Python to initiate a request.

Procedure

1. Import the SDK of the service that you want to call.

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.acs_exception.exceptions import ClientException
from aliyunsdkcore.acs_exception.exceptions import ServerException
from aliyunsdkvpc.request.v20160428 import CreateVpcRequest
from aliyunsdkvpc.request.v20160428 import DescribeVpcAttributeRequest
```

2. Create an AcsClient instance.

```
client = AcsClient(
    "<your-access-key-id>",
    "<your-access-key-secret>",
```

```
"<your-region-id>" );
```

3. Create a Request object.

```
request = CreateVpcRequest.CreateVpcRequest()
response = client.do_action_with_exception(request)
vpc_id = json.loads(response)['VpcId']
print "VPC ID is", vpc_id
request = DescribeVpcAttributeRequest.DescribeVpcAttributeRequest()
request.set_VpcId(vpc_id)
```

4. Call the service and handle the response.

```
response = client.do_action_with_exception(request)
Print response
```

2.14.2.2.2.4 Set HTTPS requests

The SDK for Python allows you to send API requests through HTTP and HTTPS.

You can specify a protocol (HTTP or HTTPS) for a request, or set a global protocol for all requests.

Note:

The default protocol of a service takes precedence over the global protocol.

Add OpenSSL support

OpenSSL support is required to send HTTPS requests by using Python. To send HTTPS requests through the SDK for Python, you must add OpenSSL support in Python.

Run `python -c "import ssl"` to check whether your Python environment supports OpenSSL. If the error message `ImportError: No module named ssl` does not appear, OpenSSL is already supported.

If OpenSSL is not supported, run the following command to install it:

```
pip install pyopenssl
```

Set the protocol to HTTP or HTTPS for a request

The following code provides an example of how to set HTTPS as the protocol type for a request.

```
request = CreateVpcRequest.CreateVpcRequest()
request.set_protocol_type("https")
```

```
# Valid values: "https" or "http".
```

Set a default protocol for all requests globally

The following code provides an example of how to set a default global protocol.

```
import aliyunsdkcore.request
aliyunsdkcore.request.set_default_protocol_type("https")
# Create a request and call client.do_action_with_exception() to send the request.
```

2.14.2.2.2.5 Handle exceptions

If an error occurs on the server side or SDK side when you use the Python SDK, the Python SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Generally, you are not required to handle the errors returned by the Python SDK. You are only required to handle the errors on the server side according to the error message.

- `ServerException` is the error message on the server side.
- `ClientException` is the error message on the SDK side.

For example, if the following error occurs, modify the ID of AccessKey according to the detailed error message.

```
aliyunsdkcore.acs\_exception.exceptions.ServerException: HTTP Status: 404 Error: InvalidAccessKeyId.NotFound Specified access key is not found.
```

To handle the errors returned by the Python SDK, see the following code example for reference:

```
try:
    response = client.do_action_with_exception(request)
except ServerException as e:
    # Add your own error handling logic here.
    # For example, print the detailed error message.
    print e.get_http_status()
    print e.get_error_code()
```

```
print e.get_error_msg()
```

2.14.2.2.2.6 Common errors

This topic describes the common errors when you use the SDK and troubleshoot the problems based on the corresponding causes and solutions.

Error code	Error message	Cause	Solution
SDK.InvalidRegionId	Can not find endpoint to access.	The SDK cannot automatically obtain the endpoint of the called service in the specified region.	Check whether the provided region ID and endpoint are correct. Use the following code to set the endpoint: <pre>from aliyunsdkcore.profile import region_provider region_provider.modify_point('product_name', 'region_id', 'endpoint')</pre>
SDK.TimeoutError	—	The request times out and all retry attempts fail.	In scenarios such as low network quality, we recommend that you increase the timeout period or the maximum number of retries.
SDK.ServerError:InvalidProtocol.NeedSsl	Your request is denied as lack of ssl protect .Recommend :https://error-center.aliyun.com/status/search?Keyword=InvalidProtocol.NeedSsl&source=PopGw	The API only accepts HTTPS requests and does not accept HTTP requests.	Before you send a request, add the following code: <pre>request.set_protocol_type('https')</pre>

2.14.2.3 Call the SDK for PHP

2.14.2.3.1 Quick start

The Apsara Stack PHP SDK allows you to access VPC without performing complex programming operations. This topic describes how to obtain and use the Apsara Stack PHP SDK.

Environment preparation

- Before using the PHP SDK, you must have an authorized account and an AccessKey pair that comprises an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).
- The Apsara Stack PHP SDK applies to PHP V5.3, 5.4 5.5, 5.6, 7.0, and 7.1. (You can run the `php-v` command to obtain the current PHP version number.)

Install the PHP SDK

To install the PHP SDK, perform the following operations:

1. Download the PHP SDK source code from the [Apsara Stack official website](#).
2. Add the PHP SDK reference to your code.

For example, if the PHP SDK is downloaded to `/path/to/aliyun-openapi-php-sdk`, use the following command:

```
require_once '/path/to/aliyun-openapi-php-sdk/aliyun-php-sdk-core/Config.php';
```

Use the PHP SDK

The following code shows you how to use the Apsara Stack PHP SDK:

1. Create a DefaultAcsClient instance and initialize it.

When you create and initialize a DefaultAcsClient instance, you must provide the values of **Region ID**, **AccessKey ID**, and **AccessKey Secret**.

2. Create an API request and set its parameters.
3. Initiate the request and handle the response or exceptions.

```
<? php
use Vpc\Request\V20140515\DescribeRegionsRequest;

# Create a DefaultAcsClient instance and initialize it.
$clientProfile = DefaultProfile::getProfile(
    "<your-region-id>",          # Your region ID.
    "<your-access-key-id>",      # Your AccessKey ID.
    "<your-access-key-secret>"  # Your AccessKey Secret.
```

```

);
$client = new DefaultAcsClient($clientProfile);

# Create an API request and set its parameters.
$request = new DescribeRegionsRequest();
$request->setPageSize(10);

# Initiate the request and process the response or exceptions.
try {
    $response = $client->getAcsResponse($request);
    print_r($response);
} catch (ServerException $e) {
    print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
} catch (ClientException $e) {
    print "Error: " . $e->getErrorCode() . " Message: " . $e->getMessage() . "\n";
}
?>

```

2.14.2.4 Call the SDK for Go

2.14.2.4.1 Quick start

The Apsara Stack Go SDK allows you to access VPC without performing complex programming operations. This topic describes how to obtain and use the Apsara Stack Go SDK.

Environment preparation

- Before using the Go SDK, you must have an authorized account and an AccessKey pair that comprises an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).

Install the Go SDK

1. Download the Go SDK source code from the [Apsara Stack official website](#).
2. Decompress the source code to the directory specified by GO_PATH.

Use the Go SDK

The following code provides an example of how to use the Apsara Stack Go SDK:

1. Create a client instance.
2. Create an API request and set its parameters.
3. Initiate the request and handle the response or exceptions.

```

package main

import (
    "github.com/aliyun/alibaba-cloud-sdk-go/services/vpc"
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"

```

```

    "fmt"
)

func main() {
    // Create a VPC client instance.
    vpcClient, err := vpc.NewClientWithAccessKey(
        "<your-region-id>", // Your region ID.
        "<your-access-key-id>", // Your AccessKey ID.
        "<your-access-key-secret>") // Your AccessKey Secret.
    if err != nil {
        // Handle exceptions.
        panic(err)
    }
    // Create an API request and set its parameters.
    request := vpc.CreateDescribeRegionsRequest()
    // Set request.PageSize to 10.
    request.PageSize = requests.NewInteger(10)
    // Initiate the request and handle exceptions.
    response, err := vpcClient.DescribeRegions(request)
    if err != nil {
        // Handle exceptions.
        panic(err)
    }
    fmt.Println(response)
}

```

2.14.2.4.2 Usage

2.14.2.4.2.1 Install the VPC SDK for Go

This topic describes how to install the VPC SDK for Go.

Context

The VPC SDK for Go supports Go V1.7 and later. You can use the following method to install the VPC SDK for Go:

Procedure

1. Download the SDK for Go source code from [Apsara Stack official website](#).
2. Decompress it to the directory where GO_PATH of the current user resides.

2.14.2.4.2.2 Configure identity verification credentials

When you use the VPC SDK to access Apsara Stack resources, you must provide an authorized account for identity verification.

The Go SDK supports the use of AccessKey pairs for identity verification. For more information about how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

To use AccessKey pairs as credentials, you must configure your credentials when initializing the client.

Notice:

Ensure that code containing your AccessKey is kept confidential and does not leak (such as being exposed to a public GitHub project). Otherwise, the information security of your Apsara Stack account may become compromised.

```
// Create a VPC client instance.
vpcClient, err := vpc.NewClientWithAccessKey(
    "<your-region-id>", // Your zone ID.
    "<your-access-key-id>", // Your AccessKey ID.
    "<your-access-key-secret>") // Your AccessKey Secret.
```

If you want to use a custom Config or a credential other than an AccessKey, you must first create a Credential object and save it. You must then submit the Credential object when initializing the client.

```
// Customize Config.
config := NewConfig()
// Create a Credential object.
credential := &credentials.BaseCredential{
    AccessKeyId:    "<your-access-key-id>",
    AccessKeySecret: "<your-access-key-secret>",
}
// Initialize the client.
client, err := NewClientWithOptions("cn-hangzhou", config, credential)
```

2.14.2.4.2.3 Call a service

This topic describes how to use the VPC SDK for Go to initiate a request.

Procedure

1. Import the VPC SDK for Go.

```
import github.com/aliyun/alibaba-cloud-sdk-go/services/vpc
```

2. Create a VPC client. The client includes all APIs of the VPC.

```
vpcClient := vpc.NewClientWithAccessKey(
    "<your-region-id>",
    "<your-access-key-id>",
    "<your-access-key-secret>")
```

3. Use `xxx.CreateXXXRequest` to create a request.

The naming convention for the method is `${service}.Create${apiName}Request`. In the code,

- **`${service}`** is the service name (lower case), such as `vpc`.
- **`${apiName}`** is the API name, such as `DescribeRegions`.

```
request := vpc.CreateDescribeRegionsRequest()
```

```
request.InstanceId = ""
```

4. Initiate the request.

```
response, err := vpcClientDescribeRegions(request)
```

5. Handle the response.

All the returned fields are deserialized into the response. You can call `response.getXXX()` to obtain the response fields.

```
instanceStatus := response.Status
```

If an error (`err != nil`) occurs, or you want to obtain the original HTTP response, you can use the following methods to obtain the original data:

```
// Obtain the original HTTP response. The response type is *http.Response.
httpResponse := response.GetOriginHttpResponse()

// Obtain the status code of the original HTTP response. The response type is integer.
statusCode := response.GetHttpStatus()

// Obtain the header of the original HTTP response. The response type is map[string][]string.
headers := response.GetHttpHeaders()

// Obtain the content of the original HTTP response. The response type is []byte.
contentBytes := response.GetHttpContentBytes()

// Obtain the content of the original HTTP response and transcode it to a string based on UTF-8. The response type is string.
contentString := response.GetHttpContentString()
```

2.14.2.4.2.4 Handle exceptions

If an error occurs on the server side or SDK side, the Alibaba Cloud Go SDK returns the corresponding exception message, namely the `ClientError` and `ServerError` in the `sdk.errors` package. These errors are based on the standard Go error API. Therefore, you can handle errors returned by the Alibaba Cloud Go SDK in the same way as handling standard Go errors.

ClientError

When an error occurs in an SDK for an invocation that cannot be handled automatically, the SDK returns a `ClientError`.

The following code shows how to determine and obtain the error message in `ClientError`:

```
response, err := vpcClient.DescribeInstances(request)
if clientError, ok := err.(*errors.ClientError); ok {
    // Obtain the error code.
    clientError.ErrorCode()
    // Obtain the error description.
```

```

clientError.Message()
// Obtain the original error (may be nil).
clientError.OriginError()
}

```

ServerError

When the SDK receives an error response from the server side, the SDK encapsulates the response into a `ServerError` and returns it to the server.

Note:

In this case, you can still obtain the original HTTP response from the error response.

The following code shows how to determine and obtain the error message in `ServerError` and the response:

```

response, err := vpcClient.DescribeInstances(request)
if serverError, ok := err.(*errors.ServerError); ok{
    // Obtain the error code.
    serverError.ErrorCode()
    // Obtain the error description.
    serverError.Message()
    // Obtain the original HTTP response.
    response.GetOriginHttpResponse()
}

```

2.14.2.4.2.5 Customize configurations

This topic describes the custom configurations that Go SDK supports.

Configuration method

The Apsara Stack SDK for Go allows you to use the following method to customize configurations:

```

config := NewConfig().
    WithEnableAsync(true).
    WithGoRoutinePoolSize(5).
    WithMaxTaskQueueSize(1000)
client, err := slb.NewClientWithOptions("<region-id>", config, credential)

```

Note:

The config module of the Apsara Stack SDK for Go cannot be called in the following manner:

```

config := &Config{EnableAsync: true,}

```

Supported custom configurations

The following table shows the supported custom configurations currently.

Configuration	Default value	Description
AutoRetry	true	Whether to enable the automatic retry
MaxRetryTime	3	The maximum number of retries With the automatic retry enabled, the maximum time consumption for a single call is Timeout (MaxRetryTime + 1).
Timeout	10time.Second	Timeout value. Full-link timeout value, containing establishing connection, redirecting, and reading response If the value is 0, no timeout occurs.
HttpTransport	nil	Enable the configuration of the underlying net/http client You can configure the original http.client of Go with this configuration, such as persistent connection.
EnableAsync	false	Whether to enable the asynchronous feature
MaxTaskQueueSize	1000	The length of the asynchronous queue, which takes effect only when EnableAsync=true If the queue is full, new calls are congested.
GoRoutinePoolSize	5	The maximum number of concurrent connections, which takes effect only when EnableAsync=true

2.14.2.4.2.6 Asynchronous method invocation

With the concurrent characteristic of the Go language, we recommend that you control the concurrent requests of SDK on the application layer. For your convenience, the Alibaba Cloud Go SDK provides the concurrent calling method that can be directly used. The related concurrency control is achieved within SDK.

Enable asynchronous method invocation for an SDK client

In the following example, the `Credential` object is used as the user credential.

```
// The maximum number of concurrent connections.
poolSize := 10

// The maximum number of cacheable requests.
maxTaskQueueSize := 10000

// Enable asynchronous method invocation when you create an SDK client.
config := sdk.NewConfig().
```

```

WithEnableAsync(true).
WithGoRoutinePoolSize(poolSize).           // Optional. Default value: 5.
WithMaxTaskQueueSize(maxTaskQueueSize) // Optional. Default value: 1,000.

// Use the custom configuration to initialize the client.
vpcClient, err := vpc.NewClientWithOptions("<your-region-id>", config, credential)

// Or enable asynchronous method invocation after you have initialized the client.
client.EnableAsync(poolSize, maxTaskQueueSize)

```

Initiate asynchronous calls

The Alibaba Cloud Go SDK supports two methods of initiating asynchronous calls as follows:

- Use channel as the returned value.

```

// this will not block
responseChannel, errChannel := client.FooWithChan(request)
// this will block
response := <-responseChannel
err = <-errChannel

```

- Use callback to control the response.

```

// this will not block
blocker := client.FooWithCallback(request, func(response *FooResponse, err error) {
    // handle the response and err
})
// The blocker is (chan int) and is used to control the synchronization. If the returned
// value is 1, the action succeeds. If the returned value is 0, the action fails.
// If <-blocker returns 0 and the action fails, the error message is transmitted to
// callback by means of err.
// this will block
result := <-blocker

```

2.14.2.4.2.7 Use CommonRequest

If the product API that you want to call does not have the corresponding SDK, you can use the generic calling method (CommonRequest) to call the product APIs. By using the CommonRequest calling method, you can call any APIs.

Example: Call a RESTful API

The following code provides an example of how to use CommonRequest to call GetClusterList:

```

package main

import (
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"
    "github.com/aliyun/alibaba-cloud-sdk-go/sdk"
    "fmt"
)

func main() {

```

```

client, err := sdk.NewClientWithAccessKey("{your_region_id}", "{your_access_key_id}", "{your_access_key_id}")
if err != nil {
    panic(err)
}

request := requests.NewCommonRequest()
request.Domain = "cs.aliyuncs.com"
request.Version = "2015-12-15"
// Because this is a RESTful API, the PathPattern field must be specified.
request.PathPattern = "/clusters"
response, err := client.ProcessCommonRequest(request)
if err != nil {
    panic(err)
}
fmt.Print(response.GetHttpContentString())
}

```

2.14.2.4.2.8 Common errors

This topic describes how to troubleshoot common errors you may encounter during the use of SDKs.

Error code	Error message	Cause	Solution
SDK.CanNotResolveEndpoint	Can not resolve endpoint, please check the user guide	The SDK cannot obtain the region endpoint of the called service.	Check whether the provided region ID and endpoint are correct. After you have obtained the endpoint, you can run the following code to set the endpoint: request.Domain = "<endpoint>"
SDK.JsonUnmarshalError	Failed to unmarshal response, but you can get the data via response.GetHttpStatusCode() and response.GetHttpContentString()	The SDK response fails to be deserialized. In most cases, the cause is that the structure of the response received by the SDK does not conform to the API metadata. For example, the fields do not match or the format is incorrect.	For more information, see Response parsing .

Error code	Error message	Cause	Solution
SDK.TimeoutError	The request timed out 4 times(3 for retry), perhaps we should have the threshold raised a little?	The request has timed out and all retry attempts have failed.	- In scenarios such as cross-region invocations or poor network quality, we recommend that you increase the timeout period or the maximum number of retries. - If the problem persists even though network quality is guaranteed, we recommend that you submit a ticket.
SDK.AsyncFunctionNotEnabled	Async function is not enabled in client, please invoke 'client.EnableAsync()' function	An asynchronous API is called when the asynchronous request switch is not turned on.	Enable the asynchronous feature. For more information, see Asynchronous method invocation .

Response parsing

Ignore SDK deserialization failures and obtain the response attributes by extracting the original HTTP response.

Note:

The SDK for Go has a dependency on JMESPath. Therefore, when the response content is in the JSON format, you can use JMESPath to parse the response.

```
response, err := client.CreateInstance(request)
if err != nil {
    // Handle exceptions.
    if clientErr, isClientErr := err.(*errors.ClientError); isClientErr {
        if clientErr.ErrorCode() == errors.JsonUnmarshalErrorCode {
            // You can obtain the data in the original response by using the following
            encapsulation method.
            // The HTTP status code in the response. Type: integer.
            statusCode := response.GetHttpStatus()
            // The HTTP header in the response. Type: map[string][]string.
            responseHeader := response.GetHttpHeaders()
            // The response body content. Type: []byte.
            responseBytes := response.GetHttpContentBytes()
            // The response body content. Type: string, equivalent to string(response.
            GetHttpContentBytes()).
            responseContent := response.GetHttpContentString()
            // You can also directly obtain the original response. Type: net/http.Response.
            httpResponse := response.GetOriginHttpResponse()
```

```
}  
}  
}
```

2.14.2.5 Call the SDK for .NET

2.14.2.5.1 Quick start

The Apsara Stack .NET SDK allows you to access VPC without performing complex programming operations. This topic describes how to obtain and call the Apsara Stack .NET SDK.

Environment preparation

- Before using the .NET SDK, you must have an authorized account and an AccessKey pair that comprises an AccessKey ID and an AccessKey Secret. For more information about how to view and obtain your AccessKey in Apsara Stack Management Console, see [Obtain an AccessKey pair](#).
- Obtain the service endpoint. For more information, see [Obtain an endpoint](#).
- The Apsara Stack .NET SDK applies to .NET Framework 4.0 and later.

Install the Apsara Stack .NET SDK

To call the SDK of a service, you must install the SDK core library and the SDK of the service. For example, to call the VPC SDK, you must obtain and install both the VPC SDK and its core library. You can use one of the following methods to install the .NET SDK:

- Add DLL reference
 1. Download the compressed package containing a DLL file from [.NET SDK release list](#), and decompress it to obtain the DLL file.
 2. Right-click your project in Solution Explorer of Visual Studio and choose **Reference** from the shortcut menu.
 3. In the pop-up menu, click **Add Reference**.
 4. In the dialog box that appears, click **Browse**. Then select the downloaded DLL file and click **Confirm**.

- Add project reference
 1. Visit the [Apsara Stack official website](#) to download the .NET SDK source code.
 2. Find the aliyun-net-openapi-XXX subfolder in the downloaded folder, and then locate the *.csproj file. It is the .NET project file. For example, in the aliyun-net-openapi-vpc sub-folder, there is a file named aliyun-net-sdk-vpc.csproj.
 3. In Visual Studio, right-click your solution.
 4. Choose **Add > Existing Projects**.
 5. In the dialog box that appears, select the .NET project file (such as aliyun-net-sdk-vpc.csproj) from the downloaded source code, and click **Open**.
 6. Right-click your project and choose **Reference > Add reference** from the shortcut menu.

Call the .NET SDK

The following code provides an example of how to call the .NET SDK:

1. Create a DefaultAcsClient instance and initialize it.
2. Create an API request and set its parameters.
3. Initiate the request and process the response or exceptions.

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Profile;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.Vpc.Model.V20140526;

class TestProgram
{
    static void Main(string[] args)
    {
        // Create a client to initiate a request.
        IClientProfile profile = DefaultProfile.GetProfile(
            "<your-region-id>",
            "<your-access-key-id>",
            "<your-access-key-secret>");
        DefaultAcsClient client = new DefaultAcsClient(profile);
        try
        {
            // Create a request.
            DescribeRegionsRequest request = new DescribeRegionsRequest();
            request.PageSize = 10;
            // Initiate the request and obtain the response.
            DescribeRegionsResponse response = client.GetAcsResponse(request);
            System.Console.WriteLine(response.TotalCount);
        }
        catch (ServerException ex)
        {
            System.Console.WriteLine(ex.ToString());
        }
        catch (ClientException ex)
        {
            System.Console.WriteLine(ex.ToString());
        }
    }
}
```

```
}  
}  
}
```

2.14.2.5.2 Usage

2.14.2.5.2.1 Install the SDK for .NET

This topic describes how to install the VPC SDK for .NET.

You can use one of the following methods to install the SDK for .NET:

- Add DLL reference
 1. Download the compressed package that contains the relevant DLL file from [.NET SDK release list](#), and decompress it to obtain the DLL file.
 2. Right-click your project in Solution Explorer of Visual Studio and choose **Reference** from the shortcut menu.
 3. In the pop-up menu, click **Add Reference**.
 4. In the dialog box that appears, click **Browse**. Then select the downloaded DLL file and click **Confirm**.
- Add project reference
 1. Visit [Apsara Stack official website](#) to download the source code of the SDK for .NET.
 2. Find the aliyun-net-openapi-XXX subfolder in the downloaded folder, and then locate the *.csproj file. It is the .NET project file. For example, in the aliyun-net-openapi-vpc sub-folder, there is a file named aliyun-net-sdk-vpc.csproj.
 3. In Visual Studio, right-click your solution.
 4. Choose **Add > Existing Projects**.
 5. In the dialog box that appears, select the .NET project file (such as aliyun-net-sdk-vpc.csproj) from the downloaded source code, and click **Open**.
 6. Right-click your project and choose **Reference > Add reference** from the shortcut menu.

2.14.2.5.2.2 Configure identity verification credentials

When using the Alibaba Cloud .NET SDK to access Alibaba Cloud Apsara Stack services, you must provide an Alibaba Cloud account for authentication.

The .NET SDK supports the use of AccessKey pairs for identity verification. For more information about how to obtain an AccessKey, see [Obtain an AccessKey pair](#).

To use AccessKey pairs as credentials, you must configure your credentials when initializing the client.

**Notice:**

Ensure that code containing your AccessKey is kept confidential and is not exposed (such as being uploaded to a public GitHub project). Otherwise, the information security of your Apsara Stack tenant account may become compromised.

```
IClientProfile clientProfile = DefaultProfile.GetProfile(
    "<your-region-id>", // The region ID.
    "<your-access-key-id>", // The AccessKey ID of the RAM account.
    "<your-access-key-secret>"); // The AccessKey Secret of the RAM account.
```

2.14.2.5.2.3 Call a service

This topic describes how to use the Apsara Stack VPC SDK for .NET to initiate a request.

1. Create a default client instance.

```
DefaultAcsClient client = new DefaultAcsClient(clientProfile);
```

2. Create a request.

The naming convention for requests is `${apiName}Request`. **`${apiName}`** is the API name, such as `DescribeRegions`.

When multiple SDKs are used, different requests may have the same name. Differentiate the requests based on the `PageSize` value.

```
DescribeRegionsRequest request = new DescribeRegionsRequest();
```

```
request.PageSize = 10;
```

3. Call a service and process the response.

```
DescribeRegionsResponse response = client.GetAcsResponse(request);
```

All the returned fields are deserialized into the response. You can call `response.getXXX()` to obtain the response fields.

```
System.Console.WriteLine(response.TotalCount);
```

2.14.2.5.2.4 Handle exceptions

If an error occurs on the server side or SDK side when you use Alibaba Cloud .NET SDK, the .NET SDK returns the corresponding exception message. An exception message contains the detailed error information, namely the error code and the error message.

Typically, you do not need to handle the exceptions that the SDK for .NET returns. You need only to handle exceptions related to the server.

- `ServerException` indicates the error message generated on the server side.
- `ClientException` indicates the error message for SDK exceptions.

For example, if the following exception occurs, you can modify the AccessKey ID based on the error message.

```
InvalidAccessKeyId.NotFound : Specified access key is not found.
```

If you need to handle SDK exceptions, you can use the following example as a reference:

```
try
{
    DescribeRegionsResponse response = client.GetAcsResponse(request);
    // Handle the response.
    // ...
}
catch (ServerException e)
{
    // You can add your own exception handling logic here.
    // In this example, an error message is displayed when an exception occurs.
    Console.WriteLine("ErrorCode=" + e.ErrorCode);
    Console.WriteLine("ErrorMessage=" + e.ErrorMessage);
    // If the problem persists, you can submit a ticket with the request ID included to the
    // Alibaba Cloud development team.
    Console.WriteLine("ErrorCode=" + e.RequestId);
}
catch (ClientException e)
{
    // You can add your own exception handling logic here.
    // In this example, an error message is displayed when an exception occurs.
    Console.WriteLine("ErrorCode=" + e.ErrorCode);
    Console.WriteLine("ErrorMessage=" + e.ErrorMessage);
}
```

}

2.14.2.5.2.5 Call an API through CommonRequest

If the product API that you want to call does not have the corresponding SDK, you can use the generic calling method (CommonRequest) to call the product APIs. By using the CommonRequest calling method, you can call any APIs.

Characteristics of CommonRequest calling

The CommonRequest calling method has the following characteristics:

- Light weight: You only need the core package to initiate the call, without downloading or installing the SDK of each product.
- Easy and convenient: You can call the latest API without updating the SDK.
- Fast iteration

Use CommonRequest

To initiate a CommonRequest request, you must obtain the values for the following parameters. You can obtain the values of these parameters from the API documentation.

- Domain: the service endpoint.
- Version: the version of the API, in the format of YYYY-MM-DD.

You can obtain the API version from the common parameters in the API documentation.

- API information: the name of the API to be called.

You must obtain the **Action** parameter, and run `request.ApiName = "<Action>"` to specify the API name.

For example, to initiate a CommonRequest request for **RunInstances**, you need to specify the API name by using `request.ApiName = "RunInstances"`.

Example: Call a RESTful API

The following code provides an example of how to use CommonRequest to call GetClusterList:

```
using Aliyun.Acs.Core;
using Aliyun.Acs.Core.Exceptions;
using Aliyun.Acs.Core.Profile;

class Sample
{
    static void Main(string[] args)
    {
        // Create a client instance to initiate a request.
        IClientProfile profile = DefaultProfile.GetProfile(
```

```
"<your-region-id>",
"<your-access-key-id>",
"<your-access-key-secret>");
DefaultAcsClient client = new DefaultAcsClient(profile);

try
{
    // Create a request.
    CommonRequest request = new CommonRequest();
    request.Domain = "cs.aliyuncs.com";
    request.Version = "2015-12-15";

    // Because this is a RESTful API, the UriPattern field must be specified.
    request.UriPattern = "/clusters";

    // Initiate a request and obtain the response.
    CommonResponse response = client.GetCommonResponse(request);
    System.Console.WriteLine(response.Data);
}
catch (ServerException ex)
{
    System.Console.WriteLine(ex.ToString());
}
catch (ClientException ex)
{
    System.Console.WriteLine(ex.ToString());
}
}
```

2.14.2.5.2.6 Common errors

This topic describes the common errors when you use the .NET SDK. Troubleshoot the problems based on the corresponding causes and solutions.

Error code	Cause	Solution
SDK.InvalidRegionId	SDK cannot automatically obtain the endpoint of the called product in the specified region.	Check if your endpoint is correct.
InvalidAccessKeyId.NotFound	The configured AccessKey ID is invalid.	Check if your AccessKey ID is correct.
SDK.ConnectionReset	The endpoint cannot be connected when you initiate a request.	Check if your network is available.

Error code	Cause	Solution
SDK.InvalidProfile	The DefaultProfile parameter that you provided when initializing DefaultAcsClient is invalid.	Make sure that the provided DefaultProfile parameter object is properly initialized and configured with corresponding parameters.
SDK.SessionTokenExpired	The DefaultProfile parameter that you provided when initializing DefaultAcsClient is invalid.	Make sure that the provided SessionToken parameter is in the validity period, which is generally one hour.
SignatureDoesNotMatch	The provided SessionToken is invalid or has expired.	Make sure that the provided DefaultProfile parameter object is properly initialized and configured with corresponding parameters.
SDK.InvalidProfile	The AccessKey Secret does not match the AccessKey ID.	Make sure that the provided AccessKey Secret is valid.

2.14.2.6 Obtain an endpoint

You can obtain the endpoint of a VPC service in the Apsara Stack Operations console.

Procedure

1. Log on to Apsara Stack Operations.

For how to log on to Apsara Stack Operations, see **Operations of basic platforms > Apsara Stack Operations > Log on to Apsara Stack Operations** in Operations Guide .

2. Click **Products** in the left-side navigation pane.
3. Choose **Apsara Infrastructure Management Framework** in the product list to go to the Apsara Infrastructure Management Framework page.
4. Choose **Operations > Machine Operations**. The **Machine Operations** page appears.

5. Select a machine and then click **Terminal** to log on to the machine.

Machine Operations									
Search Allows fuzzy or batch search. Separate multiple machines with commas or space.				Reset	☐ Exact Match		Machine Bucket Change	Machine Online/Offline	Refresh
Hostname	IP	Cluster	Project	IDC	Room	Rack	Warranty	Status	Actions
vm010012016112	10.12.16.112	tianji-A-3788	tianji	amtest72				GOOD	Terminal Machine Operation
a50e05101.cloud.e08.amtest72	10.12.16.112	tianji-A-3788	tianji	amtest72	A5-8	E08		GOOD	Terminal Machine Operation
a50e07101.cloud.e08.amtest72	10.12.16.112	tianji-A-3788	tianji	amtest72	A5-8	E08		GOOD	Terminal Machine Operation
a50e09001.cloud.e08.amtest72	10.12.16.112	tianji-A-3788	tianji	amtest72	A5-8	E09		GOOD	Terminal Machine Operation
vm010012016020	10.12.16.020	tianji-A-3788	tianji	amtest72				GOOD	Terminal Machine Operation
a50f11014.cloud.f11.amtest72	10.12.16.014	tianji-A-3788	tianji	amtest72	A5-6	F11		GOOD	Terminal Machine Operation
a50e09106.cloud.e10.amtest72	10.12.16.106	tianji-A-3788	tianji	amtest72	A5-6	E10		GOOD	Terminal Machine Operation

6. Run the following command to obtain the JSON data:

```
curl -l "http://127.0.0.1:7070/api/v3/column/c.sr.service_registration,c.sr.id?c.sr.service_registration"
```

```
{
  "c.sr.id": "vpc-controller",
  "c.sr.service_registration": "{\n\"db.vpcregiondb.name\": \"vpcregiondb\", \"db.vpcregiondb.passwd\": \"caMjyyf1cGhpt63k\", \"db.vpcregiondb.port\": \"3098\", \"db.vpcregiondb.url\": \"vpcregiondb.mysql.minirds.env12.ops.shuguang.com\", \"db.vpcregiondb.user\": \"vpcregiondb\", \"mvss.dns\": \"mvss.env12.ops.shuguang.com\", \"mvss.ips\": \"10.12.16.112\", \"mvss.vips\": \"10.12.16.112\", \"vpcmaster.dns\": \"virtualmaster.env12.ops.shuguang.com\", \"vpcmaster.ips\": \"10.12.16.112\", \"vpcmaster.vips\": \"10.12.16.112:9627:9627\"}"
},
{
  "c.sr.id": "vpc-xnet",
  "c.sr.service_registration": "{\n\"db.xnet.name\": \"xnet\", \"db.xnet.passwd\": \"5Ljqr4nddwoaWisd\", \"db.xnet.port\": \"3096\", \"db.xnet.url\": \"xnet.mysql.minirds.env12.ops.shuguang.com\", \"db.xnet.user\": \"xnet\", \"xnet.dns\": \"xnet.env12.ops.shuguang.com\", \"xnet.ips\": \"10.12.16.208\", \"xnet.vips\": \"10.12.16.208\", \"vpcdriver.dns\": \"vpcdriver.env12.ops.shuguang.com\", \"vpcdriver.ips\": \"10.12.16.208\", \"vpcdriver.vips\": \"10.12.16.208:8000,8001,10152,9997,8087:80,8000,8001,10152,9997,8087\"}"
},
{
  "c.sr.id": "vpc-yaochi",
  "c.sr.service_registration": "{\n\"vbs.ips\": \"10.12.16.112,10.12.16.113\", \"vpc-inner.openapi.endpoint\": \"vpc-inner.env12.ops.shuguang.com\", \"vpc-internal.openapi.endpoint\": \"vpc-internal.env12.ops.shuguang.com\", \"vpc.base.endpoint\": \"vbs.env12.ops.shuguang.com\", \"vpc.driver.endpoint\": \"vpcdriver.env12.ops.shuguang.com\", \"vpc.openapi.endpoint\": \"vpc.env12.ops.shuguang.com\", \"vpcyaochidb.db.host\": \"vpcyaochidb.mysql.minirds.env12.ops.shuguang.com\", \"vpcyaochidb.db.name\": \"vpcyaochidb\", \"vpcyaochidb.db.password\": \"bzobajlqrNNhm5za\", \"vpcyaochidb.db.port\": \"3095\", \"vpcyaochidb.db.user\": \"vpcyaochidb\"}"
}
}
```

7. Obtain the endpoint of a VPC based on the ID (vpc-yaochi) and the key value (vpc.openapi.endpoint) of the VPC service.

2.14.2.7 Obtain an AccessKey pair

You can obtain an AccessKey pair in the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center >**

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

**Note:**

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.15 Log Service

2.15.1 API reference

2.15.1.1 Overview

Log Service is a platform-based service specific to logs. Log Service supports real-time collection, storage, and delivery of various types of logs.

Log Service allows you to perform log operations through the Apsara Stack console. In addition, it allows you to use the Log Service API to write and query logs as well as manage your projects and Logstores. [Table 2-439: API operations supported by Log Service](#) lists the currently available API operations.

Table 2-439: API operations supported by Log Service

Object	Operation
Log	Basic concepts such as log and log group
Config	List , Create , Delete , Get , Update
-	GetAppliedMachineGroups
MachineGroup	List , Create , Delete , Get , Update
-	Apply , Remove

Object	Operation
-	GetAppliedConfigs
Logstore	List , Create , Delete , Get , Update
-	GetLogs , GetHistograms
Shard	List , Split , Merge
-	PostLogStoreLogs
-	GetCursor
-	PullLogs

You can call API operations to:

- Collect logs based on the [Logtail configuration](#) and [machine group](#) information.
- Create a [Logstore](#) and write logs to and query logs from the Logstore.

Note:

- The Log Service API is a RESTful API.
- Security verification is required for all the API requests. For more information about the API request signing mechanism and process, see [Request signatures](#).

2.15.1.2 Obtain an AccessKey pair

You can obtain your AccessKey pair from the Apsara Stack console.

Obtain an AccessKey pair of a department

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click the  icon, and then choose **User Center** >

Department Management.

3. Select a department and click **Create AccessKey** to obtain an AccessKey pair of this department.

Note:

The AccessKey pair is automatically allocated to a level-1 department. The sub-departments use the same AccessKey pair as their level-1 department.

Obtain an AccessKey pair of a personal account

Follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the Web page, click your avatar and select **Personal Information**.

The system displays your AccessKey ID.

3. Click **Show** under **AccessKey Secret** to view the AccessKey Secret.

2.15.1.3 Common request headers

Log Service APIs are RESTful APIs based on the HTTP protocol, which support a set of common request headers that can be used in all API requests (unless otherwise stated, each Log Service API request must provide these common request headers). The detailed definitions of these headers are described in [Table 2-440: Header definition](#).

Table 2-440: Header definition

Header name	Type	Description
Accept	String	The type of the value that the client expects the server to return. Currently, two types are supported: application/json and application/x-protobuf. This field is optional and is valid only for GET requests. The specific value is subject to the definition of each API.
Accept-Encoding	String	The compression algorithm that the client expects Log Service to return. Currently, LZ4 and DEFLATE are supported. It can be null. This field is optional and valid only for GET requests. The specific value is subject to the definition of each API.
Authorization	String	The signature content. For more information, see the Request signature .
Content-Length	Numerical value	The length of the HTTP request body defined in RFC 2616. If the request has no body, it is unnecessary to provide this request header.
Content-MD5	String	The string generated after the request body undergoes MD5 calculation, and the calculation result is in uppercase. If the request has no body, this request header is not required.

Header name	Type	Description
Content-Type	String	The type of the HTTP request body defined in RFC 2616. Currently, Log Service API requests support only application/x-protobuf. If the request has no body, it is unnecessary to provide this request header. The specific value is subject to the definition of each API.
Date	String	The time when the request is sent. Currently, parameters only support the RFC 822 format, and the GMT standard time is used. The formatted string is as follows: %a, %d %b %Y %H:%M:%S GMT (for example: Mon, 3 Jan 2010 08:33:47 GMT).
Host	String	The complete host name of the HTTP request, protocol headers such as http:// are not included. For example, big-game.regionid.example.com.
x-log-apiversion	String	The API version. The current version is 0.6.0.
x-log-bodyrawsize	Numerical value	The initial size of the request body. When the request has no body, the value is 0. When the body is a compressed data, the value is the size of the initial data before compression. The value range for this field is 0-3x1024x1024. This field is optional and only required when the body is compressed.
x-log-compress-type	String	The compression type of the API request body. Currently, LZ4 and DEFLATE are supported (RFC 1951. For more information about the zlib format, see RFC 1950). If the body is not compressed, this request header is not required.
x-log-date	String	The time when the request is sent. The time format is the same as that of the Date header. This request header is optional. If a request contains this common request header, this value replaces the value of the standard Date header for server request authentication. Whether an x-log-date header is present or not, the standard HTTP Date header must be provided.
x-log-signaturemethod	String	The signature computing method. Currently, only hmac-sha1 is supported.

**Note:**

- The maximum difference between the time expressed in the Date header of a request and the time the server receives the request is 15 minutes. If the request contains the x-

log-date header, the time difference is calculated based on the value of the x-log-date header.

- If the compression algorithm is specified in x-log-compresstype of the request, the raw data must be compressed and then put into the HTTP body. The Content-Length and Content-MD5 header are also calculated based on the HTTP body.
- When HTTP requests are sent from certain platforms, they cannot specify a Date header (the sending time is automatically specified in the platform's internal database). Therefore, the correct Date value cannot be used to calculate the request signature. In this case, specify the x-log-date header and use the header value to calculate the request signature. After receiving an API request, the Log Service server first determines whether the request contains an x-log-date header. If an x-log-date header exists, the server uses the header value for signature authentication. Otherwise, the server uses the HTTP standard header Date for signature authentication.

2.15.1.4 Common response headers

Log Service APIs are RESTful APIs based on the HTTP protocol. All Log Service API responses provide a set of common response headers, whose detailed definitions are described in [Table 2-441: Definitions of common response headers](#).

Table 2-441: Definitions of common response headers

Header name	Type	Description
Content-Length	Numerical value	The length of the HTTP response content defined in RFC 2616.
Content-MD5	String	The MD5 value of the HTTP response content defined in RFC 2616, It is an uppercase string produced after the MD5 calculation of the request body.
Content-Type	String	The type of the HTTP response content defined in RFC 2616. Currently, Log Service supports two response types: application/json and application/x-protobuf.
Date	String	The time when the request is returned. Currently, parameters only support the RFC 822 format, and the GMT standard time is used. The formatted string is as follows: %a, %d %b %Y %H:%M:%S GMT (for example: Mon, 3 Jan 2010 08:33:47 GMT).

Header name	Type	Description
x-log-requestid	String	The unique ID generated in Log Service that marks this request . This response header is irrelevant to actual applications. It is mainly used to track and investigate problems. For the API request troubleshooting purpose, you can provide the Log Service team with this ID.

2.15.1.5 Request signature

All the HTTP requests of Log Service APIs are subjected to security authentication. This ensures the security of log data. Security authentication is based on an AccessKey pair and is completed by using the symmetric encryption algorithm.

This process is as follows:

1. The requester generates a signature string based on the API request content that includes the HTTP header and body.
2. The requester uses an AccessKey pair that consists of an AccessKey ID and AccessKey Secret to sign the signature string generated in step 1. A digital signature is generated for this API request.
3. The requester sends both the API request content and digital signature to the server.
4. After receiving the request, the server repeats step 1 and step 2.

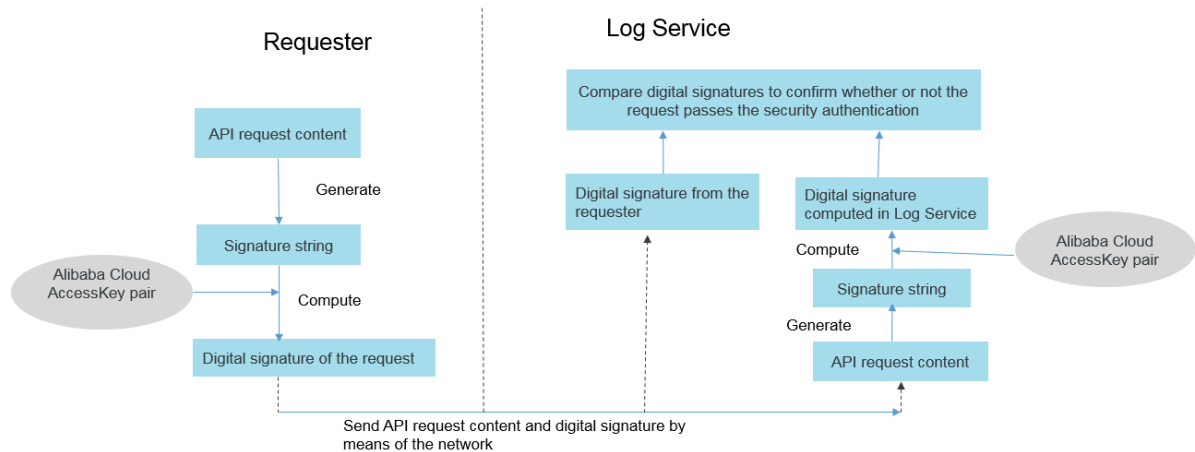

**Note:**

The server retrieves the AccessKey pair from the back end to calculate the signature string and generate the expected digital signature for this request.

5. The server compares the expected digital signature with the digital signature sent from the requester. If both signatures are the same, the request passes security authentication. Otherwise, the request is immediately rejected.

Figure 2-3: Security authentication process illustrates the preceding process.

Figure 2-3: Security authentication process

The preceding security authentication process can also be used for the following purposes:

- Identify which user sends the API request. A user must specify the AccessKey pair that is used to generate the digital signature before sending the request. The server can then use this AccessKey pair to verify the identity of the user and implement access control.
- Check whether the user request is tampered during transmission over the network. The server recalculates the signature string based on the received request content. Therefore, if the content is tampered during transmission, the digital signature sent from the requester does not match with the digital signature obtained from the server.

API request signature

To pass security authentication for an API request, you must use the client to sign the API request to generate a correct digital signature. You must also use the HTTP Authorization request header to transfer the digital signature of the request over the network. The format of the Authorization header is as follows:

```
Authorization:LOG <AccessKeyId>:<Signature>
```

As shown in the preceding format, the value of the Authorization header contains the AccessKey ID. The corresponding AccessKey Secret is used to create a signature value. The following steps describe how to generate the signature value.

1. Prepare an AccessKey pair

You must use an AccessKey pair that consists of an AccessKey ID and AccessKey Secret to generate a digital signature for an API request.

2. Generate a signature string for the request

The signature string of a Log Service API is generated based on the method, header, and body of the HTTP request. The generation method is as follows:

```
SignString = VERB + "\n"
            + CONTENT-MD5 + "\n"
            + CONTENT-TYPE + "\n"
            + DATE + "\n"
            + CanonicalizedLOGHeaders + "\n"
            + CanonicalizedResource
```

In the preceding formula, `\n` indicates the newline escape character and a plus sign (+) indicates the string concatenation operator. [Table 2-442: Signature string definitions](#) describes the definitions of the other parts.

Table 2-442: Signature string definitions

Parameter	Description	Examples
VERB	The method name of the HTTP request.	PUT, GET, and POST
CONTENT-MD5	The MD5 value of the HTTP request body, which must be an uppercase string.	875264590688CA6171F6 228AF5BBB3D2
CONTENT-TYPE	The type of the HTTP request body.	application/x-protobuf
DATE	The standard timestamp header of the HTTP request, which follows the RFC 1123 format and uses GMT.	Mon, 3 Jan 2010 08:33:47 GMT
CanonicalizedLOGHeaders	The string constructed by custom headers prefixed with <code>x-log</code> and <code>x-acs</code> in the HTTP request. The construction method is described as follows.	x-log-apiversion:0.6.0\nx-log-bodyrawsize:50\nx-log-signaturemethod:hmac-sha1

Parameter	Description	Examples
CanonicalizedResource	The string constructed by the HTTP request resources. The construction method is described as follows.	/logstores/app_log

For HTTP requests without the request body, both the CONTENT-MD5 and CONTENT-TYPE fields are empty. The generation method of the signature string is as follows:

```
SignString = VERB + "\n"
            + "\n"
            + "\n"
            + DATE + "\n"
            + CanonicalizedLOGHeaders + "\n"
            + CanonicalizedResource
```

As described in [Common request headers](#), a custom request header named `x-log-date` is used for Log Service APIs. If you specify a custom request header when sending a request, the header value will replace the value of the HTTP standard request header `Date` to calculate the signature string.

The CanonicalizedLOGHeaders construction method is as follows:

- Convert the names of all HTTP request headers that are prefixed with `x-log` and `x-ac` to lowercase letters.
- Sort all Log Service custom request headers obtained in the preceding step in lexicographical order.
- Delete any spaces on either side of a separator between the request header and content.
- Separate all headers and contents with separators (`\n`) to form the final CanonicalizedHeaders.

The CanonicalizedResource construction method is as follows:

- Set CanonicalizedResource to an empty string (`""`).
- Specify the Log Service resources to be accessed. For example, `/logstores/logstorename`. This field can be left blank if the `logstorename` does not exist.
- If the request contains a query string (`QUERY_STRING`), add a question mark (`?`) and the query string to the end of the CanonicalizedResource string.

The `QUERY_STRING` is a string generated after URL request parameters are sorted in lexicographical order. Use equal signs (`=`) between parameter names and parameter

values to produce a string. Sort the name-value pairs in lexicographical order. Then, use ampersands (&) to connect the pairs to construct a string. The formula is as follows:

```
QUERY_STRING = "KEY1=VALUE1" + "&" + "KEY2=VALUE2"
```

3. Generate a digital signature for the request

Log Service APIs support only one digital signature algorithm, which is also the default signature algorithm `hmac-sha1`. The signature formula is as follows:

```
Signature = base64(hmac-sha1(UTF8-Encoding-Of(SignKeyString), AccessKeySecret))
```

Use the HMAC-SHA1 method defined in [RFC 2104](#) as the signature method. The AccessKey Secret in the preceding formula must correspond to the AccessKey ID that is used in the Authorization header. Otherwise, the request cannot pass authentication by the server.

After a signature string is calculated, use this value to construct a security authentication header for the Log Service API request in Authorization header format. Then, insert the header into the HTTP request before sending the request.

Examples of the request signature process

The following two examples demonstrate how to sign the Log Service API request. Assume that the AccessKey pair you use to sign the Log Service API request is as follows:

```
AccessKeyId = "<yourAccessKeyId>"  
AccessKeySecret = "<yourAccessKeySecret>"
```

- You must send the following GET request to list all the Logstores in the `ali-test-project` project. The HTTP request is as follows:

```
GET /logstores HTTP 1.1  
Mon, 09 Nov 2015 06:11:16 GMT  
Host: ali-test-project.regionid.example.com  
x-log-apiversion: 0.6.0  
x-log-signaturemethod: hmac-sha1
```

The following signature string is generated for the Log Service API request:

```
GET\n\n\nMon, 09 Nov 2015 06:11:16 GMT\nx-log-apiversion:0.6.0\nx-log-signaturemethod:hmac-sha1\n/logstores? logstoreName=&offset=0&size=1000
```

This request is a GET request, which does not have the HTTP request body. Therefore, the `CONTENT-TYPE` and `CONTENT-MD5` fields are empty. After the previously specified

AccessKey Secret is used to calculate the signature string, the digital signature is generated as follows:

```
jEYOTCJs2e88o+y5F4/S5IsnBJQ=
```

The digitally signed HTTP request content is sent as follows:

```
GET /logstores HTTP 1.1
Mon, 09 Nov 2015 06:11:16 GMT
Host: ali-test-project.regionid.example.com
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
```

- You must write the following log into the Logstore named test-logstore in the ali-test-project project.

```
topic=""
time=1447048976
source="10.10.10.1"
"TestKey": "TestContent"
```

Therefore, the following HTTP request must be constructed based on Log Service API definition:

```
POST /logstores/test-logstore HTTP/1.1
Date: Mon, 09 Nov 2015 06:03:03 GMT
Host: test-project.regionid.example.com
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
Content-MD5: 1DD45FA4A70A9300CC9FE7305AF2C494
Content-Length: 52
x-log-apiversion:0.6.0
x-log-bodyrawsize:50
x-log-compresstype:lz4
x-log-signaturemethod:hmac-sha1
<Log contents are serialized to byte streams in protocol buffers format>
```

In this HTTP request, the written log content is serialized in protocol buffers format (for more information about this format, see [Protocol buffers format](#)) and then used as the request body. Therefore, the Content-Type header value of this request is application/x-protobuf. Similarly, the Content-MD5 header value is the MD5 value of the request

body. Based on the preceding signature string construction method, the signature string corresponding to this request is as follows:

```
POST\n1DD45FA4A70A9300CC9FE7305AF2C494\napplication/x-protobuf\nMon, 09
Nov 2015 06:03:03 GMT\nx-log-apiversion:0.6.0\nx-log-bodyrawsize:50\nx-log-
compresstype:lz4\nx-log-signaturemethod:hmac-sha1\n/logstores/test-logstore
```

In the similar way, the AccessKey Secret in the preceding example is used to calculate the signature string. The final signature is as follows:

```
XWLGyHGg2F2hcfXWxMLiNkGki6g=
```

The digitally signed HTTP request content is sent as follows:

```
POST /logstores/test-logstore HTTP/1.1
Date: Mon, 09 Nov 2015 06:03:03 GMT
Host: test-project.regionid.example.com
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
Content-MD5: 1DD45FA4A70A9300CC9FE7305AF2C494
Content-Length: 52
x-log-apiversion:0.6.0
x-log-bodyrawsize:50
x-log-compresstype:lz4
x-log-signaturemethod:hmac-sha1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
<Log contents are serialized to byte streams in protocol buffers format>
```

2.15.1.6 Common error codes

When an API request error occurs, Log Service returns an error message, including the HTTP status code and the specific error details in the response body. The error details in the response body are in the following formats:

```
{
  "errorCode" : <ErrorCode>,
  "errorMessage" : <ErrorMessage>
}
```

Among all the error messages that may be returned by Log Service, some of them are applicable to the majority of the APIs, while the others are unique to certain APIs. [Table 2-443: Common error codes](#) are described in the following table and appear in the responses of multiple APIs. The special error codes of an API are described in the reference to that particular API.

Table 2-443: Common error codes

HTTP status code	Error code	Error message	Description
411	MissingContentLength	Content-Length does not exist in HTTP header when it is necessary.	The error message returned when the required Content-Length request header is not provided.
415	InvalidContentType	Content-Type {type} is unsupported.	The error message returned when the specified Content-Type is not supported.
400	MissingContentType	Content-Type does not exist in HTTP header when body is not empty.	The error message returned when the Content-Type header is not specified when the HTTP request body is not empty.
400	MissingBodyRawSize	x-log-bodyrawsize does not exist in header when it is necessary.	The error message returned when the required x-log-bodyrawsize request header is not provided in the compression scenario.
400	InvalidBodyRawSize	x-log-bodyrawsize is invalid.	The error message returned when the x-log-bodyrawsize value is invalid.
400	InvalidCompressType	x-log-compresstype {type} is unsupported.	The error message returned when the compression type specified in x-log-compresstype is not supported.
400	MissingHost	Host does not exist in HTTP header.	The error message returned when the HTTP standard request header Host is not provided.
400	MissingDate	Date does not exist in HTTP header.	The error message returned when the HTTP standard request header Date is not provided.

HTTP status code	Error code	Error message	Description
400	InvalidDateFormat	Date {date} must follow RFC822.	The error message returned when the Date request header value does not conform to the RFC822 standard.
400	MissingAPIVersion	x-log-apiversion does not exist in HTTP header.	The error message returned when the HTTP request header x-log-apiversion is not provided.
400	InvalidAPIVersion	x-log-apiversion {version} is unsupported.	The error message returned when the value of the HTTP request header x-log-apiversion is not supported.
400	MissAccessKeyId	x-log-accesskeyid does not exist in header.	The error message returned when no AccessKey ID is provided in the Authorization header.
401	Unauthorized	The AccessKeyId is unauthorized.	The error message returned when the provided AccessKey ID value is unauthorized.
400	MissingSignatureMethod	x-log-signaturemethod does not exist in HTTP header.	The error message returned when x-log-signaturemethod does not exist in HTTP header.
400	InvalidSignatureMethod	signature method {method} is unsupported.	The error message returned when the signature method specified by the x-log-signaturemethod header is not supported.
400	RequestTimeTooSkewed	Request time exceeds server time more than 15 minutes.	The error message returned when the request sent time is more than 15 minutes before or after the current server time.
404	ProjectNotExist	Project {name} does not exist.	The error message returned when the Log Service project does not exist.

HTTP status code	Error code	Error message	Description
401	SignatureNotMatch	Signature {signature} is not matched.	The error message returned when the digital signature of the request does not match with that computed in Log Service.
403	WriteQuotaExceed	Write quota is exceeded.	The error message returned when the log write quota is exceeded.
403	ReadQuotaExceed	Read quota is exceeded.	The error message returned when the log read quota is exceeded.
500	InternalServerError	Internal server error message.	The error message returned when an internal server error occurred.
503	ServerBusy	The server is busy, please try again later.	The error message returned when the server is disconnected. Please try again later.

The {...} in the error message indicates the specific error information. For example, {name} in the ProjectNotExist error message is replaced by a specific project name.

2.15.1.7 Logstore operations

2.15.1.7.1 CreateLogstore

You can call this operation to create a Logstore for a project.

Examples:

```
POST /logstores
```

Request syntax

```
POST /logstores HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
{
  "logstoreName": <logStoreName>,
  "ttl": <ttl>,
  "shardCount": <shardCount>
```

```
}
```

Request parameters

[Table 2-444: Request parameters](#) describes the request parameters.

Table 2-444: Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore. The name must be unique within a project.
ttl	Integer	Yes	The data retention time. Unit: days.
shardCount	Integer	Yes	The number of shards in the Logstore.

Request header

No special request header is required. For more information about the common request headers of Log Service API, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-445: Error codes specific to CreateLogstore](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-445: Error codes specific to CreateLogstore

HTTP status code	Error code	Error message
400	LogstoreAlreadyExist	logstore {logstoreName} already exists
500	InternalServerError	Specified Server Error Message

HTTP status code	Error code	Error message
400	LogstoreInfoInvalid	logstore info is invalid
400	ProjectQuotaExceed	Project Quota Exceed

Detailed description

Logstores cannot be created for a project if the quota is exhausted.

Examples

Sample requests:

```
POST /logstores HTTP/1.1
Header :
{
  x-log-apiversion=0.6.0,
  Authorization=LOG <yourAccessKeyId>:<yourSignature>,
  Host=ali-test-project.regionid.example.com,
  Date=Wed, 11 Nov 2015 07:35:00 GMT,
  Content-Length=55,
  x-log-signaturemethod=hmac-sha1,
  Content-MD5=7EF43D0B8F4A807B95E775048C911C72,
  User-Agent=sls-java-sdk-v-0.6.0,
  Content-Type=application/json
}
Body :
{
  "logstoreName": "test-logstore",
  "ttl": 1,
  "shardCount": 2
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header:
{
  Date=Wed, 11 Nov 2015 07:35:00 GMT,
  Content-Length=0,
  x-log-requestid=5642EFA499248C827B012B39,
  Connection=close,
  Server=nginx/1.6.1
}
```

2.15.1.7.2 DeleteLogstore

You can call this operation to delete a Logstore, including all shards and indexes of the Logstore.

Request syntax

```
DELETE /logstores/{logstoreName} HTTP/1.1
Authorization: <AuthorizationString>
```

```
Date: <GMT Date>  
Host: <Project Endpoint>  
x-log-apiversion: 0.6.0  
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-446: DeleteLogstore request Parameters](#) describes the request parameters.

Table 2-446: DeleteLogstore request Parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore. The name must be unique within a project.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-447: Error codes specific to DeleteLogstore](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-447: Error codes specific to DeleteLogstore

HTTP status code	Error code	Error message
404	LogStoreNotExist	logstore {logstoreName} does not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
DELETE /logstores/test_logstore HTTP/1.1  
Header :
```

```
{
  x-log-apiversion=0.6.0,
  Authorization=LOG <yourAccessKeyId>:<yourSignature>,
  Host=ali-test-project.regionid.example.com,
  Date=Wed, 11 Nov 2015 08:09:38 GMT,
  Content-Length=0,
  x-log-signaturemethod=hmac-sha1,
  User-Agent=sls-java-sdk-v-0.6.0,
  Content-Type=application/json
}
```

Sample responses:

```
HTTP/1.1 200 OK
Body:
{
  Date=Wed, 11 Nov 2015 08:09:39 GMT,
  Content-Length=0,
  x-log-requestid=5642F7C399248C817B013A07,
  Connection=close,
  Server=nginx/1.6.1
}
```

2.15.1.7.3 UpdateLogstore

You can call this operation to update the attributes of a Logstore. You can only update Time To Live (TTL) and shard attributes.

Request syntax

```
PUT /logstores/{logstoreName} HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
{
  "logstoreName": <logstoreName>,
  "ttl": <ttl>,
  "shardCount": <shardCount>
}
```

Request parameters

[Table 2-448: UpdateLogstore request parameters](#) describes the request parameters.

Table 2-448: UpdateLogstore request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore. The name must be unique within a project.
ttl	Integer	Yes	The lifecycle of the log data. Valid values : 1 to 365. Unit: days.

Parameter	Type	Required	Description
shardCount	Integer	Yes	The number of shards. Valid values: 1 to 10.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-449: Error codes specific to UpdateLogstore](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-449: Error codes specific to UpdateLogstore

HTTP status code	Error code	Error message
404	ProjectNotExist	Project {ProjectName} does not exist
404	LogStoreNotExist	logstore {logstoreName} does not exist
400	LogStoreAlreadyExist	logstore {logstoreName} already exists
500	InternalServerError	Specified Server Error Message
400	ParameterInvalid	invalid shard count, you can only increase the count

Detailed description

The number of shards can be increased but cannot be decreased.

Examples

Sample requests:

```
PUT /logstores/test-logstore HTTP/1.1
```

```
Header:
{
  x-log-apiversion=0.6.0,
  Authorization=LOG <yourAccessKeyId>:<yourSignature>,
  Host=ali-test-project.regionid.example.com,
  Date=Wed, 11 Nov 2015 08:28:19 GMT,
  Content-Length=55,
  x-log-signaturemethod=hmac-sha1,
  Content-MD5=757C60FC41CC7D3F60B88E0D916D051E,
  User-Agent=sls-java-sdk-v-0.6.0,
  Content-Type=application/json
}
Body :
{
  "logstoreName": "test-logstore",
  "ttl": 1,
  "shardCount": 2
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header:
{
  Date=Wed, 11 Nov 2015 08:28:20 GMT,
  Content-Length=0,
  x-log-requestid=5642FC2399248C8F7B0145FD,
  Connection=close,
  Server=nginx/1.6.1
}
```

2.15.1.7.4 GetLogstore

You can call this operation to view the attributes of a Logstore.

Request syntax

```
GET /logstores/{logstoreName} HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-450: GetLogstore request parameters](#) describes the request parameters.

Table 2-450: GetLogstore request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore. The name must be unique within a project.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

```
{
  "logstoreName" : <logstoreName>,
  "ttl": <ttl>,
  "shardCount": <shardCount>,
  "createTime": <createTime>,
  "lastModifyTime": <lastModifyTime>
}
```

Error codes

As described in [Table 2-451: Error codes specific to GetLogstore](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-451: Error codes specific to GetLogstore

HTTP status code	Error code	Error message
404	ProjectNotExist	Project {ProjectName} does not exist
404	LogstoreNotExist	logstore {logstoreName} does not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
GET /logstores/test-logstore HTTP/1.1
Header :
{
  x-log-apiversion=0.6.0,
  Authorization=LOG <yourAccessKeyId>:<yourSignature>,
  Host=ali-test-project.regionid.example.com,
  Date=Wed, 11 Nov 2015 07:53:29 GMT,
  Content-Length=0,
```

```
x-log-signaturemethod=hmac-sha1,  
User-Agent=sls-java-sdk-v-0.6.0,  
Content-Type=application/json  
}
```

Sample responses:

```
HTTP/1.1 200 OK  
Header :  
{  
  Date=Wed, 11 Nov 2015 07:53:30 GMT,  
  Content-Length=107,  
  x-log-requestid=5642F3FA99248C817B01352D,  
  Connection=close,  
  Content-Type=application/json,  
  Server=nginx/1.6.1  
}  
Body :  
{  
  "logstoreName" : test-logstore,  
  "ttl": 1,  
  "shardCount": 2,  
  "createTime": 1447833064,  
  "lastModifyTime": 1447833064  
}
```

2.15.1.7.5 ListLogstore

You can call this operation to list the names of all the Logstores in a specified project.

Request syntax

```
GET /logstores HTTP/1.1  
Authorization: <AuthorizationString>  
Date: <GMT Date>  
Host: <Project Endpoint>  
x-log-apiversion: 0.6.0  
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-452: ListLogstore request parameters](#) describes the request parameters.

Table 2-452: ListLogstore request parameters

Parameter	Type	Required	Description
offset(optional)	Integer	No	The starting position of returned records. Default value: 1.
size(optional)	Integer	No	The maximum number of entries to return on each page. Default and maximum value: 500.

Parameter	Type	Required	Description
logstoreName	String	No	The name of the Logstore to be filtered. Partial matching is supported.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

When the request is successful, the response body contains the list of names of all the Logstores in a specified project. [Table 2-453: Response parameters](#) describes the response parameters.

Table 2-453: Response parameters

Parameter	Type	Description
count	Integer	The number of returned Logstores.
total	Integer	The total number of Logstores.
logstores	String array	The list of names of returned Logstores.

As described in [Table 2-454: Error codes specific to ListLogstore](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-454: Error codes specific to ListLogstore

HTTP status code	Error code	Error message
404	ProjectNotExist	Project {ProjectName} does not exist
500	InternalServerError	Specified Server Error Message
400	ParameterInvalid	Invalid parameter size, (0.6.0]
400	InvalidLogStoreQuery	logstore Query is invalid

Examples

Sample requests:

```
GET /logstores HTTP/1.1
Header:
{
  x-log-apiversion=0.6.0,
  Authorization=LOG <yourAccessKeyId>:<yourSignature>,
  Host=ali-test-project.regionid.example.com,
  Date=Wed, 11 Nov 2015 08:09:39 GMT,
  Content-Length=0,
  x-log-signaturemethod=hmac-sha1,
  User-Agent=sls-java-sdk-v-0.6.0,
  Content-Type=application/json
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header:
{
  Date=Wed, 11 Nov 2015 08:09:39 GMT,
  Content-Length=52,
  x-log-requestid=5642F7C399248C8D7B01342F,
  Connection=close,
  Content-Type=application/json,
  Server=nginx/1.6.1
}
Body:
{
  "count":1,
  "logstores":["test-logstore"],
  "total":1
}
```

2.15.1.7.6 ListShards

You can call this operation to list all the available shards in a Logstore.

Request syntax

```
GET /logstores/<logstorename>/shards HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-455: ListShards request parameters](#) describes the request parameters.

Table 2-455: ListShards request parameters

Parameter	Type	Required	Description
logstoreName	String	No	The name of the Logstore.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

Content-Type: application/json

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The array that consists of shards.

```
[
  {
    "shardID":0
    "status": "readwrite",
    "inclusiveBeginKey": "00000000000000000000000000000000",
    "exclusiveEndKey": "80000000000000000000000000000000",
    "createTime":1453949705
  },
  {
    ...
  },
  {
    ...
  }
]
```

Detailed description

None

Special error codes

As described in [Table 2-456: Error codes specific to ListShards](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-456: Error codes specific to ListShards

HTTP status code	Error code	Error message
404	LogStoreNotExist	logstore {logstoreName} does not exist
500	InternalServerError	Specified Server Error Message
400	LogStoreWithoutShard	logstore has no shard

The {name} variable in the error message is replaced with a Logstore name.

Examples

Sample requests:

```
GET /logstores/sls-test-logstore/shards
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Thu, 12 Nov 2015 03:40:31 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
Header:
{
  "content-length": "57",
  "server": "nginx/1.6.1",
  "connection": "close",
  "date": "Thu, 12 Nov 2015 03:40:31 GMT",
  "content-type": "application/json",
  "x-log-requestid": "56440A2F99248C050600C74C"
}
Body :
[
  {
    "shardID" : 1,
    "status" : "readwrite",
    "inclusiveBeginKey" : "00000000000000000000000000000000",
    "exclusiveEndKey" : "80000000000000000000000000000000",
    "createTime" : 1453949705
  },
  {
    "shardID" : 2,
    "status" : "readwrite",
    "inclusiveBeginKey" : "80000000000000000000000000000000",
    "exclusiveEndKey" : "ffffffffffffffffffffffffffffffff",
    "createTime" : 1453949705
  },
]
```

```
{
  "shardID" : 0,
  "status" : "readonly",
  "inclusiveBeginKey" : "00000000000000000000000000000000",
  "exclusiveEndKey" : "ffffffffffffffffffffffff",
  "createTime" : 1453949705
}
```

2.15.1.7.7 SplitShard

You can call this operation to split a specified shard in the read/write state.

Request syntax

```
POST /logstores/<logstorename>/shards/<shardid>? action=split&key=<splitkey> HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-457: SplitShard request parameters](#) describes the request parameters.

Table 2-457: SplitShard request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to which the shard to be split belongs.
shardid	Integer	Yes	The ID of the shard to be split.
splitkey	String	Yes	The location where the shard is split.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

Content-Type: application/json

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The following array consists of three shards. The first one is the original shard to be split. The other two are the new shards generated after the split.

```
[
  {
    "shardID":33
    "status" : "readonly",
    "inclusiveBeginKey" : "ee0000000000000000000000000000",
    "exclusiveEndKey" : "ffffffffffffffffffffffffffffffff",
    "createTime" :1453949705
  },
  {
    "shardID":163
    "status" : "readwrite",
    "inclusiveBeginKey" : "ee0000000000000000000000000000",
    "exclusiveEndKey" : "ef0000000000000000000000000000",
    "createTime" :1453949705
  },
  {
    "shardID":164
    "status" : "readwrite",
    "inclusiveBeginKey" : "ef0000000000000000000000000000",
    "exclusiveEndKey" : "ffffffffffffffffffffffffffffffff",
    "createTime" :1453949705
  }
]
```

Detailed description

None

Special error codes

As described in [Table 2-458: Error codes specific to SplitShard](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-458: Error codes specific to SplitShard

HTTP status code	Error code	Error message
404	LogStoreNotExist	logstore {logstoreName} does not exist
400	ParameterInvalid	invalid shard id
400	ParameterInvalid	invalid mid hash
500	InternalServerError	Specified Server Error Message
400	LogStoreWithoutShard	logstore has no shard

The {name} variable in the error message will be replaced with a Logstore name.

Examples

Sample requests:

```
POST /logstores/logstorename/shards/33? action=split&key=ef000000000000000000
000000000000
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Thu, 12 Nov 2015 03:40:31 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
Header:
{
  "content-length": "57",
  "server": "nginx/1.6.1",
  "connection": "close",
  "date": "Thu, 12 Nov 2015 03:40:31 GMT",
  "content-type": "application/json",
  "x-log-requestid": "56440A2F99248C050600C74C"
}
Body :
[
  {
    "shardID": 33
    "status" : "readonly",
    "inclusiveBeginKey" : "ee000000000000000000000000000000",
    "exclusiveEndKey" : "ffffffffffffffffffffffffffffffff",
    "createTime" : 1453949705
  },
  {
    "shardID": 163
    "status" : "readwrite",
    "inclusiveBeginKey" : "ee000000000000000000000000000000",
    "exclusiveEndKey" : "ef000000000000000000000000000000",
    "createTime" : 1453949705
  },
  {
    "shardID": 164
    "status" : "readwrite",
    "inclusiveBeginKey" : "ef000000000000000000000000000000",
    "exclusiveEndKey" : "ffffffffffffffffffffffffffffffff",
    "createTime" : 1453949705
  }
]
```

```
]
```

2.15.1.7.8 MergeShards

You can call this operation to merge two adjacent shards that are in the read/write state.

If the ID of a shard is specified, the server will automatically find the adjacent shard at the right of the specified shard.

Request syntax

```
POST /logstores/<logstorename>/shards/<shardid>? action=merge HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-459: MergeShards request parameters](#) describes the request parameters.

Table 2-459: MergeShards request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore.
shardid	Integer	Yes	The ID of the shard.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

Content-Type: application/json

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The following array consists of three shards. The first one is the merged shard. The other two are those before the merging.

```
[
  {
    'shardID': 167,
    'status': 'readwrite',
    'inclusiveBeginKey': 'e0000000000000000000000000000000',
    'createTime': 1453953105,
```

```

    'exclusiveEndKey': 'ffffffffffffffffffffffffffff'
  },
  {
    'shardID': 30,
    'status': 'readonly',
    'inclusiveBeginKey': 'e0000000000000000000000000000000',
    'createTime': 0,
    'exclusiveEndKey':
    'e7000000000000000000000000000000'
  },
  {
    'shardID': 166,
    'status': 'readonly',
    'inclusiveBeginKey': 'e7000000000000000000000000000000',
    'createTime': 1453953073,
    'exclusiveEndKey': 'ffffffffffffffffffffffffffff'
  }
]

```

Detailed description

None

Special error codes

As described in [Table 2-460: Error codes specific to MergeShards](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-460: Error codes specific to MergeShards

HTTP status code	Error code	Error message
404	LogStoreNotExist	logstore {logstoreName} does not exist
400	ParameterInvalid	invalid shard id
400	ParameterInvalid	cannot merge the last shard
500	InternalServerError	Specified Server Error Message
400	LogStoreWithoutShard	logstore has no shard

The {name} variable in the error message will be replaced with a Logstore name.

Examples

Sample requests:

```

POST /logstores/logstorename/shards/30? action=merge
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",

```

```

"x-log-bodyrawsize": 0,
"User-Agent": "log-python-sdk-v-0.6.0",
"Host": "ali-test-project.regionid.example.com",
>Date": "Thu, 12 Nov 2015 03:40:31 GMT",
"x-log-apiversion": "0.6.0",
"Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}

```

Sample responses:

```

Header:
{
  "content-length": "57",
  "server": "nginx/1.6.1",
  "connection": "close",
  "date": "Thu, 12 Nov 2015 03:40:31 GMT",
  "content-type": "application/json",
  "x-log-requestid": "56440A2F99248C050600C74C"
}
Body :
[
  {
    'shardID': 167,
    'status': 'readwrite',
    'inclusiveBeginKey': 'e0000000000000000000000000000000',
    'createTime': 1453953105,
    'exclusiveEndKey': 'ffffffffffffffffffffffffffffffff'
  },
  {
    'shardID': 30,
    'status': 'readonly',
    'inclusiveBeginKey': 'e0000000000000000000000000000000',
    'createTime': 0,
    'exclusiveEndKey': 'e7000000000000000000000000000000'
  },
  {
    'shardID': 166,
    'status': 'readonly',
    'inclusiveBeginKey': 'e7000000000000000000000000000000',
    'createTime': 1453953073,
    'exclusiveEndKey': 'ffffffffffffffffffffffffffffffff'
  }
]

```

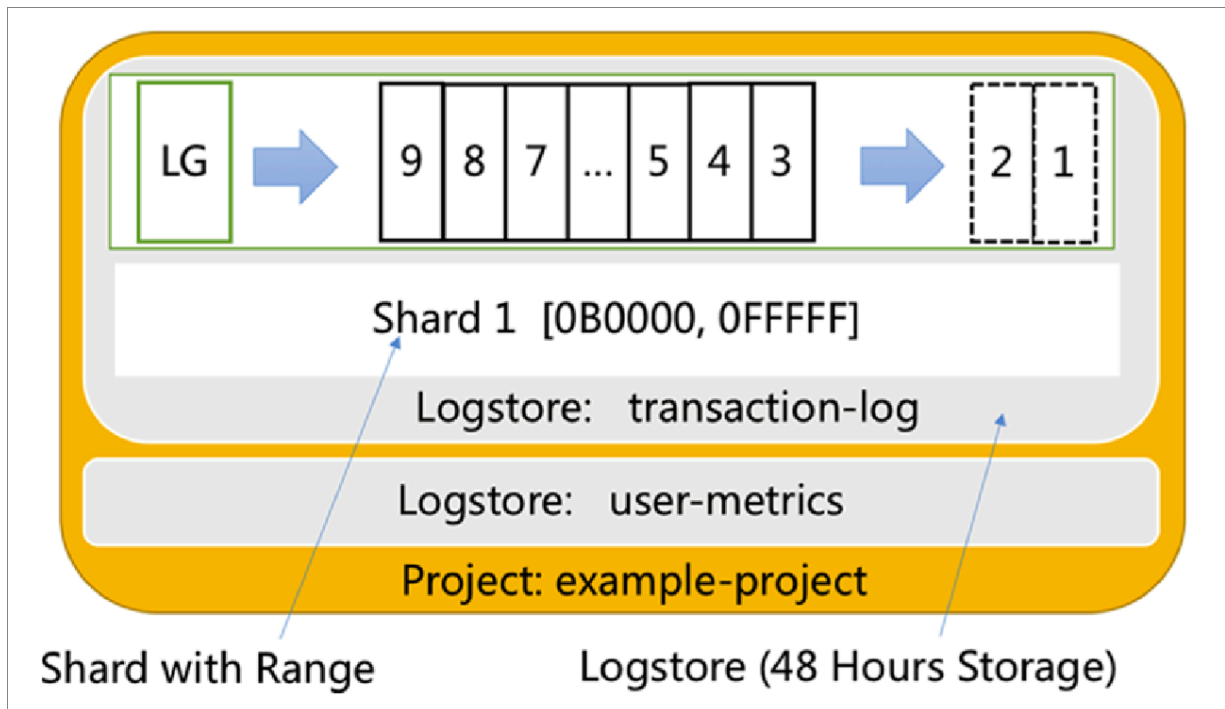

2.15.1.7.9 GetCursor

You can call this operation to get a cursor based on the time. [Figure 2-4: Relationships among a project, a Logstore, a shard, and a cursor](#) shows the relationships among a project, a Logstore, a shard, and a cursor.

- A project can have multiple Logstores.
- Each Logstore can have multiple shards.

- A cursor can be used to locate a specified log.

Figure 2-4: Relationships among a project, a Logstore, a shard, and a cursor

Request syntax

```
GET /logstores/ay42/shards/2? type=cursor&from=1402341900 HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
```

Request parameters

[Table 2-461: GetCursor request parameters](#) describes the request parameters.

Table 2-461: GetCursor request parameters

Parameter	Type	Required	Description
shard	String	Yes	-
type	String	Yes	The cursor.
from	String	Yes	The point in time. Valid values: begin, end, and a time point expressed in UNIX format and measured in seconds.

Logstore lifecycle:

The lifecycle of a Logstore is specified by the `lifeCycle` parameter. For example, the current time is 2015-11-11 09:00:00 and the `lifeCycle` parameter is set to 24. The time range for the consumable data in each shard is [2015-11-10 09:00:00,2015-11-11 09:00:00). The time is the server time.

By using the `from` parameter, you can locate the logs within the lifecycle in the shard.

Assume that the Logstore lifecycle is [`begin_time`,`end_time`) and the `from` parameter is set to `from_time`.

```
from_time <= begin_time or from_time == "begin": returns to the cursor position
corresponding to the begin_time.
from_time <= end_time or from_time = "end": returns to the cursor position where the
next log entry is written at the current point in time. No log data is available at the
current cursor position.
from_time > begin_time and from_time < end_time: returns to the cursor position for the
first packet whose receipt time on the server is greater than or equal to from_time.
```

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

```
{
  "cursor": "MTQ0NzI5OTYwNjg5NjYzMjM1Ng=="
}
```

Detailed description

None

Error codes

As described in [Table 2-462: Error codes specific to GetCursor](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-462: Error codes specific to GetCursor

HTTP status code	Error code	Error message
404	LogStoreNotExist	Logstore {Name} does not exist
400	ParameterInvalid	Parameter From is not valid
400	ShardNotExist	Shard {ShardID} does not exist
500	InternalServerError	Specified Server Error Message
400	LogStoreWithoutShard	the logstore has no shard

Examples

Sample requests:

```
GET /logstores/sls-test-logstore/shards/0? type=cursor&from=begin
Header:
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",

}
```

2.15.1.710 PullLogs

You can call this operation to read logs based on the cursor and the number of returned log groups. You must specify a shard before reading logs. If Storm is used to read log data,

elective and collaborative consumption can be performed through LoghubClientLib. Only LogGroupList data in PB format can be read.

Request syntax

```
GET /logstores/ay42/shards/0? type=logs&cursor=MTQ0NzMyOTQwMTEwMjEzMDkwNA
==&count=100 HTTP/1.1
Accept: application/x-protobuf
Accept-Encoding: lz4
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Table 2-463: [URL parameters](#) describes the URL parameters.

Table 2-463: URL parameters

Parameter	Type	Required	Description
type	String	Yes	The logs.
cursor	String	Yes	Specifies where to start reading log data, which is equivalent to the start point.
count	Integer	Yes	The number of returned log groups. Valid values: 1 to 1000.

Request header

- Accept: application/x-protobuf
- Accept-Encoding: LZ4, deflate or "" .

For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

- x-log-cursor: the cursor for the next batch of log data to be read.
- x-log-count: the number of returned logs.

For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

Data from serialized logs in PB format, which may be compressed.

Detailed description

None

Special error codes

As described in [Table 2-464: Error codes specific to PullLogs](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-464: Error codes specific to PullLogs

HTTP status code	Error code	Error message
404	LogStoreNotExist	Logstore {Name} does not exist
400	ParameterInvalid	Parameter Cursor is not valid
400	ParameterInvalid	ParameterCount should be in [0-1000]
400	ShardNotExist	Shard {ShardID} does not exist
400	InvalidCursor	this cursor is invalid
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
Read log data from Shard 0.
GET /logstores/sls-test-logstore/shards/0? cursor=MTQ0NzMyOTQwMTEwMjEzMDkwNA
==&count=1000&type=log
Header:
{
  "Authorization"="LOG <yourAccessKeyId>:<yourSignature>",
  "x-log-bodyrawsize"=0,
  "User-Agent" : "sls-java-sdk-v-0.6.0",
  "x-log-apiversion" : "0.6.0",
  "Host" : "ali-test-project.regionid.example.com",
  "x-log-signaturemethod" : "hmac-sha1",
  "Accept-Encoding" : "lz4",
  "Content-Length": 0,
  "Date" : "Thu, 12 Nov 2015 12:03:17 GMT",
  "Content-Type" : "application/x-protobuf",
  "accept" : "application/x-protobuf"
```

}

Sample responses:

```
Header:
{
  "x-log-count" : "1000",
  "x-log-requestid" : "56447FB20351626D7C000874",

  "Date" : "Thu, 12 Nov 2015 12:01:54 GMT",
  "x-log-compresstype" : "lz4",
  "Content-Type" : "application/x-protobuf"
}
Body:
The <LogGroupList data in PB format> after the compression.
```

Page flip

To flip the page (get the next token) without returning data, you can send HTTP HEAD requests.

2.15.1.7.11 PostLogStoreLogs

You can call this operation to write log data to a specified Logstore. Only [LogGroup data in protocol buffers \(PB\) format](#) can be written to a specified Logstore. You can use the following two methods to write log data:

- **Load balancing mode:** Log data is automatically written to all the writable shards in the Logstore. This mode is applicable to the scenario where you do not need to consider the order in which you consume the log data that is written to multiple shards.
- **KeyHash mode:** A key is required when log data is written. Log Service automatically selects a shard whose range includes the key. Then, the log data is written to the shard. For example, hash a producer (such as an instance) to a specified shard based on the name of the producer to make sure that the data writing and consumption in this shard are strictly ordered. This ensures that a key appears only on one shard at a given point in time when shards are merged or split.

Request syntax**Load balancing mode**

```
POST /logstores/<logstorename>/shards/lb HTTP/1.1
Authorization: <AuthorizationString>
Content-Type: application/x-protobuf
Content-Length: <Content Length>
Content-MD5: <Content MD5>
```

```
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-bodyrawsize: <BodyRawSize>
x-log-compresstype: lz4
x-log-signaturemethod: hmac-sha1
<Compressed log data in PB format>
```

KeyHash mode

x-log-hashkey is added to the request header to determine the shard whose range includes the key. This parameter is optional. If it is left blank, Log Service automatically switches to the load balancing mode.

```
POST /logstores/<logstorename>/shards/lb HTTP/1.1
Authorization: <AuthorizationString>
Content-Type: application/x-protobuf
Content-Length: <Content Length>
Content-MD5: <Content MD5>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-bodyrawsize: <BodyRawSize>
x-log-compresstype: lz4
x-log-hashkey : 14d2f850ad6ea48e46e4547edbbb27e0
x-log-signaturemethod: hmac-sha1
<Compressed log data in PB format>
```

Request parameters

[Table 2-465: PostLogStoreLogs request parameters](#) describes the request parameters.

Table 2-465: PostLogStoreLogs request parameters

Parameter	Type	Required	Description
logstorename	String	Yes	The name of the Logstore to write logs to.

Request header

In the KeyHash mode, you must add the x-log-hashkey header. For more information, see the preceding example. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

No response parameter is returned after the successful request.

Detailed description

- When you call this operation to write logs, the maximum number of logs in a log group is 4,096, or the maximum size for logs in a log group is 3 MB. The size of the values in each log cannot be larger than 1 MB. If either of the two limits is reached, the request will fail, and no log data will be written.
- Log Service checks the format of the written log data. The request will fail, and no log data will be written if any log does not conform to this format.

Error codes

As described in [Table 2-466: Error codes specific to PostLogStoreLogs](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-466: Error codes specific to PostLogStoreLogs

HTTP status code	Error code	Error message	Description
400	PostBodyInvalid	Protobuffer content cannot be parsed.	The error message returned because the protocol buffers content cannot be parsed.
400	InvalidTimestamp	Invalid timestamps are in logs.	The error message returned because invalid timestamps appear in logs.
400	InvalidEncoding	Non-UTF8 characters are in logs.	The error message returned because logs contain non-UTF-8 characters.
400	InvalidKey	Invalid keys are in logs.	The error message returned because invalid keys appear in logs.
400	PostBodyTooLarge	Logs must be less than 3M and 4096 lines.	The error message returned because the number of logs exceeds 4,096 or the size of logs is greater than 3 MB.

HTTP status code	Error code	Error message	Description
400	PostBodyUncompressError	Body is uncompressed fail.	The error message returned because log extraction fails.
499	PostBodyInvalid	The post data time is out of range.	The error message returned because the log time is not within the valid range [-7 days, +15 minutes].
404	LogStoreNotExist	logstore {Name} does not exist.	The error message returned because the Logstore does not exist.

The {name} variable in the error message will be replaced with a Logstore name.

Examples

Sample requests:

```
POST /logstores/sls-test-logstore
{
  "Content-Length": 118,
  "Content-Type": "application/x-protobuf",
  "x-log-bodyrawsize": 1356,
  "Host": "ali-test-project.regionid.example.com",
  "Content-MD5": "6554BD042149C844761C2C094A8FECCE",
  "Date": "Thu, 12 Nov 2015 06:54:26 GMT",
  "x-log-apiversion": "0.6.0",
  "x-log-compresstype": "lz4",
  "x-log-signaturemethod": "hmac-sha1",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
<Binary log data in PB format compressed with LZ4>
```

Sample responses:

```
Header
{
  "date": "Thu, 12 Nov 2015 06:53:03 GMT",
  "connection": "close",
  "x-log-requestid": "5644160399248C060600D216",
  "content-length": "0",
  "server": "nginx/1.6.1"
```

}

2.15.1.7.12 GetLogs

You can call this operation to query log data in a Logstore under a specified project.

You can also query the logs that meet the specific conditions by specifying the relevant parameters.

When a log is written to the Logstore, the latency of querying this log by using Log Service query APIs (GetHistograms and GetLogs) varies with the log type. Based on the log timestamp, Log Service classifies logs into the following two types:

- **Real-time data:** The time point in a log is the current time point on the server (-180s, 900s]. For example, if the log time is UTC 2014-09-25 12:03:00 and the time when the server receives the log is UTC 2014-09-25 12:05:00, the log is processed as the real-time data, which usually appears in normal scenarios.
- **Historical data:** The time point in a log is the current time point on the server (-7 x 86400s, -180s]. For example, if the log time is UTC 2014-09-25 12:00:00 and the time when the server receives the log is UTC 2014-09-25 12:05:00, the log is processed as the historical data, which usually appears in the supplementary data scenario.

The maximum latency between a real-time data write and a query is three seconds.

Request syntax

```
GET /logstores/<logstorename>? type=histogram&topic=<logtopic>&from=<starttime>&
to=<endtime>&query=<querystring>&line=<linenum>&offset=<startindex>&reverse=<ture|
false> HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-bodyrawsize: 0
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

The request parameters are described in [Table 2-467: GetLogs request parameters](#).

Table 2-467: GetLogs request parameters

Name	Type	Required	Description
logstorename	String	Yes	The name of the Logstore to which the log to be queried belongs.

Name	Type	Required	Description
type	String	Yes	The type of Logstore data to be queried. This parameter must be log in GetLogs API.
from	Integer	Yes	The query start time (the number of seconds since 1970-1-1 00:00:00 UTC).
to	Integer	Yes	The query end time (the number of seconds since 1970-1-1 00:00:00 UTC).
topic	String	No	The topic of the log to be queried.
query	String	No	The query expression. For the detailed syntax of query statements, see the Query syntax section of the User Guide .
line	Integer	No	The maximum number of logs returned from the request. Valid values: 0 to 100. Default value: 100.
offset	Integer	No	The returned log start point of the request. Valid values: 0 and a positive integer. Default value: 0.
reverse	Boolean	No	Indicates whether logs are returned in reverse order according to the log timestamp. true indicates reverse order and false indicates sequence order. The default value is false.

Request header

The GetLogs API does not have any special request headers. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

The GetLogs API does not have any special response headers. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

The response header contains a special element that indicates whether the returned results of the request are complete. The specific formats of response elements are described in [Table 2-468: GetLogs response elements](#).

Table 2-468: GetLogs response elements

Name	Type	Description
progress	String	The status of the query results. The two optional values Incomplete and Complete indicate whether the results are complete or not.
count	Integer	The total number of logs in the current query results.

Response elements

After the successful request, the response body contains the logs that meet the query conditions. The response results of this API may be incomplete when the log volume to be queried is large (measured in TBs). The response body of the GetLogs API is an array, and each element in this array is a log. The structure of each element in the array is described in [Table 2-469: Element structure](#).

Table 2-469: Element structure

Name	Type	Description
__time__	Integer	The log timestamp (the number of seconds since 1970-1-1 00:00:00 UTC).
__source__	String	The log source, which is specified when logs are written.
[content]	Key-value pair	The original content of the log, which is organized in key-value pairs.

Detailed description

- The time interval defined by the request parameters from and to in this API follows the left-closed and right-opened principle, that is, the time interval includes the start time, but not the end time. If the from and to values are the same, the time interval is invalid and the function returns an error directly.
- Each call to this API must return results within a specified time, and each query can only scan a specified number of logs. The results returned from this request are incomplete if the log volume to be processed for this request is large (whether the results are complete is indicated by using x-log-progress in the response header). At the same time, the server caches the results of the query within 15 minutes. When a portion of the query request results are cache hits, the server continues to scan the log data that are not cache hits for this request. To reduce the workload of merging multiple query results, the server cache hit query results and the new hits of the current query are merged and returned to you. Therefore, Log Service allows you to call the API multiple times with the same parameter to obtain the final complete results. Log Service API cannot predict how many times the API must be called before obtaining the complete results because the volume of the logs to be queried fluctuates dramatically. Therefore, you must check the x-log-progress status in the returned results of each request to determine whether or not to continue the query. Each call to this API consumes the same number of query CUs again.

Special error codes

As described in [Table 2-470: Error codes specific to GetLogs](#), in addition to the [Common error codes](#) of Log Service APIs, the API may also return the following special error codes.

Table 2-470: Error codes specific to GetLogs

HTTP status code	Error code	Error message	Description
404	LogStoreNotExist	logstore {Name} does not exist	The error message returned when the Logstore does not exist.
400	InvalidTimeRange	request time range is invalid	The error message returned when the time interval of the request is invalid.

HTTP status code	Error code	Error message	Description
400	InvalidQueryString	query string is invalid	The error message returned when the query string of the request is invalid.
400	InvalidOffset	offset is invalid	The error message returned when the offset of the request is invalid.
400	InvalidLine	line is invalid	The error message returned when the line of the request is invalid.
400	InvalidReverse	Reverse value is invalid	The error message returned when the Reverse parameter value is invalid .
400	IndexConfigNotExist	logstore without index config	The error message returned when the Logstore does not enable the index.

**Note:**

The {name} variable in the preceding error message will be replaced with a specific Logstore name.

Examples

Using a project named big-game as an example, query the logs with the groupA topic in the app_log Logstore of the project. The time interval for this query is 2014-09-01 00:00:00-2014-09-01 22:00:00. The keyword for this query is error. The query starts from the beginning of the time interval, and a maximum of 20 logs are returned.

Sample requests:

```
GET /logstores/app_log type=log&topic=groupA&from=1409529600&to=1409608800&
query=error&line=20&offset=0 HTTP/1.1
Authorization: <AuthorizationString>
Date: Wed, 3 Sept. 2014 08:33:46 GMT
Host: big-game.regionid.example.com
x-log-bodyrawsize: 0
x-log-apiversion: 0.4.0
```

`x-log-signaturemethod: hmac-sha1`**Sample responses:**

```

HTTP/1.1 200 OK
Content-MD5: 36F9F7F0339BEAF571581AF1B0AAAFB5
Content-Type: application/json
Content-Length: 269
Date: Wed, 3 Sept. 2014 08:33:47 GMT
x-log-requestid: efag01234-12341-15432f
x-log-progress : Complete
x-log-count : 10000
x-log-processed-rows: 10000
x-log-elapsed-millisecond:5
{
  "progress": "Complete",
  "count": 2,
  "logs": [
    {
      "__time__": 1409529660,
      "__source__": "10.237.0.17",
      "Key1": "error",
      "Key2": "Value2"
    },
    {
      "__time__": 1409529680,
      "__source__": "10.237.0.18",
      "Key3": "error",
      "Key4": "Value4"
    }
  ]
}

```

In this sample response the x-log-progress status is Complete, which indicates the log query is completed and the returned results are complete. For this request, two logs meet the query condition and are displayed as the values of logs. If the x-log-progress status is Incomplete in the response result, you must repeat the request to obtain the complete results.

2.15.1.7.13 GetHistograms

You can call this operation to query the log distribution in a Logstore of a specific project. By specifying the relevant parameters, it can also query the distribution of the logs that meet the specified criteria.

When a log is written to the Logstore, the latency of querying this log by using Log Service query APIs (GetHistograms and GetLogs) varies according to the log type. Based on the log timestamp, Log Service classifies logs into the following two types:

- **Real-time data:** For this type, the point of time in a log is the current time point on the server (-180 seconds, 900 seconds]. For example, if the log time is UTC 2014-09-25 12:03

:00 and the time when the server receives the log is UTC 2014-09-25 12:05:00, the log is processed as the real-time data, which usually appears in normal scenarios.

- Historical data: The time point in a log is the current time point on the server ($-7 \times 86400s$, $-180s$]. For example, if the log time is UTC 2014-09-25 12:00:00 and the time when the server receives the log is UTC 2014-09-25 12:05:00, the log is processed as the historical data, which usually appears in the data supplementation scenario.

The latency between a real-time data write and a query is three seconds.

Request syntax

```
GET /logstores/<logstorename>? type=histogram&topic=<logtopic>&from=<starttime>&to=<endtime>&query=<querystring> HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-bodyrawsize: 0
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

The request parameters are described in [Table 2-471: GetHistograms request parameters](#).

Table 2-471: GetHistograms request parameters

Name	Type	Required	Description
logstorename	String	Yes	The name of the Logstore to which the log to be queried belongs.
type	String	Yes	The type of Logstore data to be queried. The value of this parameter must be histogram in the GetHistograms API.
from	Integer	Yes	The query start time (the number of seconds elapsed since 1970-1-1 00:00:00 UTC).
to	Integer	Yes	The query end time (the number of seconds elapsed since 1970-1-1 00:00:00 UTC).

Name	Type	Required	Description
topic	String	No	The topic of the log to be queried.
query	String	No	The query statement. For more information about the syntax of query statements, see the Query syntax .

Request header

The GetHistograms API does not have any special request headers. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

The GetHistograms API does not have any special response headers. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response elements

When a GetHistograms request is successful, the response body contains the distribution of the numbers of log hits returned by the query along the time axis. The response results evenly divide the time range into several (1-60) sub-intervals and return the number of logs that meet the query conditions in each sub-interval. Because Log Service must return results within a limited period to ensure real-time functionality, each query can only scan the specified number of logs. The response results of this API may be incomplete when the log volume to be queried is large. Therefore, the response element contains a specialized member that indicates whether or not the request's return results are complete. The specific response element format is described in [Table 2-472: GetHistograms response elements](#).

Table 2-472: GetHistograms response elements

Name	Type	Description
progress	String	The status of the query results. The two optional values Incomplete and Complete indicate whether or not the results are complete.

Name	Type	Description
count	Integer	The total number of logs in the current query results.
histograms	Array	The distribution of the current query results in the sub-intervals. For more information about the structure, see the following table.

The structure of each element in the histograms array is described in [Table 2-473: Histograms array element structure](#).

Table 2-473: Histograms array element structure

Name	Type	Description
from	Integer	The start time for the sub-interval (the number of seconds since 1970-1-1 00:00:00 UTC).
to	Integer	The end time for the sub-interval (the number of seconds since 1970-1-1 00:00:00 UTC).
count	Integer	The number of logs that meet the query conditions for this sub-interval in the current query results.
progress	String	indicates whether the current query results in this sub-interval are complete. Optional values: Incomplete and Complete.

Detailed description

- All the time intervals in this API, whether the time intervals defined by the request parameters from and to, or sub-intervals in the returned results, follow the left-closed and right-opened principle, that is, the time interval includes the start time, but not

the end time. If the from and to values are the same, the time interval is invalid and the function directly returns an error.

- The sub-interval division method in the response of this API is consistent and unchanging. If the queried time range remains unchanged, the sub-interval division in the response is also unchanged.
- Each call to this API must return results within a specified time, and each query can only scan a specified number of logs. The results returned from this request are incomplete if the volume of the logs to be processed for this request is large (whether or not the results are complete is indicated by using the progress in the returned results). At the same time, Log Service caches the query results within 15 minutes. When part of the query request results matches those in the cache, the server continues to scan the log data that is not hit in the cache for this request. To reduce the workload of merging multiple query results, the query results of server cache hits and the new hits of the current query are merged and returned. Therefore, Log Service allows you to repeatedly call the API with the same parameters to eventually obtain the complete results. Log Service API cannot predict how many times the API must be called before obtaining the complete results because the volume of the logs to be queried fluctuates dramatically. Therefore, you must check the progress member status in the returned results of each request to determine whether to proceed. Each call to this API consumes the same number of query CUs.

Special error codes

As described in [Table 2-474: Error codes specific to GetHistograms](#), in addition to the [Common error codes](#) of Log Service APIs, the API may also return the following special error codes.

Table 2-474: Error codes specific to GetHistograms

HTTP status code	Error code	Error message	Description
404	LogStoreNotExist	logstore {Name} not exist	The error message returned when the Logstore does not exist.
400	InvalidTimeRange	request time range is invalid	The error message returned when the time interval of the request is invalid.

HTTP status code	Error code	Error message	Description
400	InvalidQueryString	query String is invalid	The error message returned when the query string of the request is invalid.

The {name} variable in the preceding error message will be replaced with a specific Logstore name.

Examples

Using a project named big-game as an example, query the distribution of the logs with the topic groupA in the app_log Logstore of the big-game project. The time interval for this query is 2014-09-01 00:00:00-2014-09-01 22:00:00. The keyword for this query is error.

Sample requests:

```
GET /logstores/app_log? type=histogram&topic=groupA&from=1409529600&to=1409608800&query=error HTTP/1.1
Authorization: <AuthorizationString>
Date: Wed, 3 Sept. 2014 08:33:46 GMT
Host: big-game.regionid.example.com
x-log-bodyrawsize: 0
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Sample responses:

```

    {
      "from": 1409529600,
      "to": 1409569200,
      "count": 2,
      "progress": "Complete"
    },
    {
      "from": 1409569200,
      "to": 1409608800,
      "count": 1,
      "progress": "Incomplete"
    }
  ]
}
```

```
}
```

In this sample response, the server divides the entire histogram into two equal time intervals: [2014-09-01 00:00:00, 2014-09-01 11:00:00) and [2014-09-01 11:00:00, 2014-09-01 22:00:00). Because the amount of data is too large, the first query returns incomplete data. In the response, the number of hit logs is 3, but the results are incomplete. Only the results that fall into the time interval [2014-09-01 00:00:00 2014-09-01 11:00:00) are complete, with 2 hits. The results for the other interval are incomplete, but there is already 1 hit. In this situation, to obtain the complete results, you must repeatedly call the preceding sample request until the progress value in the response changes to Complete.

Sample responses:

```
HTTP/1.1 200 OK
Content-Type: application/json
Content-MD5: E6AD9C21204868C2DE84EE3808AAA8C8
Content-Type: application/json
Date: Wed, 3 Sept. 2014 08:33:48 GMT
Content-Length: 232
x-log-requestid: afag01322-1e241-25432e
{
  "progress": "Incomplete",
  "count": 4,
  "histograms": [
    {
      "from": 1409529600,
      "to": 1409569200,
      "count": 2,
      "progress": "Complete"
    },
    {
      "from": 1409569200,
      "to": 1409608800,

      "progress": "complete"
    }
  ]
}
```

2.15.1.7.14 CreateIndex

You can call this operation to create an index for a specified Logstore.

Examples:

```
POST /logstores/{logstoreName}/index
```

Request syntax

```
POST /logstores/<logstoreName>/index HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: <x-log-bodyrawsize>
User-Agent: <User-Agent>
x-log-apiversion: <APIVersion>
```

```
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
Content-MD5: <Content-MD5>
Content-Length: <Content-Length>
{
  "line": <full text index>,
  "keys": <key-value index>,
  "ttl": <ttl>
}
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore for which an index is created.
ttl	Integer	No	The lifecycle of the index to be created. Valid values: 7, 30, and 90. Unit: days.
keys	Object	No	The index configuration that is specified as a key-value pair. Key indicates the field name, and value indicates the field index configuration.
line	Object	No	The configuration of the full-text index.

You must specify the keys parameter or the line parameter or both. The configuration of the full-text index includes the following attributes.

Parameter	Type	Required	Description
caseSensitive	Bool	No	Specifies whether the field is case-sensitive.
chn	Bool	No	Specifies whether the field contains Chinese characters.
token	Array	Yes	The list of delimiters.

Parameter	Type	Required	Description
include_keys	Array	No	The list of included fields. This parameter and the exclude_keys parameter cannot be specified at the same time.
exclude_keys	Array	No	The list of excluded fields. This parameter and the include_keys parameter cannot be specified at the same time.

The configuration of the field index includes the following attributes.

Parameter	Type	Required	Description
type	String	Yes	The type of the field.
alias	String	No	The alias of the field.
chn	Bool	No	Specifies whether the field contains Chinese characters. This parameter exists only when the type parameter is set to text.
token	Array	No.	The list of delimiters. This parameter takes effect only when the type parameter is set to text.
caseSensitive	Bool	No	Specifies whether the field is case-sensitive. This parameter takes effect only when the type parameter is set to text.

Parameter	Type	Required	Description
doc_value	Bool	No	Specifies whether to enable statistical analysis on the field.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	IndexInfoInvalid	required field token is lacking or of error format
400	IndexAlreadyExist	log store index is already created
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Note:

{Project} and {logstoreName} in the error messages are replaced by a project name and a Logstore name, respectively.

Examples

Sample requests:

```

POST /logstores/my-logstore/index HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1

"<",
">",
"/",
":",
"\n",
"\t",
"\r",
]
}
},
"ttl": 90
}
```

2.15.1.7.15 DeleteIndex

You can call this operation to delete the index of a specified Logstore.

Examples:

```
DELETE /logstores/{logstoreName}/index
```

Request syntax

```
DELETE /logstores/<logstoreName>/index HTTP/1.1
```

```
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to be deleted.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	ParameterInvalid	log store index not created
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
DELETE /logstores/my-logstore/index HTTP/1.1

Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 06 May 2018 13:22:57 GMT
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Sample responses:

```
HTTP/1.1 200

Server: nginx/1.12.1
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 06 May 2018 13:22:57 GMT
x-log-requestid: 5AEF01B1A458E41C2F8326A8
```

2.15.1.716 GetIndex

You can call this operation to query the index of a specified Logstore.

Examples:

```
GET /logstores/{logstoreName}/index
```

Request syntax

```
GET /logstores/<logstoreName>/index HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

When the request is successful, the response body includes the indexes of the specified project and Logstore. The format is described in the following table.

Parameter	Type	Description
index_mode	String	The type of the index.
keys	Dict	The index configuration that is specified as a key-value pair. Key indicates the field name, and value indicates the field index configuration.
line	Object	The configuration of the full-text index.

Parameter	Type	Description
storage	String	The storage type. pg is supported.
ttl	Integer	The lifecycle of the index. Valid values: 7, 30, and 90. Unit: days.
lastModifyTime	Integer	The last time when the index was updated. The time is displayed in the Unix timestamp format.

The configuration of the full-text index includes the following attributes.

Parameter	Type	Description
caseSensitive	Bool	Indicates whether the field is case-sensitive.
chn	Bool	Indicates whether the field contains Chinese characters.
token	Array	The list of delimiters.
include_keys	Array	The list of included fields.
exclude_keys	Array	The list of excluded fields.

The corresponding index configuration of each field includes the following attributes.

Parameter	Type	Description
type	String	The type of the field.
alias	String	The alias of the field.
chn	Bool	Indicates whether the field contains Chinese characters . This parameter takes effect only when the type parameter is set to text.
token	Array	The list of delimiters. This parameter takes effect only when the type parameter is set to text.

Parameter	Type	Description
caseSensitive	Bool	Indicates whether the field is case-sensitive. This parameter takes effect only when the type parameter is set to text.
doc_value	Bool	Indicates whether to enable statistical analysis on the field.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	IndexConfigNotExist	index config doesn't exist
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
GET /logstores/logstore-4/index HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 06 May 2018 13:08:42 GMT
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Sample responses:

2.15.1.7.17 UpdateIndex

You can call this operation to update the index of a specified Logstore.

Examples:

```
PUT /logstores/{logstoreName}/index
```

Request syntax

```

PUT /logstores/<logstoreName>/index HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0

```

```
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
Content-MD5: <Content-MD5>
Content-Length: <ContentLength>
{
  "line": <full text index>,
  "keys": <key-value index>,
  "ttl": <ttl>
}
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore.
ttl	Integer	No	The lifecycle of the index to be updated . Value values: 7, 30, and 90. Unit: days.
keys	Object	No	The index configuration that is specified as a key-value pair . Key indicates the field name, and value indicates the field index configuration.
line	Object	No	The configuration of the full-text index.

You must specify the keys parameter or the line parameter or both. The configuration of the full-text index includes the following attributes.

Parameter	Type	Required	Description
token	Array	Yes	The list of delimiters.
caseSensitive	Bool	No	Specifies whether the field is case-sensitive.
chn	Bool	No	Specifies whether the field contains Chinese characters.

Parameter	Type	Required	Description
include_keys	Array	No	The list of included fields. This parameter and the exclude_keys parameter cannot be specified at the same time.
exclude_keys	Array	No	The list of the excluded fields. This parameter and the include_keys parameter cannot be specified at the same time.

The configuration of the field index includes the following attributes.

Parameter	Type	Required	Description
type	String	Yes	The type of the field.
alias	String	No	The alias of the field.
chn	Bool	No	Specifies whether the field contains Chinese characters. This parameter takes effect only when the type parameter is set to text.
token	Array	No	The list of delimiters. This parameter takes effect only when the type parameter is set to text.
caseSensitive	Bool	No	Specifies whether the field is case-sensitive. This parameter takes effect only when the type parameter is set to text.

Parameter	Type	Required	Description
doc_value	Bool	No	Specifies whether to enable statistical analysis on the field.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	ParameterInvalid	log store index is not created
400	ParameterInvalid	key config must has type
400	IndexInfoInvalid	required field token is lacking or of error format
400	IndexInfoInvalid	required fields line/keys are lacking or of error format
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Examples

```

2.15.1.8 Logtail machine group operations

2.15.1.8.1 CreateMachineGroup

You can call this operation to create a machine group to which the configurations on Logtail are distributed and applied.

Examples:

```
POST /machinegroups
```

Request syntax

```

POST /machinegroups HTTP/1.1
Authorization: <AuthorizationString>
Content-Type: application/json
Content-Length: <Content Length>
Content-MD5: <Content MD5>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
{
  "groupName": "testgroup",
  "groupType": "",
  "groupAttribute": {
    "externalName": "testgroup",
    "groupTopic": "testgrouptopic"
  },
  "machineIdentifyType": "ip",
  "machineList": [
    "test-ip1",
    "test-ip2"
  ]
}

```

```
}
```

Request parameters

[Table 2-475: Request body parameters](#) describes the request body parameters.

Table 2-475: Request body parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group. The name must be unique within a project.
groupType	String	No	The type of the machine group. Default value: null.
machineIdentifyType	String	Yes	The type of a machine identifier, which can be either IP address or user-defined identifier.
groupAttribute	Object	Yes	The attribute of the machine group. Default value: null.
machineList	Array	Yes	The list of machine identifiers. Valid values: IP addresses or user-defined identifiers.

[Table 2-476: groupAttribute details](#) describes groupAttribute details.

Table 2-476: groupAttribute details

Parameter	Type	Required	Description
groupTopic	String	No	The topic of the machine group. Default value: null.
externalName	String	No	The ID of the external management system (Armory) on which the machine group depends on. Default value: null.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-477: Error codes specific to CreateMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-477: Error codes specific to CreateMachineGroup

HTTP status code	Error code	Error message
400	GroupAlreadyExist	group {GroupName} already exists
400	InvalidParameter	invalid group resource json
500	InternalServerError	Internal server error

Detailed description

None

Examples

Sample requests:

```
POST /machinegroups HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 17:57:33 GMT",
  "Content-Length": "187",
  "x-log-signaturemethod": "hmac-sha1",
  "Content-MD5": "82033D507DEAAD72067BB58DFDCB590D",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/json",
  "x-log-bodyrawsize": "0"
}
```

```
Body :
{
  "groupName": "test-machine-group",
  "groupType": "",
  "machineIdentifyType": "ip",
  "groupAttribute": {
    "groupTopic": "testtopic",
    "externalName": "testgroup"
  },
  "machineList": [
    "127.0.0.1",
    "127.0.0.2"
  ]
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
  "Date": "Tue, 10 Nov 2015 17:57:33 GMT",
  "Content-Length": "0",
  "x-log-requestid": "5642300D99248CB76D005D36",
  "Connection": "close",
  "Server": "nginx/1.6.1"
}
```

2.15.1.8.2 DeleteMachineGroup

You can call this operation to delete a machine group. The configurations on Logtail that are applied to the machine group will be deleted along with the machine group.

Examples:

```
DELETE /machinegroups/{groupName}
```

Request syntax

```
DELETE /machinegroups/{groupName} HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-478: URL parameters](#) describes the URL parameters.

Table 2-478: URL parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-479: Error codes specific to DeleteMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-479: Error codes specific to DeleteMachineGroup

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
DELETE /machinegroups/test-machine-group-4 HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 19:13:28 GMT",
  "Content-Length": "0",
  "x-log-signaturemethod": "hmac-sha1",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/x-protobuf",
  "x-log-bodyrawsize": "0"
```

```
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
  "Date": "Tue, 10 Nov 2015 19:13:28 GMT",
  "Content-Length": "0",
  "x-log-requestid": "564241D899248C827B000CFE",
  "Connection": "close",
  "Server": "nginx/1.6.1"
}
```

2.15.1.8.3 UpdateMachineGroup

You can call this operation to update the information of a machine group. If the configurations on Logtail are applied to a machine group, they are automatically added or removed when machines are added to or removed from the machine group.

Examples:

```
PUT /machinegroups/{groupName}
```

Request syntax

```
PUT /machinegroups/{groupName} HTTP/1.1
Authorization: <AuthorizationString>
Content-Type: application/json
Content-Length: <Content Length>
Content-MD5: <Content MD5>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
{
  "groupName": "test-machine-group",
  "groupType": "",
  "groupAttribute": {
    "externalName": "testgroup",
    "groupTopic": "testgrouptopic"
  },
  "machineIdentifyType": "ip",
  "machineList": [
    "test-ip1",
    "test-ip2"
  ]
}
```

Request parameters

[Table 2-480: URL parameters](#) describes the URL parameters.

Table 2-480: URL parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group.

[Table 2-481: Request body parameters](#) describes the request body parameters.

Table 2-481: Request body parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group. The name must be unique within a project.
groupType	String	No	The type of the machine group. Default value: null.
machineIdentifyType	String	Yes	The type of a machine identifier, which can be either IP address or user-defined identifier.
groupAttribute	Object	Yes	The attribute of the machine group. Default value: null.
machineList	Array	Yes	The list of machine identifiers. Valid values: IP addresses or user-defined identifiers.

[Table 2-482: groupAttribute details](#) describes groupAttribute details.

Table 2-482: groupAttribute details

Parameter	Type	Required	Description
groupTopic	String	No	The topic of the machine group. Default value: null.
externalName	String	No	The ID of the external management system (Armory) on which the machine group depends. Default value: null.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-483: Error codes specific to UpdateMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-483: Error codes specific to UpdateMachineGroup

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
400	InvalidParameter	invalid group resource json
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
PUT /machinegroups/test-machine-group HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 18:41:43 GMT",
  "Content-Length": "194",
  "x-log-signaturemethod": "hmac-sha1",
  "Content-MD5": "2CEBAEBE53C078891527CB70A855BAF4",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/json",
  "x-log-bodyrawsize": "0"
}
```

```
Body :
{
  "groupName": "test-machine-group",
  "groupType": "",
  "machineIdentifyType": "userdefined",
  "groupAttribute": {
    "groupTopic": "testtopic2",
    "externalName": "testgroup2"
  },
  "machineList": [
    "uu_id_1",
    "uu_id_2"
  ]
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
  "Date": "Tue, 10 Nov 2015 18:41:43 GMT",
  "Content-Length": "0",
  "x-log-requestid": "56423A6799248CA57B00035C",
  "Connection": "close",
  "Server": "nginx/1.6.1"
}
```

2.15.1.8.4 ListMachineGroup

Examples:

```
GET /machinegroups? offset=1&size=100
```

Request syntax

```
GET /machinegroups? offset=1&size=100 HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-484: URL parameters](#) describes the URL parameters.

Table 2-484: URL parameters

Parameter	Type	Required	Description
offset	Integer	No	The starting position of returned records. Default value: 0.

Parameter	Type	Required	Description
size	Integer	No	The maximum number of entries to return on each page. Default and maximum value: 500.
groupName	String	No	The name of the machine group to be filtered. Partial matching is supported.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

When the request is successful, the response body contains the list of names of all machine groups in the specified project. [Table 2-485: ListMachineGroup response parameters](#) describes ListMachineGroup response parameters.

Table 2-485: ListMachineGroup response parameters

Parameter	Type	Description
count	Integer	The number of returned machine groups.
total	Integer	The total number of returned machine groups.
machinegroups	JSON array	The list of names of returned machine groups.

```
{
  "machinegroups": [
    "test-machine-group",
    "test-machine-group-2"
  ],
  "count": 2,
  "total": 2
}
```

```
}
```

Error codes

As described in [Table 2-486: Error codes specific to ListMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-486: Error codes specific to ListMachineGroup

HTTP status code	Error code	Error message
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
GET /machinegroups? groupName=test-machine-group&offset=0&size=3 HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 18:34:44 GMT",
  "Content-Length": "0",
  "x-log-signaturemethod": "hmac-sha1",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/x-protobuf",
  "x-log-bodyrawsize": "0"
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
  "Date": "Tue, 10 Nov 2015 18:34:44 GMT",
  "Content-Length": "83",
  "x-log-requestid": "564238C499248C8F7B0001DE",
  "Connection": "close",
  "Content-Type": "application/json",
  "Server": "nginx/1.6.1"
}
Body :
{
  "machinegroups": [
    "test-machine-group",
    "test-machine-group-2"
  ],
  "count": 2,
  "total": 2
}
```

```
}
```

2.15.1.8.5 GetMachineGroup

You can call this operation to view the details of a machine group.

Examples:

```
GET /machinegroups/{groupName}
```

Request syntax

```
GET /machinegroups/{groupName} HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-487: URL parameters](#) describes the URL parameters.

Table 2-487: URL parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

[Table 2-488: GetMachineGroup response parameters](#) describes the response parameters.

Table 2-488: GetMachineGroup response parameters

Parameter	Type	Description
groupName	String	The name of the machine group. The name must be unique within a project.

Parameter	Type	Description
groupType	String	The type of the machine group. Valid values: null and Armory. Default value: null.
machineIdentifyType	String	The type of a machine identifier, which can be either IP address or user-defined identifier.
groupAttribute	JSON object	The attribute of the machine group. Default value: null.
machineList	JSON array	The list of machine identifiers. Valid values: IP addresses or user-defined identifiers.
createTime	Integer	The time when the machine group was created.
lastModifyTime	Integer	The last time when the machine group was updated.

Table 2-489: [groupAttribute details](#) describes groupAttribute details.

Table 2-489: groupAttribute details

Parameter	Type	Required	Description
groupTopic	String	No	The topic of the machine group, which is typically not specified.
externalName	String	No	The ID of the external management system (Armory) on which the machine group depends.

```
{
  "groupName": "test-machine-group",
  "groupType": "",
  "groupAttribute": {
    "externalName": "testgroup",
    "groupTopic": "testtopic"
  },
  "machineIdentifyType": "ip",
  "machineList": [
    "127.0.0.1",
    "127.0.0.2"
  ],
}
```

```
"createTime": 1447178253,
"lastModifyTime": 1447178253
}
```

Error codes

As described in [Table 2-490: Error codes specific to GetMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-490: Error codes specific to GetMachineGroup

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
GET /machinegroups/test-machine-group HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 18:15:24 GMT",
  "Content-Length": "0",
  "x-log-signaturemethod": "hmac-sha1",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/x-protobuf",
  "x-log-bodyrawsize": "0"
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
  "Date": "Tue, 10 Nov 2015 18:15:23 GMT",
  "Content-Length": "239",
  "x-log-requestid": "5642343B99248CB36D0060B8",
  "Connection": "close",
  "Content-Type": "application/json",
  "Server": "nginx/1.6.1"
}
Body :
{
  "groupName": "test-machine-group",
```

```
"groupType": "",
"groupAttribute": {
  "externalName": "testgroup",
  "groupTopic": "testtopic"
},
"machineIdentifyType": "ip",
"machineList": [
  "127.0.0.1",
  "127.0.0.2"
],
"createTime": 1447178253,
"lastModifyTime": 1447178253
}
```

2.15.1.8.6 ApplyConfigToMachineGroup

You can call this operation to apply a configuration to a machine group.

Examples:

```
PUT /machinegroups/{GroupName}/configs/{ConfigName}
```

Request parameters

[Table 2-491: ApplyConfigToMachineGroup request parameters](#) describes the request parameters.

Table 2-491: ApplyConfigToMachineGroup request parameters

Parameter	Type	Required	Description
GroupName	String	Yes	The name of the machine group.
ConfigName	String	Yes	The name of the log configuration to be applied to the machine group.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-492: Error codes specific to ApplyConfigToMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-492: Error codes specific to ApplyConfigToMachineGroup

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
404	ConfigNotExist	config {ConfigName} does not exist
500	InternalServerError	internal server error

Examples

Sample requests:

```
PUT /machinegroups/sample-group/configs/logtail-config-sample
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Mon, 09 Nov 2015 09:44:43 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
{
  "date": "Mon, 09 Nov 2015 09:44:43 GMT",
  "connection": "close",
  "x-log-requestid": "56406B0B99248CAA230BA094",
  "content-length": "0",
  "server": "nginx/1.6.1"
```

```
}
```

2.15.1.8.7 RemoveConfigFromMachineGroup

You can call this operation to remove a configuration from a machine group.

Examples:

```
DELETE /machinegroups/{GroupName}/configs/{ConfigName}
```

Request parameters

[Table 2-493: RemoveConfigFromMachineGroup request parameters](#) describes the request parameters.

Table 2-493: RemoveConfigFromMachineGroup request parameters

Parameter	Type	Required	Description
GroupName	String	Yes	The name of the machine group.
ConfigName	String	Yes	The name of the log configuration.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-494: Error codes specific to RemoveConfigFromMachineGroup](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-494: Error codes specific to RemoveConfigFromMachineGroup

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
404	ConfigNotExist	config {ConfigName} does not exist
500	InternalServerError	internal server error

Examples

Sample requests:

```
DELETE /machinegroups/sample-group/configs/logtail-config-sample
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Mon, 09 Nov 2015 09:48:48 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
{
  "date": "Mon, 09 Nov 2015 09:48:48 GMT",
  "connection": "close",
  "x-log-requestid": "56406C0099248CAA230BE135",
  "content-length": "0",
  "server": "nginx/1.6.1"
}
```

2.15.1.8.8 ListMachines

You can call this operation to query the status of your machines that are in a machine group and connected to the server.

Examples:

```
GET /machinegroups/{groupName}/machines? offset=1&size=10
```

Request syntax

```
GET /machinegroups/{groupName}/machines HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
```

```
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-495: URL parameters](#) describes the URL parameters.

Table 2-495: URL parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group.
offset	Integer	No	The starting position of returned records. Default value: 0.
size	Integer	No	The maximum number of entries to return on each page. Default and maximum value: 500.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

[Table 2-496: ListMachines response parameters](#) describes the response parameters.

Table 2-496: ListMachines response parameters

Parameter	Type	Description
count	Integer	The number of returned machines.
total	Integer	The total number of machines.
machines	JSON array	The list of names of returned machines.

[Table 2-497: Machine details](#) describes the machine details.

Table 2-497: Machine details

Parameter	Type	Description
ip	String	The IP address of the machine.
machine-uniqueid	String	The DMI UUID of the machine .
userdefined-id	String	The user-defined identifier of the machine.

```
{
  "count":10,
  "total":100,
  "machines":
  [{
    "ip" : "testip1",
    "machine-uniqueid" : "testuuid1",
    "userdefined-id" : "testuserdefinedid1",
    "lastHeartbeatTime" : 1447182247
  },
  {
    "ip" : "testip1",
    "machine-uniqueid" : "testuuid2",
    "userdefined-id" : "testuserdefinedid2",
    "lastHeartbeatTime" : 1447182247
  },
  {
    "ip" : "testip2",
    "machine-uniqueid" : "testuuid",
    "userdefined-id" : "testuserdefinedid"
    "lastHeartbeatTime" : 1447182247
  }
  ]
}
```

Error codes

As described in [Table 2-498: Error codes specific to ListMachines](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-498: Error codes specific to ListMachines

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
500	InternalServerError	internal server error

Detailed description

This operation only obtains the list of server-connected machines that work properly.

Examples

Sample requests:

```
GET /machinegroups/test-machine-group-5/machines? offset=0&size=3 HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 19:04:57 GMT",
  "Content-Length": "0",
  "x-log-signaturemethod": "hmac-sha1",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/x-protobuf",
  "x-log-bodyrawsize": "0"
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
  "Date": "Tue, 10 Nov 2015 19:04:58 GMT",
  "Content-Length": "324",
  "x-log-requestid": "56423FD999248C827B000A57",
  "Connection": "close",
  "Content-Type": "application/json",
  "Server": "nginx/1.6.1"
}
Body :
{
  "machines": [
    {
      "ip": "10.101.166.116",
      "machine-uniqueid": "",
      "userdefined-id": "",
      "lastHeartbeatTime": 1447182247
    },
    {
      "ip": "10.101.165.193",
      "machine-uniqueid": "",
      "userdefined-id": "",
      "lastHeartbeatTime": 1447182246
    },
    {
      "ip": "10.101.166.91",
      "machine-uniqueid": "",
      "userdefined-id": "",
      "lastHeartbeatTime": 1447182248
    }
  ],
  "count": 3,
  "total": 8
}
```

```
}
```

2.15.1.8.9 GetAppliedConfigs

You can call this operation to retrieve the name of the configuration that is applied to a machine group.

Examples:

```
GET /machinegroups/{groupName}/configs
```

Request syntax

```
GET /machinegroups/{groupName}/configs HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-499: URL parameters](#) describes the URL parameters.

Table 2-499: URL parameters

Parameter	Type	Required	Description
groupName	String	Yes	The name of the machine group.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

When the request is successful, the response body includes the list of all machines in the specified machine group. [Table 2-500: Machine list](#) describes the list of machines.

Table 2-500: Machine list

Parameter	Type	Description
count	Integer	The number of returned configurations.

Parameter	Type	Description
configs	String array	The list of names of returned configurations.

```
{
  "count":2,
  "configs":
  ["config1","config2"]
}
```

Error codes

As described in [Table 2-501: Error codes specific to GetAppliedConfigs](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-501: Error codes specific to GetAppliedConfigs

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
GET /machinegroups/test-machine-group/configs HTTP/1.1
Header :
{
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Tue, 10 Nov 2015 19:45:48 GMT",
  "Content-Length": "0",
  "x-log-signaturemethod": "hmac-sha1",
  "User-Agent": "sls-java-sdk-v-0.6.0",
  "Content-Type": "application/x-protobuf",
  "x-log-bodyrawsize": "0"
}
```

Sample responses:

```
HTTP/1.1 200 OK
Header :
{
```

```

    "Date": "Tue, 10 Nov 2015 19:45:48 GMT",
    "Content-Length": "53",
    "x-log-requestid": "5642496C99248C8C7B00173F",
    "Connection": "close",
    "Content-Type": "application/json",
    "Server": "nginx/1.6.1"
  }
  Body :
  {
    "configs": [
      "two",
      "three",
      "test_logstore"
    ],
    "count": 3
  }

```

2.15.1.9 Logtail configuration operations

2.15.1.9.1 CreateConfig

You can call this operation to create log configurations in a project.

Examples:

```
POST /configs
```

Request syntax

```

POST /configs HTTP/1.1
Authorization: <AuthorizationString>
Content-Type: application/json
Content-Length: <Content Length>
Content-MD5: <Content MD5>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
{
  "configName": "testcategory1",
  "inputType": "file",
  "inputDetail": {
    "logType": "common_reg_log",
    "logPath": "/var/log/httpd/",
    "filePattern": "access*.log",
    "localStorage": true,
    "timeFormat": "%Y/%m/%d %H:%M:%S",
    "logBeginRegex": ".*",
    "regex": "(\\w+)(\\s+)",
    "key": ["key1", "key2"],
    "filterKey": ["key1"],
    "filterRegex": ["regex1"],
    "fileEncoding": "utf8",
    "topicFormat": "none"
  },
  "outputType": "LogService",
  "outputDetail": {
    "logstoreName": "perfcounter"
  }
}

```

```
}
```

Request parameters

[Table 2-502: CreateConfig request parameters](#) describes the request parameters.

Table 2-502: CreateConfig request parameters

Parameter	Type	Required	Description
configName	String	Yes	The name of the log configuration. The name must be unique within a project.
inputType	String	Yes	The input type. Only the file type is supported.
inputDetail	JSON	Yes	See Table 2-503: inputDetail details .
outputType	String	Yes	The output type. Only LogService is supported.
outputDetail	JSON	Yes	See Table 2-504: outputDetail details .
logSample	String	No	The log sample of the Logtail configuration. The log size cannot exceed 1,000 bytes.

[Table 2-503: inputDetail details](#) describes inputDetail types.

Table 2-503: inputDetail details

Parameter	Type	Required	Description
logType	String	Yes	The type of the log. Only the common_reg_log type is supported.
logPath	String	Yes	The parent directory where the log is located. For example, /var/logs/.
filePattern	String	Yes	The type of the log file. For example, access*.log.

Parameter	Type	Required	Description
localStorage	Boolean	Yes	Specifies whether to enable local cache. Logs up to 1 GB can be locally cached when the link to Log Service is disconnected.
timeFormat	String	Yes	The format of the log time. For example, %Y/%m/%d %H:%M:%S.
logBeginRegex	String	Yes	The characteristics (regular expression) of the first line of a log entry. This parameter is used to match a log entry that consists of multiple lines.
regex	String	Yes	The regular expression for extracting logs.
key	Array	Yes	The key that is generated after logs are extracted.
filterKey	Array	Yes	The key used to filter logs. A log is considered valid only when the key value matches the regular expression specified in the corresponding filterRegex column.
filterRegex	Array	Yes	The regular expression corresponding to each filterKey. The length of filterRegex must be the same as that of filterKey.

Parameter	Type	Required	Description
topicFormat	String	No	The topic generation method. The following four methods are supported: • A part of the log file path is used as the topic. For example, <code>/var/log/(. *.log</code>. • <code>none</code> indicates that the topic is empty. • <code>default</code> indicates that the log file path is used as the topic (for internal users only). • <code>group_topic</code> indicates that the topic attribute of the machine group to which this configuration is applied is used as the topic.
preserve	Boolean	No	Valid values: <code>true</code> and <code>false</code> . <code>true</code> indicates that the monitoring of the directory never times out, while <code>false</code> indicates that the timeout for directory monitoring is 30 minutes. The default value is <code>true</code> .
preserveDepth	Integer	No	Specifies the depth of the monitored directories if <code>preserve</code> is set to <code>false</code> . The maximum depth is 3.
fileEncoding	String	No	The encoding format of the log file. UTF-8 and GBK are supported.

Table 2-504: [outputDetail details](#) describes outputDetail types.

Table 2-504: outputDetail details

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the corresponding Logstore.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-505: Error codes specific to CreateConfig](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-505: Error codes specific to CreateConfig

HTTP status code	Error code	Error message
400	ConfigAlreadyExist	config {Configname} already exists
400	InvalidParameter	invalid config resource json
500	InternalServerError	internal server error

Detailed description

The configuration fails to be created if an error occurs during the creation. For example, the configuration already exists, the format is incorrect, the required parameters are not specified, or the quota is exhausted.

Examples**Sample requests:**

```
POST /configs HTTP/1.1
```

```

Header :
{
  'Content-Length': 737,
  'Host': 'ali-test-project.regionid.example.com',
  'x-log-bodyrawsize': 737,
  'Content-MD5': 'FBA01ECF7255BE143379BC70C56BBF68',
  'x-log-signaturemethod': 'hmac-sha1',

    "filterRegex": [],
    "topicFormat": "none",
    "fileEncoding": "utf8"
  },
  "outputType": "LogService",
  "outputDetail": {
    "logstoreName": "sls-test-logstore"
  }
}

```

Sample responses:

```

HTTP/1.1 200 OK
Header
{
  'date': 'Mon, 09 Nov 2015 07:45:30 GMT',
  'connection': 'close',
  'x-log-requestid': '56404F1A99248CA26C002180',
  'content-length': '0',
  'server': 'nginx/1.6.1'
}

```

```
}
```

2.15.1.9.2 ListConfig

You can call this operation to list all configurations of a project on multiple pages.

Examples:

```
GET /configs? offset=1&size=100
```

Request syntax

```
GET /configs? offset=0&size=100 HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-506: URL parameters](#) describes the URL parameters.

Table 2-506: URL parameters

Parameter	Type	Required	Description
offset(optional)	Integer	No	The starting position of returned records. Default value: 0.
size(optional)	Integer	No	The maximum number of entries to return on each page. Default and maximum value: 500.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The response body contains a list of all configurations in the project. [Table 2-507: Response parameters](#) describes the response parameters.

Table 2-507: Response parameters

Parameter	Type	Description
count	Integer	The number of returned configurations.
total	Integer	The total number of configurations in Log Service .
configs	String array	The name list of returned configurations.

Error codes

As described in [Table 2-508: Error codes specific to ListConfig](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-508: Error codes specific to ListConfig

HTTP status code	Error code	Error message
404	ConfigNotExist	config {Configname} does not exist
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
GET /configs? offset=0&size=10 HTTP/1.1
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Mon, 09 Nov 2015 09:19:13 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
Header :
{
```

```
"content-length": "103",
"server": "nginx/1.6.1",
"connection": "close",
"date": "Mon, 09 Nov 2015 09:19:13 GMT",
"content-type": "application/json",
"x-log-requestid": "5640651199248CAA2300C2BA"
}
Body:
{
  "count": 3,
  "configs":
  [
    "logtail-config-sample",
    "logtail-config-sample-2",
    "logtail-config-sample-3"
  ],
  "total": 3
}
```

2.15.1.9.3 GetAppliedMachineGroups

You can call this operation to list the machine groups to which the configuration is applied.

Examples:

```
GET /configs/{configName}/machinegroups
```

Request syntax

```
GET /configs/{configName}/machinegroups HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-509: URL parameters](#) describes the URL parameters.

Table 2-509: URL parameters

Parameter	Type	Required	Description
ConfigName	String	Yes	The name of the configuration.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

When the request is successful, the response body includes the list of all machines in the specified machine group. [Table 2-510: Response parameters](#) describes the response parameters.

Table 2-510: Response parameters

Parameter	Type	Description
count	Integer	The number of returned machine groups.
machinegroups	String array	The list of names of returned machine groups.

```
{
  "count":2,
  "machinegroups":
  ["group1","group2"]
}
```

Error codes

As described in [Table 2-511: Error codes specific to GetAppliedMachineGroups](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-511: Error codes specific to GetAppliedMachineGroups

HTTP status code	Error code	Error message
404	GroupNotExist	group {GroupName} does not exist
500	InternalServerError	internal server error

Detailed description

None

Examples

Sample requests:

```
GET /configs/logtail-config-sample/machinegroups
Header:
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Mon, 09 Nov 2015 09:51:38 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
Header :
{
  "content-length": "44",
  "server": "nginx/1.6.1",
  "connection": "close",
  "date": "Mon, 09 Nov 2015 09:51:38 GMT",
  "content-type": "application/json",
  "x-log-requestid": "56406CAA99248CAA230BE828"
}
Body:
{
  "count": 1,
  "machinegroups":
  [
    "sample-group"
  ]
}
```

2.15.1.9.4 GetConfig

You can call this operation to query the details of a configuration.

Examples:

```
GET /configs/{configName}
```

Request syntax

```
GET /configs/<configName> HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

[Table 2-512: GetConfig request parameters](#) describes the request parameters.

Table 2-512: GetConfig request parameters

Parameter	Type	Required	Description
ConfigName	String	Yes	The name of the log configuration.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

[Table 2-513: GetConfig response parameters](#) describes the response parameters.

Table 2-513: GetConfig response parameters

Parameter	Type	Description
configName	String	The name of the log configuration. The name must be unique within a project.
inputType	String	The input type. Only the file type is supported.
inputDetail	JSON	The output type. The following table describes inputDetail.
outputType	String	The output type. Only LogService is supported.
outputDetail	JSON	The following table describes outputDetail.
createTime	Int	The time when the configuration was created.
lastModifyTime	Int	The time when the resource was updated on the server.

[Table 2-514: inputDetail details](#) describes inputDetail parameters.

Table 2-514: inputDetail details

Parameter	Type	Description
logType	String	The type of the log. Only the common_reg_log type is supported.
logPath	String	The parent directory where the log is located. For example, /var/logs/.
filePattern	String	The pattern of the log file. For example, access*.log.
localStorage	Boolean	Indicates whether to enable local cache. Logs up to 1 GB can be locally cached when the link to Log Service is disconnected.
timeFormat	String	The format of the log time. For example, %Y/%m/%d %H:%M:%S.
logBeginRegex	String	The characteristics (regular expression) of the first line of a log entry. This parameter is used to match a log entry that consists of multiple lines.
regex	String	The regular expression for extracting logs.
key	Array	The key generated after logs are extracted.
filterKey	Array	The key used to filter logs. A log is considered valid only when the key value matches the regular expression specified in the corresponding filterRegex column.
filterRegex	Array	The regular expression corresponding to each filterKey. The length of filterRegex must be the same as that of filterKey.

Parameter	Type	Description
topicFormat	String	Indicates that a part of the log file path is used as the topic. For example, <code>/var/log/(.*)log</code> . The default value is none, which indicates that the topic is empty.
preserve	Boolean	Valid values: true and false . true indicates that the monitoring of the directory never times out, while false indicates that the timeout for directory monitoring is 30 minutes. The default value is true.
preserveDepth	Integer	Specifies the depth of the monitored directories if preserve is set to false. The maximum depth is 3.
fileEncoding	String	The encoding format of the log file. UTF-8 and GBK are supported.

Table 2-515: [outputDetail details](#) describes the outputDetail parameters.

Table 2-515: outputDetail details

Parameter	Type	Required	Description
endpoint	String	No	The endpoint of the region where the project is located. The value of this parameter does not include the project name as the prefix. If this parameter is not specified , the default value is EndPoint.
logstoreName	String	Yes	The name of the Logstore.

Error codes

As described in [Table 2-516: Error codes specific to GetConfig](#), in addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-516: Error codes specific to GetConfig

HTTP status code	Error code	Error message
404	ConfigNotExist	Config {Configname} does not exist
500	InternalServerError	Specified Server Error Message

Detailed description

N/A

Examples

Sample requests:

```
GET /configs/logtail-config-sample
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Mon, 09 Nov 2015 08:29:15 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
Header :
{
  "content-length": "730",
  "server": "nginx/1.6.1",
  "connection": "close",
  "date": "Mon, 09 Nov 2015 08:29:15 GMT",
  "content-type": "application/json",

}

```

2.15.1.9.5 DeleteConfig

You can call this operation to delete a specified configuration. If the configuration is applied to a machine group, the Logtail configuration is also deleted from the machine group.

Examples:

```
DELETE /configs/{configName}
```

Request syntax

```

DELETE /configs/<configName> HTTP/1.1
Authorization: <AuthorizationString>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1

```

Request parameters

[Table 2-517: URL parameters](#) describes the URL parameters.

Table 2-517: URL parameters

Parameter	Type	Required	Description
ConfigName	String	Yes	The name of the log configuration.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-518: Error codes specific to DeleteConfig](#), in addition to the [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-518: Error codes specific to DeleteConfig

HTTP status code	Error code	Error message
404	ConfigNotExist	config {Configname} not exist
400	InvalidParameter	invalid config resource json
500	InternalServerError	internal server error

Examples

Sample requests:

```
DELETE /configs/logtail-config-sample
Header :
{
  "Content-Length": 0,
  "x-log-signaturemethod": "hmac-sha1",
  "x-log-bodyrawsize": 0,
  "User-Agent": "log-python-sdk-v-0.6.0",
  "Host": "ali-test-project.regionid.example.com",
  "Date": "Mon, 09 Nov 2015 09:28:21 GMT",
  "x-log-apiversion": "0.6.0",
  "Authorization": "LOG <yourAccessKeyId>:<yourSignature>"
}
```

Sample responses:

```
Header :
{
  "date": "Mon, 09 Nov 2015 09:28:21 GMT",
  "connection": "close",
```

```

    "x-log-requestid": "5640673599248CAA230836C6",
    "content-length": "0",
    "server": "nginx/1.6.1"
  }

```

2.15.1.9.6 UpdateConfig

You can call this operation to update a configuration. If the updated configuration is applied to a machine group, the machines in this machine group are also updated.

Examples:

```
PUT /configs/{configName}
```

Request syntax

```

PUT /configs/<configName> HTTP/1.1
Authorization: <AuthorizationString>
Content-Type: application/json
Content-Length: <Content Length>
Content-MD5: <Content MD5>
Date: <GMT Date>
Host: <Project Endpoint>
x-log-apiversion: 0.6.0
x-log-signaturemethod: hmac-sha1
{
  "configName": "testcategory1",
  "inputType": "file",
  "inputDetail": {
    "logType": "common_reg_log",
    "logPath": "/var/log/httpd/",
    "filePattern": "access.log",
    "localStorage": true,
    "timeFormat": "%Y/%m/%d %H:%M:%S",
    "logBeginReg": ".*",
    "regex": "(\\w+)(\\s+)",
    "key": ["key1", "key2"],
    "filterKey": ["key1"],
    "filterRegex": ["regex1"],
    "topicFormat": "none"
  },
  "outputType": "LogService",
  "outputDetail": {
    "logstoreName": "perfcounter"
  }
}

```

Request parameters

[Table 2-519: UpdateConfig request parameters](#) describes the request parameters.

Table 2-519: UpdateConfig request parameters

Parameter	Type	Required	Description
configName	String	Yes	The name of the log configuration to be updated. The name must be unique within a project.
inputType	String	Yes	The input type. Only the file type is supported.
inputDetail	JSON	Yes	The following table describes inputDetail.
outputType	String	Yes	The output type. Only LogService is supported.
outputDetail	JSON	Yes	The following table describes outputDetail.

[Table 2-520: inputDetail details](#) describes the inputDetail parameters.

Table 2-520: inputDetail details

Parameter	Type	Required	Description
logType	String	Yes	The type of the log. Only the common_reg_log type is supported.
logPath	String	Yes	The parent directory where the log is located. For example, /var/logs/.
filePattern	String	Yes	The pattern of the log file. For example, access*.log.
localStorage	Boolean	Yes	Specifies whether to enable local cache. Logs up to 1 GB can be locally cached when the link to Log Service is disconnected.
timeFormat	String	Yes	The format of the log time. For example, %Y/%m/%d %H:%M:%S.

Parameter	Type	Required	Description
logBeginRegex	String	Yes	The characteristics (regular expression) of the first line of a log entry. This parameter is used to match a log entry that consists of multiple lines.
regex	String	Yes	The regular expression for extracting logs.
key	Array	Yes	The key that is generated after logs are extracted.
filterKey	Array	Yes	The key used to filter logs . A log is considered valid only when the key value matches the regular expression specified in the corresponding filterRegex column.
filterRegex	Array	Yes	The regular expression corresponding to each filterKey. The length of filterRegex must be the same as that of filterKey.
topicFormat	String	No	A part of the log file path is used as the topic. For example, <code>/var/log/(. *).log</code> . The default value is none, which indicates that the topic is empty.
preserve	Boolean	No	Valid values: true and false. true indicates that the monitoring of the directory never times out, while false indicates that the timeout for directory monitoring is 30 minutes. The default value is true.
preserveDepth	Integer	No	Specifies the depth of the monitored directories if preserve is set to false. The maximum depth is 3.

Parameter	Type	Required	Description
fileEncoding	String	No	The encoding format of the log file. UTF-8 and GBK are supported. The default value is UTF-8.

[Table 2-521: outputDetail details](#) describes outputDetail parameters.

Table 2-521: outputDetail details

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

As described in [Table 2-522: Error codes specific to UpdateConfig](#), in addition to the [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

Table 2-522: Error codes specific to UpdateConfig

HTTP status code	Error code	Error message
404	ConfigNotExist	config {Configname} does not exist
400	InvalidParameter	invalid config resource json
400	BadRequest	config resource configname not match request
500	InternalServerError	internal server error

Detailed description

The configuration fails to be created if an error occurs during the creation period. For example, the format is incorrect, the required parameters are missing, or the quota is exhausted.

Examples

Sample requests:

```

PUT /configs/logtail-config-sample
Header :
{
  "Content-Length": 737,

2.15.1.10 Consumer group operations

2.15.1.10.1 CreateConsumerGroup

You can call this operation to create a consumer group for a specified Logstore.

Examples:

```
POST /logstores/{logstoreName}/consumergroups
```

Request syntax

```
POST /logstores/<logstoreName>/consumergroups HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
Content-Length: <ContentLength>
{
  "consumerGroup": <consumerGroup>,
  "timeout": <timeout>,
  "order": <order>
}
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore for which the consumer group is created.

Parameter	Type	Required	Description
consumerGroup	String	Yes	The name of the consumer group to be created. The name must be unique within a project.
timeout	Integer	Yes	The heartbeat timeout. If no heartbeat packet is received during this period, the consumer group will be deleted.
order	Bool	Yes	Specifies whether to consume log data in order.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	ConsumerGroupAlreadyExist	consumer group already exist
400	JsonInfoInvalid	consumerGroup or timeout is of error format

HTTP status code	Error code	Error message
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
POST /logstores/my-logstore/consumergroups HTTP/1.1
Header:
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Fri, 04 May 2018 08:02:22 GMT
Content-Type: application/json
Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
Content-Length: 65
Connection: Keep-Alive
Body:
{
  "consumerGroup": "consumer-group-1",
  "timeout": 300,
  "order": true
}
```

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Fri, 04 May 2018 08:15:11 GMT
x-log-requestid: 5AEC168FA796F4195BF404CB
```

2.15.1.10.2 DeleteConsumerGroup

You can call this operation to delete a specified consumer group.

Examples:

```
DELETE /logstores/{logstoreName}/consumergroups/{consumerGroupName}
```

Request syntax

```
DELETE /logstores/<logstoreName>/consumergroups/<consumerGroupName> HTTP/1.1
```

```
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/x-protobuf
Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to which the consumer group belongs.
consumerGroup	String	Yes	The name of the consumer group to be deleted.

Request header

No special request header is required. For more information about common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Detailed description

If you attempt to delete a consumer group that does not exist, the system will return a success message.

Examples

Sample requests:

```
DELETE /logstores/logstore-test/consumergroups/consumer-group-1 HTTP/1.1
Header:
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Fri, 04 May 2018 08:02:22 GMT
Content-Type: application/json
Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
Content-Length: 65
Connection: Keep-Alive
```

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Fri, 04 May 2018 08:15:11 GMT
x-log-requestid: 5AEC168FA796F4195BF404CB
```

2.15.1.10.3 GetCheckPoint

You can call this operation to query the checkpoints of one or all shards that are consumed by a specified consumer group.

Examples:

```
GET /logstores/{logstoreName}/consumergroups/{consumerGroupName}? shard={shardId}
```

Request syntax

```
GET /logstores/<logstoreName>/consumergroups/<consumerGroup>? shard=<shardId>
HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
```

Connection: Keep-Alive

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to which the consumer group belongs.
consumerGroup	String	Yes	The name of the consumer group.
shardId	Integer	No	The ID of the shard. If the shard ID is not specified, checkpoints of all shards are returned.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

If the request is successful, the response body contains the checkpoint of the shard that is consumed by the specified consumer group. The response parameters are described as follows.

Parameter	Type	Description
shard	Integer	The ID of the shard.
checkpoint	String	The value of the checkpoint.
updateTime	Integer	The last time when the checkpoint was updated.
consumer	String	The consumer of the shard.

Error codes

In addition to [Common response headers](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
404	ConsumerGroupNotExist	consumer group not exist
500	InternalServerError	Specified Server Error Message

Detailed description

If the specified shard does not exist, an empty list is returned. If the shard ID is not specified , checkpoints of all shards are returned.

Examples

Sample requests:

```
GET /logstores/my-logstore/consumergroups/consumer_group_test? shard=0
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Fri, 04 May 2018 09:26:53 GMT
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Type: application/json
Content-Length: 111
Connection: close
Access-Control-Allow-Origin: *
Date: Fri, 04 May 2018 09:26:53 GMT
x-log-requestid: 5AEC275D1FFC036AB254B20C
[
  {
    "shard": 0,
    "checkpoint": "MTUyNDE1NTM3OTM3MzkwODQ5Ng==",
    "updateTime": 1524224984800922,
    "consumer": "consumer_1"
  }
]
```

]

2.15.1.10.4 HeartBeat

You can call this operation to send a heartbeat packet to the server for a specified consumer.

Examples:

```
POST /logstores/{logstoreName}/consumergroups/{consumerGroupName}? type=
heartbeat&consumer={consumer}
```

Request syntax

```
POST /logstores/<logstoreName>/consumergroups/<consumerGroup>? type=heartbeat
&consumer=<consumer> HTTP/1.1
  Authorization: <AuthorizationString>
  x-log-bodyrawsize: 0
  User-Agent: <UserAgent>
  x-log-apiversion: 0.6.0
  Host: <Project Endpoint>
  x-log-signaturemethod: hmac-sha1
  Date: <GMT Date>
  Content-Type: application/json
  Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
  Content-Length: <ContentLength>
  <shard ID list>
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore. The name must be unique within a project.
consumerGroup	String	Yes	The name of the consumer group. The name must be unique within a project.
consumer	String	Yes	The consumer of shards.
{Shard ID List}	Array	Yes	The ID list of shards that are being consumed.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

If the request is successful, the HTTP status code 200 and the ID list of all shards consumed by the consumer are returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	NotExistConsumerWithBody	non-exist consumer with non-empty body of heartbeat message
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
404	ConsumerGroupNotExist	consumer group not exist
500	InternalServerError	Specified Server Error Message

Detailed description

The heartbeat packet is sent only when the connection between the consumer and the server is established.

Examples

Sample requests:

```
POST /logstores/my-logstore/consumergroups/consumer_group_test? type=heartbeat&
consumer=consumer_1 HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
```

```
Date: Sun, 06 May 2018 09:44:10 GMT
Content-Type: application/json
Content-MD5: 8D5162CA104FA7E79FE80FD92BB657FB
Content-Length: 3
Connection: Keep-Alive
[0]
```

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Type: application/json
Content-Length: 5
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 06 May 2018 09:44:11 GMT
x-log-requestid: 5AEECE6B1FFC0366B2553FB5
[0,1]
```

2.15.1.10.5 ListConsumerGroup

You can call this operation to query all consumer groups of a specified Logstore.

Examples:

```
GET /logstores/{logstoreName}/consumergroups
```

Request syntax

```
GET /logstores/<logstoreName>/consumergroups HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to which consumer groups belong.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

If the request is successful, the response body contains the list of all consumer groups in the specified project and Logstore. The response parameters are described as follows.

Parameter	Type	Description
consumerGroup	String	The name of the consumer group.
timeout	Integer	The heartbeat timeout. If no heartbeat packet is received during this period, the consumer group will be deleted.
order	Bool	Indicates whether to consume log data in order.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
GET /logstores/my-logstore/consumergroups HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Fri, 04 May 2018 08:47:30 GMT
Content-Type: application/x-protobuf
```

Connection: Keep-Alive

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Type: application/json
Connection: close
Access-Control-Allow-Origin: *
Date: Fri, 04 May 2018 08:47:31 GMT
x-log-requestid: 5AEC1E23048191954B42EAB9
[
  {
    "name": "test-consumer-group",
    "timeout": 30,
    "order": true
  }
]
```

2.15.1.10.6 UpdateCheckpoint

You can call this operation to update the checkpoint of a shard for a consumer group in a specified project and Logstore.

Examples:

```
POST /logstores/{logstoreName}/consumergroups/{consumerGroupName}? forceSuccess={forceSuccess}&type=checkpoint&consumer={consumer}
```

Request syntax

```
POST /logstores/<logstoreName>/consumergroups/<consumerGroupName>?
forceSuccess=<forceSuccess>&type=checkpoint&consumer=<consumer> HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
Content-Length: <ContentLength>
Connection: Keep-Alive
{
  "shard": <shardID>,
  "checkpoint": <checkpoint>
}
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to which the consumer group belongs.

Parameter	Type	Required	Description
consumerGroup	String	Yes	The name of the consumer group.
forceSuccess	Bool	No	Specifies whether to force update.
consumer	String	No	The consumer of the shard.
shard	Integer	Yes	The ID of the shard.
checkpoint	String	Yes	The value of the checkpoint.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	InvalidShardCheckPoint	shard checkpoint not encoded by base64
404	ProjectNotExist	The Project does not exist : { Project}
404	LogStoreNotExist	logstore {logstoreName} dose not exist
404	ConsumerGroupNotExist	consumer group not exist
404	ShardNotExist	shard not exist
500	InternalServerError	Specified Server Error Message

Detailed description

If the consumer is not specified, the checkpoint of the shard can be updated only when forceSuccess is set to true.

Examples

Sample requests:

```
POST /logstores/logstore-4/consumergroups/consumer_group_test? forceSuccess=false
&type=checkpoint&consumer=consumer_1 HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 06 May 2018 09:14:53 GMT
Content-Type: application/json
Content-MD5: 59457BAFB3F85A5117BDE243947583B0
Content-Length: 55
Connection: Keep-Alive
{
  "shard": 0,
  "checkpoint": "MTUyNDE1NTM3OTM3MzkwODQ5Ng=="
}
```

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 06 May 2018 09:14:54 GMT
x-log-requestid: 5AEEC78E1FFC0366B24F1C63
```

2.15.1.10.7 UpdateConsumerGroup

You can call this operation to modify the attributes of a specified consumer group.

Examples:

```
PUT /logstores/{logstoreName}/consumergroups/{consumerGroupName}
```

Request syntax

```
PUT /logstores/<logstoreName>/consumergroups/<consumerGroupName> HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
```

```
Content-Length: <ContentLength>
{
  "timeout": <timeout>,
  "order": <order>
}
```

Request parameters

Parameter	Type	Required	Description
logstoreName	String	Yes	The name of the Logstore to which the consumer group belongs.
consumerGroup	String	Yes	The name of the consumer group.
timeout	Integer	No	The heartbeat timeout. If no heartbeat packet is received during this period, the consumer group will be deleted.
order	Bool	No	Specifies whether to consume log data in order.

Note:

You must specify timeout or order, or both.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	JsonInfoInvalid	timeout is of error value type
404	ProjectNotExist	The Project does not exist : { Project}
404	ConsumerGroupNotExist	consumer group not exist
404	LogStoreNotExist	logstore {logstoreName} dose not exist
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
PUT /logstores/logstore-test/consumergroups/consumer-group-1 HTTP/1.1
Header:
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Fri, 04 May 2018 08:02:22 GMT
Content-Type: application/json
Content-MD5: F58544E4D022CC28A93D0B7CC208A5AA
Content-Length: 65
Connection: Keep-Alive
Body:
{
  "order": false,
  "timeout": 100
}
```

Sample responses:

```
HTTP/1.1 200
Server: nginx/1.12.1
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Fri, 04 May 2018 08:15:11 GMT
```

x-log-requestid: 5AEC168FA796F4195BF404CB

2.15.1.11 Project operations

2.15.1.11.1 CreateProject

You can call this operation to create a project.

Examples:

POST /

Request syntax

```
POST / HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/json
Content-MD5: <Content-MD5>
Content-Length: <ContentLength>
Connection: Keep-Alive
{
  "projectName": <ProjectName>,
  "description": <Description>
}
```

Request parameters

Parameter	Type	Required	Description
projectName	String	Yes	The name of the project to be created.
description	String	Yes	The description of the project to be created.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
400	ProjectAlreadyExist	Project {project} already exist
400	ParameterInvalid	The body is not valid json string
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
POST / HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project-test.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 27 May 2018 07:43:26 GMT
Content-Type: application/json
Content-MD5: A7967D81EFF5E3CD447FB6D8DF294E20
Content-Length: 80
Connection: Keep-Alive
{
  "projectName": "my-project-test",
  "description": "Description of my-project-test"
}
```

Sample responses:

```
HTTP/1.1 200
Server: nginx
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 27 May 2018 07:43:27 GMT
x-log-requestid: 5B0A619F205DC3F30EDA9322
```

2.15.1.11.2 DeleteProject

You can call this operation to delete a specified project.

Examples:

```
DELETE /
```

Request syntax

```
DELETE / HTTP/1.1
  Authorization: <AuthorizationString>
  x-log-bodyrawsize: 0
  User-Agent: <UserAgent>
  x-log-apiversion: 0.6.0
  Host: <Project Endpoint>
  x-log-signaturemethod: hmac-sha1
  Date: <GMT Date>
  Content-Type: application/x-protobuf
  Connection: Keep-Alive
```

Request parameters

Parameter	Type	Required	Description
projectName	String	Yes	The name of the project to be deleted . The name is a part of the host in the header.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

The HTTP status code 200 is returned.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
404	ProjectNotExist	The Project does not exist : { Project}

HTTP status code	Error code	Error message
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
DELETE / HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project-test.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 27 May 2018 08:25:04 GMT
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Sample responses:

```
HTTP/1.1 200
Server: nginx
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 27 May 2018 08:25:04 GMT
x-log-requestid: 5B0A6B60BB6EE39764D458B5
```

2.15.1.11.3 GetProject

You can call this operation to query a project by project name.

Examples:

```
GET /
```

Request syntax

```
GET / HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Project Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/x-protobuf
```

Connection: Keep-Alive

Request parameters

Parameter	Type	Required	Description
projectName	String	Yes	The name of the project to be queried . The name is a part of the host in the header.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

When the request is successful, the response body contains the detailed information of the project in the following format.

Parameter	Type	Description
createTime	String	The time when the project was created.
description	String	The description of the project.
lastModifyTime	String	The last time when the project was modified.
owner	String	The account ID of the project creator.
projectName	String	The name of the project.
status	String	The status of the project.
region	String	The region to which the project belongs.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
404	ProjectNotExist	The Project does not exist : { Project}
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
DELETE / HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: my-project-test.cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 27 May 2018 08:25:04 GMT
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Sample responses:

```
HTTP/1.1 200
Server: nginx
Content-Length: 0
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 27 May 2018 08:25:04 GMT
x-log-requestid: 5B0A6B60BB6EE39764D458B5
```

2.15.1.11.4 ListProject

You can call this operation to query the list of all projects in a region.

Examples:

```
GET /? offset={offset}&size={size}
```

Request syntax

```
GET /? offset={offset}&size={size} HTTP/1.1
Authorization: <AuthorizationString>
x-log-bodyrawsize: 0
User-Agent: <UserAgent>
x-log-apiversion: 0.6.0
Host: <Endpoint>
x-log-signaturemethod: hmac-sha1
Date: <GMT Date>
Content-Type: application/x-protobuf
```

Connection: Keep-Alive

Request parameters

Parameter	Type	Required	Description
offset	Integer	No	The starting position of returned records. Default value: 0.
size	Integer	No	The maximum number of entries to return on each page. Default and maximum value: 500.

Request header

No special request header is required. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

No special response header is returned. For more information about the common response headers of Log Service APIs, see [Common response headers](#).

Response parameters

When the request is successful, the response body contains the project list in the following format.

Parameter	Type	Description
count	Integer	The number of returned projects.
total	Integer	The total number of projects in a region.
projects	Array	The list of all projects in a region.

Parameters of projects are described as follows.

Parameter	Type	Description
createTime	String	The time when the project was created.

Parameter	Type	Description
description	String	The description of the project.
lastModifyTime	String	The last time when the project was modified.
owner	String	The account ID of the project creator.
projectName	String	The name of the project.
status	String	The status of the project.
region	String	The region to which the project belongs.

Error codes

In addition to [Common error codes](#) of Log Service APIs, this operation may also return the following special error codes.

HTTP status code	Error code	Error message
500	InternalServerError	Specified Server Error Message

Examples

Sample requests:

```
GET /? offset=0&size=2&projectName= HTTP/1.1
Authorization: LOG <yourAccessKeyId>:<yourSignature>
x-log-bodyrawsize: 0
User-Agent: sls-java-sdk-v-0.6.1
x-log-apiversion: 0.6.0
Host: cn-shanghai.log.aliyuncs.com
x-log-signaturemethod: hmac-sha1
Date: Sun, 27 May 2018 09:03:33 GMT
Content-Type: application/x-protobuf
Connection: Keep-Alive
```

Sample responses:

```
HTTP/1.1 200
Server: nginx
Content-Type: application/json
Content-Length: 345
Connection: close
Access-Control-Allow-Origin: *
Date: Sun, 27 May 2018 09:03:33 GMT
x-log-requestid: 5B0A7465AAEA20CA70DE3064
{
  "count": 2,
```

```
"total": 11,
"projects": [
  {
    "projectName": "project1",
    "status": "Normal",
    "owner": "",
    "description": "",
    "region": "cn-shanghai",
    "createTime": "1524222931",
    "lastModifyTime": "1524539357"
  },
  {
    "projectName": "project123456",
    "status": "Normal",
    "owner": "",
    "description": "",
    "region": "cn-shanghai",
    "createTime": "1471963876",
    "lastModifyTime": "1524539357"
  }
]
```

2.15.1.11.5 GetProjectLogs

You can call this operation to count all the logs in a project.

Request syntax

```
GET /logs/? query=SELECT * FROM <logStoreName> where __line__ = 'abc' and __date__ > '
2017-09-01 00:00:00' and __date__ < '2017-09-02 00:00:00'&line=20&offset=0 HTTP/1.1
Authorization: <AuthorizationString>
Date: Wed, 3 Sept. 2014 08:33:46 GMT
Host: big-game.cn-hangzhou.log.aliyuncs.com
x-log-bodyrawsize: 0
x-log-apiversion: 0.4.0
x-log-signaturemethod: hmac-sha1
```

Request parameters

Attribute name	Type	Required	Description
query	String	Yes	The SQL query criteria

Request header

The GetProjectLogs API does not have any special request headers. For more information about the common request headers of Log Service APIs, see [Common request headers](#).

Response header

For more information about the common response headers of Log Service APIs, see [Common response headers](#).

The response header contains a special element that indicates whether the returned results of the request are complete. The specific response element format is as follows:

Name	Type	Description
x-log-progress	String	The status of the query results. The two values, Incomplete and Complete, indicate whether the results are complete.
x-log-count	Integer	The total number of logs in the current query results.
x-log-processed-rows	Integer	The number of rows processed in this calculation.
x-log-elapsed-millisecond	Integer	The time (in milliseconds) spent in this calculation.

Response elements

After the successful request, the response body contains the computing results. The response body of GetProjectLogs is an array, and each element in the array is a log. The element formats are as follows.

Name	Type	Description
__time__	Integer	The log timestamp (the number of seconds since 1970-1-1 00:00:00 UTC).
__Source__	String	The log source, which is specified when logs are written.
[content]	Key-value pair	The original content of the log, which is organized in key-value pairs.

Detailed description

- The query of this API is a standard SQL query statement.
- Specify the project you want to query in the domain name of the request.
- Specify the Logstore you want to query in the FROM condition of the query statement.
Logstore is equivalent to a table in SQL.

- You must specify the time range you want to query in the SQL query condition. The time range is specified by `__date__` (timestamp type) or `__time__` (integer type, the unit is in UNIX time).
- Each call to this API must return results within a specified time, and each query can only scan a specified number of logs. The results returned from this request are incomplete if the log volume to be processed for this request is large (whether the results are complete is indicated by using the `x-log-progress` in the response header). At the same time, Log Service caches the query results within 15 minutes. When part of the query request results matches those in the cache, the server continues to scan the log data that is not hit in the cache for this request. To reduce the workload of merging multiple query results, the query results of server cache hits and the new hits of the current query are merged and returned. Therefore, Log Service allows you to repeatedly call the API with the same parameters to eventually obtain the complete results. Log Service API cannot predict how many times the API must be called before obtaining the complete results API because the volume of the logs to be queried fluctuates dramatically. Therefore, you must check the `x-log-progress` status in the returned results of each request to determine whether to continue the query. You must note that each call to this API consumes the same number of query CUs.

Special error codes

In addition to the [Common error codes](#) of Log Service APIs, the API may also return the following special error codes.

HTTP status code	Error code	Error message	Description
400	ParameterInvalid	parameter is invalid	The error message returned when the request parameter is invalid. For more information, see the detailed error message.

Examples

Take a project named `big-game` in the region `Hangzhou` as an example. Query the logs whose topic is `groupA` in the `app_log` Logstore of the `big-game` project. The time interval for this query is `2014-09-01 00:00:00-2014-09-01 22:00:00`. The keyword for this query is `error`. The query starts from the start the time interval, and up to 20 logs will be returned.

Sample requests

```
GET /logs/? query=SELECT * FROM <logStoreName> where __line__ = 'abc' and __date__ >'
2017-09-01 00:00:00' and __date__ < '2017-09-02 00:00:00'&line=20&offset=0 HTTP/1.1
Authorization: <AuthorizationString>
Date: Wed, 3 Sept. 2014 08:33:46 GMT
Host: big-game.cn-hangzhou.log.aliyuncs.com
x-log-bodyrawsize: 0
x-log-apiversion: 0.4.0
x-log-signaturemethod: hmac-sha1
```

Sample responses

```
HTTP/1.1 200 OK
Content-MD5: 36F9F7F0339BEAF571581AF1B0AAAFB5
Content-Type: application/json
Content-Length: 269
Date: Wed, 3 Sept. 2014 08:33:47 GMT
x-log-requestid: efag01234-12341-15432f
x-log-progress : Complete
x-log-count : 10000
x-log-processed-rows: 10000
x-log-elapsed-millisecond:5
{
  "progress": "Complete",
  "count": 2,
  "logs": [
    {
      "__time__": 1409529660,
      "__source__": "10.237.0.17",
      "Key1": "error",
      "Key2": "Value2"
    },
    {
      "__time__": 1409529680,
      "__source__": "10.237.0.18",
      "Key3": "error",
      "Key4": "Value4"
    }
  ]
}
```

In this sample response, the x-log-progress status is Complete, which indicates the log query is completed and the returned results are complete. For this request, two logs meet the query condition and are displayed as the values of logs. If the x-log-progress status is Incomplete in the response result, you must repeat the request to obtain the complete results.

2.15.1.12 Description of common resources

2.15.1.12.1 Data model

This topic describes commonly used terms in Log Service to help you better understand and use Log Service.

project

The basic unit of management in Log Service. A project is used to isolate and control resources. You can use a project to manage all the logs and related log sources of an application.

Logstore

The unit used in Log Service for data collection, storage, and consumption. Each Logstore belongs to a project, and each project can have multiple Logstores. You can create multiple Logstores for a project as needed. Typically, an independent Logstore is created for each type of logs of an application. For example, you have a game application named big-game, and it stores three types of logs on the server: `operation_log`, `application_log`, and `access_log`. You can create a project named big-game, and then create three Logstores in this project to collect, store, and consume these three types of logs, respectively.

log

The smallest unit of data that can be processed in Log Service. Log Service uses a semi-structured data model to define a log. The data model is as follows:

- **Topic:** The user-defined field used to mark a batch of logs. For example, access logs can be marked based on the sites. By default, this field is an empty string, which is also a valid topic.
- **Time:** The reserved field in a log used to indicate the time when a log is generated (the number of seconds that have elapsed since 00:00:00 Thursday, January 1, 1970 UTC). Typically, this field is generated based on the time in the log.
- **Content:** The field used to record the detailed content of a log. The content consists of one or more content items. Each content item is a key-value pair.
- **Source:** The field used to indicate the source of a log. For example, the IP address of the machine where a log is generated. This field is empty by default.

Log Service has different requirements for the values of different fields, as described in [Table 2-523: Log fields](#).

Table 2-523: Log fields

Field	Requirement
time	An integer in the UNIX timestamp format, in seconds.
topic	A UTF-8 encoded string that is up to 128 bytes in length.
source	A UTF-8 encoded string that is up to 128 bytes in length.
content	One or more key-value pairs. A key is a UTF-8 encoded string that is up to 128 bytes in length. It can contain only letters, underscores (_), and digits. It cannot start with a digit. A value is a UTF-8 encoded string that is up to 1024 × 1024 bytes in length.

**Note:**

The key in the content cannot use any of the following keywords: `__time__`, `__source__`, `__topic__`, `__partition_time__`, `__extract_others__`, and `__extract_others__`.

topic

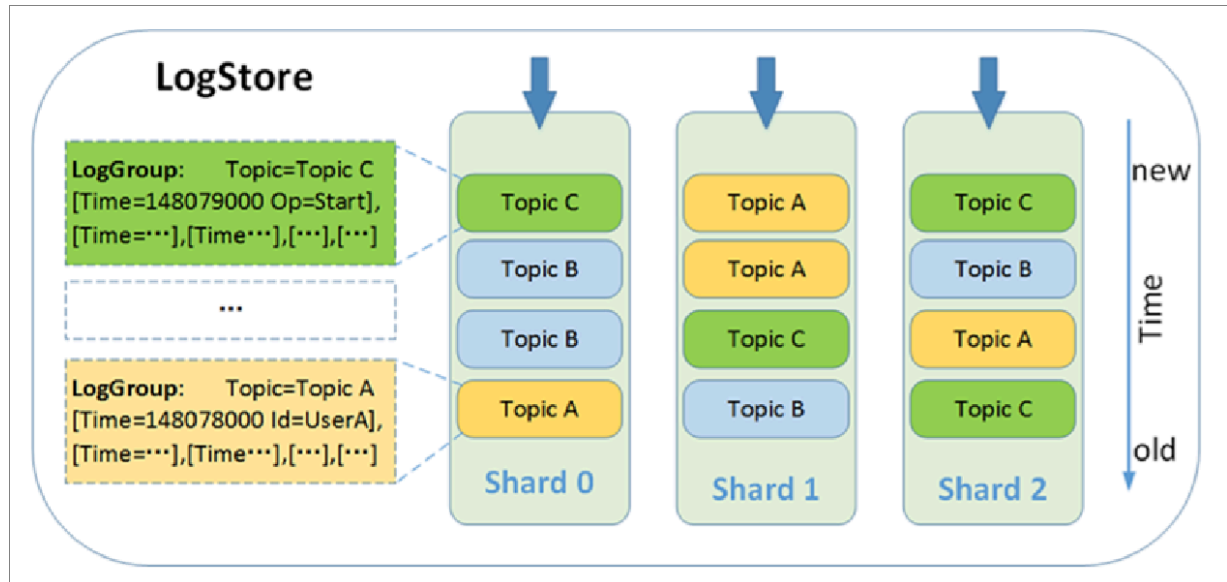

A topic is used to classify logs in a Logstore. Topics can be specified when you write logs. For example, you can use your ID as the log topic when writing logs. If you do not need to classify logs in a Logstore, use the same topic for all logs.

**Note:**

An empty string is a valid log topic and is the default log topic.

Figure 2-5: The relationship among Logstores, log topics, and logs shows the relationship among Logstores, log topics, and logs.

Figure 2-5: The relationship among Logstores, log topics, and logs

Various log formats are used in actual scenarios. The following example shows you how to map an original NGINX access log to the log data model of Log Service. Assume that the IP address of your NGINX server is 10.10.10.1. A raw log on this server is as follows:

```
10.1.1.1 - - [01/Mar/2012:16:12:07 +0800] "GET /Send? AccessKeyId=<yourAccessKeyId>
HTTP/1.1" 200 5 "-" "Mozilla/5.0 (X11; Linux i686 on x86_64; rv:10.0.2) Gecko/20100101
Firefox/10.0.2"
```

Table 2-524: Log data model of Log Service shows how to map the raw log to the log data model of Log Service.

Table 2-524: Log data model of Log Service

Field	Content	Description
topic	""	The default value (empty string) is used.
time	1330589527	The precise time when the log is generated (in seconds), which is converted from the timestamp of the raw log.
source	"10.10.10.1"	The IP address of the server is used as the log source.
content	Key-value pair	The specific content of a log.

You can decide how to extract the raw log content and combine the extracted content into key-value pairs, as described in [Table 2-525: Custom key-value pairs](#).

Table 2-525: Custom key-value pairs

Key	Value
ip	10.1.1.1
method	GET
status	200
length	5
ref_url	-
browser	Mozilla/5.0 (X11; Linux i686 on x86_64; rv:10.0.2) Gecko/20100101 Firef

Logs

A collection of log entries.

LogGroup

A collection of logs.

LogGroupList

A collection of log groups used to return the results.

Encoding method

As described in [Table 2-526: Supported encoding method](#), the system supports the following content encoding method and allows future extensions. The RESTful API layer is indicated by Content-Type.

Table 2-526: Supported encoding method

Definition	Content-Type	Example
Protocol buffers	The data model is encoded by protocol buffers.	application/x-protobuf

Protocol buffers are used to define the objects in the data model as follows:

```
message Log
{
  required uint32 Time = 1; // UNIX Time Format
  message Content
```

```

{
  required string Key = 1;
  required string Value = 2;
}
repeated Content Contents= 2;
}
message LogGroup
{
  repeated Log Logs= 1;
  optional string Reserved = 2; // reserved fields
  optional string Topic = 3;
  optional string Source = 4;
}
message LogGroupList
{
  repeated LogGroup logGroupList = 1;
}

```

**Note:**

Protocol buffers do not require the key-value pair to be unique. However, you cannot use the same key. Otherwise, the behavior is undefined.

2.15.1.12.2 Data encoding methods

Protocol Buffer is a structured data interchange format developed by Google. It is widely used in both internal and external Google services. Currently, Log Service uses Protocol Buffer format as the standard log writing format. You must serialize the original log data into Protocol Buffer data streams before writing logs to Log Service by using APIs.

```

message Log
{
  required uint32 time = 1; // UNIX Time Format
  message Content
  {
    required string key = 1;
    required string value = 2;
  }
  Repeated content contents = 2;
}
message LogGroup
{
  repeated Log logs= 1;
  optional string reserved =2; // Internal field, which does not need to be specified
  optional string topic = 3;
  optional string source = 4;
}
message LogGroupList
{
  repeated LogGroup logGroupList = 1;
}

```

**Note:**

- PB does not require the key-value pair to be unique. You must avoid such situation. Otherwise, the behavior is undefined.
- For more information about Protocol Buffer format, see [Github](#).
- For more information about the API for writing logs to Log Service, see [PostLogStoreLogs](#).

2.15.1.12.3 Logstores

A data storage unit is referred to as a Logstore. By default, you can create up to 10 Logstores for each project. A Logstore name is unique in a project. A Logstore is the portal for all log data. You can read from or write to the Logstore.

The Logstore naming rules are as follows:

- The name contains only lowercase letters, numbers, hyphens (-), and underscores (_).
- The name must begin and end with a lowercase letter or number.
- The name must be 2 to 63 bytes in length.

Example of the complete resource:

```
{
  "logstoreName": "access_log",
  "ttl": 1,
  "shardCount": 2,
  "createTime": 1439538649,
  "lastModifyTime": 1439538649
}
```

The meaning of each parameter is described in [Table 2-527: Parameter description](#).

Table 2-527: Parameter description

Parameter	Type	Required	Description
logstoreName	String	Yes	The Logstore name, which must be unique in the same project.
TTL	Integer	Yes	The Time to Live (TTL) of log data. The unit is in days and the minimum value is 1 day.
shardCount	Integer	Yes	The log data service unit.
createTime (OutputOnly)	Integer	No	The time when the resource is created in Log Service (output only).

Parameter	Type	Required	Description
lastModifyTime (OutputOnly)	Integer	No	The time when the resource is updated in Log Service (output only).

2.15.1.12.4 Shard

A shard is a basic read and write unit in each Logstore. You can specify the number of shards in each Logstore. Each shard has certain service capabilities:

- Writing: 5 MBit/s, 2000 times/s
- Read: 10 MBit/s, 100 times/s

To read data from a shard, you must specify the corresponding shard. To write data to a shard, you can use Server Load Balancer. By using Server Load Balancer, data is automatically written to shards based on the system load in the backend, which guarantees the high availability of log writing.

The example of the complete resource is described in [Table 2-528: Example of the complete resource](#).

Table 2-528: Example of the complete resource

Parameter	Type	Required	Description
shardID	Integer	Yes	The unique ID of a shard in the Logstore, which is automatically generated by the system.

2.15.1.12.5 Logtail configuration

You can create up to 100 Logtail configurations for a project. The configuration name is unique under a project.

You can use the configuration to specify the location, method, and parameters for log collection.

The configuration naming rules are as follows:

- The name can only contain lowercase letters, numbers, hyphens (-), and underscores (_).
- The name must begin and end with a lowercase letter or number.
- The name must be 2 to 128 characters in length.

Example of the complete resource:

```
{
  "configName": "testcategory1",
  "inputType": "file",
  "inputDetail": {
    "logType": "common_reg_log",
    "logPath": "/var/log/httpd/",
    "filePattern": "access.log",
    "localStorage": true,
    "timeFormat": "%Y/%m/%d %H:%M:%S",
    "logBeginRegex": ".*",
    "regex": "(\\w+)(\\s+)",
    "key": [ "key1", "key2"],
    "filterKey": ["key1"],
    "filterRegex": [ "regex1"],
    "topicFormat": "none"
  },
  "outputType": "sls",
  "outputDetail": {
    "logstoreName": "perfcounter"
  },
  "createTime": 1400123456,
  "lastModifyTime": 1400123456
}
```

The configuration parameters and descriptions are described in [Table 2-529: Configuration](#).

Table 2-529: Configuration

Attribute name	Type	Required	Description
configName	String	Yes	The log configuration name, which is unique in the same project.
inputType	String	Yes	The input type. The default type is file.
inputDetail	JSON	Yes	See the following table.
outputType	String	Yes	The output type. Currently , only LogService is supported.
outputDetail	String	Yes	See the following table.
createTime(output-only)	Integer	No	The creation time of the configuration.
lastModifyTime(output-only)	Integer	No	The time when the resource is updated on the server.

The inputDetail types and descriptions are described in [Table 2-530: inputDetail](#).

Table 2-530: inputDetail

Attribute name	Type	Required	Description
logType	String	Yes	The log type. Currently, only common_reg_log is supported.
logPath	String	Yes	The parent directory where the log is located, for example, /var/logs/.
filePattern	String	Yes	The pattern of a log file, for example, access*.log.
localStorage	Boolean	Yes	Indicates whether to activate the local cache. Logs of 1 GB can be locally cached when the link to Log Service is disconnected.
timeFormat	String	Yes	The format of log time, for example, %Y/%m/%d %H:%M:%S.
logBeginRegex	String	Yes	The characteristics (regular expression) of the first log line, which is used to match with logs that are composed of multiple lines.
regex	String	Yes	The regular expression for extracting logs.
key	Array	Yes	The key that is generated after logs are extracted.
filterKey	Array	Yes	The key for filtering logs. The log meets the requirements only when the key value matches the regular expression specified in the corresponding filterRegex column.

Attribute name	Type	Required	Description
filterRegex	Array	Yes	The regular expression corresponding to each filterKey. The length of filterRegex must be the same as that of filterKey.
topicFormat	String	No	Uses part of the log file path as the topic, for example, <code>/var/log/(. *.log</code> . The default value is none, which indicates that the topic is empty.
preserve	Boolean	No	true indicates that the monitored directory never times out. false indicates that the timeout for monitored directory is 30 minutes. The default value is true.
preserveDepth	Integer	No	If preserve is set to false , specify the depth of the directories without monitoring timeout. The maximum depth is 3.

The outputDetail types and their descriptions are described in [Table 2-531: outputDetail](#).

Table 2-531: outputDetail

Attribute name	Type	Required	Description
logstoreName	String	Yes	The Logstore name.

2.15.1.12.6 Logtail machine group

After a machine with Logtail installed is started normally, the machine is automatically associated with the current user based on the user information in the Logtail configuration. Currently, the machine can be identified in the following three ways:

- IP: The IP address corresponding to the hostname. This is the easiest way to understand , but the IP address may be duplicated in environments such as Virtual Private Cloud (VPC).

- UUID (machine-uniqueid): The UUID in DMI devices. For more information, see [RFC 4122](#).
- Userdefined-id: You can customize the machine identifier in the Logtail directory.

Attributes of each machine are as follows:

```
{
  "ip" : "testip1",
  "machine-uniqueid" : "testuuid1",
  "userdefined-id" : "testuserdefinedid1",
  "lastHeartbeatTime" : 1397781420
}
```

The machine attributes are described in [Table 2-532: Parameter description](#).

Table 2-532: Parameter description

Parameter	Type	Description
ip	String	The IP address corresponding to the machine hostname.
uuid	String	The unique primary key marked by the machine, uploaded by Logtail.
userdefined-id	String	The user-defined machine identification, uploaded by Logtail.
lastHeartbeatTime(output-only)	Integer	The last heartbeat time of the machine (the number of seconds since the epoch time).

machinegroup

Machinegroup is the machine group that belongs to the current user in the project. The machine group can be identified in two ways (IP address and user-defined). The IP address is more easily identified while the user-defined identifier can solve the problem of identical IP addresses in the VPC environment. You can select either of the two machine identification methods.

Machine group naming rules:

- The name contains only lowercase letters, numbers, hyphens (-), and underscores (_).
- The name must begin and end with a lowercase letter or number.
- The name must be 2 to 128 characters in length.

Example of the complete resource:

```
{
  "groupName": "testgroup",
  "groupType": "",
  "groupAttribute": {
    "externalName": "testgroup",
    "groupTopic": "testgrouptopic"
  },
  "machineIdentifyType": "ip",
  "machineList": [
    "ip1",
    "ip2"
    ...
  ],
  "createTime": 1431705075,
  "lastModifyTime": 1431705075
}
```

The machinegroup parameter is described in [Table 2-533: Parameter description](#).

Table 2-533: Parameter description

Attribute name	Type	Required	Description
groupName	String	Yes	The machine group name , which is unique in the same project.
groupType	String	No	The machine group type, which is empty by default.
machineIdentifyType	String	Yes	The machine identification type, which can be IP address or user-defined identifier.
groupAttribute	Object	Yes	The machine group attribute, which is empty by default.
machineList	Array	Yes	The specific machine identifier, which can be an IP address or user-defined identifier.
createTime(output-only)	Integer	No	The resource creation time .
lastModifyTime(output-only)	Integer	No	The time when the resource is updated on the server.

The groupAttribute types and descriptions are described in [Table 2-534: groupAttribute description](#).

Table 2-534: groupAttribute description

Attribute name	Type	Required	Description
groupTopic	String	No	The topic of a machine group, which is empty by default.
externalName	String	No	The external identification that the machine group depends on, which is empty by default.

2.15.2 SDK reference

2.15.2.1 Introduction

2.15.2.1.1 Overview

To facilitate the use of Log Service., Log Service provides software development kits (SDKs) in multiple programming languages (Java, .NET, Python, PHP, and C). Select to use an appropriate version as per your needs.

Log Service SDKs are implemented based on Log Service APIs and provide the same capabilities as Log Service APIs. For more information about Log Service APIs, see [API references](#).

Similar to using Log Service APIs, you must have an active Alibaba Cloud AccessKey (consisting of an AccessKey ID and AccessKey Secret).

To use the Log Service SDK, you need to understand the endpoint of Log Service. For more information about how to specify the root endpoint in an SDK, see [SDK configurations](#).

Though the implementation details of Log Service SDKs vary with different languages, the SDKs can be considered as Log Service APIs encapsulated in different languages and basically implement the similar functions as follows.

- Log Service APIs are [uniformly encapsulated](#), removing the need for constructing specific API requests and parsing responses. The APIs in different languages are similar, facilitating the switchover between different languages.

- The digital signature logic is implemented for Log Service APIs, greatly simplifying the use of APIs and removing the need for understanding the details of the API signature logic.
- The logs collected to Log Service are encapsulated in ProtoBuffer format, allowing you to write logs without a deep understanding of the ProtoBuffer format.
- Implementation of the compression method defined in the Log Service APIs removes the need to focus on the compression details. SDKs in some languages allow you to specify whether to write logs in the compression mode. The compression mode is used by default.
- Unified [error handling method](#) is provided, allowing you to handle request exceptions in the method that languages are familiar with.
- Currently, SDKs in all languages only support synchronous requests.

[Table 2-535: SDK-related documents and source code](#) describes the download addresses, usage instructions, and complete programming references for the SDKs of different languages.

Table 2-535: SDK-related documents and source code

SDK language	Related document
Java	Java SDK
.NET	.NET SDK
PHP	PHP SDK
Python	Python SDK
C	C SDK
GO	GO SDK
iOS	iOS SDK
Android	Android SDK

2.15.2.1.2 SDK configurations

You must specify the basic configurations before you use SDKs to interact with Log Service, just as you use APIs to interact with Log Service. All SDKs provided by Alibaba Cloud define a Client class, which serves as the entry point for constructing client instances. The basic configurations are specified when the client instances are constructed.

The following basic configurations are used:

- Endpoint: You must determine the endpoint that is used by the client to access Log Service.
- An AccessKey pair that consists of an AccessKey ID and an AccessKey Secret: You must specify the AccessKey pair that is used by the client to access Log Service.

The following sections describe how to use both configurations:

Endpoint

When you use the SDK, you must first determine the access method and endpoint.

1. When you select an endpoint for a client instance, make sure that the region where your project is located is the same as the region of your endpoint. Otherwise, you cannot use the SDK to access your project.
2. All API endpoints support only HTTP.

AccessKey pair

As described in the "AccessKey pair" section of the API reference document, all requests that interact with Log Service must be authenticated. An AccessKey pair is used to authenticate the requests. An AccessKey pair consists of an AccessKey ID and an AccessKey Secret. When you create a client instance, you must specify both an AccessKey ID and an AccessKey Secret. You must obtain an AccessKey pair in the Apsara Stack console.

Note:

- An Apsara Stack account can have multiple AccessKey pairs. You must specify the AccessKey ID and AccessKey Secret of the same AccessKey pair when you create a client instance. Otherwise, authentication fails.
- You must enable the AccessKey pair used to create the client instance. Otherwise, requests are rejected by the server. You can also log on to the Apsara Stack console to view the status of the AccessKey pair.

Examples

Assume that you want to access a project, and have an AccessKey pair that is enabled. The following AccessKey pair is used:

```
AccessKeyId = "<yourAccessKeyId>"
AccessKeySecret = "<yourAccessKeySecret>"
```

The following code snippets show you how to create a client instance:

Java:

```
String endpoint = "regionid.example.com"; // During actual usage, specify the endpoint
based on your region and access method.
String accessKeyId = "<youraccessKeyId>"; // Specify your AccessKey ID.
String accessKeySecret = "<youraccessKeySecret>"; // Specify your AccessKey Secret.
Client client = new Client(endpoint, accessKeyId, accessKeySecret);
//use client to operate log service project.....
```

.NET(C#):

```
String endpoint = "regionid.example.com"; // During actual usage, specify the endpoint
based on your region and access method.
String accessKeyId = "<youraccessKeyId>"; // Specify your AccessKey ID.
String accessKeySecret = "<youraccessKeySecret>"; // Specify your AccessKey Secret.
SLSClient client = new SLSClient(endpoint, accessKeyId, accessKeySecret);
//use client to operate sls project.....
```

PHP:

```
$endpoint = 'regionid.example.com'; // The Hangzhou region is used in this example.
During actual usage, specify the endpoint based on your region and access method.
$accessKeyId = '<youraccessKeyId>'; // Specify your AccessKey ID.
$accessKey = '<youraccessKey>'; // Specify your AccessKey Secret.
$client = new Aliyun_Sls_Client($endpoint, $accessKeyId, $accessKey);
//use client to operate sls project.....
```

Python:

```
# // During actual usage, specify the endpoint based on your region and access method.
endpoint = 'regionid.example.com'
# Specify your AccessKey ID.
accessKeyId = '<youraccessKeyId>'
# Specify your AccessKey Secret.
accessKey = '<youraccessKey>'
client = LogClient(endpoint, accessKeyId, accessKey)
#use client to operate log project.....
```

2.15.2.1.3 Troubleshooting

The possible SDK errors can be classified into the following types:

- Errors returned by the server. This type of errors are returned by the server and handled by SDKs. For more information about this type of errors, see the common error codes of Log Service APIs and the description of each API.
- Network errors that occur when you send requests to the server by using SDKs. This type of errors include network disconnection and server response timeout.
- Errors that are generated by SDKs and related to platforms or programming languages, for example, memory overflows.

All SDKs provided by Alibaba Cloud handle errors by throwing exceptions based on the following principles:

- The first and second types of errors are encapsulated as the `LogException` class and thrown to users by SDKs.
- The third type of errors are not handled by SDKs, but are thrown to users as the platform - or language-specific native exception class.

LogException

The `LogException` class is defined by SDKs to handle the logical errors of Log Service. It inherits the base class for all exceptions from each programming language, and provides the following exception information:

- **Error code:** indicates the error type. Errors returned by the server share the same error codes as the APIs. The error code for network errors that occur when you send requests by using SDKs is `RequestError`. For more information about error codes, see the API reference for the programming language that is relevant to your case.
- **Error message:** indicates the message that is returned together with an error. Errors returned by the server share the same error messages as that returned by APIs. The error message for network errors that occur when you send requests by using SDKs is “request is failed”. For more information about error messages, see the API reference for the programming language that is relevant to your case.
- **Request ID:** indicates the server request ID that corresponds to the current error. This ID is returned only when the error message is returned by the server. Otherwise, an empty string is returned. You can provide the request ID to the Log Service team to track and locate the error.

Failed requests and retries

When you use SDKs to access Log Service, the request may fail due to temporary network disconnection, transmission delay, and slow server response. These errors are thrown as exceptions. Log Service does not implement any retry logic. Therefore, you must define custom processing logic such as retrying failed requests or reporting errors to handle such exceptions.

Examples

You want to access a project named **big-game**, and retry the request for a specified number of times if network exceptions occur. The following code snippets can be used:

Java:

```
// Other code...
String accessId = "<youraccessId>"; // Specify your AccessKey ID.
```

```

String accessKey = "<youraccessKey>"; // Specify your AccessKey Secret.
String project = "big-game";
String endpoint = "regionid.example.com";
int max_retries = 3;
/*
 * Create a client instance.
 */
Client client = new Client(accessId, accessKey, endpoint);
ListLogStoresRequest lsRequest = new ListLogStoresRequest(project);
for (int i = 0; i < max_retries; i++)
{
    try
    {
        ListLogStoresResponse res = client.ListLogStores(lsRequest)
        // Process the returned data...
        break;
    }
    catch(LogException ex)
    {
        if (e.GetErrorCode() == "RequestError")
        {
            if (i == max_retries - 1)
            {
                System.out.println("request is still failed after all retries.");
                break;
            }
            else
                System.out.println("request error happens, retry it!");
        }
        else
        {
            System.out.println("error code : " + e.GetErrorCode());
            System.out.println("error message : " + e.GetErrorMessage());
            System.out.println("error requestId : " + e.GetRequestId());
            break;
        }
    }
    catch(...)
    {
        System.out.println("unrecoverable exception when listing logstores.");
        break;
    }
}
// Other code...

```

.NET (C#):

```

// Other code...
String accessId = "your_access_id"; // Specify your AccessKey ID.
String accessKey = "your_access_key"; // Specify your AccessKey Secret.
String project = "big-game";
String endpoint = "regionid.example.com";
int max_retries = 3;
// Create a client instance.
SLSCClient client = new SLSCClient(endpoint, accessId, accessKey);
ListLogstoresRequest request = new ListLogstoresRequest();
request.Project = project;
for (int i = 0; i < max_retries; i++)
{
    try
    {
        ListLogstoresResponse response = client.ListLogstores(request);
        // Process the returned data...
    }
}

```

```

        break;
    }
    catch(LogException ex)
    {
        if (e.errorCode == "SLSRequestError")
        {
            if (i == max_retries - 1)
            {
                Console.WriteLine( "request is still failed after all retries." );
                break;
            }
            else
            {
                Console.WriteLine("request error happens, retry it!");
            }
        }
        else
        {
            Console.WriteLine("error code :" + e.errorCode;
            Console.WriteLine("error message :" + e.Message;
            Console.WriteLine("error requestId :" + e.RequestId;
            break;
        }
    }
    catch(...)
    {
        Console.WriteLine("unrecoverable exception when listing logstores.");
        break;
    }
}
// Other code...

```

PHP:

```

<? php
// Other code...
$endpoint = 'regionid.example.com';
$accessId = 'your_access_id'; // Specify your AccessKey ID.
$accessKey = 'your_access_key'; // Specify your AccessKey Secret.
$maxRetries = 3;
// Create an SLS client.
$client = new Aliyun_Sls_Client($endpoint, $accessId, $accessKey);
$project = 'big-game';
$request = new Aliyun_Sls_Models_ListLogstoresRequest($project);
for($i = 0; $i < $maxRetries; ++$i)
{
    try
    {
        $response = $client->ListLogstores($request);
        // Process the returned data...
        break;
    }
    catch (Aliyun_Sls_Exception $e)
    {
        if ($e->getErrorCode()=='RequestError')
        {
            if ($i+1 == $maxRetries)
            {
                echo "error code :". $e->getErrorCode() . PHP_EOL;
                echo "error message :". $e->getErrorMessage() . PHP_EOL;
                break;
            }
            echo 'request error happens, retry it!' . PHP_EOL;

```

```

    }
    else
    {
        echo "error code :" . $e->getErrorCode() . PHP_EOL;
        echo "error message :" . $e->getErrorMessage() . PHP_EOL;
        echo "error requestId :" . $e->getRequestId() . PHP_EOL;
        break;
    }
}
catch (Exception $ex)
{
    echo 'unrecoverable exception when listing logstores.' . PHP_EOL;
    var_dump($ex);
    break;
}
}
// Other code...

```

Python:

```

// Other code...
endpoint = 'regionid.example.com'
accessId = 'your_access_id' # Specify your AccessKey ID.
accessKey = 'your_access_key' # Specify your AccessKey Secret.
maxRetries = 3
# Create a client instance.
client = Client(endpoint, accessId, accessKey)
project = 'big-game'
lsRequest = ListLogstoresRequest(project)
for i in xrange(maxRetries):
    try:
        res = client.ListLogstores(lsRequest)
        # Process the returned data...
        break
    except LogException as e:
        if e.getErrorCode() == "RequestError":
            if i+1 == maxRetries:
                print "error code :" + e.getErrorCode()
                print "error message :" + e.getErrorMessage()
                break
            else:
                print "request error happens, retry it!"
        else:
            print "error code :" + e.getErrorCode()
            print "error message :" + e.getErrorMessage()
            print "error requestId :" + e.getRequestId()
            break
    except Exception as e:
        print 'unrecoverable exception when listing logstores.'
        break
// Other code...

```

2.15.2.1.4 API specifications

SDKs of different programming languages have different implementations. However, all APIs comply with the request-response principle. You can call these APIs by using the following methods:

1. Create a request instance by using request parameters.

2. Call the corresponding API in the SDK and pass in the request instance.
3. The results from the API call are returned in the form of a response instance.

The following code snippets explain how to obtain the names of all the Logstores in a project:

Java

```
// Other code...
String accessId = "<youraccessId>"; // Specify your AccessKey ID.
String accessKey = "<youraccessKey>"; // Specify your AccessKey Secret.
String project = "your_project"; // Specify your project name.
String endpoint = "region_endpoint"; // The Hangzhou region is used in this example.
During actual usage, specify the endpoint based on your region and access method.
// Create a client instance.
Client client = new Client(endpoint, accessId, accessKey);
// Specify the project request parameter to initialize the ListLogstores request class.
ListLogStoresRequest lsRequest = new ListLogStoresRequest(project);
// Use the request instance to call the ListLogstores API. The response parameter is the
corresponding response instance.
ListLogStoresResponse res = client.ListLogStores(lsRequest);
// Access the response instance to retrieve the request results.
ArrayList<String> names = res.GetLogStores();
// Other code...
```

.NET(C#)

```
// Other code...
String accessId = "<youraccessId>"; // Specify your AccessKey ID.
String accessKey = "<youraccessKey>"; // Specify your AccessKey Secret.
String project = "your_project"; // Specify your project name.
String endpoint = "region_endpoint"; // The Hangzhou region is used in this example.
During actual usage, specify the endpoint based on your region and access method.
// Create a client instance.
SLSClient client = new SLSClient(endpoint, accessId, accessKey);
// Specify the project request parameter to initialize the ListLogstores request class.
ListLogStoresRequest lsRequest = new ListLogStoresRequest();
lsRequest.Project = project;
// Use the request instance to call the ListLogstores API. The response parameter is the
corresponding response instance.
ListLogStoresResponse res = client.ListLogStores(lsRequest);
// Access the response instance to retrieve the request results.
List<String> names = res.Logstores;
// Other code...
```

PHP

```
// Other code...
$accessId = "<youraccessId>"; // Specify your AccessKey ID.
$accessKey = "<youraccessKey>"; // Specify your AccessKey Secret.
$project = "your_project"; // Specify your project name.
$endpoint = "region_endpoint"; // The Hangzhou region is used in this example. During
actual usage, specify the endpoint based on your region and access method.
// Create an SLS client instance.
$client = new Aliyun_Sls_Client($endpoint, $accessId, $accessKey);
// Specify the project request parameter to initialize the ListLogstores request class.
$request = new Aliyun_Sls_Models_ListLogstoresRequest($project);
```

```
// Use the request instance to call the ListLogstores API. The response parameter is the
corresponding response instance.
$response = $client->listLogstores($request);
// Access the response instance to retrieve the request results.
$names = $response->getLogstores();
// Other code...
```

Python

```
// Other code...
accessId = '<youraccessId>'; // Specify your AccessKey ID.
accessKey = '<youraccessKey>'; // Specify your AccessKey Secret.
project = 'your_project'; // Specify your project name.
endpoint = 'region_endpoint'; // The Hangzhou region is used in this example. During
actual usage, specify the endpoint based on your region and access method.
# Create a client instance.
client = LogClient(endpoint, accessId, accessKey)
# Specify the project request parameter to initialize the ListLogstores request class.
lsRequest = ListLogstoresRequest(project)
# Use the request instance to call the ListLogstores API. The response parameter is the
corresponding response instance.
res = client.list_logstores(lsRequest)
# Access the response instance to retrieve the request results.
names = res.get_logstores();
// Other code...
```

SDKs implement multiple sets of APIs similar to ListLogstores. SDKs also define the corresponding request and response classes. In addition to the basic request-response APIs, SDKs of different programming languages provide auxiliary APIs that encapsulate these basic APIs. This eliminates the need to create requests and parse the final responses on your own. For more information about the auxiliary APIs, see the API reference of each SDK.

2.15.2.2 Java SDK

This is a quick start guide for the Log Service Java SDK.

Download URL

The Log Service Java SDK provides a suite of development tools to help simplify the use of Log Service. You can choose to download the SDK or configure the SDK as a Maven dependency. The SDK supports Java SE 6.0 and later. Click [here](#) to download the latest SDK.

Step 1 Create an account

You must create an account to access Log Service.

Step 2 Obtain an AccessKey pair

You must request an AccessKey pair to use the Log Service Java SDK.

Log on to the Apsara Stack console. Select an AccessKey pair for the SDK.

The AccessKey pair is used in the following steps. It must be kept confidential. For more information about how to use the AccessKey pair, see [SDK Configurations](#).

Step 3 Create a project and a Logstore

Use the Log Service Java SDK to create a project and a Logstore.

Note:

- Make sure that you use the same account to obtain an AccessKey pair and create a project and a Logstore.
- Names of each project must be unique within Log Service. Names of each Logstore must be unique within a project.
- After a project is created, the region to which it belongs cannot be changed. A project cannot be migrated between different regions.

Step 4 Configure the Java development environment

The Log Service Java SDK supports Java SE 6.0 and later. You can download the SDK from the [official Java website](#) and set up the Java development environment as instructed.

Step 5 Install the Log Service Java SDK

You must install the Log Service Java SDK after setting up the Java development environment. You can install the Log Service Java SDK by using the following two methods:

We recommend that you use [Apache Maven](#) to obtain the latest SDK. You can add the following configurations to your Maven project:

```
<dependency>
  <groupId>com.google.protobuf</groupId>
  <artifactId>protobuf-java</artifactId>
  <version>2.5.0</version>
</dependency>
<dependency>
  <groupId>com.aliyun.openservices</groupId>
  <artifactId>aliyun-log</artifactId>
  <version>0.6.7</version>
  <exclusions>
    <exclusion>
      <groupId>com.google.protobuf</groupId>
      <artifactId>protobuf-java</artifactId>
    </exclusion>
  </exclusions>
</dependency>
```

You can also download the Java SDK and reference the local package in your Java project.

1. Download the Java SDK. The Java SDK is updated periodically. Use Maven to obtain the latest version.
 2. Extract the downloaded SDK into a directory. The Java SDK does not require additional installation steps.
 3. Add all .jar packages including third-party dependencies in the SDK to your Java project.
- For more information, see IDE documents.

Step 6 Start a new Java project

To interact with Log Service and obtain the output, you can run the following code in any text editor or Java IDE:

```
package sdksample;
import java.util.ArrayList;
import java.util.List;
import java.util.Vector;
import java.util.Date;
import com.aliyun.openservices.log.Client;
import com.aliyun.openservices.log.common.*;
import com.aliyun.openservices.log.exception.*;
import com.aliyun.openservices.log.request.*;
import com.aliyun.openservices.log.response.*;
import com.aliyun.openservices.log.common.LogGroupData;
import com.aliyun.openservices.log.common.LogItem;
import com.aliyun.openservices.log.common.Logs.Log;
import com.aliyun.openservices.log.common.Logs.Log.Content;
import com.aliyun.openservices.log.common.Logs.LogGroup;
import com.aliyun.openservices.log.common.Consts.CursorMode;
public class sdksample {
    public static void main(String args[]) throws LogException, InterruptedException {
        String endpoint = "<log_service_endpoint>"; // Select the endpoint that matches the
        region of the project created in the preceding step.

        GetLogsResponse res4 = client.GetLogs(req4);
        if(res4 != null && res4.IsCompleted()){
            for (QueriedLog log : res4.GetLogs()){
                LogItem item = log.GetLogItem();
                for(LogContent content : item.GetLogContents()){
                    System.out.print(content.GetKey()+"."+content.GetValue());
                }
                System.out.println();
            }
        }
    }
}

```

Precautions

- If you improve the I/O performance of your system, do not use the SDK to write data to Log Service. For more information about the common practices of writing data. See the “Producer Library” section of User Guide .
- If you consume log data, do not call the API to pull log data by using the SDK. Alibaba Cloud provides an advanced consumer library, which shields the implementation details of Log Service and provides advanced features such as load balancing and ordered consumption. For more information about the consumer library. See the “Consumer Library” section of User Guide .

2.15.2.3 .NET SDK

Log Service provides you with the .NET SDK to improve operation efficiency.

Where to download

The Log Service .NET SDK allows developers in the Windows platform to use Log Service with .NET Framework. At present, this SDK supports .NET Framework 3.5, 4.0, and 4.5. SDK files vary with .NET Framework versions but provides the same interfaces and functions.

Step 1 Create an account

Before accessing Log Service, you must obtain an Apsara Stack Management Console account.

Step 2 Obtain an AccessKey pair

Before using the Log Service .NET SDK, you must obtain an AccessKey pair.

Log on to Apsara Stack Management Console and obtain an AccessKey pair for the SDK.

The AccessKey pair is required to perform the following steps. Keep your AccessKey pair confidential to prevent security issues. For more information about how to use the AccessKey pair in Log Service SDKs, see [SDK configuration](#).

Step 3 Create a Log Service project and a Logstore

Use the Log Service Java SDK to create a project and a Logstore.

**Note:**

- Make sure you use the same account to obtain the AccessKey pair and create the Log Service project and Logstore.
- A project name must be globally unique in Log Service, and a Logstore name must be unique across a project.
- Once a project is created, you cannot modify the region or migrate the project between regions.

Step 4 Install the .NET development environment

At present, the Log Service .NET SDK supports .NET Framework 3.5, 4.0, and 4.5. To enable the use of Log Service SDKs, we recommend that you install:

- Microsoft .NET Framework 3.5, 4.0, or 4.5 (The actual version depends on the target environment required by your programs.)
- Visual Studio 2010 and later

Step 5 Download and prepare the Log Service .NET SDK

Install the .NET development environment before you download and prepare the Log Service .NET SDK. The preparation steps are as follows:

1. Download the SDK: Click [here](#).
2. Decompress the downloaded package to a directory. The Log Service .NET SDK is a software development kit that does not require installation. You can perform the following steps to use the SDK in your Visual Studio projects.

Step 6 Start a new Log Service .NET project

If the Log Service .NET development environment and the .NET SDK are in place, you can create a Log Service .NET project.

2.15.2.4 Use .NET Core SDK

Context

The Log Service .NET Core SDK allows developers across different platforms to use Log Service with .NET Core.

Procedure

1. Create an account.

Before accessing Log Service, you must obtain an Apsara Stack Management Console account.

2. Obtain an AccessKey pair.

Before using the Log Service .NET Core SDK, you must obtain an AccessKey pair.

Log on to Apsara Stack Management Console and obtain an AccessKey pair for the SDK.

The AccessKey pair is required to perform the following steps. Keep your AccessKey pair confidential to prevent security issues. For more information about how to use the AccessKey pair in Log Service SDKs, see [SDK configuration](#).

3. Create a Log Service project and a Logstore.

Before using the SDK, you must create a Log Service project and a Logstore in the console.

a. Log on to Apsara Stack Management Console.

b. Click **Create Project** in the upper-right corner.

c. Enter **Project Name** and **Region**, and click **OK**.

d. On the **Projects** page, click the name of the project, and then click **Create** to create a Logstore.

After you have created a project, you can also click **Create** to create a Logstore as prompted.

e. Complete the configurations and click **OK**.

You must specify the Logstore name, data retention time, and number of shards. Set the number of shards as needed. In this example, you need to configure four shards.

Note:

- Make sure you use the same account to obtain the AccessKey pair and create the Log Service project and Logstore.
- A project name must be globally unique in Log Service, and a Logstore name must be unique across a project.
- Once a project is created, you cannot modify the region or migrate the project between regions.

4. Install .NET Core.

At present, the Log Service .NET Core SDK supports the following versions:

- .NET Core 2.0
- .NET Framework 4.6.2 (with .NET Core 1.x SDK)
- .NET Framework 4.6.1 (with .NET Core 2.0 SDK)

5. Download and prepare the Log Service .NET Core SDK.

Install .NET Core before you download and prepare the Log Service .NET Core SDK.

- a) Download the .NET Core SDK.
- b) Decompress the downloaded package to a directory.

The Log Service .NET Core SDK is a software development kit that does not require installation. You can perform the following steps to use the SDK in your Visual Studio projects.

6. Create a new Log Service .NET Core project.

2.15.2.5 PHP SDK

The Log Service PHP SDK provides a suite of development tools to help simplify the use of Log Service.

Download URL

Download the SDK from GitHub at <https://github.com/aliyun/aliyun-log-php-sdk>.

Step 1 Create an account

You must create an account to access Log Service.

Step 2 Obtain an AccessKey pair

You must request an AccessKey pair to use the Log Service PHP SDK.

Log on to the Apsara Stack console and select an AccessKey pair for the SDK.

The AccessKey pair is used in the following steps. It must be kept confidential. For more information about how to use the AccessKey pair, see [SDK configurations](#).

Step 3 Create a project and a Logstore

Use the Log Service PHP SDK to create a project and a Logstore.

Note:

- Make sure that you use the same account to obtain an AccessKey pair and create a project and a Logstore.
- Names of each project must be unique within Log Service. Names of each Logstore must be unique within a project.
- After a project is created, the region to which it belongs cannot be changed. A project cannot be migrated between different regions.

Step 4 Configure the PHP development environment

The PHP SDK supports PHP 5.2.1 and later. Install any PHP version supported by the SDK on your local computer and set up the corresponding PHP development environment.

Step 5 Download and install the PHP SDK

Install the PHP SDK after setting up your PHP development environment. The detailed procedure is as follows:

1. Download the latest PHP SDK from [GitHub](#).
2. Extract the downloaded SDK into a specified directory. The PHP SDK does not require additional installation steps. In addition to SDK code, the PHP SDK provides a set of third-party dependencies and an autoloader class for easy use. The following steps show you how to use the PHP SDK for your project.

Step 6 Start a new PHP project

To interact with Log Service and obtain the output, you can run the following sample code in any text editor or PHP IDE:

```
<? php
/* Use the autoloader class to load all necessary PHP modules. Specify the path of the
file that contains the autoloader class.*/
require_once realpath(dirname(__FILE__) . '/../Log_Autoload.php');
$endpoint = 'regionid.example.com'; // The Hangzhou region is used in this example.
During actual usage, specify the endpoint based on your region and access method.
$accessKeyId = '<youraccessKeyId>'; // Specify your AccessKey ID.
$accessKey = '<youraccessKey>'; // Specify your AccessKey Secret.
$project = 'your_project'; // The name of the project created in the preceding step.
$logstore = 'your_logstore'; // The name of the Logstore created in the preceding step.
$client = new Aliyun_Log_Client($endpoint, $accessKeyId, $accessKey);
# List the names of all Logstores in the current project.
$req1 = new Aliyun_Log_Models_ListLogstoresRequest($project);
$res1 = $client->listLogstores($req1);
var_dump($res1);
# Create a Logstore.
$req2 = new Aliyun_Log_Models_CreateLogstoreRequest($project,$logstore,3,2);
$res2 = $client->createLogstore($req2);
# Wait until the Logstore takes effect.
sleep(60);
# Write logs.
$topic = "";
```

```

$source = "";
$logitems = array();
for ($i = 0; $i < 5; $i++)
{
    $contents = array('index1' => strval($i));
    $logItem = new Aliyun_Log_Models_LogItem();
    $logItem->setTime(time());
    $logItem->setContents($contents);
    array_push($logitems, $logItem);
}
$req2 = new Aliyun_Log_Models_PutLogsRequest($project, $logstore, $topic, $source, $logitems);
$res2 = $client->putLogs($req2);
var_dump($res2);
# Pull the data immediately.
# List the shard IDs in the Logstore.
$listShardRequest = new Aliyun_Log_Models_ListShardsRequest($project,$logstore);
$listShardResponse = $client -> listShards($listShardRequest);
foreach($listShardResponse->getShardIds() as $shardId)
{
    # Obtain the cursor corresponding to each shard ID.
    $getCursorRequest = new Aliyun_Log_Models_GetCursorRequest($project,$logstore,$shardId,null, time() - 60);
    $response = $client -> getCursor($getCursorRequest);
    $cursor = $response->getCursor();
    $count = 100;
    while(true)
    {
        # Start to read data from a cursor.
        $batchGetDataRequest = new Aliyun_Log_Models_BatchGetLogsRequest($project,$logstore,$shardId,$count,$cursor);
        var_dump($batchGetDataRequest);
        $response = $client -> batchGetLogs($batchGetDataRequest);
        if($cursor == $response -> getNextCursor())
        {
            break;
        }
        $logGroupList = $response -> getLogGroupList();
        foreach($logGroupList as $logGroup)
        {
            print ($logGroup->getCategory());
            foreach($logGroup -> getLogsArray() as $log)
            {
                foreach($log -> getContentsArray() as $content)
                {
                    print($content-> getKey().": ".$content->getValue()."\t");
                }
                print("\n");
            }
        }
        $cursor = $response -> getNextCursor();
    }
}
# Wait one minute before querying logs.
sleep(60);
# Query the distribution of logs. Note: Make sure that indexes are created before you query logs. The PHP SDK does not provide the interface which is used to create indexes. Therefore, you must create indexes in the console.
$topic = "";
$query="";
$from = time()-3600;
$to = time();
$res3 = NULL;
while (is_null($res3) || (! $res3->isCompleted()))

```

```
{
    $req3 = new Aliyun_Log_Models_GetHistogramsRequest($project, $logstore, $from, $to, $topic, $query);
    $res3 = $client->getHistograms($req3);
}
var_dump($res3);
# Query log data.
$res4 = NULL;
while (is_null($res4) || (! $res4->isCompleted()))
{
    $req4 = new Aliyun_Log_Models_GetLogsRequest($project, $logstore, $from, $to, $topic, $query, 5, 0, False);
    $res4 = $client->getLogs($req4);
}
var_dump($res4);
```

2.15.2.6 Python SDK

Log Service provides developers with the Python SDK to facilitate the use of Log Service.

Download link

Download link: [Click to download](#).

SDK GitHub:

<https://github.com/aliyun/aliyun-log-python-sdk>

1. Create an account

An Apsara Stack Management Console account is required for accessing Log Service.

2. Obtain an AccessKey

Before using the Log Service Python SDK, you must request an AccessKey.

Log on to Apsara Stack Management Console and obtain an AccessKey for the SDK.

The AccessKey will be used in the following steps and must be kept confidential. For more information about how to use the AccessKey in the Log Service SDK, see [SDK configuration](#).

3. Create a Log Service project and a Logstore

Before using the SDK, you must create a Log Service project and a Logstore in the console.

1. Log on to Apsara Stack Management Console.
2. Click **Create Project** in the upper-right corner.
3. Enter a **project name** and **region**, and click **OK**.
4. On the **Projects** page, click the name of the project, and then click **Create**.

After you create a project, you can also click **Create** to create a Logstore as prompted.

5. Complete the configurations, and click **Confirm**.

You must specify the Logstore name ,data retention time, and number of shards. Set the number of shards as needed. In this example, you must configure four shards.

Note:

- Make sure you use the same account to obtain the AccessKey and create the Log Service project and Logstore.
- A project name must be globally unique in Log Service, and a Logstore name must be unique in the same project.
- After the project is created, you cannot modify the region or migrate the project between regions.

4 Install the Python environment

The Python SDK is a pure Python library and supports all Python operating systems, including Linux, Mac OS X and Windows. Install Python as follows:

1. Download and install the latest Python [installation package](#).

Note:

- Currently, Python SDK supports Python 2.6, 2.7, 3.3, 3.4, 3.5, and 3.6 environments. You can run the `python -V` command to query the current version of Python.
- Python does not support Python 2.6 and Python 3.3. We recommend that you use Python 2.7, Python 3.4, and later versions.

2. Download and install the Python package management tool [pip](#).

After pip is installed, run the `pip -V` command to check whether the installation is successful and query the current pip version.

5 Install Python SDK

Run the following command as an administrator in Shell to install Python SDK.

```
pip install -U aliyun-log-python-sdk
```

6 Start a Python program

Now, you can start using the Python SDK. To interact with Log Service and obtain the relevant output, run the following sample code in a text editor or Python IDE.

For more information, see [Github](#).

```
# encoding: utf-8
import time
from aliyun.log.logitem import LogItem
from aliyun.log.logclient import LogClient
from aliyun.log.getlogsrequest import GetLogsRequest
from aliyun.log.putlogsrequest import PutLogsRequest
from aliyun.log.listlogstoresrequest import ListLogstoresRequest
from aliyun.log.gethistogramsrequest import GetHistogramsRequest
def main(_):
    endpoint = " # Select the endpoint that matches the region of the project created in the
preceding step.
    accessKeyId = " # Use your Alibaba Cloud AccessKey ID.
    accessKey = " # Use your Alibaba Cloud AccessKey Secret.
    project = " # The name of the project created in the preceding step.
    logstore = " # The name of the Logstore created in the preceding step.
    # Note: Configure four shards for the created Logstore for later testing.
    # Construct a client
    client = LogClient(endpoint, accessKeyId, accessKey)
    # List all LogStores
    req1 = ListLogstoresRequest(project)
    res1 = client.list_logstores(req1)
    res1.log_print()
    topic = ""
    source = ""
    # Send 10 data packets, each of which contains 10 logs.
    for i in range(10):
        logitemList = [] # LogItem list
        for j in range(10):
            contents = [('index', str(i * 10 + j))]
            logItem = LogItem()
            logItem.set_time(int(time.time()))
            logItem.set_contents(contents)
            logitemList.append(logItem)
        req2 = PutLogsRequest(project, logstore, topic, source, logitemList)
        res2 = client.put_logs(req2)
        res2.log_print()
    # List all shards and read the data written in the last minute.
    listShardRes = client.list_shards(project, logstore)
    for shard in listShardRes.get_shards_info():
        shard_id = shard["shardID"]
        start_time = int(time.time() - 60)
        end_time = start_time + 60
        res = client.get_cursor(project, logstore, shard_id, start_time)
        res.log_print()
        start_cursor = res.get_cursor()
        res = client.get_cursor(project, logstore, shard_id, end_time)
        end_cursor = res.get_cursor()
        while True:
            loggroup_count = 100 # Read 100 packets each time.
            res = client.pull_logs(project, logstore, shard_id, start_cursor, loggroup_count,
end_cursor)
            res.log_print()
            next_cursor = res.get_next_cursor()
            if next_cursor == start_cursor:
                break
            start_cursor = next_cursor
    # Note: You can use the following interfaces to query data only when the index
function is enabled.
    time.sleep(60)
    topic = ""
    query = "index"
```

```

From = int(time.time()) - 600
To = int(time.time())
res3 = None
# Query the number of logs that match the query criteria during the past 10 minutes.
Retry if not all execution results are correct.
while (res3 is None) or (not res3.is_completed()):
    req3 = GetHistogramsRequest(project, logstore, From, To, topic, query)
    res3 = client.get_histograms(req3)
res3.log_print()
# Obtain the number of logs that match the query conditions.
total_log_count = res3.get_total_count()
log_line = 10
# Read 10 logs each time until all log data is queried. Retry three times if not all query
results are correct during each query.
for offset in range(0, total_log_count, log_line):
    res4 = None
    for retry_time in range(0, 3):
        req4 = GetLogsRequest(project, logstore, From, To, topic, query, log_line, offset,
False)
        res4 = client.get_logs(req4)
        if res4 is not None and res4.is_completed():
            break
        time.sleep(1)
    if res4 is not None:
        res4.log_print()
listShardRes = client.list_shards(project, logstore)
shard = listShardRes.get_shards_info()[0]
# Split a shard
if shard["status"] == "readwrite":
    shard_id = shard["shardID"]
    inclusiveBeginKey = shard["inclusiveBeginKey"]
    midKey = inclusiveBeginKey[-1] + str((int(inclusiveBeginKey[-1:])) + 1)
    client.split_shard(project, logstore, shard_id, midKey)
# Merge shards.
shard = listShardRes.get_shards_info()[1]
if shard["status"] == "readwrite":
    shard_id = shard["shardID"]
    client.merge_shard(project, logstore, shard_id)
# Delete shards
shard = listShardRes.get_shards_info()[-1]
if shard["status"] == "readonly":
    shard_id = shard["shardID"]
    client.delete_shard(project, logstore, shard_id)
if __name__ == '__main__':
    main()

```

2.15.2.7 Android SDK

The Log Service Android SDK is used to collect user data on an Android platform and currently provides a log data writing function.

Through GitHub

<https://github.com/aliyun/aliyun-log-android-sdk>

2.15.2.8 C SDK

The C SDK of Log Service is used to access logs from various platforms, such as the MIPS and OpenWrt systems.

The C SDK uses libCurl as the network library. The apr/apr-util library solves the issues of memory and different platforms. You only need to simply compile the source code to use the C SDK.

In addition, the C Producer Library and C Producer Lite Library provide you with a one-stop log collection solution that is simple, highly available, resource-efficient, and applicable to different platforms.

2.15.2.9 GO SDK

Log Service provides developers with the Go SDK to facilitate the use of Log Service.

The Log Service Go SDK provides the following functions:

- Writing and consuming data in batches.
- Querying and indexing data by using keywords.
- Managing Logtail configurations and machine groups.

GitHub URL: <https://github.com/aliyun/aliyun-log-go-sdk>

For more information about the usage instructions and sample codes, see README.

2.15.2.10 iOS SDK

The Log Service SDK is implemented based on APIs and provides the log writing function.

Swift

```
/*
    Use the endpoint, AccessKey ID, and AccessKey Secret to construct the Log Service
    client.
    @endPoint: see https://help.aliyun.com/document_detail/29008.html
*/
let myClient = try! LOGClient(endPoint: "",
                             accessKeyID: "",
                             accessKeySecret: "",
                             projectName: "")
/* Create a log group. */
let logGroup = try! LogGroup(topic: "mTopic", source: "mSource")
/* Store a log. */
let log1 = Log()
try! log1.PutContent("K11", value: "V11")
try! log1.PutContent("K12", value: "V12")
try! log1.PutContent("K13", value: "V13")
logGroup.PutLog(log1)
/* Store a log. */
let log2 = Log()
try! log2.PutContent("K21", value: "V21")
```

```
try! log2. PutContent("K22", value: "V22")
try! log2. PutContent("K23", value: "V23")
logGroup.PutLog(log2)
/* Send the log. */
myClient.PostLog(logGroup,logStoreName: ""){ response, error in
    // handle response however you want
    if error?.domain == NSErrorDomain && error?.code == NSErrorTimedOut {
        print("timed out") // note, `response` is likely `nil` if it timed out
    }
}
```

2.16 Apsara Stack Security

2.16.1 API overview

This document introduces all of the operations that you can call by using Apsara Stack Security service APIs.

2.16.2 Apsara Stack Security Console

2.16.2.1 List of operations

This topic introduces all of the Apsara Stack Security console operations that you can call. For more information, see the corresponding operation description.

Operation	Description
DescribeAliyunAccounts	Queries Alibaba Cloud accounts.
ModifyAliyunAccount	Modifies the information of an Alibaba Cloud account .
DescribeFeatures	Queries the deployed Apsara Stack Security features.

2.16.2.2 Make API requests

2.16.2.2.1 Request structure

Apsara Stack Security API is based on Remote Procedure Call (RPC). This topic describes the structure of the API requests.

Description

You can send an HTTP request to call an API operation. The URL of the request must be in the following format:

```
http://endpoint/?Action=xx&parameters
```

Where:

- **endpoint**: the endpoint used to call a cloud service. The endpoint for the Apsara Stack Security console is `yundunprivate.[RegionId].example.com`.
- **Action**: the operation that you want to perform.

For example, you can set this parameter to **DescribeFeatures** to query the deployed Apsara Stack Security features.

- **parameters**: the request parameters. Request parameters include common request parameters and custom request parameters. Request parameters must be separated with ampersands (&).
 - Common request parameters include information such as the API version and authentication information.
 - For more information about the custom request parameters, see the corresponding operation description.

Example

Call the **DescribeFeatures** operation to query the deployed Apsara Stack Security features.

```
https://yundunprivate.[RegionId].example.com/?Action=DescribeFeatures&AccessKeyId=key-test&Format=JSON&SecureTransport=true&SignatureMethod=HMAC-SHA1&SignatureNonce=15215528852396&SignatureVersion=1.0&SourceIp=1xxx6&Timestamp=2018-03-02Txxxxxx&Version=2018-01-16&Signature=xxxx%xxxx%3D
```

API requests are presented in the following easy-to-read format in this document:

```
https://yundunprivate.[RegionId].example.com/?Action=DescribeFeatures
&Format=JSON
&Version=2018-01-16
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2012-06-01T12:00:00Z
```

2.16.2.2.2 Signature mechanism

Apsara Stack Security authenticates each access request. You need to include a signature for the submitted HTTP or HTTPS request.

API authorization

To ensure the security of your account, we recommend that you use a Resource Access Management (RAM) user to call API operations. Before using a RAM user to call an API operation, you must grant the RAM user the corresponding permission to call the API by creating an authorization policy and attaching the policy to the RAM user.

API signature

To ensure secure calls to the API, Alibaba Cloud authenticates each API request through the signature. When you manually make an API request, you need to use AccessKey Secret to calculate the signature, that is, the hash-based message authentication code (HMAC) value, based on the encoded and sorted request string. For more information, see the definition in [RFC 2104](#).

This topic uses the raw access parameters in the following table to describe how to create an API signature.

Parameter	Description
Access point	http://yundunprivate.[RegionId].example.com/?
API-specific parameters	Action=DescribeFeatures
Common parameters (excluding the Signature parameter)	&Timestamp=2016-02-23T12:46:24Z &Format=JSON &AccessKeyId=<yourAccessKeyId> &SignatureMethod=HMAC-SHA1 &SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf &Version=2018-01-16 &SignatureVersion=1.0
AccessKey secret	<yourAccessKeySecret>

1. Use the request parameters to construct a canonicalized query string.

**Note:**

The request parameters include common request parameters (excluding the Signature parameter) and API-specific parameters.

a. Sort the parameters.

Sort the request parameters in alphabetical order.

b. Encode the parameters.

Use UTF-8 to URL-encode the parameter names and values. The encoding rules are as follows:

- Letters, digits, hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
- Other characters are encoded in the %XY format, where XY is the hexadecimal representation of the character in ASCII. For example, the double quotation mark (") is encoded as %22.
- Extended UTF-8 characters are encoded in the %XY%ZA... format.
- Note that a space is encoded as %20, instead of a plus sign (+).

c. Connect the encoded parameter names and values with equal signs (=).

d. Then, sort the parameter name and value pairs connected by equal signs in alphabetical order, and connect them with ampersands (&) to produce the canonicalized query string.

2. Use the canonicalized query string to construct the string for signature calculation based on the following rules:

```
StringToSign=HTTPMethod + "&" + percentEncode( "/" ) + "&" +
percentEncode(CanonicalizedQueryString)
```

3. Calculate the HMAC value of the StringToSign string according to the definition in [RFC 2104](#).

Note:

The key used for signature calculation is your AccessKey secret adding the ampersand (&) (ASCII 38). Secure Hash Algorithm 1 (SHA1) is used as the hash algorithm.

4. Encode the preceding HMAC value into a string based on Base64 encoding rules to obtain the signature value.

```
LEW8N4y7Uasop*****
```

5. Set the Signature parameter in the request parameters to this signature value to sign the request.

2.16.2.2.3 Common request parameters

The following table describes the common request parameters that are used to indicate information such as the API version and authentication information.

Name	Type	Required	Description
Version	String	Yes	The API version in the format of YYYY-MM-DD. Set the value to 2018-01-16.
AccessKeyId	String	Yes	The key ID that Alibaba Cloud assigns to a user for service access .
Signature	String	Yes	The signature string.
SignatureMethod	String	Yes	The signature method. Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Follow the ISO 8601 standard to specify the date and use the offset from Coordinated Universal Time (UTC) to specify the time zone. The format is YYYY-MM-DDThh:mm:ssZ. For example, 2014-05-26T12:00:00Z indicates 20:00:00 on May 26, 2014, Beijing time.
SignatureVersion	String	Yes	The signature algorithm version. Set the value to 1.0.
SignatureNonce	String	Yes	The unique random number used to prevent network replay attacks . You must use different random numbers for different requests.
ResourceOwnerAccount	String	No	The owner account of the resource to be accessed through this API request, that is, the logon username.

Name	Type	Required	Description
Format	String	No	The format of the response. Set the value to JSON or XML.  Note: Default value: XML.

2.16.2.2.4 Response structure

Apsara Stack Security API responses support both the XML and JSON formats. The system always returns a unique identification code **RequestId** each time you send a request to call an operation, no matter whether the call is successful or not.

Sample responses (XML format)

```
<? xml version="1.0" encoding="UTF-8"? >
<!-- The root node of the result -->
<Operation name+Response>
  <!-- Returned request ID -->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!-- Returned data -->
</Operation name+Response>
```

Sample responses (JSON format)

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /* Returned data */
}
```

2.16.2.3 APIs

2.16.2.3.1 DescribeAliyunAccounts

Description

You can call this operation to query Alibaba Cloud accounts.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeAliyunAccounts.

Parameter	Type	Required	Description
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of records to return on each page.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
TotalCount	Integer	The total number of returned pages.
HttpStatusCode	Integer	The HTTP status code returned.
AliyunAccounts	Array	The Alibaba Cloud accounts. For more information, see the following descriptions.
Id	Integer	The account record ID.
Aliuid	Long	The ID of the Alibaba Cloud account.
Account	String	The name of the Alibaba Cloud account.
AccessKey	String	The AccessKey ID of the Alibaba Cloud account.
AccessSecret	String	The AccessKey secret of the Alibaba Cloud account.
DataSecret	String	The DataSecret of the Alibaba Cloud account.
LicenseAegisNum	Integer	The number of Server Guard licenses.
LicenseTime	Long	The time when the licenses expire, in timestamp format.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://yundunprivate.[RegionId].example.com/?Action=DescribeAliyunAccounts
&CurrentPage=1
```

```
&PageSize=10  
&<Common request parameters>
```

- Sample response (JSON format)

```
{  
  "TotalCount":1,  
  "PageSize":30,  
  "RequestId":"7E33A454-20AA-49B1-8A9B-8979EFBDEDFC",  
  "CurrentPage":1,  
  "AliyunAccounts":[  
    {  
      "Account":"1113454564",  
      "AccessSecret":"*****",  
      "AccessKey":"<yourAccessKeyId>",  
      "Id":2,  
      "LicenseAegisNum":0,  
      "Aliuid":1441871509587522,  
      "LicenseTime":1589596257000,  
      "DataSecret":"*****"  
    }  
  ],  
  "HttpStatusCode":200  
}
```

2.16.2.3.2 ModifyAliyunAccount

Description

You can call this operation to modify the information of an Alibaba Cloud account with a specified account record ID.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyAliyunAccount.
Id	Integer	Yes	The account record ID.
Aliuid	Long	No	The ID of the Alibaba Cloud account.
Account	String	No	The name of the Alibaba Cloud account.
AccessKey	String	No	The AccessKey ID of the Alibaba Cloud account.
AccessSecret	String	No	The AccessKey secret of the Alibaba Cloud account.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://yundunprivate.[RegionId].example.com/?Action=ModifyAliyunAccount
&Id=2
&Account=1113454564
&Aliuid=1441871509587522
&AccessKey=<yourAccessKeyId>
&AccessSecret=xxxxxxxxx
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "C92B6187-603B-4E01-B0D7-74817F43852D"
}
```

2.16.2.3.3 DescribeFeatures

Description

You can call this operation to obtain a list of the deployed Apsara Stack Security features.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeFeatures.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Features	List	The list of the deployed Apsara Stack Security features.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://yundunprivate.[RegionId].example.com/?Action=DescribeFeatures
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "BAEF6CE3-9990-4BDA-A056-4D269A724817",
  "Features": [
    "Basic",
    "Audit",
    "Sas",
    "Waf"
  ]
}
```

2.16.3 Threat Detection Service (TDS)

2.16.3.1 List of operations by function

The following tables list API operations available for use in Threat Detection Service (TDS) of Apsara Stack Security. For more information, see the corresponding operation description.

Security overview

Operation	Description
DescribeDomain	Queries the domain names for TDS and Rainbow.
DescribeEventsCount	Queries the number of security events, attacks, and vulnerabilities on the current day.
DescribeOverviewEventsTrend	Queries the overall security trend.

Network traffic management

Operation	Description
DescribeHostTraffic	Queries the chart data on network traffic.
DescribeHostTrafficTrend	Queries the chart data on traffic trends at the network ingress or egress.
DescribeTopTraffic	Queries top network traffic data.

Access analysis

Operation	Description
DescribeAccessCount	Queries the number of accesses to online applications.
DescribeTopAccess	Queries the top 10 most accessed domain names in the application access records of the previous day.
DescribeAccessList	Queries online application access analysis records.
DescribeAccessTypeCount	Queries the number of times an online application is accessed by a malicious IP address or a crawler.
DescribeMaliciousIpDetail	Queries the information about a specified malicious IP address.
DescribeMaliciousIpBehaviorList	Queries attack events based on a malicious IP address.
DescribeMaliciousIpBehaviorMap	Queries an attack region chart based on a malicious IP address.

Screen

Operation	Description
DescribeScreenName	Queries the name of the screen for monitoring the security of traffic at Internet boundaries.
ModifyScreenName	Modifies the name of the screen for monitoring the security of traffic at Internet boundaries.
DescribeFlowMap	Queries the network traffic, requests, and network traffic maps from the screen for monitoring the security of traffic.
DescribeFlowTop	Queries the top N regions with the most number of normal access requests or attacks from the screen for monitoring the security of traffic.
DescribeScore	Queries a security score from the service security situation and scoring screen.
DescribeDailyCount	Queries the number of system vulnerabilities, information leakage events, and intrusion trace events that occurred on the current day from the service security situation and scoring screen.

Operation	Description
DescribeScreenAttackCount	Queries the number of attacks that occurred on the current day from the service security situation and scoring screen.
DescribeScreenAttackTrend	Queries the attack trend in the last seven days from the service security situation and scoring screen.
DescribeScreenHighRiskAssets	Queries the top 5 assets that interest hackers most from the service security situation and scoring screen .

Event analysis

Operation	Description
DescribeEventsTrend	Queries the emergency trend in the last 30 days.
DescribeEventTypeCount	Queries the statistical chart data on the distribution of emergencies in the last 30 days.
DescribeSecurityEventCount	Queries the types and number of emergencies.
DescribeSecurityEventList	Queries emergencies.
DescribeListByType	Displays all related emergencies by asset type.
DescribeDdosAnalyse	Queries the analysis on DDoS attack events.
DescribeDdosFlowDetail	Queries detailed information about the DDoS attack traffic.

Security report

Operation	Description
AddReportConfig	Adds a security report configuration.
DescribeReportConfigs	Queries a security report configuration.
ModifyReportConfig	Modifies a security report configuration.
DeleteReportConfigs	Deletes a security report configuration.

Threat detection

Operation	Description
DescribeTrendCount	Queries the number of common and targeted attacks that occurred on the current day and in the last seven days.

Operation	Description
DescribeAttackDistribute	Queries the chart data of attack events in the last week by type.
DescribeAttackTrend	Queries the attack trend in the last week.
DescribeAttackTypeCount	Queries application attack types and quantities.
DescribeAttackList	Queries attack events.
DescribeCountByType	Queries the number of threat events by type, such as threats to servers, networks, or applications.
DescribeSecurityThreatCount	Queries the statistics on security threat events.
DescribeSecurityThreatList	Queries threat events.
DescribeThreatCount	Queries the number of common attack events.
DescribeThreatCountByType	Queries the number of targeted attack events detected in threat analysis by type.
DescribeThreatTop	Queries attack and threat events in the last week.
DescribeThreatAnalyseList	Queries threat events detected in threat analysis.
DescribeHighRiskAssets	Queries high-risk assets.

Asset management

Operation	Description
DescribeDistributionByCodeType	Queries the information about regions.
DescribeSystemByCodeType	Queries the information about operating system versions.
DescribeAssetGroup	Queries detailed information about an asset group.
CreateNatAsset	Adds a Network Address Translation (NAT) asset.
ModifyRegion	Modifies the region of an asset.
ModifyAssetGroup	Modifies the information about an asset group.
ModifyGroup	Modifies the group of an asset.
ModifyAsset	Modifies the information about an asset.
DescribeTotalAssetNumber	Queries the total number of assets.
DescribeAllDistribution	Queries the proportion of assets in each region.
DescribeAssetsList	Queries assets.
DescribeUuidIpList	Queries the IP address of a specified asset based on the universally unique identifier (UUID) of the asset.

Operation	Description
DescribeIpList	Queries asset IP addresses based on keywords.
DescribePortList	Queries ports based on an IP address.
DescribeThisMonthAssets	Queries the number of new assets added in the last month.
DescribeAssetsTotalCount	Queries the chart data on the total number of assets in the last week.
DeleteAsset	Deletes the information about an asset.

Alert settings

Operation	Description
CreateContact	Adds an alert recipient.
DescribeContactsList	Queries alert recipients.
ModifyContact	Modifies an alert recipient.
DeleteContact	Deletes an alert recipient.
DescribeAlarmConfig	Queries alert configurations.
ModifyAlarmConfig	Modifies alert configurations.
DescribeReadStatus	Queries the number of alert messages that users have not read.

2.16.3.2 Make API requests

2.16.3.2.1 Request structure

Apsara Stack Security API is based on Remote Procedure Call (RPC). This topic describes the structure of the API requests.

Description

You can send an HTTP request to call an API operation. The URL of the request must be in the following format:

```
http://endpoint/?Action=xx&parameters
```

Where:

- **endpoint**: the endpoint used to call a cloud service. The endpoint for Threat Detection Service is `sasprivate.[RegionId].example.com`.

- **Action**: the operation that you want to perform.

For example, you can set this parameter to **DescribeScore** query the overall score of the service security situation.

- **parameters**: the request parameters. Request parameters include common request parameters and custom request parameters. Request parameters must be separated with ampersands (&).
 - Common request parameters include information such as the API version and authentication information.
 - For more information about the custom request parameters, see the corresponding operation description.

Example

Call the **DescribeFeatures** operation to query the deployed Apsara Stack Security features.

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeScore&AccessKeyId=key-test&Format=JSON&SecureTransport=true&SignatureMethod=HMAC-SHA1&SignatureNonce=15215528852396&SignatureVersion=1.0&SourceIp=1xxx6&Timestamp=2018-03-02Txxxxxxx&Version=2018-01-16&Signature=xxxx%xxxx%3D
```

API requests are presented in the following easy-to-read format in this document:

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeScore
&Format=JSON
&Version=2018-01-16
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2012-06-01T12:00:00Z
```

2.16.3.2.2 Signature mechanism

Apsara Stack Security authenticates each access request. You need to include a signature for the submitted HTTP or HTTPS request.

API authorization

To ensure the security of your account, we recommend that you use a Resource Access Management (RAM) user to call API operations. Before using a RAM user to call an API operation, you must grant the RAM user the corresponding permission to call the API by creating an authorization policy and attaching the policy to the RAM user.

API signature

To ensure secure calls to the API, Alibaba Cloud authenticates each API request through the signature. When you manually make an API request, you need to use AccessKey Secret to calculate the signature, that is, the hash-based message authentication code (HMAC) value, based on the encoded and sorted request string. For more information, see the definition in [RFC 2104](#).

This topic uses the raw access parameters in the following table to describe how to create an API signature.

Parameter	Description
Access point	http://yundunprivate.[RegionId].example.com/?
API-specific parameters	Action=DescribeFeatures
Common parameters (excluding the Signature parameter)	&Timestamp=2016-02-23T12:46:24Z &Format=JSON &AccessKeyId=<yourAccessKeyId> &SignatureMethod=HMAC-SHA1 &SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf &Version=2018-01-16 &SignatureVersion=1.0
AccessKey secret	<yourAccessKeySecret>

1. Use the request parameters to construct a canonicalized query string.

Note:

The request parameters include common request parameters (excluding the Signature parameter) and API-specific parameters.

a. Sort the parameters.

Sort the request parameters in alphabetical order.

b. Encode the parameters.

Use UTF-8 to URL-encode the parameter names and values. The encoding rules are as follows:

- Letters, digits, hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
- Other characters are encoded in the %XY format, where XY is the hexadecimal representation of the character in ASCII. For example, the double quotation mark (") is encoded as %22.
- Extended UTF-8 characters are encoded in the %XY%ZA... format.
- Note that a space is encoded as %20, instead of a plus sign (+).

c. Connect the encoded parameter names and values with equal signs (=).

d. Then, sort the parameter name and value pairs connected by equal signs in alphabetical order, and connect them with ampersands (&) to produce the canonicalized query string.

2. Use the canonicalized query string to construct the string for signature calculation based on the following rules:

```
StringToSign=HTTPMethod + "&" + percentEncode( "/" ) + "&" +
percentEncode(CanonicalizedQueryString)
```

3. Calculate the HMAC value of the StringToSign string according to the definition in [RFC 2104](#).

Note:

The key used for signature calculation is your AccessKey secret adding the ampersand (&) (ASCII 38). Secure Hash Algorithm 1 (SHA1) is used as the hash algorithm.

4. Encode the preceding HMAC value into a string based on Base64 encoding rules to obtain the signature value.

```
LEW8N4y7Uasop*****
```

5. Set the Signature parameter in the request parameters to this signature value to sign the request.

2.16.3.2.3 Common request parameters

The following table describes the common request parameters that are used to indicate information such as the API version and authentication information.

Name	Type	Required	Description
Version	String	Yes	The API version in the format of YYYY-MM-DD. Set the value to 2018-01-16.
AccessKeyId	String	Yes	The key ID that Alibaba Cloud assigns to a user for service access.
Signature	String	Yes	The signature string.
SignatureMethod	String	Yes	The signature method. Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Follow the ISO 8601 standard to specify the date and use the offset from Coordinated Universal Time (UTC) to specify the time zone. The format is YYYY-MM-DDThh:mm:ssZ. For example, 2014-05-26T12:00:00Z indicates 20:00:00 on May 26, 2014, Beijing time.
SignatureVersion	String	Yes	The signature algorithm version. Set the value to 1.0.
SignatureNonce	String	Yes	The unique random number used to prevent network replay attacks. You must use different random numbers for different requests.
ResourceOwnerAccount	String	No	The owner account of the resource to be accessed through this API request, that is, the logon username.

Name	Type	Required	Description
Format	String	No	The format of the response. Set the value to JSON or XML.  Note: Default value: XML.

2.16.3.2.4 Response structure

Apsara Stack Security API responses support both the XML and JSON formats. The system always returns a unique identification code **RequestId** each time you send a request to call an operation, no matter whether the call is successful or not.

Sample responses (XML format)

```
<? xml version="1.0" encoding="UTF-8"? >
<!-- The root node of the result -->
<Operation name+Response>
  <!-- Returned request ID -->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!-- Returned data -->
</Operation name+Response>
```

Sample responses (JSON format)

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /* Returned data */
}
```

2.16.3.3 Security overview operations

2.16.3.3.1 DescribeDomain

Description

You can call this operation to query the domain names for Threat Detection Service and Rainbow.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeDomain.

Parameter	Type	Required	Description
Lang	String	No	The value of this parameter is automatically obtained by the system.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
RainbowDomain	String	The domain name for Rainbow.
SasDomain	String	The domain name for Threat Detection Service.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeDomain
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "AEC7335C-51B5-414F-9ADD-3AF47A3C5BAE",
  "RainbowDomain": "rainbow.example.com",
  "SasDomain": "sas.example.com"
}
```

2.16.3.3.2 DescribeEventsCount

Description

You can call this operation to query the number of security events, attacks, and vulnerabilities on the current day in security overview.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEventsCount.
Distribution	String	No	The region name.
StartDate	String	No	The start time of the time frame specified for query, in timestamp format.
EndDate	String	No	The end time of the time frame specified for query, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Event	Integer	The number of security events in the current day.
EventTrend	Integer	The increment or decrement of security events in the current day compared to the security events in the last day.
HackerCount	Integer	The number of attack events in the last 30 days.
Threat	Integer	The number of attack events in the current day.
ThreatTrend	Integer	The increment or decrement of attack events in the current day compared to the attack events in the last day.
Vul	Integer	The number of vulnerabilities in the current day.
VulTrend	Integer	The increment or decrement of vulnerabilities in the current day compared to the vulnerabilities in the last day.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeEventsCount
&EndDate=1234567891
&StartDate=1234566456
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "EventTrend":0,
  "RequestId":"27B97133-D561-4F46-ADEF-A0858736D5C3",
  "ThreatTrend":0,
  "Event":0,
  "HackerCount":0,
  "Vul":0,
  "VulTrend":0,
  "Threat":0
}
```

2.16.3.3 DescribeOverviewEventsTrend

Description

You can call this operation to query the chart data on overall security trends, including trends in security incidents, threats, and vulnerabilities.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeOverviewEventsTrend.
Distribution	String	No	The region name.
StartDate	String	Yes	The start time of the query, in timestamp format.
EndDate	String	Yes	The end time of the query, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.
TimeScope	Struct	The time range of the query. For more information, see the following parameter descriptions.
Interval	Integer	The time interval of the query.
Start	Long	The start time of the query.
LineDatas	Array	The list of security trends. For more information, see the following parameter descriptions.
Name	String	The event type.
Data	List	The number of events detected.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DescribeOverviewEventsTrend
&EndDate=1519886538
&StartDate=1519886538
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "F7D239C2-C534-4032-8B8F-D288F22AB945",
  "TimeScope": {
    "Start": -28800000,
    "Interval": 86400000
  },
  "LineDatas": [
    {
      "Data": [
        0
      ],
      "Name": "Emergency"
    },
    {
      "Data": [
        0
      ],
      "Name": "Emergency"
    }
  ]
}
```

```
"Name": "Attack"
},
{
  "Data": [
    0
  ],
  "Name": "Vulnerability"
}
]
```

2.16.3.4 Network traffic management operations

2.16.3.4.1 DescribeHostTraffic

Description

You can call this operation to obtain the chart data on network traffic.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeHostTraffic.
Distribution	String	No	The name of the region.
StartTime	String	No	The start time of the time frame specified for query, in timestamp format.
EndTime	String	No	The end time of the time frame specified for query, in timestamp format.

Name	Type	Required	Description
Type	String	Yes	The type of the network traffic chart. This parameter determines the time frame during which the traffic details is returned. Valid values: - Default: indicates that the traffic data in the last 24 hours is returned by default. - Six_hour: indicates that the traffic data in the last 6 hours is returned. - One_day: indicates that the traffic data in the last day is returned. By default, the traffic data in the last 24 hours is returned.
Interval	String	Yes	The interval for displaying traffic data.  Note: This parameter takes effect only when the Type parameter is set to Default.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.
TimeScope	Struct	The time frame during which the data is collected and returned. For more information, see the following parameter descriptions.
Interval	Integer	The time length of the time frame specified for query.

Name	Type	Description
Start	Long	The start time of the time frame specified for query.
LineBars	Array	The list of network traffic. For more information, see the following parameter descriptions.
Name	String	The traffic data type.
Data	List	The traffic data.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeHostTraffic
&EndTime=1519886538
&Interval=300
&StartTime=1519886538
&Type=DEFAULT
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "50EBF449-96B3-457B-91C1-8FAC448C1F67",
  "LineBars": [
    {
      "data": [
        0,
        1355,
        0,
        0
      ],
      "name": "Inbound traffic"
    },
    {
      "data": [
        0,
        272601536,
        467252288,
        0,
        0
      ],
      "name": "Outbound traffic"
    },
    {
      "data": [
        0
      ],
      "name": "QPS"
    }
  ]
}
```

```
]
}
```

2.16.3.4.2 DescribeHostTrafficTrend

Description

You can call this operation to query the chart data on traffic trends at the network ingress or egress.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeHostTrafficTrend.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Categories	List	The horizontal axis information, which is generally the timeline information in timestamp format.
LineBars	Array	The list of network traffic. For more information, see the following parameter descriptions.
Name	String	The traffic data type.
Data	List	The traffic data.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DescribeHostTrafficTrend
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "RequestId":"085208CE-65DF-4A72-A207-C1ED83602081",
  "Categories":[
    "2018-02-11 16:39:00",
    "2018-02-11 16:40:00",
    "2018-02-11 16:41:00",
    "2018-02-11 16:42:00"
  ],
  "LineBars":[
    {
      "data":[
        0,
        2257,
        0,
        2257
      ],
      "name":"Traffic at the network ingress"
    },
    {
      "data":[
        577215272,
        569825463,
        574829082,
        586378445
      ],
      "name":"Traffic at the network egress"
    }
  ]
}
```

2.16.3.4.3 DescribeTopTraffic

Description

You can call this operation to query detailed information about a type of network traffic within a time range.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeTopTraffic.
Distribution	String	No	The name of the region.

Parameter	Type	Required	Description
Field	String	Yes	The type of the traffic. Valid values: • inbps: indicates inbound traffic. • outbps: indicates outbound traffic. • qps: indicates queries per second (QPS).
DateTime	String	Yes	The beginning of the time range where data is queried, in timestamp format.
Size	Integer	No	The number of records to return.
Type	String	Yes	The type of the network traffic chart. This parameter determines the time range of the returned traffic details. Valid values: • Default: indicates that the traffic data in the last 24 hours is returned. • Six_hour: indicates that the traffic data in the last 6 hours is returned. • One_day: indicates that the traffic data in the last day is returned. By default, the traffic data in the last 24 hours is returned.
Interval	String	Yes	The time range of the returned traffic details.  Note: This parameter takes effect only when the Type parameter is set to Default.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Traffics	Array	The network traffic details. For more information, see the following descriptions.
Ip	String	The IP address.
Service	String	The type of the cloud product, such as RDS, SLB, or ECS.
Value	Long	The traffic data.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeTopTraffic
&DateTime=123456478
&Field=inbps
&Interval=5
&Size=10
&Type=SIX_HOUR
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "8D1511FF-64BD-4AB2-B8EA-E7336F7F9A57",
  "Traffics": [
    {
      "ip": "x.x.x.x",
      "product": "ECS",
      "value": 186971775440
    }
  ]
}
```

2.16.3.5 Access analysis operations

2.16.3.5.1 DescribeAccessCount

Description

You can call this operation to query the number of times an online application is accessed.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccessCount.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
AccessCount	Struct	The number of times the application is accessed. For more information, see the following parameter descriptions.
CrawlerCount	Integer	The number of times the application is accessed by a crawler.  Note: If the value is 0, this parameter is not returned.
MaliciousCount	Integer	The number of times the application is accessed from a malicious IP address.  Note: If the value is 0, this parameter is not returned.
NormalCount	Integer	The number of normal access records.  Note: If the value is 0, this parameter is not returned.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAccessCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "68233B45-CAA5-4433-9E15-A8B77BA7E017",
  "AccessCount": {
    "NormalCount": 10,
    "MaliciousCount": 10,
    "CrawlerCount": 10
  }
}
```

2.16.3.5.2 DescribeTopAccess

Description

You can call this operation to query the 10 most accessed domain names in the application access records of the previous day.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeTopAccess.
Distribution	String	No	The region.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
StatisticsValues	Array	The 10 most accessed domain names. For more information, see the following descriptions.
StatKey	String	The domain name.
Count	Integer	The number of visits.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeTopAccess
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "B4913E57-31D6-49D7-8C95-E504F2C8F6A2",
  "StatisticsValues": [
    {
      "StatKey": "www.example.com",
      "Count": 1
    }
  ]
}
```

2.16.3.5.3 DescribeAccessList

Description

You can call this operation to query online application access records.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeAccessList.
Size	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.

Parameter	Type	Required	Description
AccessType	Integer	No	The type of the access. Valid values : 0: indicates the access from a normal IP address. 1: indicates the access from a malicious IP address. 2: indicates the access from a crawler IP address.
Distribution	String	No	The region.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
ApplicationAccesses	Array	The detailed application access records. For more information, see the following descriptions.
Id	Integer	The ID of the access record.
ReportDate	String	The date of the access.
Domain	String	The accessed domain name.
AccessType	Integer	The type of the access. Valid values: 0: indicates the access from a normal IP address. 1: indicates the access from a malicious IP address. 2: indicates the access from a crawler IP address.
AccessPageCount	Integer	The number of accessed pages.
FirstAccessDate	Long	The first access time of the day, in timestamp format.
SourceIp	String	The IP address of the visitor.
SourceLocation	String	The home region of the IP address of the visitor.

Parameter	Type	Description
MaxQPS	Integer	The maximum number of accesses per second.
HasAttack	Boolean	Indicates whether Web attacks were detected during the access. Valid values: - false: indicates no. - true: indicates yes.
UserAgent	String	The proxy used for the access.
Aliuid	String	The ID of the Alibaba Cloud account.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAccessList
&Size=10
&Start=5
&AccessType=0
&Distribution=UNKNOWN
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "RequestId":"793163EF-DEEE-4783-804D-7C600DFA234B",
  "ApplicationAccesses":[
    "AccessPageCount":1,
    "AccessType":0,
    "Aliuid":0,
    "Domain":"aaa.example.com",
    "FirstAccessDate":158956478944,
    "HasAttack":true,
    "Id":123456,
    "MaxQps":15,
    "ReportDate":"20150601",
    "SourceIp":"x.x.x.x",
    "SourceLocation":"Hangzhou",
    "UserAgent":"xxxxx"
  ]
}
```

2.16.3.5.4 DescribeAccessTypeCount

Description

You can call this operation to query the number of times an online application is accessed by a malicious IP address or a crawler.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccessTypeCount.
Distribution	String	No	The home region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
AccessCounts	Array	The number of records involving malicious or crawler access to an application. For more information, see the following parameter descriptions.
AccessType	Integer	The access type. Valid values: 1: indicates access with a malicious IP address. 2: indicates crawler access.
Count	Integer	The number of access records.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAccessTypeCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "2877C944-4310-441C-AB9B-0CBA86E8AA96",
  "AccessCounts": [
    {
      "Count": 0,
      "AccessType": 1
    },
    {
      "Count": 0,
      "AccessType": 2
    }
  ]
}
```

2.16.3.5.5 DescribeMaliciousIpDetail

Description

You can call this operation to query the information about a specified malicious IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMaliciousIpDetail.
Ip	String	Yes	The malicious IP address.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
AttackType	Integer	The ID of the attack event type.
AttackTypeName	String	The type of the attack event.
CcServer	String	The IP address of the C&C server.
Domain	String	The domain name.

Parameter	Type	Description
Idc	String	The operator.
Ip	String	The malicious IP address.
IsBotnet	String	Indicates whether the malicious IP address belongs to a Botnet (regardless of whether the IP address belongs to the Botnet controller or a device controlled by the Botnet). Valid values: 0: indicates no. 1: indicates yes.
Location	String	The home region.
TotalCount	Integer	The number of times that the malicious IP address has been reported.
TotalIpCount	Integer	The number of client IP addresses that have launched attacks.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeMaliciousIpDetail
&Ip=192.168.x.x
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "2191ECA9-57B5-4B35-98C3-8DCD69E1C4B7",
  "TotalIpCount": 0,
  "AttackType": 0,
  "Ip": "192.168.x.x",
  "Domain": "aaa.example.com",
  "CcServer": "aaa",
  "Idc": "aaa",
  "Location": "aaa",
  "AttackTypeName": "aaa",
  "IsBotnet": 0,
  "TotalCount": 0,
```

```
}
```

2.16.3.5.6 DescribeMaliciousIpBehaviorList

Description

You can call this operation to query attack events triggered by a malicious IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMaliciousIpBehaviorList.
Distribution	String	No	The name of the region.
Limit	Integer	Yes	The number of records to return.
Offset	Integer	Yes	The position of the first record to return.
Ip	String	Yes	The malicious IP address.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
MaliciousIpBehaviorList	Array	The attack events. For more information, see the following descriptions.
AttackInfo	String	The victim URL.
AttackType	Integer	The ID of the attack event type.
AttackTypeName	String	The type of the attack event.
Ip	String	The malicious IP address.
RequestType	String	The type of the attack request.
Time	String	The time when the attack was launched.
VictimDomain	String	The domain name that has been attacked.
VictimIp	String	The IP address of the server that has been attacked.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeMaliciousIpBehaviorList
&Ip=192.168.x.x
&Limit=2
&Offset=0
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "F1686A4C-6D08-4596-85F3-44A1577AE26F",
  "TotalCount": 1,
  "Items": [
    {
      "attackInfo": "test.example.com/to/be/attacked.html? a=b",
      "attackType": 1,
      "attackTypeName": "Web attack",
      "ip": "xx.xx.xx.xx",
      "requestType": "GET",
      "time": "2015-07-07 10:43:05",
      "victimDomain": "test.example.com",
      "victimIp": "10.0.x.x"
    }
  ]
}
```

2.16.3.5.7 DescribeMaliciousIpBehaviorMap

Description

You can call this operation to query the attack region chart based on malicious IP addresses

.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMaliciousIpBehaviorMap.
Limit	Integer	Yes	The number of records to return.
Ip	String	Yes	The malicious IP address.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Ip	String	The malicious IP address.
To	List	The attack destination.
Location	Struct	The detailed information about the region of the malicious IP address. For more information, see the following descriptions.
Area	String	The name of the area.
AreaId	String	The code of the area.
City	String	The name of the city.
CityId	String	The code of the city.
Continent	String	The name of the continent.
Country	String	The name of the country.
CountryId	String	The code of the country.
Region	String	The region. For a region in China, the value is the province name and city name.
RegionId	String	The ID of the region.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[RegionId].example.com/?Action=DescribeMaliciousIpBehaviorMap
&Ip=192.168.xx.xx
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "189A498F-427A-4635-9076-3749A8EC7669",
  "Ip": "192.168.x.x",
  "To": [
    {
      "ip": "xx.xx.xx.xx",
      "isMine": false,
      "location": {
        "area": "East China",
        "areaId": "300000",
        "city": "Hangzhou",
```

```

        "cityId" : "330100",
        "continent" : "Asia",
        "country" : "China",
        "countryId" : "CN",
        "region" : "Zhejiang Province",
        "regionId" : "330000"
    }
  },

```

2.16.3.6 Large screen operations

2.16.3.6.1 DescribeScreenName

Description

You can call this operation to query the name of the screen that displays the traffic data on the Internet boundary.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScreenName.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Company	String	The name of the screen.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeScreenName
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "Company": "test",
  "RequestId": "C5490100-FB39-4AF5-879F-FD75837020BA"
}
```

2.16.3.6.2 ModifyScreenName

Description

You can call this operation to modify the name of the screen that displays the traffic security data on the Internet boundary.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyScreenName.
Name	String	Yes	The modified screen name.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyScreenName
&Name=test
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "C5490100-FB39-4AF5-879F-FD75837020BA"
}
```

2.16.3.6.3 DescribeFlowMap

Description

You can call this operation to query the network traffic and request information in the last two minutes as well as network traffic map information on the Internet Perimeter Traffic Security Monitoring screen.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeFlowMap.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
FlowCount	Integer	The total traffic.
RequestCount	Integer	The total number of access requests.
SasScreenFlowMaps	Array	The information on the Internet Perimeter Traffic Security Monitoring screen. For more information, see the following parameter descriptions.
City	String	The city code.
Continent	String	The continent information.
Country	String	The international code.

Name	Type	Description
Region	String	The region name, which displays a city name in China or a country name outside China.
Requests	Integer	The number of access requests.
Type	Integer	The access request type. Valid values: 0: indicates a normal request. 1: indicates an attack.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeFlowMap
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "B2175A71-E1DD-44F9-AD5B-F7EC22439A8A",
  "FlowClount": 13597562841,
  "SasScreenFlowMaps": [
    {
      "Region": "Hangzhou",
      "Continent": "Asia",
      "Country": "CN",
      "City": "hz",
      "Requests": 1,
      "Type": 0
    }
  ],
  "RequestCount": 0
}
```

2.16.3.6.4 DescribeFlowTop

Description

You can call this operation to obtain the top N regions with most normal access requests or attacks in the last two minutes on the Internet Perimeter Traffic Security Monitoring screen.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeFlowTop.
Type	Integer	Yes	The type of access requests whose statistics are to be returned. Valid values: • 5: indicates that the top 5 regions with most access requests (including normal access requests and attacks) are returned. • 1: indicates that the top N regions with most normal access requests are returned. • 2: indicates that the top N regions with most attacks are returned.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.
SasScreenFlowMaps	Array	The information on the Internet Perimeter Traffic Security Monitoring screen. For more information, see the following parameter descriptions.
Region	String	The region name, which displays a city name in China or a country name outside China.
Requests	Integer	The number of requests.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeFlowTop
&Type=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "3F156598-D362-45AB-BC87-E3199197B8D0",
  "SasScreenFlowMaps": [
    {
      "Region": "",
      "Requests": 29616
    }
  ],
  "TotalCount": 1
}
```

2.16.3.6.5 DescribeScore

Description

You can call this operation to obtain a security score on the service security situation and scoring dashboard.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeScore.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Aliuid	Integer	The ID of the Alibaba Cloud account.
CountDate	String	The statistical time.
CreateDate	String	The creation time.
ModifiedDate	String	The modification time.
Id	Integer	The primary key ID.

Parameter	Type	Description
Score	Integer	The security score.
Details	Array	The security score details. For more information, see the following descriptions.
EventName	String	The name of the event.
EventType	String	The type of the event.
HostName	String	The name of the server.
Product	String	The type of the cloud product.
VmIp	String	The IP address of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeScore
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "441D233D-C05A-40C5-824C-0C301C328CB6",
  "Details": [
    {
      "EventName": "Webshell",
      "EventType": "SECURITY_EVENT",
      "HostName": "iZys605x4c3wlmidxkfy****",
      "Product": "HOST",
      "VmIp": "192.168.xx.xx"
    }
  ],
  "Score": 33,
  "id": 682292,
  "modifiedDate": "2018-03-22 11:33:09",
  "aliuid": -1,
  "countDate": "2018-03-22 00:00:00",
  "createDate": "2018-03-22 00:00:10"
}
```

2.16.3.6.6 DescribeDailyCount

Description

You can call this operation to query the number of system flaws, information leaks, and intrusions of the current day on the Service Security Situation and Score screen.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDailyCount.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Event	Struct	The description and number of security events of the current day. For more information, see the following parameter descriptions.
Info	String	The description of security events.
Total	Integer	The total number of security events of the current day.
Leakage	Struct	The description and number of information leak events of the current day. For more information, see the following parameter descriptions.
Info	String	The description of information leak events.
Total	Integer	The total number of information leak events of the current day.
Vul	Struct	The description and number of flaws of the current day. For more information, see the following parameter descriptions.
Info	String	The description of the flaws.
Total	Integer	The total number of flaws of the current day.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeDailyCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "D5B980D1-660D-4265-8E4E-7F7936533E40",
  "Event": [
    {
      "Total ": 10
    }
  ],
  "Leakage": [
    {
      "Total ": 10
    }
  ],
  "Vul": [
    {
      "Total ": 10
    }
  ]
}
```

2.16.3.6.7 DescribeScreenAttackCount

Description

You can call this operation to query the number of attacks occurred on the current day from the Service Security Situation and Score screen.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScreenAttackCount.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Crack	Integer	The number of brute-force attacks.

Name	Type	Description
Web	Integer	The number of Web application attacks.
Ddos	Integer	The number of DDoS attacks.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DescribeScreenAttackCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "Ddos":0,
  "RequestId":"7A9D6B6B-D7BD-4D89-B77E-9AB21CEC15E7",
  "Web":0,
  "Crack":0
}
```

2.16.3.6.8 DescribeScreenAttackTrend

Description

You can call this operation to query the attack trend in the last seven days on the Service Security Situation and Score screen.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScreenAttackTrend.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Interval	Integer	The time interval of the query.

Name	Type	Description
Start	Long	The start time of the query.
AttackItems	List	The list of attack events. For more information, see the following parameter descriptions.
AttackName	String	The attack description, such as targeted attacks or common attacks.
AttackData	String	The number of attacks.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeScreenAttackTrend
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "B787F4A8-C2DC-4CC8-9443-F2F655A9DDFD",
  "Start": 1517673600000,
  "AttackItems": [
    {
      "AttackData": [
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0
      ],
      "AttackName": "Common attack"
    },
    {
      "AttackData": [
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0
      ],
      "AttackName": "Targeted attack"
    }
  ],
  "Interval": 86400000
}
```

```
}
```

2.16.3.6.9 DescribeScreenHighRiskAssets

Description

You can call this operation to query the top 5 attackers' favorite assets displayed on the Service Security Situation and Score screen.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScreenHighRiskAssets.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
ScreenHighRiskAssets	List	A list of high-risk assets. For more information, see the following parameter descriptions.
AssetGroup	String	The name of the asset group.
Distribution	String	The region of the asset.
HostName	String	The customized asset names.
Ip	String	The IP address of the asset.
NormalCount	Integer	The number of normal attacks launched to the asset.
SepecificCount	Integer	The number of targeted attacks launched to the asset.
Service	String	The asset type, such as RDS, SLB, or ECS.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeScreenHighRiskAssets
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "05B2B418-3248-4F95-89CC-A3141E736E37",
  "Total": 0,
  "ScreenHighRiskAssets": [
    {
      "Ip": "xx.xx.xx.xx",
      "Product": "",
      "HostName": "Group 1",
      "NormalCount": 3000,
      "SpecificCount": 500,
      "Distribution": "",
      "AssetGroup": ""
    }
  ]
}
```

2.16.3.7 Event analysis operations

2.16.3.7.1 DescribeEventsTrend

Description

You can call this operation to query the urgent event trend in the last 30 days.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEventsTrend.
Distribution	String	No	The region name.
StartDate	String	No	The start time of the time frame specified for query, in timestamp format.
EndDate	String	No	The end time of the time frame specified for query, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
TimeScope	Struct	The time frame during which the urgent event trend is queried. For more information , see the following parameter descriptions.
Interval	Integer	The time interval between the query and response.
Start	Long	Start time of the time frame specified for query.
Events	Array	A list of security events. For more information, see the following parameter descriptions.
Name	String	The description of the security event.
Data	List	The number of security events.
ExtendData	Struct	The additional information about the security events. For more information, see the following parameter descriptions.
TodayCount	Integer	The number of events that occurred on the current day.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DescribeEventsTrend
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "DB86A047-3153-4149-8301-6043CD7A4A9C",
  "events": [
    {
      "Data": [
        0
      ],
      "Name": "Security event"
    }
  ]
}
```

```
},
"ExtendData":{
  "TodayCount":0
},
"TimeScope":{
  "Start":1440000000,
  "Interval":86400000
}
}
```

2.16.3.7.2 DescribeEventTypeCount

Description

You can call this operation to query the chart data on the distribution of emergencies in the last 30 days.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEventTypeCount.
Distribution	String	No	The name of the region.
StartDate	String	No	The start time of data collection, in timestamp format.
EndDate	String	No	The end time of data collection, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.
Pieltems	Struct	The chart data on security event types. For more information, see the following parameter descriptions.
Name	String	The name of the security event type.
Data	String	The percentage of each type of security event.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeEventTypeCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":2,
  "RequestId":"3E8B3881-1E05-4899-9973-1DD2AFC7C57B",
  "Pieltems":[
    {
      "data":0.02,
      "name":"Webpage defacement"
    },
    {
      "data":0.01,
      "name":"Successful brute-force attack"
    }
  ]
}
```

2.16.3.7.3 DescribeSecurityEventCount

Description

You can call this operation to query the types and numbers of security events.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSecurityEventCount.
Distribution	String	No	The name of the region.
Status	Integer	No	The status of security events. Valid values: 0: indicates all security events. 1: indicates ignored security events. Default value: 0.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Categorys	Array	The list of security event types. For more information, see the following parameter descriptions.
Category	Integer	The ID of the security event type.
CategoryName	String	The name of the security event type.
Count	Integer	The number of security events.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeSecurityEventCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "Categorys": [
    {
      "Category": 1,
      "CategoryName": "Webpage defacement",
      "Count": 0
    }
  ],
  "RequestId": "1AD76A32-A3BE-4A1C-8273-3327A2226F93"
}
```

2.16.3.7.4 DescribeSecurityEventList

Description

You can call this operation to query security events.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeSecurityEventList.
Distribution	String	No	The name of the region.
Size	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.
Category	Integer	No	The ID of the security event category.
Status	Integer	No	The type of security events to collect. Valid values: 0: indicates all events. 1: indicates ignored events. Default value: 0.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
SecurityEvents	Array	The security events. For more information, see the following descriptions.
Aliuid	Long	The ID of the Alibaba Cloud account.
Assets	String	The name of the asset.
Category	Integer	The ID of the main security event category.
CategoryName	String	The name of the main security event category.
Create	String	The time when the record was created.
DestinationIp	String	The destination IP address.

Parameter	Type	Description
DetailStr	String	The detailed information about the security event.
Distribution	String	The region.
EventName	String	The name of the security event sub-category.
EventType	String	The ID of the security event sub-category.
FileMd5	String	The MD5 value of the Server Guard file, used as a supplement to global infection data.
Id	Integer	The primary key ID.
IsFinished	Integer	Indicates whether the event has finished, mainly used for distributed denial of service (DDoS) attacks, botnet attacks, and other security events of which the end time needs to be updated.
Modified	String	The time when the record was last modified.
Product	String	The cloud product.
Status	Integer	The type of security events that were collected. Valid values: 0: indicates all events. 1: indicates ignored events.
ThreatStr	String	The detailed information about the threat.
Time	String	The time when the event occurred.
Uuid	String	The universally unique identifier (UUID) of the asset.
VmIp	String	The IP address of the asset.
UniqueInfo	String	The identifier that identifies whether the same event is occurring.
Detail	Struct	The detailed information about the event . For more information, see the following descriptions.
AssetGroup	String	The asset group.
Assets	String	The name of the asset.
Distribution	String	The region.

Parameter	Type	Description
FilePath	String	The file path.
HasDownload	Boolean	Indicates whether the file has been downloaded.
Md5	String	The MD5 value of the file.
Status	Integer	The type of security events that were collected. Valid values: 0: indicates all events. 1: indicates ignored events.
TfsFileName	String	The name of the file.
Type	String	The name of the security event sub-category.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeSecurityEventList
&Category=4
&Size=5
&Start=1
&Status=0
&<Common request parameters>
```

2.16.3.7.5 DescribeListByType

Description

You can call this operation to query the security event information by asset.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeListByType.
Distribution	String	No	The name of the region.
StartDate	String	No	The start time of the queried security events, in timestamp format.
EndDate	String	No	The end time of the queried security events, in timestamp format.
Limit	Integer	Yes	The number of returned records.
Start	Integer	Yes	The start position of the first record to be returned.

Name	Type	Required	Description
Type	String	No	The type of the asset. Valid values: • Server • Application • Network • Personnel • Information

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.
OverviewAssets	Array	The event information listed by asset. For more information, see the following parameter descriptions.
Index	String	The identifier of the record.
Details	String	The event details. For more information, see the following parameter descriptions.
Type	String	The type of the event.
Category	String	The category of the event.
Content	String	The content of the event.
Page	String	The page on which the event occurred.
Time	String	The time when the event occurred.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeListByType
&Limit=10
&Start=0
&EndDate=1519886538
&StartDate=1519886538
&Type=server
```

<Common request parameters>

  ]
}
```

2.16.3.7.6 DescribeDdosAnalyse

Description

You can call this operation to query the analysis on distributed denial of service (DDoS) attack events.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeDdosAnalyse.
Limit	Integer	Yes	The number of records to return.
Offset	Integer	Yes	The position of the first record to return.
StartTime	String	No	The beginning of the time range where data is queried, in timestamp format.
EndTime	String	No	The end of the time range where data is queried, in timestamp format.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
DdosAnalyses	Array	The DDoS attack analysis report. For more information, see the following descriptions.
AssetType	String	The cloud product to which the victim IP address belongs.
Ip	String	The IP address of the victim server.
Num	Integer	The ID of the record in the attack analysis report.
Time	String	The time when the attack occurred.
Items	Array	The DDoS attack details.
Name	String	The type of the attack.
Pre	Float	The percentage of the attack type compared to all attack types.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeDdosAnalyse
&EndTime=1519886538
&Limit=10
&Offset=0
&StartTime=1517886538
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount": 1,
  "RequestId": "EAF74731-4EBF-456E-AD8B-4067AEF817F6",
  "DdosAnalyses": [{
    "Ip": "x.x.x.x",
    "Items": [
      {
        "Pre": 98.99311157999256,
        "Name": "ack"
      }
    ],
    "Num": 1,
```

```
"Time": "2015-08-06 10:23:55",  
  "AssetType": "HOST"  
}
```

2.16.3.7.7 DescribeDdosFlowDetail

Description

You can call this operation to query DDoS attack traffic details.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDdosFlowDetail.
VmIp	String	Yes	The victim IP address.
Distribution	String	No	The region.
StartTime	String	No	The start time of the time frame specified for query, in timestamp format.
EndTime	String	No	The end time of the time frame specified for query, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Categories	List	The X-axis information. This parameter typically indicates the timeline information in timestamp format.
CategoriesType	String	The type of the timeline, which is milliseconds (ms).
LineBars	List	The DDoS attack traffic information. For more information, see the sample response.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeDdosFlowDetail
&Vmlp=x.x.x.x
&EndDate=1534667456
&StartDate=1534567456
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "213C2229-0133-47E1-A5D5-75D68DC5F02D",
  "Categories": [
    "1520768550000",
    "1520768850000",
    "1520769150000",
    "1520769450000"
  ],
  "CategoriesType": "ms",
  "LineBars": [
    {
      "data": [
        0,
        0,
        0,
        0
      ],
      "name": "Inbound traffic"
    },
    {
      "data": [
        0,
        0,
        0,
        0
      ],
      "name": "Outbound traffic"
    },
    {
      "data": [
        0,
        0,
        0,
        0
      ],
      "name": "QPS"
    }
  ]
}
```

2.16.3.8 Security report operations

2.16.3.8.1 AddReportConfig

Description

You can call this operation to add security report settings.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to AddReportConfig.
Name	String	Yes	The name of the security report.
Description	String	Yes	The description of the security report task.
Type	String	Yes	The type of the report. Valid values : • 1: indicates a daily report. • 2: indicates a weekly report. • 3: indicates a monthly report.
ReportFormat	String	Yes	The format of the security report. Currently, this parameter can only be set to html, which indicates the HTML format.
ReportStatus	Integer	Yes	The status of the report sending feature. Valid values: • 0: indicates disabled. • 1: indicates enabled.
Email	String	Yes	The email address of the report recipient.
Content	String	Yes	The report content.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=AddReportConfig
&Content=aa
&Description=description
&Email=aaa@example.com
&Name=test
&ReportFormat=html
&ReportStatus=0
&Type=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "840C7302-A3CD-48B4-9B5A-7C025A946D0F"
}
```

2.16.3.8.2 DescribeReportConfigs

Description

You can call this operation to query the security report configuration records.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeReportConfigs.
PageSize	String	Yes	The number of records to return on each page.
CurrentPage	String	Yes	The number of the page to return.
Name	String	No	The name of the security report.
Status	Integer	No	The status of the report sending feature. Valid values: 0: indicates disabled. 1: indicates enabled.

Parameter	Type	Required	Description
Type	String	Yes	The type of the report. Valid values : • 1: indicates a daily report. • 2: indicates a weekly report. • 3: indicates a monthly report.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
ReportConfigResults	Array	The security report configuration details. For more information, see the following descriptions.
Content	List	The content of the security report.
DepartmentName	String	The name of the department.
Description	String	The description of the security report configuration.
Email	List	The email addresses of senders.
Format	List	The report formats.
Id	Integer	The ID of the security report configuration list.
Name	String	The name of the security report.
Status	Integer	The status of the report sending feature. Valid values: • 0: indicates disabled. • 1: indicates enabled.
Type	Integer	The type of the report. Valid values: • 1: indicates a daily report. • 2: indicates a weekly report. • 3: indicates a monthly report.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeReportConfigs
&CurrentPage=1
&PageSize=10
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId":"55D22C46-5EA2-481C-9615-B6CE080B5E18",
  "Total":1,
  "ReportConfigResults":[
    {
      "Status":-1,
      "Type":1,
      "Format":[],
      "Description":"",
      "Email":[
        "xx@example.com"
      ],
      "Content":[
        "aaaaa"
      ],
      "DepartmentName":"****",
      "Id":6,
      "Name":""
    }
  ]
}
```

2.16.3.8.3 ModifyReportConfig

Description

You can call this operation to modify the security report configuration information.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyReportConfig.
Id	Integer	Yes	The ID of the security report configuration record.

Parameter	Type	Required	Description
Name	String	Yes	The name of the security report.
Description	String	Yes	The description of the security report task.
Type	String	Yes	The type of the report. Valid values : • 1: indicates a daily report. • 2: indicates a weekly report. • 3: indicates a monthly report.
ReportFormat	String	Yes	The format of the security report. This parameter can be set to html only, which indicates the HTML format.
Status	Integer	Yes	The status of the report sending feature. Valid values: • 0: indicates disabled. • 1: indicates enabled.
Email	String	Yes	The email address of the report recipient.
Content	String	Yes	The report content.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyReportConfig
&Content=test
&Description=test
&Email=test@example.com
&Id=123
&Name=111
&ReportFormat=html
```

```
&Status=0
&Type=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId":"840C7302-A3CD-48B4-9B5A-7C025A946D0F"
}
```

2.16.3.8.4 DeleteReportConfigs

Description

You can call this operation to delete the security report configuration records.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteReportConfigs.
Id	String	Yes	The ID of the security report task.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DeleteReportConfigs
&Id=123321
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"840C7302-A3CD-48B4-9B5A-7C025A946D0F"
}
```

}

2.16.3.9 Threat Detection Service operations

2.16.3.9.1 DescribeTrendCount

Description

You can call this operation to query the number of common and targeted attacks that occurred on the current day and in the last seven days.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTrendCount.
Distribution	String	No	The name of the region.
StartDate	String	Yes	The beginning of the time range to query, in timestamp format.
EndDate	String	Yes	The end of the time range to query, in timestamp format.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TodayCount	Integer	The number of common attacks that occurred on the current day.
TodaySpecialCount	Integer	The number of targeted attacks that occurred on the current day.
TimeScope	Struct	The time range during which the data was queried. For more information, see the following parameter description.
Interval	Integer	The time interval between the query and response.
Start	Long	The beginning of the time range where the data was queried.

Parameter	Type	Description
Items	Array	The list of attack events. For more information, see the following parameter description.
Name	String	The description of the attack event.
Data	List	The number of attack events that occurred every day in the last seven days.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeTrendCount
&EndDate=154451231211
&StartDate=154461231211
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "TodayCount":0,
  "timeScope":{"Interval":86400000,
    "Start":1519920000000
  },
  "Items":[
    {
      "Data":[0,0,0,2,1,437290,0],
      "Name":"Common attack"
    },
    {
      "Data":[0,0,0,0,0,0,0],
      "Name":"Targeted attack"
    }
  ],
  "TodaySpecialCount":0,
  "RequestId":"5A725105-FE73-4D75-A88D-88E559AE452C"
}
```

2.16.3.9.2 DescribeAttackDistribute

Description

You can call this operation to query the chart data of attacks in the last seven days by type.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAttackDistribute.
Distribution	String	No	The name of the region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Pieltems	Array	The list of different types of attacks. For more information, see the following parameter descriptions.
Data	Integer	The number of the specific type of attacks.
Name	String	The name of the attack type.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAttackDistribute
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "D3155ED6-721C-4C40-8509-0E00861E2B5C",
  "Pieltems": [
    {
      "data": 100,
      "name": "Path traversal"
    },
    {
      "data": 0,
      "name": "Trojan script"
    }
  ]
}
```

```
}
```

2.16.3.9.3 DescribeAttackTrend

Description

You can call this operation to obtain the chart data on attack trends in the last seven days.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAttackTrend.
Distribution	String	No	The name of the region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.
TimeScope	Struct	The time frame during which the data is collected and returned. For more information, see the following parameter descriptions.
Interval	Integer	The time length of the time frame during which the data is collected.
Start	Long	The start time of the time frame specified for query.
LineBarItems	Array	The list of attack trends. For more information, see the following parameter descriptions.
Name	String	The description of the attack.
Data	List	The number of attacks on each of the last seven days.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAttackTrend
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "50D070D7-9BE4-45A2-B234-1915ED487186",
  "TimeScope": {
    "Start": 1517846400000,
    "Interval": 86400000
  },
  "LineBarItems": [
    {
      "Data": [
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0
      ],
      "Name": "SQL injection"
    },
    {
      "Data": [
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0
      ],
      "Name": "XSS attack"
    }
  ]
}
```

2.16.3.9.4 DescribeAttackTypeCount

Description

You can call this operation to query the types of all application attacks that meet specified conditions and the number of attacks of each type.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAttackTypeCount.
Distribution	String	No	The region name.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Attacks	Array	The list of attack types and number of attacks of each type. For more information, see the following parameter descriptions.
AttackType	String	The attack type.
AttackTypeDesc	String	The description of the attack type.
Count	Integer	The number of attack events of the attack type.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAttackTypeCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "5A725105-FE73-4D75-A88D-88E559AE452C",
  "Attacks": [
    {
      "AttackTypeDesc": "SQL injection",
      "AttackType": "sql",
      "Count": 0
    },
    {
      "AttackTypeDesc": "XSS attack",
```

```
"AttackType": "xss",  
"Count": 0  
}  
}  
}
```

2.16.3.9.5 DescribeAttackList

Description

You can call this operation to query attacks.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeAttackList.
Distribution	String	No	The name of the region.
Size	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.
AttackType	String	No	The type of the attack.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
AttackList	Array	The attacks. For more information, see the following descriptions.
Id	Integer	The ID of the attack.
Aliuid	Long	The ID of the Alibaba Cloud account.
AssetGroup	String	The name of the asset group.
AttackDate	String	The time when the attack was launched.
AttackType	String	The type of the attack.
AttackTypeDesc	String	The name of the attack type.
Domain	String	The attacked domain name.

Parameter	Type	Description
Method	String	The request method of the attack.
SourceIp	String	The attack source IP address.
SourceLocation	String	The source area where the attack was launched.
URL	String	The victim URL.
VmIp	String	The IP address of the victim server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAttackList
&Size=10
&Start=0
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount": 1,
  "RequestId": "A2A06A09-CB42-4B36-856E-9675CEB8C3C1",
  "ApplicationAttacks": [
    {
      "aliuid": -1,
      "assetGroup": "Default group",
      "attackDate": "2018-02-13 07:56:31",
      "attackType": "path",
      "attackTypeDesc": "Path traversal",
      "distribution": "IDC unspecified",
      "domain": "www.example.com",
      "id": 628370,
      "method": "GET",
      "sourceIp": "192.168.x.x",
      "sourceLocation": "Internal IP address",
      "url": "GET /mypic1/bom.php? dir=./data/bak/HTTP/1.1..Host: www.example.com:445..Referer: -..User-Agent: curl/7.47.0...",
      "vmIp": "10.36.x.x"
    }
  ]
}
```

2.16.3.9.6 DescribeCountByType

Description

You can call this operation to query the number of threat events by type, such as threats to servers, networks, or applications.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeCountByType.
Distribution	String	No	The region name.
StartDate	String	No	The start time of the query, in timestamp format.
EndDate	String	No	The end time of the query, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
ThreatTypes	Array	The list of threat types and number of threats of each type. For more information, see the following parameter descriptions.
Name	String	The threat type, such as threats to servers, networks, or applications.
Count	Integer	The number of threats.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeCountByType
&EndDate=1519886538
&StartDate=1517886538
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "D5B980D1-660D-4265-8E4E-7F7936533E40",
  "Items": [
```

```
{
  "Count":0,
  "Name":"host"
}
```

2.16.3.9.7 DescribeSecurityThreatCount

Description

You can call this operation to query the statistics on security threats.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSecurityThreatCount.
Distribution	String	No	The name of the region.
Status	Integer	No	The status of the threat. Valid values: 0: indicates all threats. 1: indicates ignored threats. Default value: 0.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Categorys	Array	The list of threat types. For more information, see the following parameter descriptions.
Category	Integer	The ID of the threat type.
CategoryName	String	The name of the threat type.
Count	Integer	The number of threats.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeSecurityThreatCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "05BE5EBD-A325-4556-919C-391BF623CDB0",
  "Categories": [
    {
      "Category": 1,
      "CategoryName": "Access from malicious IP addresses",
      "Count": 0
    },
    {
      "Category": 2,
      "CategoryName": "Weak password",
      "Count": 0
    }
  ]
}
```

2.16.3.9.8 DescribeSecurityThreatList

Description

You can call this operation to query threat events.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeSecurityThreatList.
Distribution	String	No	The name of the region.
Size	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.
Category	Integer	No	The ID of the threat event category.

Parameter	Type	Required	Description
Status	Integer	No	The type of threat events to collect . Valid values: • 0: indicates all events. • 1: indicates ignored events. Default value: 0.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
SecurityEvents	Array	The threat events. For more information, see the following descriptions.
Aliuid	Long	The ID of the Alibaba Cloud account.
Asset	String	The name of the asset.
Category	Integer	The ID of the main threat event category.
CategoryName	String	The name of the main threat event category .
Create	String	The time when the record was created.
DestinationIp	String	The destination IP address.
DetailStr	String	The detailed information about the threat event.
Distribution	String	The region.
FirstReportTime	String	The time when the threat event was detected for the first time.
Id	Integer	The primary key ID.
LastReportTime	String	The time when the threat event was last detected.
Modified	String	The time when the record was last modified.
Product	String	The cloud product.

Parameter	Type	Description
Status	Integer	The type of threat events that were collected . Valid values: • 0: indicates all events. • 1: indicates ignored events.
Threat	String	The name of the threat event sub-category.
ThreatType	Integer	The ID of the threat event sub-category.
Uuid	String	The universally unique identifier (UUID) of the asset.
Vmlp	String	The IP address of the asset.
UniqueInfo	String	The identifier that identifies whether the same event is occurring.
Detail	Struct	The detailed information about the threat . For more information, see the following descriptions.
AssetGroup	String	The asset group.
Assets	String	The name of the asset.
Count	Integer	The number of threats.
DepartmentName	String	The name of the department.
Distribution	String	The region.
MaliciousIp	String	The malicious IP address.
Password	String	The weak password.
Protocol	String	The protocol.
SourceIp	String	The source IP address.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

}
```

2.16.3.9.9 DescribeThreatCount

Description

You can call this operation to query the number of common attack events detected during threat analysis, including the total number of Web application attacks and brute-force attacks detected by the traffic security monitoring module.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeThreatCount.
Distribution	String	No	The region name.
StartDate	String	No	The start time of the query, in timestamp format.
EndDate	String	No	The end time of the query, in timestamp format.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
SpecificCount	Integer	The total number of attack events.
SourceIpCount	Integer	The number of attack events after deduplication.
TotalCount	Integer	The total number of records.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DescribeThreatCount
&EndDate=2018-01-01 00:00:00
&StartDate=2018-01-02 00:00:00
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "AECA76BF-1878-43C3-BC23-DDE7CF8D6111",
  "TotalCount": 0,
  "SpecificCount": 0,
  "SourceIpCount": 0
}
```

```
}
```

2.16.3.9.10 DescribeThreatCountByType

Description

You can call this operation to query the number of targeted attacks detected in threat analysis by type.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeThreatCountByType.
Distribution	String	No	The name of the region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Threats	Array	The list of threat events. For more information, see the following parameter descriptions.
Category	Integer	The ID of the threat event type.
CategoryName	String	The name of the threat event type.
Count	Integer	The number of threat events.
Tips	String	The description of the threat event type.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DescribeThreatCountByType
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
```

```

"RequestId":"E0BFC426-5DE0-4834-97AF-1CE609638623",
"Threats":[
{
"Category":"WEB_SPEC",
"CategoryName":"Targeted Web attack",
"Count":0,
"Tips":"We have detected a Web attack that was targeted at you. This indicates that
attackers are more interested in your website than others'. They have performed
malicious operations such as SQL injections, command execution, and directory
scanning."
},
{
"Category":"PORT_SPEC",
"CategoryName":"Brute-force password cracking against a targeted server",
"Count":0,
"Tips":"We have detected a brute-force attack that attempts to crack your logon
password. Attackers usually attempt to crack the passwords of random servers. This
targeted attack implies that your asset is targeted by the attacker."
}
]
}

```

2.16.3.9.11 DescribeThreatTop

Description

You can call this operation to query attack and threat events in the last seven days.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeThreatTop.
Distribution	String	No	The name of the region.
Limit	Integer	Yes	The number of records to return.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Threats	Array	The attack and threat events. For more information, see the following descriptions.
Category	String	The type of the event.
Title	String	The event description.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeThreatTop
&Limit=2
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "DC128D02-B262-4ACF-B233-69F50394C6C1",
  "Threats": [ {
    "title": "Web application attack against the IP address 192.168.xx.xx. Attack type
: path traversal",
    "category": "ATTACK"
  },
  {
    "title": "Web application attack against the IP address 192.168.xx.xx. Attack type
: path traversal",
    "category": "ATTACK"
  }
]
```

2.16.3.9.12 DescribeThreatAnalyseList

Description

You can call this operation to query threat events in threat analysis.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeThreatAnalyseList.
Distribution	String	No	The name of the region.
Limit	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.
Category	String	No	The category of the threat events.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
ThreatAnalyseResults	Array	The threat events. For more information, see the following descriptions.
Aliuid	Long	The ID of the Alibaba Cloud account.
Category	Integer	The ID of the main threat event category.
CategoryName	String	The name of the main threat event category.
Count	Integer	The number that indicates how many times the attack event has occurred.
StartTime	String	The time when the attack event occurred for the first time.
EndTime	String	The time when the attack event last occurred.
Id	Integer	The primary key ID.
SourceIp	String	The IP address of the attacker.
SourceLocation	String	The source area where the attack was launched.
Service	String	The cloud product.
Status	Integer	Indicates whether the threat has been blocked. Valid values: 0: indicates that the attack has not been blocked. 1: indicates that the attack has been blocked.
ThreatRate	String	The threat level.
Detail	Struct	The detailed asset information. For more information, see the following descriptions.
Assets	Array	The detailed asset information. For more information, see the following descriptions.
AssetGroup	String	The asset group.
DepartmentName	String	The name of the department.

Parameter	Type	Description
Distribution	String	The region.
HostName	String	The custom name of the asset.
Ip	String	The IP address of the asset.
Service	String	The type of the cloud product, such as RDS, ECS, or SLB.
Info	Array	The detailed attack information. For more information, see the following descriptions.
Label	String	The tag of the threat.
LinkText	String	The hyperlink of the threat details.
Type	String	The type of the threat details. Valid values: • 0: indicates the text type. • 1: indicates the hyperlink type.
Value	String	The threat details.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeThreatAnalyseList
&Limit=5
&Start=0
&Category=SCANNER
&<Common request parameters>
```

- Sample response (JSON format)

```

  "status": 1,
  "threatRate": "0.4"
}
]
}

```

2.16.3.9.13 DescribeHighRiskAssets

Description

You can call this operation to query high-risk assets.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeHighRiskAssets.
Limit	Integer	Yes	The number of records to return.
Distribution	String	No	The region.
StartDate	String	No	The beginning of the time range where data is queried, in timestamp format.

Parameter	Type	Required	Description
EndDate	String	No	The end of the time range where data is queried, in timestamp format.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
HighRiskAssets	Array	The high-risk assets. For more information, see the following descriptions.
AssetGroup	String	The name of the asset group.
Distribution	String	The region.
HostName	String	The custom name of the asset.
NormalAttack	Integer	The number of normal attacks that the asset has received.
Special_attack	Integer	The number of targeted attacks that the asset has received.
Service	String	The asset type, such as RDS, SLB, or ECS.
Score	Integer	The risk score.
VmIp	String	The IP address of the asset.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeHighRiskAssets
&EndDate=1519886538
&Limit=10
&StartDate=1519886538
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "RequestId":"FDE94E23-5553-447E-818C-BBE7C2EB7250",
  "HighRiskAssets":[
    {
```

```

    "VmIp": "192.168.xx.xx",
    "Normal_attack": 12,
    "Special_attack": 12,
    "Score": 12,
    "Asset_group": "aaa",
    "Distribution": "aaa",
    "Product": "",
    "HostName": ""
  }
}

```

2.16.3.10 Asset management operations

2.16.3.10.1 DescribeDistributionByCodeType

Description

You can call this operation to query the information about all regions in Apsara Stack.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDistributionByCodeType.
CodeType	String	No	The code type. A value of distribution indicates the region.
Code	String	No	The region code.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CodeNames	Array	The list of regions. For more information, see the following parameter descriptions.
CodeType	String	The code type. A value of distribution indicates the region.
Code	String	The region code.
CodeName	String	The region name.
Description	String	The region description.

Name	Type	Description
GmtCreate	Long	The creation time.
GmtModified	Long	The last modification time.
Id	Integer	The region ID.
Seq	Integer	The sequence number.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeDistributionByCodeType
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "1819325E-D09A-494B-BE9C-366E9996A974",
  "CodeNames": [
    {
      "GmtCreate": 1463367238000,
      "Description": "Hybrid cloud IDC list",
      "CodeName": "Daxing IDC",
      "GmtModified": 1463367238000,
      "CodeType": "distribution",
      "Id": 17,
      "Code": "am1",
      "Seq": 1
    }
  ]
}
```

2.16.3.10.2 DescribeSystemByCodeType

Description

You can call this operation to query the information about all operating system versions used in Apsara Stack.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSystemByCodeType.
CodeType	String	No	The code type. The value platform_type indicates the operating system version.
Code	String	No	The code of the operating system version.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CodeNames	Array	The list of operating system versions. For more information, see the following parameter descriptions.
CodeType	String	The code type. The value platform_type indicates the operating system version.
Code	String	The code of the operating system version.
CodeName	String	The name of the operating system version.
Description	String	The description of the operating system version.
GmtCreate	Long	The creation time.
GmtModified	Long	The last modification time.
Id	Integer	The primary key ID.
Seq	Integer	The sequence number.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeSystemByCodeType
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "0391CA5F-CFEF-49F6-A2A9-D425E94397B9",
  "CodeNames": [
    {
      "GmtCreate": 1463453433000,
      "Description": "Operating system type",
      "CodeName": "Windows",
      "GmtModified": 1463453433000,
      "CodeType": "platform_type",
      "Id": 22,
      "Code": "1",
      "Seq": 2
    }
  ]
}
```

2.16.3.10.3 DescribeAssetGroup

Description

You can call this operation to query asset group details in Apsara Stack.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAssetGroup.
Distribution	String	No	The region name.
Type	String	No	The asset type, such as RDS, SLB, or ECS.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Name	Type	Description
AssetsGroups	Array	A list of asset group. For more information, see the following parameter descriptions.
Id	Integer	The ID of the asset group record.
GroupId	Integer	The ID of the asset group.
GroupName	String	The name of the asset group.
Group	String	The name of the asset group.
GroupIndex	Integer	The sequence number of the asset group.
Name	String	The name of the asset group.
GroupFlag	Integer	The asset group flag. Valid values: 0: indicates a default asset group. 1: indicates a custom asset group.
Count	Integer	The number of assets in the asset group.
Data	Integer	The number of assets in the asset group.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAssetGroup
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "FA5D7665-7B3D-4776-88FF-EC2F7597AE7D",
  "AssetsGroups": [
    {
      "GroupName": "Default asset group",
      "Group": "Default asset group",
      "GroupIndex": 1,
      "Data": { "Data ": {
        "count": 0,
        "id": 1,
        "GroupFlag": 0,
        "Name": "Default asset group",
        "GroupId": {
        }
      }
    }
  ]
}
```

```
}
```

2.16.3.10.4 CreateNatAsset

Description

You can call this operation to add an NAT asset.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateNatAsset.
GroupId	String	Yes	The ID of the asset group.
Group	String	Yes	The name of the asset group.
Distribution	String	No	The region.
VmIp	String	Yes	The IP address of the NAT asset.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=CreateNatAsset
&Group=Default group
&GroupId=17
&VmIp=x.x.x.x
&Distribution=cn-hangzhou-dg-a01
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "840C7302-A3CD-48B4-9B5A-7C025A946D0F"
```

```
}
```

2.16.3.10.5 ModifyRegion

Description

You can call this operation to modify the home region of an asset.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyRegion.
AssetType	String	Yes	The name of the asset, such as the server name.
Data	String	No	The Classless Inter-Domain Routing (CIDR) block information of the asset.
Distribution	String	No	The name of the region.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyRegion
&AssetType=Server name
&Data=192.168.xx.xx/25
&Distribution=cn-hangzhou-env6-d01
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "84A27393-D0E6-4AC3-8712-478D2129CD06"
```

}

2.16.3.10.6 ModifyAssetGroup

Description

You can call this operation to modify asset group information.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAssetGroup.
SasGroupRequestList.N.Flag	Integer	No	The type of change that you want to make. Valid values: -1: deletes an asset group. 0: does not make any changes. 1: adds an asset group.
SasGroupRequestList.N.GroupFlag	Integer	No	The asset group flag. Valid values: 0: indicates a default asset group. 1: indicates a custom asset group.
SasGroupRequestList.N.GroupId	Integer	No	The ID of the asset group.
SasGroupRequestList.N.GroupIndex	Integer	No	The sequence number of the asset group.
SasGroupRequestList.N.GroupName	String	No	The name of the asset group.
SasGroupRequestList.N.Id	Long	No	The asset group record ID.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=ModifyAssetGroup
&SasGroupRequestList.1.Flag=-1
&SasGroupRequestList.1.GroupFlag=1
&SasGroupRequestList.1.GroupId=1
&SasGroupRequestList.1.GroupIndex=1
&SasGroupRequestList.1.GroupName=test
&SasGroupRequestList.1.Id=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "65ED9921-1A37-4362-9051-F467AF58CB69"
}
```

2.16.3.10.7 ModifyGroup

Description

You can call this operation to modify the home group of an asset.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyGroup.
AssetType	String	Yes	The name of the asset, such as the server name.
Data	String	No	The Classless Inter-Domain Routing (CIDR) block information of the asset.
Group	String	Yes	The name of the asset group.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyGroup
&AssetType=Server name
&Data=192.168.xx.xx/25
&Group=Default group
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "84A27393-D0E6-4AC3-8712-478D2129CD06"
}
```

2.16.3.10.8 ModifyAsset

Description

You can call this operation to modify asset information.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAsset.
Id	String	Yes	The ID of the asset record.
GroupId	String	No	The ID of the asset group.
Distribution	String	No	The name of the region.
Group	String	No	The name of the asset group.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyAsset
&Group=Default group
&GroupId=17
&Id=123
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "84A27393-D0E6-4AC3-8712-478D2129CD06"
}
```

2.16.3.10.9 DescribeTotalAssetNumber

Description

You can call this operation to query the total number of assets.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTotalAssetNumber.
Distribution	String	No	The name of the region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Name	Type	Description
TotalAssetNumber	Array	The list of assets. For more information, see the following parameter descriptions.
Count	Integer	The total number of assets.
HostCount	Integer	The total number of servers.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeTotalAssetNumber
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "76842928-BB88-4007-8F27-23E17250AC6E",
  "TotalAssetNumber": {
    "HostCount": 0,
    "Count": 0
  }
}
```

2.16.3.10.10 DescribeAllDistribution

Description

You can call this operation to query the percentages of assets in different regions in Apsara Stack.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAllDistribution.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
RegionDatas	Array	The percentages of assets in different regions. For more information, see the following parameter descriptions.
Name	String	The name of the region.
Data	String	The percentage of the assets in the region.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAllDistribution
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "DE2595A0-AC52-47F1-84D9-D3383E933AD4",
  "RegionDatas": [
    {
      "name": "Unknown",
      "data": 44.21
    },
    {
      "name": "cn-hangzhou-env6-d01",
      "data": 55.79
    }
  ]
}
```

2.16.3.10.11 DescribeAssetsList

Description

You can call this operation to query assets.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeAssetsList.
Size	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.
Distribution	String	No	The name of the region.
GroupName	String	No	The name of the asset group.
Platform	String	No	The operating system of the asset.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
SasAssets	Array	The assets. For more information, see the following descriptions.
ActiveTime	String	The time when the asset was enabled.
AegisStatus	Integer	The status of Server Guard on the asset.
Aliuid	String	The ID of the Alibaba Cloud account.
AssetType	String	The type of the asset, such as RDS, SLB, or ECS.
DataSource	Integer	The data source. Valid values: 1: indicates Server Guard. 2: indicates a custom data source. 3: indicates a cloud platform. 4: indicates Apsara Stack Security.
DepartmentName	String	The name of the department.
Distribution	String	The name of the region.
Event	Integer	The number of security events.

Parameter	Type	Description
GmtCreate	String	The time when the asset record was created .
GmtModified	String	The time when the asset record was last modified.
Group	String	The name of the asset group.
GroupId	Integer	The ID of the asset group.
HostName	String	The custom name of the asset.
Id	Integer	The ID of the asset record.
Platform	String	The operating system.
Region	String	The name of the region.
Software	List	The application information.
Status	Integer	The status of the asset. Valid values: 0: indicates that the asset is disabled. 1: indicates that the asset is enabled.
Threat	Integer	The number of threat events.
Uuid	String	The universally unique identifier (UUID) of the asset.
VmIp	String	The IP address of the asset.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAssetsList
&GroupName=1
&Platform=Linux/CentOS release 6.8 (Final)/null
&Size=10
&Start=0
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount": 0,
  "RequestId": "B78FD9E9-3ED5-4D8D-A716-F2F482BCBD4F",
  "SasAssets": [{

}
}
```

2.16.3.10.12 DescribeUuidIpList

Description

You can call this operation to query the IP address of a specified asset based on the universally unique identifier (UUID) of the asset.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeUuidIpList.
Uuid	Integer	Yes	The UUID of the asset.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
IPs	String	The IP address of the asset.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeUidIpList
&Uid=121asdf4545ads****
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "737E5F87-6892-4711-BF00-BEBD0B2E1E03",
  "Ips": "192.168.xx.xx"
}
```

2.16.3.10.13 DescribeIpList

Description

You can call this operation to obtain a list of asset IP addresses based on keywords.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeIpList.
Size	Integer	Yes	The number of returned records.
Keyword	String	No	The query keyword.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
IPs	List	The IP address list.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeIpList
&Size=1
```

```
&Keyword=0  
&<Common request parameters>
```

- Sample responses (JSON format)

```
{  
  "RequestId":"F3A98AE4-BC02-421A-854E-198837ACEDF9",  
  "IPs":["x.x.x.x"]  
}
```

2.16.3.10.14 DescribePortList

Description

You can call this operation to query ports of the server with a specified IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePortList.
Limit	Integer	Yes	The number of records to return.
Start	Integer	Yes	The position of the first record to return.
Ip	String	Yes	The IP address.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
HostPorts	Array	The ports. For more information, see the following descriptions.
FirstDetectTime	Long	The time when the port was detected for the first time.
LastDetectTime	Long	The time when the port was last detected.
Port	Integer	The port number.
Protocol	String	The protocol.
Service	String	The service provided by the port.

Parameter	Type	Description
TodayVul	Integer	The number of ports enabled on the current day.
Version	String	The name and version of the application.
YesterdayVul	Integer	The number of ports enabled on the last day.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribePortList
&Ip=192.168.xx.xx
&Limit=5
&Start=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":0,
  "RequestId":"7F25EA4D-ABC4-47C6-8134-B23230E3BF67",
  "HostPorts":[
    {
      "firstDetectTime": 1519713424712,
      "lastDetectTime": 1519713424712,
      "port": 11,
      "protocol": "ftp",
      "service": "test",
      "status": 0,
      "todayVul": 0,
      "version": "1",
      "yesterdayVul": 0
    }
  ]
}
```

2.16.3.10.15 DescribeThisMonthAssets

Description

You can call this operation to query the number of new assets added in the last 30 days.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeThisMonthAssets.
Distribution	String	No	The name of the region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The number of new assets.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeThisMonthAssets
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "E1668C9C-1301-4F93-9C20-8886A1A66A33",
  "Count": 0
}
```

2.16.3.10.16 DescribeAssetsTotalCount

Description

You can call this operation to query the chart data on the total number of assets in the last seven days.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAs setsTotalCount.
Distribution	String	No	The name of the region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TimeScope	Struct	The time frame during which the data is collected and returned. For more information, see the following parameter descriptions.
Interval	Integer	The time length of the time frame during which the data is collected.
Start	Long	The start time of the time frame during which the data is collected.
LineBars	Array	The asset quantity statistics. For more information, see the following parameter descriptions.
Name	String	The type of the asset, such as server or NAT.
Data	List	The total number of assets.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAssetsTotalCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "9954A060-03F4-4C3C-BCE0-F761F4330E30",
  "LineBars": [
```

```
{
  "data": [
    487,
    690
  ],
  "name": "Server"
},
{
  "data": [
    91,
    91
  ],
  "name": "NAT"
}
],
"TimeScope": {
}
```

2.16.3.10.17 DeleteAsset

Description

You can call this operation to delete asset information.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteAsset.
Uuid	String	Yes	The asset UUID.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[RegionId].example.com/?Action=DeleteAsset
&Uuid=d6613b93-1219-41d7-9d21-5c9a5b96d97e
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "RequestId": "840C7302-A3CD-48B4-9B5A-7C025A946D0F"
}
```

2.16.3.11 Alerting setting operations

2.16.3.11.1 CreateContact

Description

You can call this operation to add an alert contact.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateContact.
Id	Long	No	The ID of the alert contact.
Name	String	Yes	The name of the alert contact.
Email	String	Yes	The email address of the alert contact.
Mp	String	Yes	The mobile number of the alert contact.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=CreateContact
&Email=someone@example.com
```

```
&Mp=1300000****  
&Name=<yourName>  
&Id=123  
&<Common request parameters>
```

- Sample response (JSON format)

```
{  
  "RequestId": "840C7302-A3CD-48B4-9B5A-7C025A946D0F"  
}
```

2.16.3.11.2 DescribeContactsList

Description

You can call this operation to query alert contacts.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeContactsList.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of records.
ContactsList	Array	The alert contacts. For more information, see the following descriptions.
Email	String	The email address of the alert contact.
Id	Integer	The ID of the alert contact.
Mp	String	The mobile number of the alert contact.
Name	String	The name of the alert contact.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeContactsList
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "D47D0CE4-B0FB-450D-B4B6-DB99824ADA0E",
  "Total": 5,
  "ContactsList": [
    {
      "mp": "1300000****",
      "name": "test",
      "id": 3,
      "email": "someone1@example.com"
    },
    {
      "mp": "1500000****",
      "name": "test",
      "id": 4,
      "email": "someone2@example.com"
    }
  ]
}
```

2.16.3.11.3 ModifyContact

Description

You can call this operation to modify alert contacts.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyContact.
Id	Integer	Yes	The ID of the alert contact.
Email	String	Yes	The email address of the alert contact.
Mp	String	Yes	The mobile number of the alert contact.
Name	String	Yes	The name of the alert contact.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyContact
&Email=someone@example.com
&Id=123
&Mp=1300000****
&Name=John Smith
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "D47D0CE4-B0FB-450D-B4B6-DB99824ADA0E",
}
```

2.16.3.11.4 DeleteContact

Description

You can call this operation to delete an alert recipient.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteContact.
Id	Long	Yes	The ID of the alert recipient.
Name	String	No	The name of the alert recipient.
Email	String	No	The email address of the alert recipient.
Mp	String	No	The mobile number of the alert recipient.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DeleteContact
&Id=123
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "840C7302-A3CD-48B4-9B5A-7C025A946D0F"
}
```

2.16.3.11.5 DescribeAlarmConfig

Description

You can call this operation to query the alert settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAlarmConfig.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of records.

Name	Type	Description
AlarmConfigs	Array	The alert configuration information. For more information, see the following parameter descriptions.
Id	Integer	The alert configuration record ID.
Category	Integer	The alert type. Valid values: 1: indicates a security event. 2: indicates a security threat.
Email	Boolean	Indicates whether to send a notification to the recipient's email address.
Mp	Boolean	Indicates whether to send a notification to the recipient's mobile phone.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeAlarmConfig
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "49A3041D-4FEC-42E5-9AE4-A2E5AD57CFDB",
  "Total": 18,
  "AlarmConfigs": [
    {
      "mp": true,
      "id": 1,
      "category": 1,
      "email": true
    },
    {
      "mp": true,
      "id": 2,
      "category": 1,
      "email": true
    }
  ]
}
```

```
}
```

2.16.3.11.6 ModifyAlarmConfig

Description

You can call this operation to modify alert settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAlarmConfig.
Config	Struct	Yes	The modified alert settings in JSON format. For more information, see the following parameter descriptions.
Id	Integer	Yes	The alert setting record ID.
Title	String	Yes	The name of the alert.
Category	Integer	Yes	The type of the alert. Valid values: 1: indicates a security event. 2: indicates a threat.
Mp	Boolean	Yes	Indicates whether to send SMS notifications to alert the recipients.
Email	Boolean	Yes	Indicates whether to send emails to alert the recipients.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=ModifyAlarmConfig
&Config=[{"id":20,"title":"Logon security - remote logon","category":2,"mp":true,"email":true}, {"id":1,"title":"Website tampering","category":1,"mp":true,"email":true}, {"id":2,"title":"Bot behavior","category":1}]
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "49A3041D-4FEC-42E5-9AE4-A2E5AD57CFDB",
  "Total": 18,
  "AlarmConfigs": [
    {
      "mp": true,
      "id": 1,
      "category": 1,
      "email": true
    },
    {
      "mp": true,
      "id": 2,
      "category": 1,
      "email": true
    }
  ]
}
```

2.16.3.11.7 DescribeReadStatus

Description

You can call this operation to query the number of unread alert messages.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeReadStatus.
Distribution	String	No	The region.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Name	Type	Description
ReadStatus	Array	The information about unread alert messages. For more information, see the following parameter descriptions.
Type	String	The type of the unread alert message.
UnReadCount	Integer	The number of unread alert messages.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://sasprivate.[ RegionId].example.com/?Action=DescribeReadStatus
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "CFB09A1B-2653-40F7-A2E8-77C65D9C9732",
  "ReadStatus": [
    {
      "Type": "SECURITY_EVENT",
      "UnReadCount": 0
    },
    {
      "Type": "APPLICATION_VULNERABILITY",
      "UnReadCount": 0
    }
  ]
}
```

2.16.4 Server Guard

2.16.4.1 List of operations

This topic introduces all the Server Guard operations that you can call. For more information, see the corresponding operation description.

Asset management operations

Operation	Description
CreateGroup	Creates an asset group.
DescribeGroupSummary	Obtains a list of asset groups.
DescribeGroupStruct	Queries the structure of an asset group.

Operation	Description
DeleteGroup	Deletes an asset group.
DescribeAllTag	Queries the tag information of all servers.
DescribeBetachTag	Queries the tag information of a specified server.
ModifyBetachTag	Modifies the tags of multiple specified servers.
DeleteTag	Deletes the tag of a server.
DescribeAllEntity	Queries information about all servers.
DescribeEntityList	Queries a type of servers.
ModifyEntityGroup	Modifies the asset group information for a specified server.
DescribeMachines	Queries servers that match the specified criteria.
DescribeMachineDetail	Queries the detailed information about the specified server.
DescribePropertyScheduleConfig	Queries the update cycle of server information.
ModifyPropertyScheduleConfig	Modifies the synchronization cycle of host asset information.
DescribePropertyStatistic	Queries server statistics.
DescribePropertyPortItem	Obtains a list of listener ports on servers.
DescribePropertyPortDetail	Queries detailed listening port information.
DescribePropertyPortDiff	Queries listening port changes.
DescribePropertyProcItem	Obtains a list of server processes.
DescribePropertyProcDetail	Queries server process details.
DescribePropertyProcDiff	Queries process changes of servers.
DescribePropertySoftwareItem	Queries servers that have been installed with the specified application.
DescribePropertySoftwareDetail	Obtains the details of application software installed on a server.
DescribePropertySoftwareDiff	Queries changes of applications that have been installed on servers.
DescribePropertyUserItem	Queries user account information.
DescribePropertyUserDetail	Queries user account details.
DescribePropertyUserDiff	Queries user account changes.

Operation	Description
PushAllTask	Performs a quick security check on specified servers.
DescribeTopRiskyAssets	Obtains a list of top N vulnerable servers.
UnbindAegis	Disables Server Guard for a specified server.
UninstallAegis	Uninstalls the Server Guard client from a specified server.

Vulnerability management operations

Operation	Description
DescribeTarget	Queries the servers that are checked for the specified type of risks in vulnerability management.
ModifyVulTarget	Modifies the servers for detecting a specified type of vulnerability in the vulnerability management settings.
DescribeVulTargetStatistics	Queries the information about target hosts for which vulnerability detection is enabled in the vulnerability management configuration.
DescribeTargetConfig	Queries the vulnerability scanning configuration information of a specified server.
ModifyTargetConfig	Modifies the vulnerability scanning configuration for a specified server.
DescribeVulConfig	Queries the global scanning configuration for each vulnerability type.
ModifyVulConfig	Modifies the global vulnerability scanning configuration.
DescribeAutoDelConfig	Queries the number of days that an invalid vulnerability is kept for before it is automatically deleted in the vulnerability management settings.
ModifyAutoDelConfig	Modifies the number of days that an invalid vulnerability is kept for before it is automatically deleted in the vulnerability management settings.
DescribeVulLevel	Queries the vulnerability severities that require attention.

Operation	Description
ModifyVulLevel	Changes the vulnerability severities that require attention.
CreateVulWhitelist	Adds a specified vulnerability to the whitelist.
DescribeVulWhitelist	Obtains the whitelist of vulnerabilities.
DeleteVulWhitelist	Deletes a specified vulnerability from the vulnerability whitelist.
DescribeGroupedVul	Queries information about the specified vulnerability group.
DescribeVulList	Obtains a list of application vulnerabilities.
DescribeVulDetails	Queries detailed information about a vulnerability.
DescribeVulNumStatistics	Queries vulnerability statistics.
DescribeVulLevelStatistics	Obtains the statistics on vulnerabilities by vulnerability severity.
DescribeVulMachineList	Queries the vulnerability statistics of a specified server.
OperateVul	Handles detected vulnerabilities.
ModifyBatchIgnoreVul	Ignores multiple vulnerabilities.
DeleteVulBatch	Deletes a specified batch of vulnerabilities.
ExportVul	Exports vulnerability records that match the specified criteria.
DescribeVulExportInfo	Queries the information about vulnerability record export tasks.

Baseline check operations

Operation	Description
DescribeStrategy	Obtains a list of baseline check policies.
DescribeStrategyDetail	Queries the details of a specified baseline check policy.
ModifyStrategy	Modifies the basic information of a baseline check policy.
DeleteStrategy	Deletes a specified baseline check policy.

Operation	Description
DescribeStrategyTarget	Queries the information about asset groups to which a specified baseline check policy applies.
ModifyStrategyTarget	Modifies the information about the asset groups that a specified baseline check policy applies to.
DescribeUuidConfig	Checks whether baseline check is enabled for a specified server.
ModifyMachineConfig	Configures whether to apply a specified baseline check policy to a specified server.
DescribeUserSetting	Queries the number of days an invalid risk is kept for before it is automatically deleted in baseline check.
CreateUserSetting	Specifies the number of days an invalid risk is kept for before it is automatically deleted in baseline check.
DescribeRiskWhiteList	Obtains the whitelist of risk items that are exempt from the baseline check.
BatchDeleteWhiteList	Deletes multiple risks from the whitelist for baseline check.
CreateUserWhiteList	Adds a specified risk to the baseline check whitelist.
DescribeStratety	Queries the execution details of a specified baseline check policy.
DescribeStrategyExecDetail	Queries the execution details of a baseline check policy.
DescribeRiskType	Queries all types of risks detected in baseline check and view the number of risks that have been detected by a baseline check policy or on the specified servers for a specific risk type.
Describesummary	Queries the risks detected in baseline check by risk type.
OperateWarning	Handles the risk alert records detected during the baseline check.
ExportWarning	Exports risks that match the specified criteria from baseline check.

Operation	Description
DescribeExportInfo	Queries export task information, including the export progress and the download link of the exported file.

Unusual logon detection operations

Operation	Description
DescribeBaseConfigs	Queries the logon security settings.
ModifyBaseConfig	Modifies logon security settings.
DeleteBaseConfig	Deletes a logon security setting, such as an approved logon location or IP address.
DescribeSwitchConfigs	Queries the logon security configuration records in the logon security settings.
ModifySwitchConfig	Modifies the setting about whether to enable a logon security configuration record to identify a valid logon to a host in the logon security settings.
DescribeConfigTarget	Queries the information about host assets to which a specified logon security configuration record applies.

Webshell detection operations

Operation	Description
DescribeWebPath	Queries the Web directories defined in webshell settings.
ModifyWebPath	Modifies the Web directory in webshell settings.
DescribeCategoryCount	Queries the number of webshells detected by Server Guard.
DescribeWebshell	Queries records of webshell files that have been detected by Server Guard, including the detection time and webshell file path.
OperateTrojan	Handles the detected webshells.
DescribeQuaraFile	Obtains a list of quarantined files.
RollbackQuaraFile	Restores a quarantined file.

Suspicious server detection operations

Operation	Description
DescribeSuspEventTypes	Queries the unusual event types.
DescribeSuspTrendStatistics	Queries the chart data on different types of unusual server events on each day.
OperateSuspiciousEvent	Handles detected unusual events.
OperateLoginLog	Labels a detected unusual logon event as handled.
CreateSuspiciousExport	Exports the information about server unusual events based on search conditions.
DescribeSuspiciousExportInfo	Queries an unusual event export task.

Server log retrieval operations

Operation	Description
CreateLogQuery	Creates or saves server log search conditions.
DescribeLogQuery	Queries the saved server log search conditions.
DeleteLogQuery	Deletes the saved server log search conditions.
DescribeFilterFields	Queries the filter fields of a specified server log search condition.
DescribeHistogram	Obtains the statistics on server logs generated within a specified time frame.
DescribeLogInfo	Queries the host log fields based on specified query conditions.
DescribeLogItems	Queries the server log details that are returned by a query.

2.16.4.2 Make API requests

2.16.4.2.1 Request structure

Apsara Stack Security API is based on Remote Procedure Call (RPC). This topic describes the structure of the API requests.

Description

You can send an HTTP request to call an API operation. The URL of the request must be in the following format:

```
http://endpoint/?Action=xx&parameters
```

Where:

- **endpoint**: the endpoint used to call a cloud service. The endpoint for the Server Guard service is `aegis.[ RegionId].example.com`.
- **Action**: the operation that you want to perform.

For example, you can set this parameter to **DescribeFeatures** to query the deployed Apsara Stack Security features.

- **parameters**: the request parameters. Request parameters include common request parameters and custom request parameters. Request parameters must be separated with ampersands (&).
 - Common request parameters include information such as the API version and authentication information.
 - For more information about the custom request parameters, see the corresponding operation description.

Example

Call the **DescribeFeatures** operation to query the deployed Apsara Stack Security features.

```
https://yundunprivate.[ RegionId].example.com/?Action=DescribeFeatures&AccessKeyId=key-test&Format=JSON&SecureTransport=true&SignatureMethod=HMAC-SHA1&SignatureNonce=15215528852396&SignatureVersion=1.0&SourceIp=1xxx6&Timestamp=2018-03-02Txxxxxx&Version=2018-01-16&Signature=xxxx%xxxx%3D
```

API requests are presented in the following easy-to-read format in this document:

```
https://yundunprivate.[ RegionId].example.com/?Action=DescribeFeatures
&Format=JSON
&Version=2018-01-16
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
```

```
&Timestamp=2012-06-01T12:00:00Z
```

2.16.4.2.2 Signature mechanism

Apsara Stack Security authenticates each access request. You need to include a signature for the submitted HTTP or HTTPS request.

API authorization

To ensure the security of your account, we recommend that you use a Resource Access Management (RAM) user to call API operations. Before using a RAM user to call an API operation, you must grant the RAM user the corresponding permission to call the API by creating an authorization policy and attaching the policy to the RAM user.

API signature

To ensure secure calls to the API, Alibaba Cloud authenticates each API request through the signature. When you manually make an API request, you need to use AccessKey Secret to calculate the signature, that is, the hash-based message authentication code (HMAC) value, based on the encoded and sorted request string. For more information, see the definition in [RFC 2104](#).

This topic uses the raw access parameters in the following table to describe how to create an API signature.

Parameter	Description
Access point	http://yundunprivate.[RegionId].example.com/?
API-specific parameters	Action=DescribeFeatures
Common parameters (excluding the Signature parameter)	<pre>&Timestamp=2016-02-23T12:46:24Z &Format=JSON &AccessKeyId=<yourAccessKeyId> &SignatureMethod=HMAC-SHA1 &SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf &Version=2018-01-16 &SignatureVersion=1.0</pre>
AccessKey secret	<yourAccessKeySecret>

1. Use the request parameters to construct a canonicalized query string.

Note:

The request parameters include common request parameters (excluding the Signature parameter) and API-specific parameters.

a. Sort the parameters.

Sort the request parameters in alphabetical order.

b. Encode the parameters.

Use UTF-8 to URL-encode the parameter names and values. The encoding rules are as follows:

- Letters, digits, hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
- Other characters are encoded in the %XY format, where XY is the hexadecimal representation of the character in ASCII. For example, the double quotation mark (") is encoded as %22.
- Extended UTF-8 characters are encoded in the %XY%ZA... format.
- Note that a space is encoded as %20, instead of a plus sign (+).

c. Connect the encoded parameter names and values with equal signs (=).

d. Then, sort the parameter name and value pairs connected by equal signs in alphabetical order, and connect them with ampersands (&) to produce the canonicalized query string.

2. Use the canonicalized query string to construct the string for signature calculation based on the following rules:

```
StringToSign=HTTPMethod + "&" + percentEncode( "/" ) + "&" +
percentEncode(CanonicalizedQueryString)
```

3. Calculate the HMAC value of the StringToSign string according to the definition in [RFC 2104](#).

Note:

The key used for signature calculation is your AccessKey secret adding the ampersand (&) (ASCII 38). Secure Hash Algorithm 1 (SHA1) is used as the hash algorithm.

4. Encode the preceding HMAC value into a string based on Base64 encoding rules to obtain the signature value.

```
LEW8N4y7Uasop*****
```

5. Set the Signature parameter in the request parameters to this signature value to sign the request.

2.16.4.2.3 Common request parameters

The following table describes the common request parameters that are used to indicate information such as the API version and authentication information.

Name	Type	Required	Description
Version	String	Yes	The API version in the format of YYYY-MM-DD. Set the value to 2016-11-11.
AccessKeyId	String	Yes	The key ID that Alibaba Cloud assigns to a user for service access .
Signature	String	Yes	The signature string.
SignatureMethod	String	Yes	The signature method. Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Follow the ISO 8601 standard to specify the date and use the offset from Coordinated Universal Time (UTC) to specify the time zone. The format is YYYY-MM-DDThh:mm:ssZ. For example, 2014-05-26T12:00:00Z indicates 20:00:00 on May 26, 2014, Beijing time.
SignatureVersion	String	Yes	The signature algorithm version. Set the value to 1.0.
SignatureNonce	String	Yes	The unique random number used to prevent network replay attacks . You must use different random numbers for different requests.
ResourceOwnerAccount	String	No	The owner account of the resource to be accessed through this API request, that is, the logon username.

Name	Type	Required	Description
Format	String	No	The format of the response. Set the value to JSON or XML.  Note: Default value: XML.

2.16.4.2.4 Response structure

Apsara Stack Security API responses support both the XML and JSON formats. The system always returns a unique identification code **RequestId** each time you send a request to call an operation, no matter whether the call is successful or not.

Sample responses (XML format)

```
<? xml version="1.0" encoding="UTF-8"? >
<!-- The root node of the result -->
<Operation name+Response>
  <!-- Returned request ID -->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!-- Returned data -->
</Operation name+Response>
```

Sample responses (JSON format)

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /* Returned data */
}
```

2.16.4.3 Asset management operations

2.16.4.3.1 CreateGroup

Description

You can call this operation to create an asset group.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateGroup.
GroupFather	Long	Yes	The parent asset group ID.

Name	Type	Required	Description
GroupFlag	Integer	Yes	The asset group type. Valid values: 0: indicates a default group. 1: indicates a custom group.
GroupIndex	Integer	Yes	The sequence number of the asset group.
GroupName	String	Yes	The name of the asset group.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=CreateGroup
&GroupFather=0
&GroupFlag=1
&GroupIndex=1
&GroupName=Web group
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "415AE1FC-3C11-4AA9-A06F-DE13D3430366"
}
```

2.16.4.3.2 DescribeGroupSummary

Description

You can call this operation to obtain a list of asset groups.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeGroupSummary.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The number of asset groups.
Groups	List	The information about asset groups. For more information, see the following parameter descriptions.
GroupId	Long	The asset group ID.
GroupIndex	Integer	The sequence number of the asset group.
GroupLevel	Integer	The level of the asset group.
GroupName	String	The name of the asset group.
GroupFather	Integer	The ID of the parent asset group.
GroupFlag	Integer	The type of the asset group. Valid values: 1: indicates a non-leaf node group that contains child asset groups. 0: indicates a leaf node group.
MachineNum	Integer	The number of ECS instances contained in the group.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeGroupSummary
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "Groups":[
    {
      "GroupFlag":1,
      "GroupName":"Test group 21",
      "GroupIndex":1,
      "MachineNum":0,
      "GroupId":346
    },
    {
      "GroupFlag":1,
      "GroupName":"Test group 1",
      "GroupIndex":2,
      "MachineNum":0,
      "GroupId":343
    },
    {
      "GroupFlag":1,
      "GroupName":"Test group 2",
      "GroupIndex":3,
      "MachineNum":0,
      "GroupId":345
    },
    {
      "GroupFlag":0,
      "GroupName":"Not grouped",
      "GroupIndex":100,
      "MachineNum":1,
      "GroupId":336
    }
  ],
  "Count":4,
  "RequestId":"B9FB5483-3CA6-4520-9F89-068ED6AAC6EE"
}
```

2.16.4.3.3 DescribeGroupStruct

Description

You can call this operation to query the asset group structure.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeGroupStruct.
Mark	String	No	The IP address or instance name of the server.

Parameter	Type	Required	Description
TagIdList	String	No	The server tag ID.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
GroupFather	Integer	The ID of the parent asset group.
GroupId	Long	The ID of the asset group.
Groups	List	The asset groups. For more information, see the following descriptions.
GroupId	Long	The ID of the asset group.
GroupIndex	Integer	The sequence number of the asset group.
GroupLevel	Integer	The level of the asset group.
GroupName	String	The name of the asset group.
GroupFather	Integer	The ID of the parent asset group.
GroupFlag	Integer	The type of the asset group. Valid values: 1: indicates a non-leaf node group that contains child asset groups. 0: indicates a leaf node group.
ChildGroups	List	The child asset groups.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribeGroupStruct
&remark=x.x.x.x
&tagIdList=123
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "Groups":[
    {
      "groupIndex":2,
      "groupFather":0,
      "groupId":343,
```

```

    "groupName": "****",
    "groupLevel": 1,
    "groupFlag": 1,
    "childGroups": []
  },
  {
    "groupIndex": 3,
    "groupFather": 0,
    "groupId": 345,
    "groupName": "****",
    "groupLevel": 1,
    "groupFlag": 1,
    "childGroups": [
      {
        "groupIndex": 1,
        "groupFather": 345,
        "groupId": 346,
        "groupName": "****",
        "groupLevel": 2,
        "groupFlag": 1,
        "childGroups": []
      }
    ]
  },
  {
    "groupIndex": 100,
    "groupFather": 0,
    "groupId": 336,
    "groupName": "****",
    "groupFlag": 0,
    "childGroups": []
  }
],
"RequestId": "C4490A16-DDE4-4351-A366-57F9FCDC188F",
"GroupFather": 0,
"GroupId": 0
}

```

2.16.4.3.4 DeleteGroup

Description

You can call this operation to delete a specified asset group.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteGroup.

Name	Type	Required	Description
GroupFlag	Integer	Yes	The type of the asset group. Valid values: 0: indicates a default group. 1: indicates a custom group.
GroupId	Long	Yes	The ID of the asset group.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DeleteGroup
&GroupFlag=1
&GroupId=123
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "415AE1FC-3C11-4AA9-A06F-DE13D3430366"
}
```

2.16.4.3.5 DescribeAllTag

Description

You can call this operation to query the tag information of all servers.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAllTag.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
EntityList	Array	The tag information of all servers. For more information, see the following parameter descriptions.
AliUid	Long	The Alibaba Cloud account ID.
GmtCreate	Long	The creation time of the asset tag.
GmtModified	Long	The last modification time of the asset tag.
Id	Long	The ID of the asset tag.
TagName	String	The name of the asset tag.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeAllTag
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "09D7C349-5306-4335-849A-10916F89E769",
  "EntityList": [
    {
      "AliUid": "123",
      "GmtCreate": "1508897933000",
      "GmtModified": "1508897933000",
      "Id": "1",
      "TagName": "test"
    }
  ]
}
```

2.16.4.3.6 DescribeBetachTag

Description

You can call this operation to query the tag information of a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBetachTag.
UuidList	String	No	The UUID of the server.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TagInfoList	Array	The tag information of the specified server. For more information, see the following parameter descriptions.
AliUid	Long	The Alibaba Cloud account ID.
GmtCreate	Long	The creation time of the asset tag.
GmtModified	Long	The last modification time of the asset tag.
Id	Long	The ID of the asset tag.
TagName	String	The name of the asset tag.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeBetachTag
&UuidList=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "09D7C349-5306-4335-849A-10916F89E769",
  "EntityList": [
    {
      "AliUid": "123",
      "GmtCreate": "1508897933000",
```

```
"GmtModified":"1508897933000",
  "Id":"1",
  "TagName":"test"
},
]
}
```

2.16.4.3.7 ModifyBetachTag

Description

You can call this operation to modify the tags of multiple specified servers.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyBetachTag.
TagList	String	Yes	The server tag. Separate multiple tags with commas (,).
UuidList	String	Yes	The UUID of the server.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyBetachTag
&UuidList=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&TagList=test,test2
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"09D7C349-5306-4335-849A-10916F89E769",
```

```
}
```

2.16.4.3.8 DeleteTag

Description

You can call this operation to delete a server tag.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteTag.
Id	Long	No	The ID of the server tag.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DeleteTag
&Id=123
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "415AE1FC-3C11-4AA9-A06F-DE13D3430366"
}
```

2.16.4.3.9 DescribeAllEntity

Description

You can call this operation to query information about all servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeAllEntity.
GroupId	Long	No	The ID of the asset group.
Os	String	No	The operating system of the server. Valid values: - win: indicates the Windows operating system. - linux: indicates the Linux operating system.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Count	Integer	The number of returned records.
EntityList	Array	The servers. For more information, see the following descriptions.
GroupId	Integer	The ID of the asset group.
Uuid	String	The universally unique identifier (UUID) of the server.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.  Note: The public IP address of the server is displayed preferentially. If no public IP address is assigned to the server, the private IP address of the server is displayed.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribeAllEntity
&GroupId=123
&Os=win
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "Count":2,
  "RequestId":"09D7C349-5306-4335-849A-10916F89E769",
  "EntityList":[
    {
      "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "Ip":"x.x.x.x",
      "GroupId":336,
      "InstanceName":"*****"
    },
    .....
  ]
}
```

2.16.4.3.10 DescribeEntityList

Description

You can call this operation to query servers of a specified type. For example, you can query servers by security event type.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeEntityList.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
RegionNo	String	No	The ID of the region.

Parameter	Type	Required	Description
GroupId	Long	No	The ID of the asset group.
Os	String	No	The operating system of the server. Valid values: • win: indicates the Windows operating system. • linux: indicates the Linux operating system.
Account	String	No	Queries servers with unusual logons detected. Set this parameter to remoteLogin.
Health	String	No	Queries servers with baseline check issues detected. Set this parameter to exception.
Patch	String	No	Queries servers with vulnerabilities detected. Set this parameter to vul.
Suspicious	String	No	Queries servers with unusual events detected. Set this parameter to exception.
Trojan	String	No	Queries servers with webshells detected. Valid values: • webshell: indicates trojan files. • process: indicates trojan processes.

Parameter	Type	Required	Description
Status	String	No	The status of the Server Guard Agent. Valid values: • offline: indicates that the Server Guard Agent is offline. • pause: indicates that the Server Guard Agent is disabled.
TagIdList	String	No	The server tag ID.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
TotalCount	Integer	The number of returned records.
EntityList	Array	The servers. For more information, see the following descriptions.
AegisOnline	Boolean	Indicates whether the Server Guard Agent is online.
AegisVersion	String	The version of the Server Guard Agent.
BuyVersion	String	The version of the Server Guard package.
GroupId	Integer	The ID of the asset group.
ClientStatus	Boolean	Indicates whether the server is protected. A value of false indicates that the protection for the server is paused.
Flag	Integer	The type of the server. Valid values: • 0: indicates an Alibaba Cloud ECS instance. • 1: indicates an external server.
Uuid	String	The universally unique identifier (UUID) of the server.

Parameter	Type	Description
InstanceName	String	The instance name of the server.
Os	String	The type of the operating system.
Region	String	The ID of the region.
Ip	String	The IP address of the server.  Note: The public IP address of the server is displayed preferentially. If no public IP address is assigned to the server, the private IP address of the server is displayed.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribeEntityList
&Account=remoteLogin
&CurrentPage=1
&GroupId=1
&Health=exception
&Os=windows
&PageSize=20
&Patch=vul
&RegionNo=****
&Remark=x.x.x.x
&Status=offline
&Suspicious=exception
&TagIdList=1,2,3
&Trojan=webshell
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PageSize":1,
  "RequestId":"8BFB5273-6582-446A-9E0B-BAC0A1A468EA",
  "CurrentPage":1,
  "EntityList":[
    {
      "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "Os":"linux",
      "ClientStatus":false,
      "Ip":"x.x.x.x",
      "Region":"****",
    }
  ]
}
```

```
"Flag":0,
"BuyVersion":"4",
"GroupId":336,
"InstanceName":"****"
}
]
```

2.16.4.3.11 ModifyEntityGroup

Description

You can call this operation to modify the asset group information for a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyEntityGroup.
GroupId	Long	No	The modified asset group ID.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```

2.16.4.3.12 DescribeMachines

Description

You can call this operation to query servers that match the specified criteria. For example, you can query all servers in an asset group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMachines.
GroupId	Long	No	The ID of the asset group.
TagIdList	String	No	The server tag ID.
Mark	String	No	The IP address or instance name of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Count	Integer	The number of returned records.
Machines	Array	The servers. For more information, see the following descriptions.
GroupId	Integer	The ID of the asset group.
InstanceName	String	The instance name of the server.
Os	String	The type of the operating system.
Ip	String	The IP address of the server.  Note: The public IP address of the server is displayed preferentially. If no public IP address is assigned to the server, the private IP address of the server is displayed.

Parameter	Type	Description
Uuid	String	The universally unique identifier (UUID) of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribeMachines
&GroupId=123
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "Count":1,
  "Machines":[
    {
      "groupId":336,
      "os":"linux",
      "instanceName":"****",
      "uuid":"inet-db626549-870c-4d3e-b0b5-4d8a5c7268a6",
      "ip":"192.168.x.x"
    }
  ],
  "RequestId":"C984123D-C8E0-4974-9CEE-ADD0596C46DB"
}
```

2.16.4.3.13 DescribeMachineDetail

Description

You can call this operation to query the detailed information about a specified server.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeMachineDetail.
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
MachineDetail	Array	The detailed information about the server . For more information, see the following descriptions.
AegisOnline	Boolean	Indicates whether the Server Guard Agent is online.
AegisVersion	String	The version of the Server Guard Agent.
BuyVersion	String	The version of the Server Guard package.
GroupId	Integer	The ID of the asset group.
ClientStatus	Boolean	Indicates whether the server is protected. A value of false indicates that the protection for the server is paused.
Flag	Integer	The type of the server. Valid values: 0: indicates an Alibaba Cloud ECS instance. 1: indicates an external server.
GroupId	Long	The ID of the asset group.
GroupTrace	String	The full path of the asset group.
InstanceId	String	The instance ID of the server.
InstanceName	String	The instance name of the server.
Os	String	The type of the operating system.
Region	String	The ID of the region.
Ip	String	The IP address of the server.  Note: The public IP address of the server is displayed preferentially. If no public IP address is assigned to the server, the private IP address of the server is displayed.
IntranetIp	String	The private IP address of the server.
Uuid	String	The UUID of the server.

Parameter	Type	Description
Tag	String	The server tag ID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribeMachineDetail
&Uuid=6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "5D5D6F8F-6986-4996-9321-8EEA9FC048D1",
  "MachineDetail": {
    "Uuid": "inet-db626549-870c-4d3e-b0b5-4d8a5c7268a6",
    "Ip": "192.168.x.x",
    "GroupTrace": "Not grouped",
    "Os": "linux",
    "ClientStatus": true,
    "Region": "outside-of-aliyun",
    "Tag": "",
    "AegisOnline": false,
    "InstanceName": "*****"
  }
}
```

2.16.4.3.14 DescribePropertyScheduleConfig

Description

You can call this operation to query the update cycle of server information.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertyScheduleConfig.

Name	Type	Required	Description
Type	String	No	The type of the server information. Valid values: • scheduler_account_period: indicates the user information. • scheduler_port_period: indicates the port information. • scheduler_process_period : indicates the process information. • scheduler_software_period : indicates the application software information.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Config	String	The update cycle in hours.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribePropertyScheduleConfig
&Type=scheduler_account_period
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "C528C153-33E6-4CF5-8C90-A2E6FFD6191C",
  "Config": "2"
}
```

2.16.4.3.15 ModifyPropertyScheduleConfig

Description

You can call this operation to modify the synchronization cycle of server information.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyPropertyScheduleConfig.
Type	String	Yes	The type of asset information whose synchronization cycle is to be modified. Valid values: • scheduler_software_period: indicates the synchronization cycle of application software information. • scheduler_account_period: indicates the synchronization cycle of user account information. • scheduler_port_period: indicates the synchronization cycle of port information. • scheduler_process_period: indicates the synchronization cycle of process information.
ScheduleTime	String	Yes	The new synchronization cycle. Unit: hours.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
ModifyResult	Boolean	Indicates whether the modification is successful.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyPropertyScheduleConfig
&Type=scheduler_software_period
&ScheduleTime=24
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "ModifyResult":true,
  "RequestId":"2932CB78-51FB-459C-A3E8-76BE2968069A"
}
```

2.16.4.3.16 DescribePropertyStatistic

Description

You can call this operation to query the server statistics.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertyStatistic.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
PropertyStatistics	Array	The list of server statistics. For more information, see the following parameter descriptions.
PortCount	String	The number of enabled ports.
PortGetDate	String	The port information update time.
ProcCount	String	The number of running processes.
ProcGetDate	String	The process information update time.

Name	Type	Description
RootUserCount	String	The number of user accounts with root permission.
UserCount	String	The total number of user accounts.
UserGetDate	String	The user account information update time.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribePropertyStatistic
&Uuids=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "PropertyStatistics":[
    {
      "UserGetDate":1514373155000,
      "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "RootUserCount":1,
      "UserCount":33,
      "ProcCount":89,
      "PortGetDate":1514115614000,
      "PortCount":6,
      "ProcGetDate":1514373133000
    }
  ],
  "RequestId":"C1CACE7E-E868-4E44-A52E-4CB1463B62BB"
}
```

2.16.4.3.17 DescribePropertyPortItem

Description

You can call this operation to obtain a list of listener ports on hosts.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertyPortItem.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query output. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
Port	String	No	The port number.
ProcName	String	No	The process name.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
Count	Integer	The number of records on the current page.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
PropertyPortItems	Array	The list of listener ports on hosts. For more information, see the following parameter descriptions.
Count	Integer	The number of hosts that have enabled the specified port.
Port	String	The port number.
Proto	String	The network protocol, such as TCP or UDP.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertyPortItem
&Port=22
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"9D38986A-F145-4FA8-AE1C-1DB1C2BDF4C0",
  "CurrentPage":1,
  "PropertyPortItems":[
    {
      "Proto":"tcp",
      "Port":"22",
      "Count":2
    }
  ],
  "Count":1
}
```

2.16.4.3.18 DescribePropertyPortDetail

Description

You can call this operation to query detailed information about a listening port.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertyPortDetail.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.

Parameter	Type	Required	Description
GroupId	Long	No	The ID of the asset group.
Ip	String	No	The IP address of the server.
Port	String	No	The port number.
Extend	String	No	Indicates whether fuzzy match is enabled to search for port numbers. Valid values: 1: indicates that fuzzy match is enabled. 0: indicates that fuzzy match is disabled.
ProcName	String	No	The name of the process.
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
TagIdListString	String	No	The server tag ID.
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
Count	Integer	The number of records returned on the current page.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
PropertyPorts	Array	The information about the listening port. For more information, see the following descriptions.
BindIp	String	The IP address bound to the port.
Create	String	The time when the port was enabled.

Parameter	Type	Description
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
Port	String	The port number.
ProcName	String	The name of the process.
Proto	String	The network protocol, such as TCP and UDP.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertyPortDetail
&Uuid=inet-f6ac9a93-0818-4052-90e2-d24f18ee198b
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"D85484BB-4DC2-44EC-AD67-0B3765EC9213",
  "CurrentPage":1,
  "PropertyPorts":[
    {
      "InstanceName":"****",
      "Uuid":"inet-f6ac9a93-0818-4052-90e2-d24f18ee198b",
      "Proto":"tcp",
      "Create":1514373168000,
      "Ip":"x.x.x.x",
      "Port":"22",
      "ProcName":"sshd",
      "BindIp":"0.0.0.0"
    }
  ],
  "Count":1
}
```

2.16.4.3.19 DescribePropertyPortDiff

Description

You can call this operation to query listening port changes.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertyPortDiff.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
DiffStatus	String	No	The type of the listening port change. Valid values: - start: indicates that the listening port is enabled. - stop: indicates that the listening port is disabled.
Ip	String	No	The IP address of the server.
Port	String	No	The port number.
Extend	String	No	Indicates whether fuzzy match is enabled to search for port numbers. Valid values: 1: indicates that fuzzy match is enabled. 0: indicates that fuzzy match is disabled.
ProcName	String	No	The name of the process.
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
TagIdListString	String	No	The server tag ID.

Parameter	Type	Required	Description
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
PropertyPortDiffs	Array	The listening port changes. For more information, see the following descriptions.
BindIp	String	The IP address bound to the port.
Create	String	The time when the port was enabled.
DiffKeyList	String	The port fields that have been changed, including Proto, ProcName, and BindIp.
DiffStatus	String	The type of the listening port change. Valid values: - start: indicates that the listening port is enabled. - stop: indicates that the listening port is disabled.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
ProcName	String	The name of the process.
Port	String	The port number.
Proto	String	The network protocol, such as TCP and UDP.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertyPortDiff
&Uuid=inet-f6ac9a93-0818-4052-90e2-d24f18ee198b
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"AFC431E3-F8E3-4652-91CB-9FF4053F282A",
  "CurrentPage":1,
  "PropertyPortDiffs":[
    {
      "InstanceName":"****",
      "Uuid":"inet-f6ac9a93-0818-4052-90e2-d24f18ee198b",
      "Proto":"tcp",
      "Create":1514366856000,
      "Ip":"x.x.x.x",
      "Port":"22",
      "ProcName":"sshd",
      "DiffKeyList":"proto,procName,bindIp",
      "DiffStatus":"stop",
      "BindIp":"0.0.0.0"
    }
  ]
}
```

2.16.4.3.20 DescribePropertyProcItem

Description

You can call this operation to obtain a list of server processes.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertyProcItem.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query output. Default value: 20.

Name	Type	Required	Description
CurrentPage	Integer	No	The current page number. Default value: 1.
Name	String	No	The process name.
User	String	No	The user who started the process.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
Count	Integer	The number of records on the current page.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
PropertyProcltems	Array	The list of server processes. For more information, see the following parameter descriptions.
Count	Integer	The number of servers on which the process is running.
Name	String	The process name.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribePropertyProcltem
&Name=init
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "PropertyProcltems":[
    {
      "Count":2,
      "Name":"init"
    }
  ]
}
```

```
}  
},  
"PageSize":20,  
"RequestId":"8BE95FB1-66B7-4509-AF82-3AA67368A5D8",  
"CurrentPage":1,  
"Count":1  
}
```

2.16.4.3.21 DescribePropertyProcDetail

Description

You can call this operation to query server process details.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertyProcDetail.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
GroupId	Long	No	The ID of the asset group.
Ip	String	No	The IP address of the server.
Name	String	No	The name of the process.
Extend	String	No	Indicates whether fuzzy match is enabled to search for process names. Valid values: 1: indicates that fuzzy match is enabled. 0: indicates that fuzzy match is disabled.
User	String	No	The user who started the process.

Parameter	Type	Required	Description
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
Cmdline	String	No	The process parameter.
TagIdListString	String	No	The server tag ID.
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
Count	Integer	The number of records returned on the current page.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
PropertyProcs	Array	The details of the server process. For more information, see the following descriptions.
Cmdline	String	The process parameter.
Create	String	The time when the information was reported.
EuidName	String	The permissions that the process has to access resources and files.
InstanceName	String	The instance name of the server.
Md5	String	The MD5 value of the executable file.
Name	String	The name of the process.
Path	String	The path of the process.
Pid	String	The ID of the process.
ProcName	String	The name of the process.
Pname	String	The name of the parent process.

Parameter	Type	Description
StartTime	String	The time when the process was started.
User	String	The user who started the process.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertyProcDetail
&Uuid=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "PropertyProcs":[
    {
      "InstanceName":"****",
      "Path":"/sbin/init",
      "Pname":"N/A",
      "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "User":"root",
      "Create":1514373133000,
      "StartTime":"2017-12-26 22:34:45",
      "Pid":"1",
      "EuidName":"root",
      "Cmdline":"/sbin/init",
      "Name":"init",
      "Md5":"70023aaf3f480d198d3b078d8c39****"
    }
  ],
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"AB20A6D4-43EB-44E2-AD64-E03EAC1C14D9",
  "CurrentPage":1,
  "Count":1
}
```

2.16.4.3.22 DescribePropertyProcDiff

Description

You can call this operation to query process changes of a server.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertyProcDiff.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
DiffStatus	String	No	The type of the process change. Valid values: - start: indicates that the process is started. - stop: indicates that the process is stopped.
Ip	String	No	The IP address of the server.
Name	String	No	The name of the process.
User	String	No	The user who started the process.
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
CurrentPage	Integer	The number of the current page returned.

Parameter	Type	Description
PageSize	Integer	The number of records returned on each page.
PropertyProcDiffs	Array	The server process changes. For more information, see the following descriptions.
Cmdline	String	The process parameter.
Create	String	The time when the information was reported.
DiffKeyList	String	The names of the fields that have been changed.
DiffStatus	String	The type of the process change.
EuidName	String	The permissions that the process has to access resources and files.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
Md5	String	The MD5 value of the executable file.
Name	String	The name of the process.
Path	String	The path of the process.
Pid	String	The ID of the process.
Pname	String	The name of the parent process.
StartTime	String	The time when the process was started.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribePropertyProcDiff
&Uuid=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
```

```

"RequestId":"D0951162-E933-4E2B-BDE2-B8FD806CEF9F",

    "InstanceName":"****",
    "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
    "Create":1514366744000,
    "Cmdline":"/sbin/init",
    "Euidname":"root",
    "Md5":"70023aaf3f480d198d3b078d8c39****"
  },
]
}

```

2.16.4.3.23 DescribePropertySoftwareItem

Description

You can call this operation to query servers that have been installed with the specified application.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertySoftwareItem.
PageSize	Integer	No	The maximum number of records displayed on a page. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
Name	String	No	The name of the application.
Path	String	No	The application installation path.
SoftwareVersion	String	No	The version of the application.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The number of returned records.
Count	Integer	The number of records on the current page.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
PropertySoftwareItems	Array	A list of servers that have been installed with the application. For more information, see the following parameter descriptions.
Count	Integer	The number of servers that have been installed with the application.
Name	String	The name of the application.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribePropertySoftwareItem
&Name=spice-vdagent
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "PropertySoftwareItems":[
    {
      "count":2,
      "Name":"spice-vdagent"
    }
  ],
  "PageSize":20,
  "RequestId":"0F2A3DEA-A5B3-4C2A-8BFC-4724A205E28B",
  "CurrentPage":1,
  "count": 1,
```

}

2.16.4.3.24 DescribePropertySoftwareDetail

Description

You can call this operation to query the details of software installed on a server.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertySoftwareDetail.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
Ip	String	No	The IP address of the server.
Name	String	No	The name of the software.
Extend	String	No	Indicates whether fuzzy match is enabled to search for software names.. Valid values: 1: indicates that fuzzy match is enabled. 0: indicates that fuzzy match is disabled.
Path	String	No	The installation path of the software.
Remark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
SoftwareVersion	String	No	The version of the software.

Parameter	Type	Required	Description
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
Count	Integer	The number of records returned on the current page.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
PropertySoftwares	Array	The details of software installed on the server. For more information, see the following descriptions.
Create	String	The time when the information was reported.
InstallTime	String	The time when the software was installed.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
Path	String	The installation path of the software.
Version	String	The version of the software.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribePropertySoftwareDetail
&Uuid=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PropertySoftwares":[
    {
      "InstanceName":"****",
      "Path":"/usr/libexec/gvfs-gphoto2-volume-monitor",
      "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "InstallTime":"2016-06-29 06:55:22",
      "Version":"1.4.3",
      "Create":1514172615000,
      "Ip":"x.x.x.x"
    }
  ],
  "PageSize":20,
  "RequestId":"31409246-AB88-4B36-A2B8-16D21BA9E170",
  "CurrentPage":1,
  "Count":1
}
```

2.16.4.3.25 DescribePropertySoftwareDiff

Description

You can call this operation to query changes of applications that have been installed on servers.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertySoftwareDiff.
PageSize	Integer	No	The maximum number of records displayed on a page. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.

Name	Type	Required	Description
DiffStatus	String	No	The type of the application changes. Valid values: - create: indicates an installation. - delete: indicates an uninstallation. - modified: indicates a modification.
Ip	String	No	The IP address of the server.
Name	String	No	The name of the application.
Path	String	No	The path where the application is installed.
SoftwareVersion	String	No	The version of the application.
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
Uuid	String	No	The UUID of the server.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The number of returned records.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
PropertySoftwareDiffs	Array	The application changes. For more information, see the following parameter descriptions.
Create	String	The time when the application change was reported.
DiffKeyList	String	The name of the fields that have been changed.

Name	Type	Description
DiffStatus	String	The type of the changes.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
Name	String	The name of the application.
Path	String	The path where the application is installed.
Version	String	The version of the application.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertySoftwareDiff
&Uuid=inet-f6ac9a93-0818-4052-90e2-d24f18ee198b
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1398,
  "PageSize":2,
  "RequestId":"3A0814BA-1A5D-43DC-A6E9-3B52EDD3700E",
  "CurrentPage":1,
  "PropertySoftwareDiffs":[
    {
      "Path":"/etc/ghostscript",
      "Uuid":"inet-f6ac9a93-0818-4052-90e2-d24f18ee198b",
      "Version":"8.70",
      "Create":1514172428000,
      "DiffKeyList":"version,path",
      "DiffStatus":"create",
      "Name":"ghostscript"
    },
    {
      "Path":"/usr/sbin/brctl",
      "Uuid":"inet-f6ac9a93-0818-4052-90e2-d24f18ee198b",
      "Version":"1.2",
      "Create":1514172428000,
      "DiffKeyList":"version,path",
      "DiffStatus":"create",
      "Name":"bridge-utils"
    }
  ]
}
```

}

2.16.4.3.26 DescribePropertyUserItem

Description

You can call this operation to query user account information.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePropertyUserItem.
PageSize	Integer	No	The maximum number of records displayed on a page. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
User	String	No	The username of the account.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The number of returned records.
Count	Integer	The number of records on the current page.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
PropertyUserItems	Array	The returned user account information. For more information, see the following parameter descriptions.
Count	Integer	The number of servers under the account.
Name	String	The username of the account.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertyUserItem
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":2,
  "PropertyUserItems":[
    {
      "User":"abrt",
      "Count": 2
    },
    {
      "User":"adm",
      "Count": 2
    }
  ],
  "PageSize":20,
  "RequestId":"E80981C2-AD12-4C60-9976-6927C1FE449B",
  "CurrentPage":1,
  "Count": 2
}
```

2.16.4.3.27 DescribePropertyUserDetail

Description

You can call this operation to query user account details.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertyUserDetail.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.

Parameter	Type	Required	Description
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
GroupId	Long	No	The ID of the asset group.
Ip	String	No	The IP address of the server.
IsRoot	String	No	Indicates whether the user account is a root account. Valid values: 1: indicates yes. 0: indicates no.
User	String	No	The name of the user account.
Extend	String	No	Indicates whether fuzzy match is enabled to search for user accounts. Valid values: 1: indicates that fuzzy match is enabled. 0: indicates that fuzzy match is disabled.
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
TagIdListString	String	No	The server tag ID.
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
Count	Integer	The number of records returned on the current page.
CurrentPage	Integer	The number of the current page returned.

Parameter	Type	Description
PageSize	Integer	The number of records returned on each page.
PropertyUsers	Array	The details of the user account. For more information, see the following descriptions.
AccountsExpirationDate	String	The time when the user account expires.
Create	String	The time when the information was reported.
GroupName	String	The information about the user group.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
IsRoot	String	Indicates whether the user account is a root account.
LastLoginIp	String	The last IP address that is used by the user account to log on to the server.
LastLoginTime	String	The last logon time of the user account.
PasswordExpirationDate	String	The time when the password of the user account expires.
User	String	The name of the user account.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribePropertyUserDetail
&Uuid=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":66,
  "PageSize":2,
  "RequestId":"2EEAE2A6-1662-471C-A5E5-8A6190B01AFF",
  "CurrentPage":1,
  "Count":1,
```

```

"PropertyUsers":[
  {
    "GroupName":[
      "root"
    ],
    "InstanceName":"****",
    "IsRoot":"1",
    "LastLoginTime":"2017-12-27 10:22:25",
    "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
    "User":"root",
    "LastLoginIp":"192.168.x.x",
    "Create":1514373155000,
    "Ip":"x.x.x.x",
    "AccountsExpirationDate":"never",
    "PasswordExpirationDate":"never"
  }
]
}

```

2.16.4.3.28 DescribePropertyUserDiff

Description

You can call this operation to query user account changes.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribePropertyUserDiff.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
DiffStatus	String	No	The type of the user account change. Valid values: - create: indicates that a new account has been added. - delete: indicates that an account has been deleted. - modified: indicates that an account has been modified.

Parameter	Type	Required	Description
IsRoot	String	No	Indicates whether the user account is a root account. Valid values: 1: indicates yes. 0: indicates no.
User	String	No	The name of the user account.
Mark	String	No	The IP address or instance name of the server.  Note: Fuzzy match is supported.
Uuid	String	No	The universally unique identifier (UUID) of the server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
PropertyUserDiffs	Array	The user account changes. For more information, see the following descriptions.
AccountsExpirationDate	String	The time when the user account expires.
Create	String	The time when the information was reported.
DiffKeyList	String	The names of the fields that have been changed.
DiffStatus	String	The type of the user account change.
GroupName	String	The information about the user group.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
IsRoot	String	Indicates whether the user account is a root account.

Parameter	Type	Description
PasswordExpirationDate	String	The time when the password of the user account expires.
User	String	The name of the user account.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribePropertyUserDiff
&Uuid=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"20903EB6-E695-44A4-85C2-B9DFE4376F1F",
  "CurrentPage":1,
  "PropertyUserDiffs":[
    {
      "GroupName":[
        "root"
      ],
      "InstanceName":"****",
      "IsRoot":"0",
      "User":"****",
      "Uuid":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "Create":1514020942000,
      "Ip":"x.x.x.x",
      "AccountsExpirationDate":"never",
      "DiffKeyList":"isRoot,groupName,accountsExpirationDate,passwordExpirationDate",
      "DiffStatus":"create",
      "PasswordExpirationDate":"never"
    }
  ]
}
```

2.16.4.3.29 PushAllTask

Description

You can call this operation to perform a quick security check on specified servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to PushAllTask.
Uuids	String	No	The universally unique identifier (UUID) of the server. Separate multiple UUIDs with commas (,).
Tasks	String	No	The type of the security check task. Valid values: • OVAL_ENTITY: indicates all security check tasks. • CMS: indicates a check for CMS vulnerabilities. • SYSVUL: indicates a check for system software vulnerabilities. • HEALTH_CHECK: indicates a baseline check. • WEBSHELL: indicates a check for webshells. • PROC_SNAPSHOT: indicates a check on process data. • PORT_SNAPSHOT: indicates a check on port data. • ACCOUNT_SNAPSHOT: indicates a check on account data. • SOFTWARE_SNAPSHOT: indicates a check on application data.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
PushTaskRsp	Struct	The task delivery result. For more information, see the following descriptions.
PushTaskResultList	Array	The tasks that fail to be delivered. For more information, see the following descriptions.

Parameter	Type	Description
GroupId	String	The ID of the asset group.
InstanceId	String	The instance ID of the server.
InstanceName	String	The instance name of the server.
Ip	String	The IP address of the server.
Message	String	The details of the task delivery result.
Online	String	Indicates whether the Server Guard client is online.
OsVersion	String	The version of the operating system.
Region	String	The region where the server resides.
Success	String	The task delivery result.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=PushAllTask
&Tasks=OVAL_ENTITY
&Uuids=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5****
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "8A773295-DB9C-423D-979E-C0E8B9F88FEA",
  "PushTaskRsp": {
    "PushTaskResultList": [
      {
        "InstanceName": "****",
        "Uuid": "inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5****",
        "Message": "{\"code\": \"client_offline\", \"message\": \"The client is offline\"}",
        "InstanceId": "i-25l6r****",
        "Ip": "x.x.x.x",
        "OsVersion": "linux",
        "Region": "cn-****-a01",
        "Online": false,
        "Success": false,
        "GroupId": 336
      }
    ]
  }
}
```

2.16.4.3.30 DescribeTopRiskyAssets

Description

You can call this operation to query top N vulnerable servers.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeTopRiskyAssets.
PageSize	Integer	No	The number of records to return , that is, the top N vulnerable servers.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
TopRiskyAssets	Array	The top N vulnerable servers. For more information, see the following descriptions.
HcCount	String	The number of at-risk items detected in the baseline check.
Ip	String	The IP address of the server.
Uuid	String	The universally unique identifier (UUID) of the server.
VulCount	String	The number of detected vulnerabilities.
WarningCount	String	The number of detected security events.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribeTopRiskyAssets
&PageSize=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount": 1,
  "RequestId": "5D8D4058-2EE3-4599-9951-BDAA3340AD4D",
  "TopRiskyAssets": [
    {
      "Ip": "192.168.x.x",
      "Uuid": "inet-dsljaoe-jjdsklaj****",
      "VulCount": 2,
      "HcCount": 1,
      "WarningCount": 2
    }
  ]
}
```

2.16.4.3.31 UnbindAegis

Description

You can call this operation to disable Server Guard for a specified server.

Note:

After this operation, Server Guard is not able to detect any security events on this server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to UnbindAegis.
Uuids	String	Yes	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=UnbindAegis
&Uuids=6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac,6dbdbfe7-06fa-4d9a-8268-
ce2dc6d673ac
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "8BFB5273-6582-446A-9E0B-BAC0A1A468EA"
}
```

2.16.4.3.32 UninstallAegis

Description

You can call this operation to uninstall the Server Guard client from a specified server.

Note:

After the client is uninstalled, Server Guard is not able to detect the security events on this server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to UninstallAegis.
Uuids	String	Yes	The UUID of the server. Separate multiple UUIDs with commas (,).
Reason	String	No	The reason for uninstalling the client.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=UninstallAegis
&Reason=Suspend the feature
&Uuids=6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac,6dbdbfe7-06fa-4d9a-8268-
ce2dc6d673ac
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "8BFB5273-6582-446A-9E0B-BAC0A1A468EA"
}
```

2.16.4.4 Vulnerability management operations

2.16.4.4.1 DescribeTarget

Description

You can call this operation to query the servers that are checked for the specified type of risks in vulnerability management.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTarget.
Type	String	No	The type of the risks. For example, vul represents vulnerabilities.
Config	String	No	The type of the vulnerabilities in JSON format. For example, {"vulType": "cve"} represents Linux software vulnerabilities.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The number of returned records.
Targets	Array	A list of servers that are checked for the specified type of risks. For more information , see the following parameter descriptions.
TargetType	String	Valid values: - groupId: indicates the ID of an asset group. - uuid: indicates the UUID of a server.
Target	String	The asset group ID or server UUID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeTarget
&Config={"vulType":"cve"}
&Type=vul
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":2,
  "RequestId":"1FF54D56-47ED-47FB-B4DB-2BDF3857D526",
  "Targets":[
    {
      "Target":"inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818",
      "TargetType":"uuid"
    },
    {
      "Target":"336",
      "TargetType":"groupId"
    }
  ]
}
```

2.16.4.4.2 ModifyVulTarget

Description

You can call this operation to modify the servers for detecting a specified type of vulnerability in the vulnerability management settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVulTarget.
Config	String	No	The vulnerability type information, in JSON format. For example, {"vulType": "cve"} indicates Linux software vulnerabilities.
Target	String	No	The specified server, in JSON format. For more information, see the sample request.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyVulTarget
&Config={"vulType": "cve"}
&Target={"target": "inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818", "targetType": "uuid", "flag": "add"}
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "1FF54D56-47ED-47FB-B4DB-2BDF3857D526"
```

```
}
```

2.16.4.4.3 DescribeVulTargetStatistics

Description

You can call this operation to query the information about target hosts for which vulnerability detection is enabled in the vulnerability management configuration.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulTargetStatistics.
Type	String	No	The vulnerability type.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of returned records.
TargetStats	Array	The list of target hosts for which vulnerability detection is enabled. For more information, see the following parameter descriptions.
VulType	String	The vulnerability type.
Targets	Array	The information about target hosts. For more information, see the following parameter descriptions.
Flag	String	Indicates whether vulnerability detection is enabled.

Name	Type	Description
TargetType	String	The type of the Target parameter value. Valid values: - groupId: indicates an asset group ID. - uuid: indicates a host asset UUID.
Target	String	The asset group ID or host asset UUID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeVulTargetStatistics
&Type=cve
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "TargetStats":[
    {
      "VulType":"cve","Targets":[]
    },
    "PageSize":10,

```

2.16.4.4.4 DescribeTargetConfig

Description

You can call this operation to query the vulnerability scanning configuration information of a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTargetConfig.
Type	String	No	The type of the vulnerability.

Name	Type	Required	Description
Uuid	String	No	The UUID of the server.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of the returned records.
TargetConfigs	Array	The list of vulnerability scanning configuration information. For more information, see the following parameter descriptions.
Type	String	The type of the vulnerability.
Config	String	Whether vulnerability scanning is enabled. Valid values: on and off.
OverAllConfig	String	Whether global vulnerability scanning is enabled. Valid values: on and off.

 **Note:**
The global vulnerability scanning configuration overrides the vulnerability scanning configuration for a single server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeTargetConfig
&Type=cve
&Uuid=inet-00f20b1a-e2dd-408b-b38e-6a6e1ed5d818
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount": 1,
  "RequestId": "092094BF-910F-4CE6-BE93-C3989B607977",
  "TargetConfigs": [
    {
      "Config": "off",
      "Type": "cve",
      "OverAllConfig": "off"
    }
  ]
}
```

```
}  
}  
}
```

2.16.4.4.5 ModifyTargetConfig

Description

You can call this operation to modify the vulnerability scanning configuration for a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyTargetConfig.
Type	String	No	The type of the vulnerability.
Uuid	String	No	The UUID of the server.
Config	String	No	The vulnerability scanning configuration. Valid values: - on: indicates enabled. - off: indicates disabled.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyTargetConfig  
&Config=on  
&Type=cms  
&Uuid=46ef7c05-0c53-486c-b446-ef6ff972551c
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "RequestId": "092094BF-910F-4CE6-BE93-C3989B607977"
}
```

2.16.4.4.6 DescribeVulConfig

Description

You can call this operation to query the global scanning configuration for each vulnerability type.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulConfig.
Type	String	No	The type of the vulnerability.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
TargetConfigs	Array	The list of global vulnerability scanning configurations. For more information, see the following parameter descriptions.
Type	String	The type of the vulnerability.
Config	String	The global scanning configuration for the vulnerability type. Valid values: on and off.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeVulConfig
```

```
&Type=cve  
&<Common request parameters>
```

- Sample responses (JSON format)

```
{  
  "TotalCount":1,  
  "RequestId":"A8E09216-31DF-45B6-A76B-E3F053752C07",  
  "TargetConfigs":[  
    {  
      "Config":"off",  
      "Type":"cve"  
    }  
  ]  
}
```

2.16.4.4.7 ModifyVulConfig

Description

You can call this operation to modify the global vulnerability scanning configuration.

Note:

The global vulnerability scanning configuration overrides the vulnerability scanning configuration for a single server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVulConfig.
Type	String	No	The type of the vulnerability.
Config	String	No	The vulnerability scanning configuration. Valid values: • on: indicates enabled. • off: indicates disabled.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyVulConfig
&Config=on
&Type=cms
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "A8E09216-31DF-45B6-A76B-E3F053752C07"
}
```

2.16.4.4.8 DescribeAutoDelConfig

Description

You can call this operation to query the number of days that an invalid vulnerability is kept for before it is automatically deleted in the vulnerability management settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAutoDelConfig.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Days	Integer	The number of days that an invalid vulnerability is kept for.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeAutoDelConfig
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "E3785090-CFF4-4C53-82E4-08F902586053",
  "Days": 7
}
```

2.16.4.4.9 ModifyAutoDelConfig

Description

You can call this operation to modify the number of days that an invalid vulnerability is kept for before it is automatically deleted in the vulnerability management settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAutoDelConfig.
Days	Integer	No	The number of days that an invalid vulnerability is kept for.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyAutoDelConfig
&Days=7
```

&<Common request parameters>

- Sample responses (JSON format)

```
{
  "RequestId": "E3785090-CFF4-4C53-82E4-08F902586053"
}
```

2.16.4.4.10 DescribeVulLevel

Description

You can call this operation to query the vulnerability severities that require attention.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulLevel.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
ConcernLevels	List	The list of vulnerability severities that require attention.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeVulLevel
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "7935CB7A-D1B7-4EE6-93D0-FF3D040CF19B",
  "ConcernLevels": ["high", "medium"]
}
```

```
}
```

2.16.4.4.11 ModifyVulLevel

Description

You can call this operation to change the vulnerability severities that require attention.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyVulLevel.
ConcernLevels	String	No	The vulnerability severities that require attention. Separate multiple severities with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyVulLevel
&ConcernLevel=high,medium
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "7935CB7A-D1B7-4EE6-93D0-FF3D040CF19B"
```

```
}
```

2.16.4.4.12 CreateVulWhitelist

Description

You can call this operation to add a specified vulnerability to the whitelist. Server Guard does not report the vulnerabilities on the whitelist.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateVulWhitelist.
Reason	String	No	The reason for adding the vulnerability to the whitelist.
Whitelist	String	No	The vulnerability to be whitelisted, in JSON format. For more information, see the sample request.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=CreateVulWhitelist
&Reason=The vulnerability is not harmful.
&Whitelist=[{"name":"oval:com.redhat.rhsa:def:20173263","type":"cve","aliasName":"
RHSA-2017:3263: curl security update"}]
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"E3785090-CFF4-4C53-82E4-08F902586053"
```

}

2.16.4.4.13 DescribeVulWhitelist

Description

You can call this operation to obtain the whitelist of vulnerabilities.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulWhitelist.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query output. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of returned records.
VulWhitelists	Array	The vulnerability whitelist. For more information, see the following parameter descriptions.
AliasName	String	The alias of the vulnerability.
Name	String	The name of the vulnerability.
Reason	String	The reason for adding the vulnerability to the whitelist.

Name	Type	Description
Type	String	The vulnerability type.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeVulWhitelist
&CurrentPage=1
&PageSize=20
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "VulWhitelists":[
    {
      "Name":"oval:com.redhat.rhsa:def:20173263",
      "AliasName":"RHSA-2017:3263: curl security update",
      "Type":"cve",
      "Reason":"Not fixed at present"
    }
  ],
  "PageSize":3,
  "RequestId":"74F97EF7-B543-43FD-A4E9-18456731F9C5",
  "CurrentPage":1
}
```

2.16.4.4.14 DeleteVulWhitelist

Description

You can call this operation to delete a specified vulnerability from the vulnerability whitelist . After this operation, Server Guard re-detects and reports the vulnerability.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteVulWhitelist.

Parameter	Type	Required	Description
Whitelist	String	No	The vulnerability to be deleted from the whitelist, in JSON format . For more information, see the sample request.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DeleteVulWhitelist
&Whitelist=[{"name":"oval:com.redhat.rhsa:def:20173263","type":"cve","aliasName":"
RHSA-2017:3263: curl security update"}]
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId":"E3785090-CFF4-4C53-82E4-08F902586053"
}
```

2.16.4.4.15 DescribeGroupedVul

Description

You can call this operation to query information about the specified vulnerability group.

The vulnerability management feature can display detected vulnerability records by group

. A vulnerability group contains all servers with a specific vulnerability detected by Server Guard.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeGroupedVul.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query output. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
Dealed	String	No	Indicates whether the vulnerability has been handled. Valid values: • Y: indicates that the vulnerability has been handled. • N: indicates that the vulnerability has not been handled.
Direction	String	No	The sorting mode of vulnerabilities in the vulnerability group. Valid values: • asc: indicates sorting in ascending order. • desc: indicates sorting in descending order.
LastTsEnd	Long	No	The end time of the last detection of the vulnerability.
LastTsStart	Long	No	The start time of the last detection of the vulnerability.

Name	Type	Required	Description
Level	String	No	The severity of the vulnerability. Valid values: • serious: critical • high: important • medium: moderate • low: low
Name	String	No	The name of the vulnerability.
Necessity	String	No	The necessity for fixing the vulnerability. Valid values: • asap: indicates that the vulnerability must be fixed as soon as possible. • later: indicates that the vulnerability can be fixed later. • nntf: indicates that the vulnerability can be ignored.
OrderBy	String	No	The field based on which the vulnerabilities in the vulnerability group are sorted. You can specify other request parameters for sorting order.
PatchId	Long	No	The ID of the patch used to fix the vulnerability.
Product	String	No	The product where the vulnerability exists.

Name	Type	Required	Description
StatusList	String	No	The status of the vulnerability. Valid values: • 1: indicates that the vulnerability has not been fixed. • 2: indicates that the vulnerability fix failed. • 3: indicates that the server has failed to be rolled back to the version before the vulnerability fix. • 4: indicates that the vulnerability is being fixed. • 5: indicates that the server is being rolled back to the version before the vulnerability fix. • 6: indicates that the vulnerability fix is being verified. • 7: indicates that the vulnerability has been fixed successfully. • 8: indicates that the vulnerability has been fixed successfully, and that the server is waiting for restart. • 9: indicates that the server has been rolled back to the version before the vulnerability fix. • 10: indicates that the vulnerability has been ignored. • 11: indicates that the server has been rolled back to the version before the vulnerability fix, and that the server is waiting for restart. • 12: indicates that the vulnerability does not exist. • 20: indicates that the vulnerability is invalid.  Note: The statuses are specified in a single parameter, separated with commas (,).

Name	Type	Required	Description
Type	String	No	The type of the vulnerability.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of returned records.
GroupedVulItems	Array	The information about the vulnerability group. For more information, see the following parameter descriptions.
AliasName	String	The alias of the vulnerability.
AsapCount	Integer	The number of assets to be fixed as soon as possible.
Count	Integer	The total number of vulnerabilities.
GmtLast	Long	The last time when the vulnerability was detected.
HandledCount	Integer	The total number of vulnerabilities handled.
Level	String	The severity of the vulnerability.
Name	String	The name of the vulnerability.
PendingCount	Integer	The number of vulnerabilities that have not been handled.
Product	String	The product affected by the vulnerability.
Status	Integer	The status of the vulnerability.
TotalCount	Integer	The total number of vulnerabilities.
Type	String	The type of the vulnerability.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeGroupedVul
&CurrentPage=1
&Dealed=y
&Direction=asc
&LastTsEnd=1517414400000
&LastTsStart=1517414500000

  "CurrentPage":1
}
```

2.16.4.4.16 DescribeVulList

Description

You can call this operation to obtain the vulnerability list of the specified host asset.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulList.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query output. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
Dealed	String	No	Indicates whether the vulnerability has been handled. Valid values: - Y: indicates that the vulnerability has been handled. - N: indicates that the vulnerability has not been handled.
Level	String	No	The severity of the vulnerability. Valid values: - serious: critical - high: important - medium: moderate - low: low
Name	String	No	The name of the vulnerability.
Necessity	String	No	The necessity for fixing the vulnerability. Valid values: - asap: indicates that the vulnerability must be fixed as soon as possible. - later: indicates that the vulnerability can be fixed later. - nntf: indicates that the vulnerability can be ignored.
Type	String	No	The type of the vulnerability.

Name	Type	Required	Description
StatusList	String	No	The status of the vulnerability. Valid values: • 1: indicates that the vulnerability has not been fixed. • 2: indicates that the vulnerability fix failed. • 3: indicates that the host has failed to be rolled back to the version before the vulnerability fix. • 4: indicates that the vulnerability is being fixed. • 5: indicates that the host is being rolled back to the version before the vulnerability fix. • 6: indicates that the vulnerability fix is being verified. • 7: indicates that the vulnerability has been fixed successfully. • 8: indicates that the vulnerability has been fixed successfully, and that the host is waiting for restart. • 9: indicates that the host has been rolled back to the version before the vulnerability fix. • 10: indicates that the vulnerability has been ignored. • 11: indicates that the host has been rolled back to the version before the vulnerability fix, and that the host is waiting for restart. • 12: indicates that the vulnerability does not exist. • 20: indicates that the vulnerability is invalid.  Note: Note: The statuses are specified in a single parameter, separated with commas (,).

Name	Type	Required	Description
Uuids	String	No	The UUID of the host asset. Separate multiple host asset UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of records returned from the query.
VulRecords	Array	The list of vulnerabilities. For more information, see the following parameter descriptions.
AliasName	String	The alias of the vulnerability.
ExtendContent	String	The extended information of the vulnerability.
ExtendContentJson	String	The extended information of the vulnerability (JSON format).
FirstTs	Long	The first time when the vulnerability was detected.
ModifyTs	Long	The last time when the vulnerability was updated.
LastTs	Long	The last time when the vulnerability was detected.
Level	String	The severity of the vulnerability.
Name	String	The name of the vulnerability.

Name	Type	Description
Necessity	String	The necessity for fixing the vulnerability. Valid values: • asap: indicates that the vulnerability must be fixed as soon as possible. • later: indicates that the vulnerability can be fixed later. • nntf: indicates that the vulnerability can be ignored.
PrimaryId	Long	The ID of the primary key.
Product	String	The product affected by the vulnerability.
RecordId	Long	The ID of the vulnerability record.
Related	String	The CVE ID of the vulnerability.
RepairTs	Long	The time when the vulnerability was fixed.
ResultCode	String	The code of the vulnerability handling result.
ResultMessage	String	The message of the vulnerability handling result.
RiskDesc	String	The risk description of the vulnerability.
RiskLevel	Integer	The risk level of the vulnerability.
Status	Integer	The status of the vulnerability. Valid values: • 1: indicates that the vulnerability is to be handled. • 2: indicates that the vulnerability has been ignored. • 3: indicates that the vulnerability has been confirmed. • 8: indicates that the vulnerability has been marked as a false positive. • 16: indicates that the vulnerability is being handled. • 32: indicates that the vulnerability has been handled.
Tag	String	The tag of the vulnerability.
Type	String	The type of the vulnerability.
Uuid	String	The UUID of the host asset.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeVulList
&CurrentPage=1
&Dealed=n
&Level=serious

2.16.4.4.17 DescribeVulDetails

Description

You can call this operation to query detailed information about a vulnerability.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulDetails.
Type	Integer	Yes	The type of the vulnerability.
Name	String	Yes	The name of the vulnerability.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Cves	Array	The vulnerability details. For more information, see the following parameter descriptions.
Classify	String	The vulnerability type code.
Classifys	Array	The detailed vulnerability information. For more information, see the following parameter descriptions.
Classify	String	The vulnerability type code.
Description	String	The description of the vulnerability type.
DemoVideoUrl	String	The URL of the vulnerability video demo.
CnvdId	String	The CNVD ID.
Complexity	String	The complexity.
Content	String	The vulnerability details.
ExtendContentJson	String	The additional information about the vulnerability (JSON format).
CveId	String	The CVE ID.
CvssScore	String	The CVSS score.
CvssVector	String	The CVSS score string.
OtherId	String	The ID of the vulnerability.
Poc	String	The proof of concept (POC) method.

Name	Type	Description
PocCreateTime	Long	The time when the POC method was created .
PocDisclosureTime	Long	The time when the POC method was revealed.
Service	String	The products that are affected by the vulnerability.
Reference	String	The corresponding reference.
ReleaseTime	Long	The time when the vulnerability was revealed.
Solution	String	The solution for fixing the vulnerability.
Summary	String	The vulnerability summary.
Title	String	The title of the vulnerability.
Vendor	String	The vendors that are affected by the vulnerability.
VulLevel	String	The severity level of the vulnerability.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeVulDetails
&Name=oval:com.redhat.rhsa:def:20170036
&Type=cve
&<Common request parameters>
```

- Sample responses (JSON format)

```

2.16.4.4.18 DescribeVulNumStatistics

Description

You can call this operation to query vulnerability statistics.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulNumStatistics.
StartTs	Long	No	The start time for statistics collection.
EndTs	Long	No	The end time for statistics collection.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CmsDealedTotalNum	Integer	The number of CMS vulnerabilities handled.
CmsNum	Integer	The number of CMS vulnerabilities.
CveNum	Integer	The number of CVE vulnerabilities.
EmgNum	Integer	The number of other vulnerabilities.
SysNum	Integer	The number of Windows OS vulnerabilities.
VulAsapSum	Integer	The number of vulnerabilities that need to be handled as soon as possible.

Name	Type	Description
VulDealedTotalNum	Integer	The total number of vulnerabilities handled.
VulSeriousTotal	Integer	The total number of critical vulnerabilities.
VulHighTotal	Integer	The total number of important vulnerabilities.
VulMediumTotal	Integer	The total number of moderate vulnerabilities.
VulLowTotal	Integer	The total number of low vulnerabilities.
VulLaterSum	Integer	The number of vulnerabilities that can be handled later.
VulNntfSum	Integer	The number of vulnerabilities that do not need to be fixed temporarily.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeVulNumStatistics
&EndTs=1514736000000
&StartTs=1514736000000
&Uids=46ef7c05-0c53-486c-b446-ef6ff972551c
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "VulHighTotal":0,
  "CveNum":1,
  "VulMediumTotal":0,
  "EmgNum":0,
  "VulLowTotal":0,
  "VulNntfSum":1,
  "VulAsapSum":0,
  "SysNum":0,
  "VulDealedTotalNum":1,
  "RequestId":"093C121C-2981-4E69-8309-CD1BDD8C872A",
  "CmsNum":0,
  "VulSeriousTotal":0,
  "CmsDealedTotalNum":0,
  "VulLaterSum":0
}
```

2.16.4.4.19 DescribeVulLevelStatistics

Description

You can call this operation to obtain the statistics on vulnerabilities by vulnerability severity.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulLevelStatistics.
StartTs	Long	No	The start time of the time frame specified for query.
EndTs	Long	No	The end time of the time frame specified for query.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
LevelStatistics	Array	The vulnerability statistics. For more information, see the following parameter descriptions.
CmsDealedTotalNum	Integer	The number of handled CMS vulnerabilities.
CmsNum	Integer	The number of CMS vulnerabilities.
CveNum	Integer	The number of CVE vulnerabilities.
EmgNum	Integer	The number of other vulnerabilities.
Level	String	The severity of the vulnerability.
SysNum	Integer	The number of Windows vulnerabilities.
VulAsapSum	Integer	The number of high-priority vulnerabilities.

Name	Type	Description
VulDealedTotalNum	Integer	The total number of handled vulnerabilities.
VulSeriousTotal	Integer	The total number of critical-risk vulnerabilities.
VulHighTotal	Integer	The total number of important-risk vulnerabilities.
VulMediumTotal	Integer	The total number of moderate-risk vulnerabilities.
VulLowTotal	Integer	The total number of low-risk vulnerabilities.
VulLaterSum	Integer	The number of medium-priority vulnerabilities.
VulNntfSum	Integer	The number of low-priority vulnerabilities.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeVulLevelStatistics

}
```

2.16.4.4.20 DescribeVulMachineList

Description

You can call this operation to query the vulnerability statistics of a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVulMachineList.
StartTs	Long	No	The start time of the time frame during which the statistics were collected.
EndTs	Long	No	The end time of the time frame during which the statistics were collected.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of the returned records.

Name	Type	Description
MachineStatistics	Array	The vulnerability statistics. For more information, see the following parameter descriptions.
CmsDealedTotalNum	Integer	The number of CMS vulnerabilities that have been handled.
CmsNum	Integer	The number of CMS vulnerabilities.
CveNum	Integer	The number of CVE vulnerabilities.
EmgNum	Integer	The number of other vulnerabilities.
SysNum	Integer	The number of Windows vulnerabilities.
VulAsapSum	Integer	The number of high-priority vulnerabilities.
VulDealedTotalNum	Integer	The total number of vulnerabilities that have been handled.
VulSeriousTotal	Integer	The total number of critical-risk vulnerabilities.
VulHighTotal	Integer	The total number of important-risk vulnerabilities.
VulMediumTotal	Integer	The total number of moderate-risk vulnerabilities.
VulLowTotal	Integer	The total number of low-risk vulnerabilities.
VulLaterSum	Integer	The number of medium-priority vulnerabilities.
VulNntfSum	Integer	The number of low-priority vulnerabilities.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeVulMachineList
&EndTs=1514736000000
&StartTs=1514736000000
&Uuids=46ef7c05-0c53-486c-b446-ef6ff972551c
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "TotalCount":0,
  "MachineStatistics":[
    {
      "Uuid":"577f9886-bf66-4c3c-88ac-28c938cb527b",
      "VulHighTotal":0,
      "CveNum":1,
      "VulMediumTotal":0,
      "EmgNum":0,
      "VulLowTotal":0,
      "VulNntfSum":0,
      "VulAsapSum":0,
      "SysNum":0,
      "VulDealedTotalNum":0,
      "CmsNum":0,
      "VulSeriousTotal":0,
      "CmsDealedTotalNum":0,
      "VulLaterSum":0
    }
  ],
  "RequestId":"A3F8BE63-9BA1-450D-BB5D-CE9205E6645D"
}
```

2.16.4.4.21 OperateVul

Description

You can call this operation to handle detected vulnerabilities.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to OperateVul.
Info	String	No	The vulnerability information, in JSON format. For more information , see the sample request.

Name	Type	Required	Description
OperateType	String	No	The type of the operation. Valid values: - vul_fix: indicates an operation to fix the vulnerability. - vul_verify: indicates an operation to verify the vulnerability fix. - vul_rebooted: indicates an operation to verify the vulnerability fix after the server is restarted. - vul_rollback: indicates an operation to undo the vulnerability fix. - vul_ignore: indicates an operation to ignore the vulnerability. - vul_undo_ignore: indicates an operation to unignore the vulnerability. - vul_delete: indicates an operation to delete the vulnerability record.
Reason	String	No	The reason why the vulnerability is ignored if the OperateType parameter is set to vul_ignore.
Type	String	No	The type of the vulnerability.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=OperateVul
&Info=[{"name":"oval:com.redhat.rhsa:def:20171100","uuid":"e49fb179-bbe7-4b6c-
ab65-e106fb58d235","tag":"oval"}]
&OperateType=vul_ignore
&Reason=Postpone the fix
&Type=cve
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"A3F8BE63-9BA1-450D-BB5D-CE9205E6645D"
}
```

2.16.4.4.22 ModifyBatchIgnoreVul

Description

You can call this operation to ignore multiple vulnerabilities.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyBatchIgnoreVul.
Info	String	No	The vulnerabilities to be ignored , in JSON format. For more information, see the sample request.
Reason	String	No	The reason for ignoring the vulnerabilities.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=ModifyBatchIgnoreVul
&Info=[{"name":"oval:com.redhat.rhsa:def:20162972","type":"cve","aliasName":"RHSA
-2016:2972: vim security update (Moderate)"}]
&Reason=Postpone handling
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"E3785090-CFF4-4C53-82E4-08F902586053"
}
```

2.16.4.4.23 DeleteVulBatch

Description

You can call this operation to delete a specified batch of vulnerabilities.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteVulBatch.
BatchName	String	No	The name of the vulnerability batch.
Resource	String	No	The scenario of the vulnerability batch.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DeleteVulBatch
```

```
&BatchName=Vulnerabilities managed by network security team  
&Resource=vulnerability  
&<Common request parameters>
```

- Sample responses (JSON format)

```
{  
  "RequestId":"E3785090-CFF4-4C53-82E4-08F902586053"  
}
```

2.16.4.4.24 ExportVul

Description

You can call this operation to export vulnerability records that match the specified criteria.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ExportVul.
AliasName	String	No	The alias of the vulnerability.
BatchName	String	No	The name of the vulnerability fix batch.
Dealed	String	No	Indicates whether the vulnerability has been handled. Valid values: • Y: indicates that the vulnerability has been handled. • N: indicates that the vulnerability has not been handled.
Level	String	No	The severity of the vulnerability.
Name	String	No	The name of the vulnerability.

Name	Type	Required	Description
Necessity	String	No	The priority of the vulnerability. Valid values: • asap: indicates that the vulnerability must be fixed as soon as possible. • later: indicates that the vulnerability can be fixed later. • nntf: indicates that the vulnerability can be ignored.
Resource	String	No	The source of the vulnerability fixing batch.
StatusList	String	No	The status of the vulnerability. Valid values: • 1: indicates that the vulnerability is pending. • 2: indicates that the vulnerability has been ignored. • 3: indicates that the vulnerability has been confirmed. • 8: indicates that the vulnerability has been marked as a false positive. • 16: indicates that the vulnerability is being handled. • 32: indicates that the vulnerability has been handled. You can specify multiple statuses and separate them with commas (,).
Type	String	No	The type of the vulnerability.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentCount	Integer	The number of records that have been exported.
ExportStatus	String	The status of the export task. Valid values: - init: indicates that the export task is being initialized. - pending: indicates that the export task is pending for summarization. - exporting: indicates that the export task is being executed. - success: indicates that the export task has been completed. - fail: indicates that the export task has failed.
Message	String	The status description or failure information of the export task.
FileName	String	The name of the exported file.
Id	Integer	The ID of the export task.
Link	String	The download link of the exported file.
Progress	Integer	The export progress.
TotalCount	Integer	The total number of records that have been exported.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ExportVul
for example, RhsA-2016:2972: vim security update (Moderate), and trigger another
vulnerability scan.
&BatchName=Security group test
&Dealed=y
&Level=low
&Name=oval:com.redhat.rhsa:def:20162972
&Necessity=later
&Resource=vulnerability
```

```
&StatusList=1
&Type=cve
&Uuids=46ef7c05-0c53-486c-b446-ef6ff972551c
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "FileName": "cve_20180303",
  "RequestId": "3B3C79B1-617E-4081-903B-86EA4AC0213F",
  "Id": 36
}
```

2.16.4.4.25 DescribeVulExportInfo

Description

You can call this operation to query a vulnerability record export task.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeVulExportInfo.
ExportId	Long	No	The ID of the vulnerability record export task.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentCount	Integer	The number of records that have been exported.

Parameter	Type	Description
ExportStatus	String	The status of the export task. Valid values: - init: indicates that the export task is being initialized. - pending: indicates that the export task is pending. - exporting: indicates that the export task is being executed. - success: indicates that the export task has been completed. - fail: indicates that the export task has failed.
Message	String	The status description or failure information of the export task.
FileName	String	The name of the exported file.
Id	Integer	The ID of the export task.
Link	String	The download link of the exported file.
Progress	Integer	The export progress.
TotalCount	Integer	The total number of records that have been exported.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribeVulExportInfo
&ExportId=10
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "Status": "success",
  "Link": "http://jiangzhi.oss-cn-shanghai.example.com/export/sys_20171124_1511510709277.zip?Expires=1511514309&OSSAccessKeyId=<yourAccessKeyId>&Signature=xxxx%xxxx%3D",
  "TotalCount": 2,
  "Message": "success",
  "FileName": "sys_20171124",
  "RequestId": "9C689776-0F8B-4290-8C11-D9242A86C75B",
  "CurrentCount": 1,
  "Id": 17,
```

```
"Progress":100
}
```

2.16.4.5 Baseline check operations

2.16.4.5.1 DescribeStrategy

Description

You can call this operation to obtain a list of baseline check policies.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeStrategy.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The total number of the returned records.
Strategies	Array	The list of baseline check policies. For more information, see the following parameter descriptions.
CycleDays	Integer	The cycle of policy execution.
CycleStartTime	Integer	The start time of policy execution. Valid values: 0: indicates the period from 00:00 to 06:00. 6: indicates the period from 06:00 to 12:00. 12: indicates the period from 12:00 to 18:00. 18: indicates the period from 18:00 to 24:00.
EcsCount	Integer	The number of hosts using the policy.
Id	Integer	The ID of the policy.

Name	Type	Description
Name	String	The name of the policy.
RiskCount	Integer	The number of at-risk items contained in the policy.
Type	Integer	The policy type. Valid values: 1: indicates a system default policy. 2: indicates a custom policy.
ConfigTargets	Array	The information about asset groups using the policy. For more information, see the following parameter descriptions.
Flag	String	A flag that indicates whether the policy applies to the specified asset group. Valid values: - add: indicates the whitelist mode, that is, the policy applies to the asset group. - del: indicates the blacklist mode, that is, the policy does not apply to the asset group.  Note: Generally, the blacklist mode is used for system default policies, and the whitelist mode is used for custom policies.
TargetType	String	The return value is fixed to groupId, which indicates that the value of the Target parameter is an asset group ID.
Target	String	The ID of the asset group.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeStrategy
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
```

```
"Count": 2,
"RequestId": "4F914046-4358-4BA9-BE42-83AA1FD1FF52",
"Strategies": [
  {
    "Name": "test",
    "RiskCount": 2,
    "CycleDays": 3,
    "Type": 2,
    "CycleStartTime": 6,
    "ConfigTargets": [
      {
        "Target": "4361221",
        "Flag": "add",
        "TargetType": "groupid"
      }
    ],
    "Id": 15161,
    "EcsCount": 0
  },
  {
    "Name": "Default policy",
    "RiskCount": 14,
    "CycleDays": 1,
    "Type": 1,
    "CycleStartTime": 0,
    "ConfigTargets": [
      {
        "Target": "none",
        "Flag": "del",
        "TargetType": "flag_item"
      }
    ],
    "Id": 20,
    "EcsCount": 48
  }
]
```

2.16.4.5.2 DescribeStratetyDetail

Description

You can call this operation to query the details of a specified baseline check policy.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeStratetyDetail.
Id	String	No	The ID of the baseline check policy.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Strategy	Array	The details of the baseline check policy. For more information, see the following parameter descriptions.
CycleDays	Integer	The cycle of policy execution.
CycleStartTime	Integer	The start time of policy execution. Valid values: • 0: indicates the period from 00:00 to 06:00. • 6: indicates the period from 06:00 to 12:00. • 12: indicates the period from 12:00 to 18:00. • 18: indicates the period from 18:00 to 24:00.
Id	Integer	The ID of the policy.
Name	String	The name of the policy.
Type	Integer	The type of the policy. Valid values: • 1: indicates a system default policy. • 2: indicates a custom policy.
RiskTypeWhiteListQueryResultList	Array	The risk information contained in the policy . For more information, see the following parameter descriptions.
Alias	String	The name of the risk category.
On	Boolean	Indicates whether to check for risks of the specified category.
TypeName	String	The code of the risk category.
SubTypes	Array	The list of risk subcategories. For more information, see the following parameter descriptions.
Alias	String	The name of the risk subcategory.
TypeName	String	The code of the risk subcategory.

Name	Type	Description
On	Boolean	Indicates whether to check for risks of the specified subcategory.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeStratetyDetail
&Id=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "99F17C4B-2E23-4B41-BBEB-C03963B06EB4",
  "Strategy": {
    "Name": "Yunwu testing",
    "CycleDays": 1,
    "CycleStartTime": 18,

            "TypeName": "memcached-check"
          },
          {
            "On": true,
            "Alias": "CentOS 7",
            "TypeName": "centos7"
          },
          {
            "On": false,
            "Alias": "Tomcat 7",
            "TypeName": "tomcat7"
          },
          {
            "On": false,
            "Alias": "MongoDB",
            "TypeName": "mongodb-check"
          }
        ]
      }
    ]
  }
}
```

}

2.16.4.5.3 ModifyStrategy

Description

You can call this operation to modify the basic information of a baseline check policy.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyStrategy.
CycleDays	String	No	The baseline check cycle.
CycleStartTime	String	No	The time when the baseline check starts. Valid values: 0: starts at 00:00 and ends at 06:00. 6: starts at 06:00 and ends at 12:00. 12: starts at 12:00 and ends at 18:00. 18: starts at 18:00 and ends at 24:00.
Id	String	No	The ID of the baseline check policy.  Note: If this parameter is set to null, a baseline check policy is added.
Name	String	No	The name of the baseline check policy.
RiskSubType eName	String	No	The sub-risk types in the baseline check policy. Separate multiple sub-risk types with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Name	Type	Description
Result	Struct	The returned information. For more information, see the following parameter descriptions.
StrategyId	Integer	The ID of the baseline check policy.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=ModifyStrategy
&CycleDays=1
&CycleStartTime=8
&Id=52
&Name=Web server
&RiskSubTypeName=redis_check,linux_password
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "161F1BEE-5268-4935-9763-C39A2F7F65DD",
  "Result": 2
  "StrategyId": 52
}
```

2.16.4.5.4 DeleteStrategy

Description

You can call this operation to delete a specified baseline check policy.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteStrategy.
Id	String	No	The ID of the baseline check policy.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DeleteStrategy
&Id=123456
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "43F670F3-AB40-4E91-BC7D-C57468834F67"
}
```

2.16.4.5.5 DescribeStrategyTarget

Description

You can call this operation to query the information about asset groups to which a specified baseline check policy applies.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeStrategyTarget.
Config	String	No	The policy configuration information. The baseline check policy ID is specified in JSON format, for example, {"strategyId": 15161}.
Type	String	No	The configuration type. Set the value to hc_strategy.

Name	Type	Required	Description
Target	String	No	The ID of the asset group to which the baseline check policy applies.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The total number of returned records.
StrategyTargets	Array	The information about asset groups to which the policy applies. For more information, see the following parameter descriptions.
Flag	String	Indicates whether the policy applies to the specified asset group. Valid values: - add: indicates the whitelist mode, that is, the policy applies to the asset group. - del: indicates the blacklist mode, that is, the policy does not apply to the asset group.  Note: Generally, the blacklist mode is used for system default policies, and the whitelist mode is used for custom policies.
TargetType	String	The return value is fixed to groupId, indicating that the value of the Target parameter is the ID of the asset group.
Target	String	The asset group ID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeStrategyTarget
&Config={"strategyId":15161}
&Type=hc_strategy
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "Count": 1,
  "StrategyTargets": [
    {
      "Flag": "del",
      "Target": "281801",
      "TargetType": "groupId"
    }
  ]
  "requestId": "B44F545D-15CF-4A57-B8BF-4340D15D0507"
}
```

2.16.4.5.6 ModifyStrategyTarget

Description

You can call this operation to modify the information about the asset groups that a specified baseline check policy applies to.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyStrategyTarget.
Config	String	No	The policy configuration information. The baseline check policy ID is specified in JSON format, for example, {"strategyId": 15161}.
Type	String	No	The configuration type. Set the value to hc_strategy.
Target	String	No	The information about asset groups that the baseline check policy applies to. For more information, see the sample request.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyStrategyTarget
&Type=hc_strategy
&Config={"strategyId":36071}
&Target=[{"targetType":"groupId","target":"1111","flag":"add"}]
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "B44F545D-15CF-4A57-B8BF-4340D15D0507"
}
```

2.16.4.5.7 DescribeUuidConfig

Description

You can call this operation to check whether baseline check is enabled for a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeUuidConfig.
Uuid	String	No	The UUID of the server.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Data	Struct	The baseline check configuration. For more information, see the following parameter descriptions.
Flag	String	Indicates whether baseline check is enabled. Valid values: - add: indicates enabled. - del: indicates disabled.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeUuidConfig
&uuid=4bc19998-e100-4b04-ab11-1e677418d311
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "Data": {
    "Flag": "del"
  },
  "RequestId": "A89978FE-BC35-427E-A4B1-7AEAE741CC2",
}
```

2.16.4.5.8 ModifyMachineConfig

Description

You can call this operation to configure whether to apply a specified baseline check policy to a specified server.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyMachineConfig.
Type	String	No	The configuration type. Set the value to hc_switch, indicating the baseline check policy switch.
Target	String	No	The specified server, in JSON format. For more information, see the sample request.
Config	String	No	The policy configuration information. The baseline check policy ID is specified in JSON format, for example, {"strategyId": 15161}.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyMachineConfig
&target={"targetType":"uuid","target":"2738e842-7d46-42f7-acb4-e6796b051ddc","ip":
"x.x.x.x","flag":"del"}
&type=hc_switch
&config={"strategyId":15161}
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
```

```
"RequestId": "A89978FE-BC35-427E-A4B1-7AEAE741CC2",  
}
```

2.16.4.5.9 DescribeUserSetting

Description

You can call this operation to query the number of days an invalid risk is kept for before it is automatically deleted in baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeUserSetting.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
InvalidWarningKeepDays	Integer	The number of days that an invalid risk is kept for.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeUserSetting  
&<Common request parameters>
```

- Sample responses (JSON format)

```
{  
  "InvalidWarningKeepDays":90,  
  "RequestId":"0A079FE2-0D1B-4A4D-A4EF-D02B5DDE12A7"
```

```
}
```

2.16.4.5.10 CreateUserSetting

Description

You can call this operation to specify the number of days an invalid risk is kept for before it is automatically deleted in baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateUserSetting.
InvalidWarningKeepDays	Integer	No	The number of days an invalid risk is kept for. Valid values: 7: indicates that the invalid risk item is to be deleted in seven days. 30: indicates that the invalid risk item is to be deleted in 30 days. 90: indicates that the invalid risk item is to be deleted in 90 days.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=CreateUserSetting
&InvalidWarningKeepDays=90
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
```

```
"RequestId": "43F670F3-AB40-4E91-BC7D-C57468834F67",  
}
```

2.16.4.5.11 DescribeRiskWhiteList

Description

You can call this operation to obtain the whitelist of risk items that are exempt from the baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRiskWhiteList.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query output. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
RiskName	String	No	The name of the risk item. This parameter supports fuzzy match.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
Count	Integer	The number of records on the current page.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
WhiteLists	Array	The risk item whitelist. For more information, see the following parameter descriptions.

Name	Type	Description
Reason	String	The reason for adding the risk item to the whitelist.
RiskId	Long	The ID of the risk item.
RiskName	String	The name of the risk item.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeRiskWhiteList
&RiskName=SSH logon baseline check
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"B452E97A-7DFA-44FC-915D-5D590A702846",
  "CurrentPage":1,
  "WhiteLists":[
    {
      "RiskName":"SSH logon baseline check",
      "RiskId":1
    }
  ],
  "Count":1
}
```

2.16.4.5.12 BatchDeleteWhiteList

Description

You can call this operation to delete multiple risks from the whitelist for baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to BatchDeleteWhiteList.

Name	Type	Required	Description
RiskIdList	String	No	The ID of the risk to be deleted from the whitelist. Separate multiple IDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=BatchDeleteWhiteList
&RiskIdList=1,2,3
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "E3785090-CFF4-4C53-82E4-08F902586053"
}
```

2.16.4.5.13 CreateUserWhiteList

Description

You can call this operation to add a specified risk to the baseline check whitelist. After this operation, the risk is not reported during baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateUserWhiteList.

Name	Type	Required	Description
RiskIdList	String	No	The ID of the risk to be added to the whitelist. Separate multiple IDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=CreateUserWhiteList
&RiskIdList=1,2,3
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "E3785090-CFF4-4C53-82E4-08F902586053"
}
```

2.16.4.5.14 DescribeStrategy

Description

You can call this operation to query the execution details of a specified baseline check policy.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeStrategy.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Strategies	Array	The list of baseline check policies. For more information, see the following parameter descriptions.
CycleDays	Integer	The execution cycle of the policy.
CycleStartTime	Integer	The start time of policy execution.
EcsCount	Integer	The number of hosts to which the policy applies.
ExecStatus	Integer	The current execution status of the policy. Valid values: 1: indicates that the policy has been executed. 2: indicates that the policy is being executed.
Id	Integer	The ID of the policy.
Name	String	The name of the policy.
ProcessRate	Integer	The progress of policy execution. Unit: percentage.
RiskCount	Integer	The number of risk items contained in the policy.
ConfigTargets	Array	The asset group to which the policy applies . For more information, see the following parameter descriptions.

Name	Type	Description
Flag	String	Indicates whether the policy applies to the specified asset group. Valid values: - add: indicates the whitelist mode, that is, the policy applies to the asset group. - del: indicates the blacklist mode, that is, the policy does not apply to the asset group.  Note: Generally, the blacklist mode is used for system default policies, and the whitelist mode is used for custom policies.
TargetType	String	The return value is fixed to groupId, indicating that the value of the Target parameter is the ID of the asset group.
Target	String	The asset group ID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeStrategy
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "requestId": "751BEDD8-A16F-49CE-A3C4-605849645D79",
  "Strategies": [
    {
      "Name": "Threat Detection Service No. 12345",
      "RiskCount": 4,
      "CycleDays": 1,
      "CycleStartTime": 6,
      "Type": 2,
      "ProcessRate": 0,
      "ConfigTargets": [
        {
          "Flag": "add",
          "Target": "5078483",
          "TargetType": "groupId"
        }
      ],
      "Id": 36071,
      "ExecStatus": 1,
    }
  ]
}
```

```
    "EcsCount": 2
  }
}
```

2.16.4.5.15 DescribeStrategyExecDetail

Description

You can call this operation to query the execution details of a baseline check policy.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeStrategyExecDetail.
StrategyId	Integer	No	The ID of the baseline check policy.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
EndTime	String	The time when the baseline check was complete.
FailCount	Integer	The number of servers that failed to pass the check.
FailedEcsList	Array	A list of servers that failed to pass the check . For more information, see the following parameter descriptions.
Ip	String	The IP address of the server.
InstanceName	String	The instance name of the server.
IntranetIp	String	The private IP address of the server.
Reason	String	The reason that causes the baseline check failure.
InProcessCount	Integer	The number of servers that are being checked.
percent	String	The baseline check progress in percentage.

Name	Type	Description
Source	String	The baseline check mode: automatic or manual.
StartTime	String	The time when the baseline check started.
SuccessCount	Integer	The number of servers that have passed the check.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeStrategyExecDetail
&StrategyId=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "requestId": "751BEDD8-A16F-49CE-A3C4-605849645D79",
  "Source": "Schedule",
  "InProgressCount": 0,
  "SuccessCount": 1,
  "Percent": 100,
  "EndTime": "2018-04-08 12:15:20",
  "FailedEcsList": [],
  "StartTime": "2018-04-08 12:15:10",
  "FailCount": 0,
}
```

2.16.4.5.16 DescribeRiskType

Description

You can call this operation to query all types of risks detected in baseline check and view the number of risks that have been detected by a baseline check policy or on the specified servers for a specific risk type.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRiskType.

Name	Type	Required	Description
StrategyId	Long	No	The ID of the baseline check policy.
Uuids	String	No	The UUID of the server. Multiple UUIDs are separated with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The number of risk types.
RiskTypes	Array	A list of risk types. For more information, see the following parameter descriptions.
Alias	String	The name of the risk type.
TypeName	String	The code of the risk type.
WarnCount	String	The number of risks that have been detected.
SubTypes	Array	A list of sub-risk types. For more information , see the following parameter descriptions.
Alias	String	The name of the sub-risk type.
TypeName	String	The code of the sub-risk type.
WarnCount	String	The number of risks that have been detected.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeRiskType
&StrategyId=10
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "11D3993A-02B8-4FD9-9116-922BCDE53A80",
  "RiskTypes": [
    {
```

```

"TypeName": "system",
"SubTypes": [
  {
    "TypeName": "group_policy",
    "Alias": "Group policy",
    "WarnCount": 0
  },
  {
    "TypeName": "baseline",
    "Alias": "Baseline policy",
    "WarnCount": 0
  },
  {
    "TypeName": "register",
    "Alias": "Registry",
    "WarnCount": 0
  }
],
"Alias": "System",
"WarnCount": 0
}
],
"count": 1,
}

```

2.16.4.5.17 Describesummary

Description

You can call this operation to query the risks detected in baseline check by risk type.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to Describesummary.
PageSize	Integer	No	The number of records displayed on a page. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
Dealed	String	No	Indicates whether the risk has been handled. Valid values: - Y: indicates that the risk has been handled. - N: indicates that the risk has not been handled.

Name	Type	Required	Description
RiskLevels	String	No	The risk level. Separate multiple risk levels with commas (,).
RiskName	String	No	The name of the risk.  Note: Fuzzy match is supported.
StatusList	String	No	The status of the risk. Valid values: 1: indicates that the risk is pending. 2: indicates that the risk has been ignored. 3: indicates that the risk has been confirmed. 8: indicates that the risk has been marked as a false positive. 16: indicates that the risk is being handled. 32: indicates that the risk has been handled. You can specify multiple statuses and separate them with commas (,).
StrategyId	Long	No	The ID of the baseline check policy.
TypeNames	String	No	The type of the risk. Separate multiple risk types with commas (,).
SubTypeNames	String	No	The type of the sub-risk. Separate multiple sub-risk types with commas (,).
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The number of returned records.

Name	Type	Description
Count	Integer	The number of returned risk records.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
WarningSummarys	Array	A list of risks. For more information, see the following parameter descriptions.
LastFoundTime	String	The latest time when the risk was detected.
Level	String	The risk level.
PendingCount	Integer	The number of pending risks.
RiskDetail	String	The risk details.
RiskId	Long	The ID of the risk.
RiskName	String	The name of the risk.
TypeAlias	String	The type of the risk.
SubTypeAlias	String	The type of the sub-risk.
TotalCount	Integer	The total number of risks.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=Describesummary
&CurrentPage=20
&Dealed=Y
&PageSize=10
&StrategyId=1
&Uuid=2738e842-7d46-42f7-acb4-e6796b051ddc
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"38AAFEED-F52F-4B2E-9F28-FC4A35F8D432",
  "CurrentPage":1,
  "count": 1,
  "WarningSummarys":[
    {
      "RiskId":1,
      "LastFoundTime":"2018-04-08 16:51:26",
```

```

    "RiskDetail": "The SSH logon security policy checks the following configurations: \n1. Checks whether the logon port is the default port 22\n2 and whether the root account is allowed\n3. Checks whether the SSH V1 protocol is used\n4. Checks whether the RSH protocol is used\n5. Checks whether authentication-based logon is performed\nSolution: \n Edit /etc/ssh/sshd_config\n1. Port (not 22)\n2. PermitRootLogin (no)\n3. Protocol (2)\n4. IgnoreRhosts (yes)\n5. e) HostbasedAuthentication (no)
    "Level": "low",
    "TypeAlias": "System",
    "SubTypeAlias": "Baseline check policy",
    "RiskName": "SSH logon baseline check"
  }
}
}

```

2.16.4.5.18 OperateWarning

Description

You can call this operation to handle the risk alert records detected during the baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to OperateWarning.
RiskWarningIds	String	No	The risk alert record ID. Separate multiple risk alert record IDs with commas (,).
OperateType	String	No	The type of the operation. Valid values: - verify: indicates an operation to verify the risk alert. - ignore: indicates an operation to ignore the risk alert. - cancellgnore: indicates an operation to cancel the ignore operation on the risk alert. - delete: indicates an operation to delete the risk alert record.
Reason	String	No	The reason why the risk alert record is ignored if the OperateType parameter is set to ignore.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=OperateWarning
&OperateType=verify
&RiskWarningIds=22,45
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "38AAFEFF-F52F-4B2E-9F28-FC4A35F8D432"
}
```

2.16.4.5.19 ExportWarning

Description

You can call this operation to export risks that match the specified criteria from baseline check.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ExportWarning.
IsSummaryExport	String	No	Indicates whether to export the summary page. Valid values: 1: exports the summary page. 0: does not export the summary page.

Name	Type	Required	Description
Dealed	String	No	Indicates whether the risk has been handled. Valid values: - Y: indicates that the risk has been handled. - N: indicates that the risk has not been handled.
RiskLevels	String	No	The risk level. Multiple risk levels are separated with commas (,).
RiskName	String	No	The name of the risk.  Note: Fuzzy match is supported.
StrategyId	Integer	No	The ID of the baseline check policy.
TypeNames	String	No	The risk type.
SubTypeNames	String	No	The sub-risk type.
Uuids	String	No	The UUID of the server. Multiple UUIDs are separated with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
FileName	String	The name of the exported file.
Id	Integer	The ID of the export task.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ExportWarning
&Dealed=n
&RiskLevels=serious,high,medium,low
&RiskName=Weak FTP password
&StrategyId=15161
&SubTypeNames=centos7
```

```
&TypeNames=cis
&Uuids=6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "FileName": "health_check_export_20180306",

```

2.16.4.5.20 DescribeExportInfo

Description

You can call this operation to query the export task information, including the export progress and the download link of the exported file.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeExportInfo.
ExportId	Long	No	The ID of the export task.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentCount	Integer	The number of records that have been exported.
FileName	String	The name of the exported file.
Id	Integer	The ID of the export task.
GmtCreate	Long	The time when the export task was created.
Link	String	The download link of the exported file.
Progress	Integer	The export progress.
TotalCount	Integer	The total number of records that have been exported.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribeExportInfo
&ExportId=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "Link": "http://hc-export.oss-cn-shanghai.example.com/export_hc/health_ckeck_export_20180303_1520065303578.zip?Expires=1520670103&OSSAccessKeyId=<yourAccessKeyId>&Signature=xxxx%xxxxx%3D",

  "Progress": 100
}
```

2.16.4.6 Unusual logon operations

2.16.4.6.1 DescribeBaseConfigs

Description

You can call this operation to query the logon security settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBaseConfigs.

Name	Type	Required	Description
Type	String	Yes	The type of the logon security configuration record. Valid values: - login_common_location: indicates an approved logon location. - login_common_ip: indicates an approved logon IP address. - login_common_time: indicates an approved logon time period. - login_common_account: indicates an approved logon account.
Target	String	No	The specified server.  Note: You must specify this parameter to query the logon security settings of a specified server. For more information about the format, see the sample request.
PageSize	Integer	No	The maximum number of records to be displayed on each page. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of the returned records.

Name	Type	Description
BaseConfigs	Array	The logon security settings. For more information, see the following parameter descriptions.
Account	String	The approved logon account.
EndTime	String	The end time of the approved logon time period.
Ip	String	The approved logon IP address.
Location	String	The approved logon location.
StartTime	String	The start time of the approved logon time period.
TotalCount	Integer	The total number of servers.
UuidCount	Integer	The number of servers to which the specified configuration record applies.
TargetList	Array	The information about servers to which the specified configuration record applies . For more information, see the following parameter descriptions.
TargetType	String	The type of the Target parameter value. Valid values: - groupId: indicates an asset group ID. - uuid: indicates a server UUID.
Target	String	The asset group ID or server UUID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeBaseConfigs
&CurrentPage=1
&PageSize=20
&Target=[{"targetType":"uuid","target":"6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac"}]
&Type=login_common_location
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "BaseConfigs": [{
```

```
"totalCount": 9,  
"location": "United States",  
"uuidCount": 1,  
"targetList": [{  
  "target": "6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac",  
  "targetType": "uuid"  
}]  
},  
"TotalCount": 1,  
"PageSize": 5,  
"RequestId": "485ABE58-4E27-4416-997C-F8F3B8748EB6",  
"CurrentPage": 1  
}
```

2.16.4.6.2 ModifyBaseConfig

Description

You can call this operation to modify logon security settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyBaseConfig.
Type	String	Yes	The type of the logon security settings. Valid values: - login_common_location: indicates approved logon locations. - login_common_ip: indicates approved logon IP addresses. - login_common_time: indicates approved logon time periods. - login_common_account: indicates approved logon accounts.

Name	Type	Required	Description
Target	String	No	The target server.  Note: You must set this parameter when you need to query the logon security settings for a server. For more information about the format, see the following sample request.
Config	String	No	The logon security settings. The formats for all the settings are as follows: • Approved logon locations: {"location": "Ganzhou City"} • Approved logon IP addresses: {"ip": "x.x.x.x"} • Approved logon time periods: {"startTime": "16:18", "endTime": "16:18"} • Approved logon accounts: {"account": "dbaadmin"}

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyBaseConfig
&Config={"startTime":"16:18","endTime":"16:18"}
&Target=[{"targetType":"uuid","target":"0c797eb1-e6b9-4b5a-8917-a7e6cbbb4b2e","
flag":"add"}, {"targetType":"uuid","target":"1759b0ea-6dd7-438b-b60d-c90179bd9ebc",
"flag":"del"}]
&Type=login_common_location
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "RequestId": "BB8F5902-BD50-49AB-B124-18E9CA92BB99"
}
```

2.16.4.6.3 DeleteBaseConfig

Description

You can call this operation to delete a logon security setting, such as an approved logon location or IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteBase Config.
Config	String	Yes	The logon security setting. The formats of the logon security settings and examples are as follows: - Approved logon location: {"location": "Ganzhou City"} - Approved logon IP address: {"ip": "x.x.x.x"} - Approved logon time range: {"startTime": "16:18", "endTime": "16:18"} - Approved logon account: {"account": "dbaa****"}

Parameter	Type	Required	Description
Type	String	Yes	The type of the logon security setting. Valid values: - login_common_location: indicates an approved logon location. - login_common_ip: indicates an approved logon IP address. - login_common_time: indicates an approved logon time range. - login_common_account: indicates an approved logon account.
Target	String	No	The target server.  Note: You must set this parameter if you want to delete a logon security setting for a server. For more information about the format, see the following sample request.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DeleteBaseConfig
&Config={"location":"Ganzhou City"}
&Target=[{"targetType":"uuid","target":"6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac"}]
&Type=login_common_location
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "E3785090-CFF4-4C53-82E4-08F902586053"
}
```

2.16.4.6.4 DescribeSwitchConfigs

Description

You can call this operation to query the logon security configuration records in the logon security settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSwitchConfigs.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The total number of returned records.
ConfigList	Array	The statuses of the logon security configuration items. For more information, see the following parameter descriptions.
Item	String	The logon security configuration items. Valid values: • login_common_location: indicates an approved logon location. • login_common_ip: indicates an approved logon IP address. • login_common_time: indicates an approved logon time range. • login_common_account: indicates an approved logon account.

Name	Type	Description
Status	Integer	The status of the configuration item. Valid values: 1: indicates enabled. 0: indicates disabled.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeSwitchConfigs
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "Count":3,
  "RequestId":"3F2C126D-870B-4AE4-8604-58BDECF873F4",
  "ConfigList":[
    {
      "Status":1,
      "Item":"login_common_ip"
    },
    {
      "Status":0,
      "Item":"login_common_account"
    },
    {
      "Status":0,"Item":"login_common_time"
    }
  ]
}
```

2.16.4.6.5 ModifySwitchConfig

Description

You can call this operation to modify the setting about whether to enable a logon security configuration record to identify a valid logon to a server in the logon security settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifySwitchConfig.
Item	String	Yes	The logon security configuration items. Valid values: - login_common_location: indicates an approved logon location. - login_common_ip: indicates an approved logon IP address. - login_common_time: indicates an approved logon time range. - login_common_account: indicates an approved logon account.
Status	Integer	Yes	The status of the logon security configuration switch. Valid values: 1: indicates enabled. 0: indicates disabled.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The total number of returned records.
ConfigList	Array	The status of the logon security configuration switch. For more information, see the following parameter descriptions.

Name	Type	Description
Item	String	The logon security configuration items. Valid values: - login_common_location: indicates an approved logon location. - login_common_ip: indicates an approved logon IP address. - login_common_time: indicates an approved logon time range. - login_common_account: indicates an approved logon account.
Status	Integer	The status of the logon security configuration switch. Valid values: 1: indicates enabled. 0: indicates disabled.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifySwitchConfig
&Item=login_common_location
&Status=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "3F2C126D-870B-4AE4-8604-58BDECF873F4"
}
```

2.16.4.6.6 DescribeConfigTarget

Description

You can call this operation to query the information about servers to which a specified logon security configuration record applies.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeConfigTarget.
Type	String	Yes	The logon security configuration record used to identify a valid logon to a server. Valid values: - login_common_location: indicates an approved logon location. - login_common_ip: indicates an approved logon IP address. - login_common_time: indicates an approved logon time range. - login_common_account: indicates an approved logon account.
Target	String	No	The specified server.  Note: You need to specify this parameter to query the logon security configuration records of a specified server. For more information about the format, see the sample request.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Count	Integer	The total number of returned records.

Name	Type	Description
TargetList	Array	The information about server to which the specified configuration record applies. For more information, see the following parameter descriptions.
TargetType	String	The type of the Target parameter value. Valid values: - groupId: indicates an asset group ID. - uuid: indicates a server UUID.
Target	String	The asset group ID or server UUID.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeConfigTarget
&Config={"uuidCount":1,"location":"Ganzhou"}
&Target=[{"targetType":"uuid","target":"6dbdbfe7-06fa-4d9a-8268-ce2dc6d673ac"}]
&Type=login_common_location
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TargetList": [{
    "Target": "inet-e53455ec-a134-4d46-9ff5-c4f3a5fe0f02",
    "TargetType": "uuid"
  }, {
    "Target": "inet-25f4ef74-29c7-49fd-85cc-b4543a2489a8",
    "TargetType": "uuid"
  }
],
  "Count": 2,
  "RequestId": "B8064EA4-9472-4D03-B7D1-6684DB5CD0BE",
}
```

2.16.4.7 Webshell detection operations

2.16.4.7.1 DescribeWebPath

Description

You can call this operation to query the Web directories defined in webshell settings.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeWebPath.
PageSize	Integer	No	The number of records to return on each page. Default value: 20.
CurrentPage	Integer	No	The number of the page to return. Default value: 1.
Type	String	No	The type of the settings. Set this parameter to web_path to specify the Web directory settings.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The number of returned records.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
Count	Integer	The number of Web directories.
ConfigList	Array	The Web directories. For more information, see the following descriptions.
WebPath	String	The path of the Web directory.
TargetList	Array	The servers that the Web directory has been applied to. For more information, see the following descriptions.
TargetType	String	This parameter always returns a value of uuid, which means that the Target parameter returns the universally unique identifier (UUID) of the server.

Parameter	Type	Description
Target	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribeWebPath
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "PageSize":5,
  "RequestId":"7B6AD7C9-0F8D-4126-B8AA-6DC308B0B534",
  "CurrentPage":1,
  "Count":1,
  "ConfigList":[
    {
      "TargetList":[
        {
          "Target":"inet-f6ac9a93-0818-4052-90e2-d24f18ee198b",
          "TargetType":"uuid"
        }
      ],
      "WebPath":"/usr/local/tomcat/webroot18"
    }
  ]
}
```

2.16.4.7.2 ModifyWebPath

Description

You can call this operation to modify the Web directory in webshell settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyWebPath.

Name	Type	Required	Description
Type	String	No	The configuration type. Set the value to web_path, indicating the web directory configuration.
Config	String	No	The Web directory configuration, in JSON format. For more information , see the sample request.
Target	String	No	The list of target servers to which the Web directory configuration applies, in JSON format. For more information, see the sample request.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=ModifyWebPath
&Type=web_path
&Config={"webPath":"/test"}
&Target={"targetType":"uuid","target":"0c797eb1-e6b9-4b5a-8917-a7e6cbbbb4b2e","
flag":"add"}
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"7B6AD7C9-0F8D-4126-B8AA-6DC308B0B534"
}
```

2.16.4.7.3 DescribeCategoryCount

Description

You can call this operation to query the number of webshells detected by Server Guard.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeCategoryCount.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Webshell	Integer	The number of webshells.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeCategoryCount
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "43F670F3-AB40-4E91-BC7D-C57468834F67",
  "Webshell": 2
}
```

2.16.4.7.4 DescribeWebshell

Description

You can call this operation to query records of webshell files that have been detected by Server Guard, including the detection time and webshell file path.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeWebshell.
GroupId	Integer	No	The ID of the asset group.
Mark	String	No	The IP address or instance name of the server.
Tag	Integer	No	The server tag ID.
Dealed	String	No	The status of the webshell event. Valid values: - n: indicates that the event is pending. - y: indicates that the event has been handled.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
WebshellList	Array	The webshell events. For more information, see the following descriptions.
Os	String	The operating system of the server.
InstanceName	String	The instance name of the server.
GroupId	Long	The ID of the asset group.
Ip	String	The IP address of the server.  Note: The public IP address of the server is displayed preferentially. If no public IP address is assigned to the server, the private IP address of the server is displayed.

Parameter	Type	Description
Uuid	String	The universally unique identifier (UUID) of the server.
FoundTime	String	The time when the webshell file was detected.
InstanceId	String	The instance ID of the server.
TrojanType	String	The type of the webshell file.
FirstFoundTime	String	The time when the webshell file was detected for the first time.
TrojanSize	Long	The size of the webshell file.
Domain	String	The domain name associated with the server.
TrojanPath	String	The path of the webshell file.
Region	String	The region where the server resides.
Status	Integer	The status of the webshell event. Valid values: • 1: indicates that the event is pending. • 2: indicates that the event has been ignored. • 3: indicates that the event has been confirmed. • 8: indicates that the event has been labeled as a false positive. • 16: indicates that the event is being handled. • 32: indicates that the event has been handled.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[ RegionId].example.com/?Action=DescribeWebshell
&Dealed=n
&GroupId=1
&Remark=xx.xx.xx.xx
&Tag=11
```

<Common request parameters>

- Sample response (JSON format)

```
{
  "WebshellList": [{
    "Uuid": "aa46dbe9-d35d-4b77-a4d9-10bc6b1b****",
    "FoundTime": "2018-02-27 03:23:18",

}
```

2.16.4.7.5 OperateTrojan

Description

You can call this operation to handle detected webshells.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to OperateTrojan.
Info	String	No	The webshell information, in JSON format. For more information, see the sample request.

Name	Type	Required	Description
OperateType	String	No	The type of the operation. Valid values: • isolate: indicates an operation to quarantine the file. • trust: indicates an operation to trust the file. • untrust: indicates an operation to cancel trusting the file. • restore: indicates an operation to restore the file.
Type	Integer	No	The type of the trojan. Set the value to 1.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
FailedCount	Integer	The number of failed operations.
SuccessCount	Integer	The number of successful operations.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=OperateTrojan
&Info=[{"uuid":"97988c2b-de9d-4159-90ab-7cc73561c64c","filePath":"/home/test/Z02
.php","webshellId":""}]
&OperateType=trust
&Type=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "43F670F3-AB40-4E91-BC7D-C57468834F67",
  "FailedCount": 0,
  "SuccessCount": 1
}
```

}

2.16.4.7.6 DescribeQuaraFile

Description

You can call this operation to obtain the list of quarantined files.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeQuaraFile.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query result. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
QuaraFiles	Array	The list of quarantined files. For more information, see the following parameter descriptions.
EventName	String	The name of the unusual event.
EventType	String	The type of the unusual event.

Name	Type	Description
FileStatus	String	The status of the quarantined file. Valid values: - quaraFailed("0"): indicates that the file failed to be quarantined. - rollbackFailed("1"): indicates that the file failed to be rolled back to a previous version. - quaraDone("2"): indicates that the file has been quarantined. - rollbackDone("3"): indicates that the file has been rolled back to a previous version. - quaraing("4"): indicates that the file is being quarantined. - rollbacking("5"): indicates that the file is being rolled back to a previous version.
Md5	String	The MD5 value of the file.
Online	Boolean	Indicates whether the Server Guard agent on the server is online.
Path	String	The file path.
Tag	String	The unique identifier of the unusual event.
Uuid	String	The UUID of the server.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeQuaraFile
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "PageSize":20,
  "RequestId":"0C7FAD74-83FA-4671-9250-A5F2A64F437A",
  "CurrentPage":1,
  "QuaraFiles":[
    {
```

```
"Path":"/bin/ping",
"Uuid":"9b0c4d55-2f1f-4766-a90a-2c9d8a0b7642",
"FileStatus":"quaraDone",

2.16.4.7.7 RollbackQuaraFile

Description

You can call this operation to restore a specified quarantined file.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RollbackQuaraFile.
EventName	String	No	The name of the unusual event.
EventType	String	No	The type of the unusual event.
Tag	String	No	The GUID of the unusual event.
Uuid	String	No	The UUID of the server.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=RollbackQuaraFile
&EventName=DDoS trojan
&EventType=Malicious process
&Tag=a50f96f958fbd59f68e4bca4d90679d6
```

```
&Uuid=00f11fcb-1a9a-4fd5-a48a-e0e5bd12a6a4  
&<Common request parameters>
```

- Sample responses (JSON format)

```
{  
  "RequestId": "0C7FAD74-83FA-4671-9250-A5F2A64F437A",  
}
```

2.16.4.8 Server exception detection operations

2.16.4.8.1 DescribeSuspEventTypes

Description

You can call this operation to query the unusual event types.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSuspEventTypes.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
EventTypes	Array	The list of unusual event types. For more information, see the following parameter descriptions.
AliseEventType	String	The name of the unusual event type.
EventType	String	The identifier of the unusual event type.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeSuspEventTypes
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "RequestId":"66BE7091-BC00-4943-8A0D-B3DCE90AD7B5",
  "EventTypes":[
    {
      "EventType":"Suspicious process",
      "AliseEventType":"Suspicious process"
    }
  ]
}
```

2.16.4.8.2 DescribeSuspTrendStatistics

Description

You can call this operation to query the chart data on different types of unusual server events on each day.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSuspTrendStatistics.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Interval	Integer	The time length of the the time frame specified for query.
StartTime	Integer	The start time of the time frame specified for query.
SuspiciousItems	List	The statistics on numbers of different types of suspicious events.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeSuspTrendStatistics
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "66BE7091-BC00-4943-8A0D-B3DCE90AD7B5",
  "Start": -28800000,
  "Interval": 86400000,
  "SuspiciousItems": [ ]
}
```

2.16.4.8.3 OperateSuspiciousEvent

Description

You can call this operation to handle detected unusual events.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to OperateSuspiciousEvent.
Data	String	No	The unusual event to be handled , in JSON format. For more information, see the sample request.

Name	Type	Required	Description
OperateType	String	No	The type of the operation. Valid values: - deal: indicates an operation to handle the unusual event. - confirm: indicates an operation to mark the unusual event as handled. - mark_misinformation: indicates an operation to mark the unusual event as false positive. - unmark_misinformation: indicates an operation to remove the false positive mark of the unusual event. - ignore: indicates an operation to ignore the unusual event.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=OperateSuspiciousEvent
&OperateType=ignore
&Data={"uuid":"97988c2b-de9d-4159-90ab-7cc73561c64c","tag":"f87eb0ee59
34f6f65343ec601ce71c2f","eventType":"Malicious processes (malware checking)","
eventName":"DDoS Trojan"},{"uuid":"97988c2b-de9d-4159-90ab-7cc73561c64c","tag":"
95347a77b8c0d6dae99a23ab69aa90f4","eventType":"Malicious processes (malware
checking)","eventName":"GateDDoS Trojan"}
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId":"654A6FD8-B55D-4D6B-AAFF-4122503D108B"
```

```
}
```

2.16.4.8.4 OperateLoginLog

Description

You can call this operation to label a detected unusual logon event as handled.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to OperateLoginLog.
Ids	String	Yes	The ID of the unusual logon log . Separate multiple log IDs with commas (,).
OperateType	String	Yes	The type of the operation. Set the value to confirm, indicating that the event has been handled.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=OperateLoginLog
&Ids=2006434
&OperateType=confirm
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "BE391ABB-6B7C-4C41-9F6C-862C1DEE3905"
```

}

2.16.4.8.5 CreateSuspiciousExport

Description

You can call this operation to export the information about unusual events on servers based on search conditions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateSuspiciousExport.
Dealed	String	No	Indicates whether the unusual event has been handled. Valid values: - Y: indicates that the event has been handled. - N: indicates that the event has not been handled.
EventNameRemark	String	No	The name of the event. Fuzzy matching is supported.
EventType	String	No	The name of the event type. Valid values: - Unusual logon - Suspicious process - Suspicious account - Sensitive file tampering - Suspicious network connection - Unusual event - Suspicious file - Malicious process
GroupId	String	No	The ID of the asset group.

Name	Type	Required	Description
Level	String	No	The risk level of the event. Valid values: • Critical: indicates a critical-risk event. • Important: indicates an important-risk event. • Moderate: indicates a moderate-risk event. • low: indicates a low-risk event. You can specify multiple event levels and separate them with commas (,).
Remark	String	No	The name or IP address of the server. Fuzzy matching is supported.
StatusList	String	No	The handling status of the event. Valid values: • 1: indicates that the event is to be handled. • 2: indicates that the event has been ignored. • 3: indicates that the event has been confirmed. • 8: indicates that the event has been labeled as a false positive. • 16: indicates that the event is being handled. • 32: indicates that the event has been handled. You can specify multiple statuses and separate them with commas (,).
Tag	String	No	The tag of the server.
Uuids	String	No	The UUID of the server. Separate multiple UUIDs with commas (,).

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
FileName	String	The name of the exported file.
Id	Long	The ID of the export task.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=CreateSuspiciousExport
&Remark=23
&EventType=Suspicious process
&Level=serious,high,medium,low
&Dealed=n
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "43F670F3-AB40-4E91-BC7D-C57468834F67",
  "FileName": "suspicious_20180408",
  "Id": 387
}
```

2.16.4.8.6 DescribeSuspiciousExportInfo

Description

You can call this operation to query an unusual event export task.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeSuspiciousExportInfo.
ExportId	Long	No	The ID of the export task.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentCount	Integer	The number of records that have been exported.
ExportStatus	String	The status of the export task. Valid values: - init: indicates that the export task is being initialized. - pending: indicates that the export task is pending. - exporting: indicates that the export task is being executed. - success: indicates that the export task has been completed. - fail: indicates that the export task has failed.
Message	String	The status description or failure information of the export task.
FileName	String	The name of the exported file.
Id	Integer	The ID of the export task.
GmtCreate	Long	The time when the export task was created.
Link	String	The download link of the exported file.
Progress	Integer	The export progress.
TotalCount	Integer	The total number of records that have been exported.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://aegis.[RegionId].example.com/?Action=DescribeSuspiciousExportInfo
&ExportId=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
```

```

"TotalCount":30,
"GmtCreate":1518071546000,
"Progress":100,
"Message":"success",
"RequestId":"654A6FD8-B55D-4D6B-AAFF-4122503D108B",
"FileName":"suspicious_20180208",
"ExportStatus":"success",
"CurrentCount":30,
"Id":11,
"Link":"http://suspicious-export.oss-cn-shanghai.example.com/export/suspicious_20180208_1518071576098.zip?Expires=1518075176&OSSAccessKeyId=<yourAccessKeyId>&Signature=xxxx%xxxx%3D"
}

```

2.16.4.8.7 DescribeVirusInfo

Description

You can call this operation to upload the MD5 values of files and use Alibaba Cloud Antivirus to determine whether the files are malicious programs.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeVirusInfo.
Md5	String	Yes	The MD5 value of the file.
Lang	String	No	The language attribute of the file, such as zh.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Data	Boolean	Indicates whether the file is malicious. Valid values: - True: Indicates that the file is malicious. - False: Indicates that the file is not malicious.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].aliyuncs.com/?Action=DescribeVirusInfo
&Md5=6f6628d923f9018b28acc5f905e03244
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "A2423F39-3272-4491-804E-D0EBDE3E894D",
  "Data": true
}
```

2.16.4.9 Server log retrieval operations

2.16.4.9.1 CreateLogQuery

Description

You can call this operation to create or save server log search conditions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateLogQuery.
Conditions	String	No	The log search condition.
QueryDetail	String	No	The log search sub-conditions.
QueryName	String	No	The saved search name.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=CreateLogQuery
&Conditions=aegis-log-login@warn_port:22
&QueryDetail=[{"itemForm":{},"d":{"name":"Logons","id":"aegis-log-login","fields":[{"name":"ip","type":"string","desc":"IP address","text":"IP(IP address)"}]}]
&QueryName=test
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "415AE1FC-3C11-4AA9-A06F-DE13D3430366"
}
```

2.16.4.9.2 DescribeLogQuery

Description

You can call this operation to query the saved server log search conditions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeLogQuery.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
ListTotal	Integer	The total number of returned records.
QueryItems	Array	The details of log search conditions. For more information, see the following parameter descriptions.
Conditions	String	The log search conditions.
QueryDetail	String	The log search sub-conditions.
QueryName	String	The name of the log search task.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeLogQuery
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "65802B9B-4D30-40F0-8691-F126652DBEBE",

                {
                  "name": "status",
                  "type": "string",
                  "desc": "User status: 0-disabled, 1-enabled"
                }
              ],
              "f": {
                "name": "ip",
                "type": "string",
                "desc": "IP address"
              },
              "searchLimit": [
                {
                  "name": "Including",
                  "value": ""
                }
              ],
              "kw": "string"
            }
          },
          "Conditions": "aegis-snapshot-host@ip:string",
          "QueryName": "aa"
        }
      ]
    }
  ]
}
```

```
}
```

2.16.4.9.3 DeleteLogQuery

Description

You can call this operation to delete the saved server log search conditions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteLogQuery.
QueryName	String	No	The name of the saved search.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DeleteLogQuery
&QueryName=test
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "415AE1FC-3C11-4AA9-A06F-DE13D3430366"
}
```

2.16.4.9.4 DescribeFilterFields

Description

You can call this operation to query the filter fields of a specified server log search condition

.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeFilterFields.
Query	String	No	The log search condition.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Total	String	The total number of search conditions.
LogFilterList	Array	The filter field information. For more information, see the following parameter descriptions.
Fields	String	The filter fields.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeFilterFields
&Query=aegis-log-login@warn_port:22
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "LogFilterList": [
    {
      "Fields": "IP;IP address,UUID;Client ID","fieldName": "default"
    }
  ],
  "Total": "20",
  "RequestId": "883e1e3d-4443-4206-871c-6c0625c01332"
}
```

```
}
```

2.16.4.9.5 DescribeHistogram

Description

You can call this operation to obtain the statistics on server logs generated within a specified time frame.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeHistogram.
Query	String	Yes	The log query conditions.
EndTime	String	Yes	The end time of the time frame specified for query.
StartTime	String	Yes	The start time of the time frame specified for query.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
Categories	String	The timeline information.
Items	Array	The log quantity statistics. For more information, see the following parameter descriptions.
Data	List	The number of logs.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeHistogram
```

```
&EndTime=2018-03-03 17:41:03
&Query=aegis-log-login@warn_port:22
&StartTime=2018-03-02 17:41:03
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "82D245FB-7A5D-4155-B59F-5B084CE93B6B",

        0
      ]
    }
  ]
}
```

2.16.4.9.6 DescribeLogInfo

Description

You can call this operation to query the server log fields based on specified query conditions.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeLogInfo.
PageSize	Integer	No	The maximum number of records to be displayed on each page of the query result. Default value: 20.

Name	Type	Required	Description
CurrentPage	Integer	No	The current page number. Default value: 1.
Query	String	Yes	The log query conditions.
EndTime	String	Yes	The end time of the query.
StartTime	String	Yes	The start time of the query.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
TotalCount	Integer	The total number of returned records.
LogInfoItems	Array	The information about server log fields. For more information, see the following parameter descriptions.
Id	String	The ID of the log source.
Name	String	The name of the log source.
Fields	Array	The list of server log fields. For more information, see the following parameter descriptions.
Name	String	The ID of the log field.
Desc	String	The name of the log field.
Type	String	The type of the log field.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[RegionId].example.com/?Action=DescribeLogInfo
&CurrentPage=1
&EndTime=2018-03-03 17:41:03
&PageSize=20
&Query=aegis-log-login@warn_port:22
&StartTime=2018-03-02 17:41:03
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount":1,
  "RequestId":"3A7CFB73-C24C-4711-B7D9-2BE74EBFFE78",
  "LogInfoItems":[
    {
      "Fields":[
        {
          "Desc":"IP address",
          "Type":"string",
          "Name":"ip"
        },
        {
          "Desc":"Client number",
          "Type":"string",
          "Name":"uuid"
        },
        {
          "Desc":"Logon source IP address",
          "Type":"string",
          "Name":"warn_ip"
        },
        {
          "Desc":"Logon port",
          "Type":"string",
          "Name":"warn_port"
        },
        {
          "Desc":"Logon username",
          "Type":"string",
          "Name":"warn_user"
        },
        {
          "Desc":"Logon type",
          "Type":"string",
          "Name":"warn_type"
        },
        {
          "Desc":"Logon count",
          "Type":"string",
          "Name":"warn_count"
        }
      ],
      "Id":"aegis-log-login",
      "Name":"Logon serial number"
    }
  ]
}
```

2.16.4.9.7 DescribeLogItems

Description

You can call this operation to query the server log details that are returned by a query.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeLogItems.
PageSize	Integer	No	The number of records displayed on a page. Default value: 20.
CurrentPage	Integer	No	The current page number. Default value: 1.
Query	String	No	The log query criterion.
AccountSnapshotOffset	Integer	No	The offset of the account snapshot log.
CrackOffset	Integer	No	The offset of the brute force password cracking log.
LoginOffset	Integer	No	The offset of the logon log.
NetworkOffset	Integer	No	The offset of the network connection log.
PortSnapshotOffset	Integer	No	The offset of the listening port snapshot log.
ProcessOffset	Integer	No	The offset of the process startup log.
ProcessSnapshotOffset	Integer	No	The offset of the process snapshot log.
EndTime	String	Yes	The end time of the time frame specified for query.
StartTime	String	Yes	The start time of the time frame specified for query.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Name	Type	Description
TotalCount	Integer	The number of returned records.
CurrentPage	Integer	The current page number.
SetPageSize	Integer	The maximum number of records displayed on a page.
AccountSnapshotOffset	Integer	The offset of the account snapshot log.
AccountSnapshotTotalCount	Integer	The total number of account snapshot log entries.
CrackOffset	Integer	The offset of the brute force password cracking log.
CrackTotalCount	Integer	The total number of brute force password cracking log entries.
LoginTotalCount	Integer	The total number of logon log entries.
NetworkOffset	Integer	The offset of the network connection log.
NetworkTotalCount	Integer	The total number of network connection log entries.
PortSnapshotOffset	Integer	The offset of the listening port snapshot log.
PortSnapshotTotalCount	Integer	The total number of listening port snapshot log entries.
ProcessOffset	Integer	The offset of the process startup log.
ProcessTotalCount	Integer	The total number of process startup log entries.
ProcessSnapshotOffset	Integer	The offset of the process snapshot log.
ProcessSnapshotTotalCount	Integer	The total number of process snapshot log entries.
LogsList	Array	A list of host log details. For more information, see the following parameter descriptions.
LogSourceID	String	The ID of the log source.
LogSource	String	The name of the log source.
MLogTime	String	The time when the log entry was created.

Name	Type	Description
MContents	Array	A list of host log entries. For more information, see the following parameter descriptions.
MKey	String	The log entry.
MValue	String	The value of the log entry.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://aegis.[ RegionId].example.com/?Action=DescribeLogItems
&CurrentPage=1
&PageSize=100
&AccountSnapshotOffset=1000
&CrackOffset=1000
&EndTime=2018-03-05 11:46:07
&LoginOffset=1000
&NetworkOffset=1000
&PortSnapshotOffset=1000
&ProcessOffset=1000
&ProcessSnapshotOffset=1000
&Query=aegis-log-login@warn_port:22
&StartTime=2018-03-02 17:41:03
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "BE391ABB-6B7C-4C41-9F6C-862C1DEE3905",
  "PageSize": 100,
  "AccountSnapshotTotalCount": 0,
  "LogsList": [],
  "CrackOffset": 0,
  "ProcessOffset": 0,
  "NetworkOffset": 0,
  "ProcessSnapshotOffset": 0,
  "LoginTotalCount": 0,
  "CurrentPage": 1,
  "PortSnapshotOffset": 0,
  "NetworkTotalCount": 0,
  "AccountSnapshotOffset": 0,
  "CrackTotalCount": 0,
  "PortSnapshotTotalCount": 0,
  "ProcessSnapshotTotalCount": 0,
  "ProcessTotalCount": 0
}
```

2.16.5 Anti-DDoS

2.16.5.1 List of operations

This topic introduces all the Apsara Stack Security Anti-DDoS operations that you can call. For more information, see the corresponding operation description.

Operation	Description
CheckIpSegment	Checks whether a CIDR block to be added for monitoring is valid.
DescribeRegionName	Queries the regions of the CIDR blocks where traffic data collection and analysis is performed.
CreateIpSegment	Adds a specified CIDR block to be monitored.
DescribeIpSegment	Obtains a list of CIDR blocks under traffic monitoring.
DeleteIpSegment	Deletes a CIDR block whose traffic is collected and monitored based on the CIDR block record ID.
ModifyIpSegment	Modifies a monitored CIDR block with a specified record ID.
CreateDdosPolicy	Adds an anti-DDoS policy for a specified IP address or CIDR block.
DescribeDdosPolicies	Queries the configured DDoS protection policies.
DeleteDdosPolicy	Deletes an anti-DDoS policy for a specified CIDR block.
ModifyDdosPolicy	Modifies a specified anti-DDoS policy.
DescribeBlockSwitchs	Queries the status of the traffic block switch in anti-DDoS.
ModifyBlockSwitchs	Changes the status of the block switch in DDoS settings.
DescribeDdosEvents	Obtains the list of DDoS events that meet the specified search criteria.
DescribeFlowAnalysisResult	Queries the analysis result of the traffic sent to an IP address.
DescribeFlowDetails	Queries the detailed traffic information for a specified IP address.
CancelCleanStatus	Disables DDoS traffic scrubbing for a specified IP address.
CreateWhiteList	Adds a whitelist of trusted IP addresses that are exempt from traffic security monitoring.

Operation	Description
DescribeWhiteList	Queries the IP addresses that have been added to a whitelist.
DeleteWhiteList	Deletes multiple risks from the whitelist for baseline check.
DescribeConsoleDdosPolicies	Obtains the records of anti-DDoS policies, including the system default policies.

2.16.5.2 Make API requests

2.16.5.2.1 Request structure

Apsara Stack Security API is based on Remote Procedure Call (RPC). This topic describes the structure of the API requests.

Description

You can send an HTTP request to call an API operation. The URL of the request must be in the following format:

```
http://endpoint/?Action=xx&parameters
```

Where:

- **endpoint**: the endpoint used to call a cloud service. The endpoint for the Anti-DDoS service is `ddosprivate.[RegionId].example.com`.
- **Action**: the operation that you want to perform.

For example, you can set this parameter to **DescribeFeatures** to query the deployed Apsara Stack Security features.

- **parameters**: the request parameters. Request parameters include common request parameters and custom request parameters. Request parameters must be separated with ampersands (&).
 - Common request parameters include information such as the API version and authentication information.
 - For more information about the custom request parameters, see the corresponding operation description.

Example

Call the **DescribeFeatures** operation to query the deployed Apsara Stack Security features.

```
https://yundunprivate.[ RegionId].example.com/?Action=DescribeFeatures&AccessKeyId=key-test&Format=JSON&SecureTransport=true&SignatureMethod=HMAC-SHA1&SignatureNonce=15215528852396&SignatureVersion=1.0&SourceIp=1xxx6&Timestamp=2018-03-02Txxxxxx&Version=2018-01-16&Signature=xxxx%xxxx%3D
```

API requests are presented in the following easy-to-read format in this document:

```
https://yundunprivate.[ RegionId].example.com/?Action=DescribeFeatures
&Format=JSON
&Version=2018-01-16
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2012-06-01T12:00:00Z
```

2.16.5.2.2 Signature mechanism

Apsara Stack Security authenticates each access request. You need to include a signature for the submitted HTTP or HTTPS request.

API authorization

To ensure the security of your account, we recommend that you use a Resource Access Management (RAM) user to call API operations. Before using a RAM user to call an API operation, you must grant the RAM user the corresponding permission to call the API by creating an authorization policy and attaching the policy to the RAM user.

API signature

To ensure secure calls to the API, Alibaba Cloud authenticates each API request through the signature. When you manually make an API request, you need to use AccessKey Secret to calculate the signature, that is, the hash-based message authentication code (HMAC) value, based on the encoded and sorted request string. For more information, see the definition in [RFC 2104](#).

This topic uses the raw access parameters in the following table to describe how to create an API signature.

Parameter	Description
Access point	http://yundunprivate.[RegionId].example.com/?

Parameter	Description
API-specific parameters	Action=DescribeFeatures
Common parameters (excluding the Signature parameter)	&Timestamp=2016-02-23T12:46:24Z &Format=JSON &AccessKeyId=<yourAccessKeyId> &SignatureMethod=HMAC-SHA1 &SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf &Version=2018-01-16 &SignatureVersion=1.0
AccessKey secret	<yourAccessKeySecret>

1. Use the request parameters to construct a canonicalized query string.

Note:

The request parameters include common request parameters (excluding the Signature parameter) and API-specific parameters.

a. Sort the parameters.

Sort the request parameters in alphabetical order.

b. Encode the parameters.

Use UTF-8 to URL-encode the parameter names and values. The encoding rules are as follows:

- Letters, digits, hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
- Other characters are encoded in the %XY format, where XY is the hexadecimal representation of the character in ASCII. For example, the double quotation mark (") is encoded as %22.
- Extended UTF-8 characters are encoded in the %XY%ZA... format.
- Note that a space is encoded as %20, instead of a plus sign (+).

c. Connect the encoded parameter names and values with equal signs (=).

d. Then, sort the parameter name and value pairs connected by equal signs in alphabetical order, and connect them with ampersands (&) to produce the canonicalized query string.

2. Use the canonicalized query string to construct the string for signature calculation based on the following rules:

```
StringToSign=HTTPMethod + "&" + percentEncode( "/" ) + " &" +
```

```
percentEncode(CanonicalizedQueryString)
```

3. Calculate the HMAC value of the StringToSign string according to the definition in [RFC 2104](#).

**Note:**

The key used for signature calculation is your AccessKey secret adding the ampersand (&) (ASCII 38). Secure Hash Algorithm 1 (SHA1) is used as the hash algorithm.

4. Encode the preceding HMAC value into a string based on Base64 encoding rules to obtain the signature value.

```
LEW8N4y7Uasop*****
```

5. Set the Signature parameter in the request parameters to this signature value to sign the request.

2.16.5.2.3 Common request parameters

The following table describes the common request parameters that are used to indicate information such as the API version and authentication information.

Name	Type	Required	Description
Version	String	Yes	The API version in the format of YYYY-MM-DD. Set the value to 2018-01-16.
AccessKeyId	String	Yes	The key ID that Alibaba Cloud assigns to a user for service access.
Signature	String	Yes	The signature string.
SignatureMethod	String	Yes	The signature method. Set the value to HMAC-SHA1.

Name	Type	Required	Description
Timestamp	String	Yes	The timestamp of the request. Follow the ISO 8601 standard to specify the date and use the offset from Coordinated Universal Time (UTC) to specify the time zone. The format is YYYY-MM-DDThh:mm:ssZ. For example, 2014-05-26T12:00:00Z indicates 20:00:00 on May 26, 2014, Beijing time.
SignatureVersion	String	Yes	The signature algorithm version. Set the value to 1.0.
SignatureNonce	String	Yes	The unique random number used to prevent network replay attacks. You must use different random numbers for different requests.
ResourceOwnerAccount	String	No	The owner account of the resource to be accessed through this API request, that is, the logon username.
Format	String	No	The format of the response. Set the value to JSON or XML.  Note: Default value: XML.

2.16.5.2.4 Response structure

Apsara Stack Security API responses support both the XML and JSON formats. The system always returns a unique identification code **RequestId** each time you send a request to call an operation, no matter whether the call is successful or not.

Sample responses (XML format)

```
<? xml version="1.0" encoding="UTF-8"? >
<!-- The root node of the result -->
<Operation name+Response>
  <!-- Returned request ID -->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
```

```
<!-- Returned data -->
</Operation name+Response>
```

Sample responses (JSON format)

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /* Returned data */
}
```

2.16.5.3 APIs

2.16.5.3.1 CheckIpSegment

Description

You can call this operation to check whether a CIDR block to be added for monitoring is valid. If a success result is returned through this API, the CIDR block specified in the request can be added.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CheckIpSegment.
IpSegmentName	String	Yes	The CIDR block to be checked, in x.x.x.x/x format. For example, 172.21.23.222/24.
InfoType	String	No	The CIDR block information type. For example, a value of distribution indicates the region information.
InfoName	String	No	The information describing the CIDR block based on the value of the InfoType parameter. For example, if the InfoType parameter is set to distribution, you can set the InfoName parameter to DXJF, indicating that the CIDR block belongs to the region where the Daxing IDC is located.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[RegionId].example.com/?Action=CheckIpSegment
&IpSegmentName=192.1.1.1/24
&InfoType=distribution
&InfoName=DXJF
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "71064826-726F-4ADA-B879-05D8055476FB"
}
```

2.16.5.3.2 DescribeRegionName

Description

You can call this operation to query the regions of the CIDR blocks where traffic data collection and analysis is performed.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRegionName.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Name	Type	Description
RegionNameList	Array	A list of regions. For more information, see the following parameter descriptions.
Id	Integer	The ID of the region.
Description	String	The region of the CIDR block.
CodeType	String	The type of the CIDR block information. For example, distribution indicates the region information.
Code	String	This parameter is used with the CodeType parameter to specify the code of the corresponding information. For example, if the CodeType parameter is set to distribution and the Code parameter is set to DXJF, this indicates that the CIDR block belongs to the region where the Daxing data center is located.
CodeName	String	This parameter is used with the CodeType parameter to specify the name of the corresponding information.
GmtCreate	String	The time when the CIDR block was created.
GmtModified	String	The latest time when the CIDR block was modified.
Seq	Integer	The sequence number of the region record.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[ RegionId].example.com/?Action=DescribeRegionName
&<Common request parameters>
```

- Sample responses (JSON format)

```

    "Code":"DD_DXJF",
    "Seq":1
  }
],
"RequestId":"26738B34-6680-4BD7-BBF8-EF8DE53D52F6"
}

```

2.16.5.3.3 CreateIpSegment

Description

You can call this operation to add a specified CIDR block to be monitored.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateIpSegment.
IpSegmentName	String	Yes	The CIDR block to be added for monitoring, in x.x.x.x/x format. For example, 172.21.23.222/24.
InfoType	String	No	The CIDR block information type. For example, a value of distribution indicates the region information.
InfoName	String	No	The information describing the CIDR block based on the value of the InfoType parameter. For example, if the InfoType parameter is set to distribution, you can set the InfoName parameter to DXJF, indicating that the CIDR block belongs to the region where the Daxing data center is located.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[RegionId].example.com/?Action=CreateIpSegment
&IpSegmentName=172.21.13.222/24
&InfoType=distribution
&InfoName=DXJF
```

<Common request parameters>

- Sample responses (JSON format)

```
{
  "RequestId": "6C91B447-DAA5-40DB-B818-E10820D99DEC"
}
```

2.16.5.3.4 DescribelpSegment

Description

You can call this operation to query Classless Inter-Domain Routing (CIDR) blocks under traffic monitoring.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribelpSegment.
CurrentPage	Integer	No	The number of the page to return.
PageSize	Integer	No	The number of records to return on each page.
InfoType	String	No	The type of the CIDR block information. For example, a value of distribution indicates the region information.
Distribution	String	No	The ID of the region. For example, a value of DXJF indicates the region where the Daxing IDC is located.
IpSegment	String	No	The CIDR block, in x.x.x.x/x format.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.

Parameter	Type	Description
TotalCount	Integer	The total number of returned pages.
IpSegmentList	Array	The CIDR blocks for traffic collection. For more information, see the following descriptions.
GmtCreate	Long	The time when the CIDR block for traffic collection was created.
GmtModified	Long	The time when the CIDR block for traffic collection was last modified.
Id	Integer	The ID of the CIDR block for traffic collection.
RegionName	String	The region name of the CIDR block.
InfoType	String	The type of the CIDR block information. For example, a value of distribution indicates the region information.
InfoName	String	The information describing the CIDR block based on the value of the InfoType parameter. For example, if the value of the InfoType parameter is distribution, the value of the InfoName parameter can be DXJF, indicating that the CIDR block belongs to the region where the Daxing IDC is located.
IpExpressions	String	The CIDR block for traffic collection, in x.x.x.x/x format.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=DescribeIpSegment
&CurrentPage=1
&Distribution=DXJF
&InfoType=distribution
&IpSegment=x.x.x.x/x
&PageSize=20
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
```

```
"PageSize":20,
"RequestId":"AC51224B-3730-4C6B-B444-2307C7F73E84",
"IpSegmentList":[
  {
    "IpExpressions":"192.168.x.x/24",
    "GmtCreate":1520565939000,
    "RegionName":"Daxing IDC",
    "GmtModified":1520565939000,
    "InfoName":"****",
    "Id":9,
    "InfoType":"distribution1"
  }
],
"CurrentPage":1
}
```

2.16.5.3.5 DeleteIpSegment

Description

You can call this operation to delete a CIDR block whose traffic is collected and monitored based on the CIDR block record ID.

**Note:**

You must obtain the record ID of the monitored CIDR block to be deleted before calling this operation.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteIpSegment.
IpId	String	Yes	The record ID of the monitored CIDR block to be deleted.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[ RegionId].example.com/?Action=DeleteIpSegment
&IpId=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "9C40FE9D-EE39-4162-8E94-7C0A32F276D8"
}
```

2.16.5.3.6 ModifyIpSegment

Description

You can call this operation to modify a monitored Classless Inter-Domain Routing (CIDR) block with a specified record ID.

**Note:**

You must know the record ID of the monitored CIDR block to be modified before calling this operation.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyIpSegment.
IpId	Integer	Yes	The record ID of the monitored CIDR block to be modified.
InfoName	String	Yes	The region to which the CIDR block belongs. For example, a value of DXJF indicates that the CIDR block belongs to the region where the Daxing IDC is located.
IpSegmentName	String	Yes	The CIDR block, in x.x.x.x/x format.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=ModifyIpSegment
&InfoName=****
&InfoType=distribution
&IpId=11
&IpSegmentName=192.168.x.x/24
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "5FFE58AA-355B-4E0E-A742-0BB5554BA959"
}
```

2.16.5.3.7 CreateDdosPolicy

Description

You can call this operation to add an anti-DDoS policy for a specified IP address or Classless Inter-Domain Routing (CIDR) block.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateDdos Policy.
ExternalServiceIP	String	Yes	The IP address or CIDR block to which the anti-DDoS policy applies , in x.x.x.x or x.x.x.x/x format.

Parameter	Type	Required	Description
FlowRate	Integer	Yes	The traffic rate threshold. Unit: Mbit/s.  Note: The value of this parameter must be greater than 0.
HttpRate	Integer	Yes	The HTTP request rate threshold. Unit: queries per second (QPS).  Note: The value of this parameter must be greater than 50.
PackageRate	Integer	Yes	The packet rate threshold. Unit: packets per second (PPS).  Note: The value of this parameter must be greater than 0.
UserId	Long	No	The user ID of the request sender. The parameter is automatically set by the system.
UserName	String	Yes	The username of the request sender. The parameter is automatically set by the system.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=CreateDdosPolicy
&ExternalServiceIP=192.168.x.x/32
&FlowRate=1
&HttpRate=60
```

```
&PackageRate=1  
&<Common request parameters>
```

- Sample response (JSON format)

```
{  
  "RequestId":"CA179B61-DD6D-4FE3-A410-CC16AC705DF4"  
}
```

2.16.5.3.8 DescribeDdosPolicies

Description

You can call this operation to query the configured DDoS protection policies.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDdosPolicies.
CurrentPage	Integer	No	The current page number.
PageSize	Integer	No	The maximum number of records displayed on a page.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of pages returned.
DdosPolicies	Array	A list of DDoS protection policies. For more information, see the following parameter descriptions.
Code	String	The region code of the CIDR block that the DDoS protection policy is applied to.

Name	Type	Description
CodeName	String	The region name of the CIDR block that the DDoS protection policy is applied to.
DepartmentName	String	The department of the user AliUID that created the DDoS protection policy.
ExternalServiceIP	String	The IP address or CIDR block that the DDoS protection policy is applied to.
FlowRate	Integer	The bandwidth threshold. Unit: Mbit/s.
HttpRate	Integer	The HTTP request threshold. Unit: QPS.
PackageRate	Integer	The packet threshold. Unit: PPS.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[RegionId].example.com/?Action=DescribeDdosPolicies
&CurrentPage=1
&PageSize=10
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "TotalCount": 1,
  "PageSize": 10,
  "RequestId": "179E1AA9-1BC2-4A66-9E4B-1640EDDE7D1C",
  "CurrentPage": 1,
  "DdosPolicies": [
    {
      "PackageRate": 200,
      "HttpRate": 0,
      "CodeName": "Daxing data center",
      "ExternalServiceIP": "x.x.x.x/x",
      "DepartmentName": "Department 1",
      "Code": "DD_DXJF",
      "FlowRate": 900,
      "AliUid": 0
    }
  ]
}
```

}

2.16.5.3.9 DeleteDdosPolicy

Description

You can call this operation to delete an anti-DDoS policy for a specified Classless Inter-Domain Routing (CIDR) block.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DeleteDdos Policy.
RegionCode	String	Yes	The ID of the region. For example, cn-hangzhou-env6-d01.
ExternalServiceIP	String	Yes	The IP address or CIDR block to which the anti-DDoS policy applies , in x.x.x.x or x.x.x.x/x format.
FlowRate	Integer	No	The traffic rate threshold. Unit: Mbit/s.  Note: The value of this parameter must be greater than 0.
HttpRate	Integer	No	The HTTP request rate threshold. Unit: queries per second (QPS).  Note: The value of this parameter must be greater than 50.
PackageRate	Integer	No	The packet rate threshold. Unit: packets per second (PPS).  Note: The value of this parameter must be greater than 0.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=DeleteDdosPolicy
&ExternalServiceIP=192.168.x.x/24
&RegionCode=cn-****-env6-d01
&FlowRate=55
&HttpRate=55
&PackageRate=55
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "8C9B8735-18BA-451B-AE9D-1428554CA360"
}
```

2.16.5.3.10 ModifyDdosPolicy

Description

You can call this operation to modify a specified anti-DDoS policy.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to ModifyDdos Policy.
Distribution	String	Yes	The ID of the region. For example, a value of DXJF indicates the region where the Daxing IDC is located.

Parameter	Type	Required	Description
ExternalServiceIP	String	Yes	The IP address or Classless Inter-Domain Routing (CIDR) block to which the anti-DDoS policy applies , in x.x.x.x or x.x.x.x/x format.
FlowRate	Integer	Yes	The traffic rate threshold. Unit: Mbit/s.  Note: The value of this parameter must be greater than 0.
HttpRate	Integer	Yes	The HTTP request rate threshold. Unit: queries per second (QPS).  Note: The value of this parameter must be greater than 50.
PackageRate	Integer	Yes	The packet rate threshold. Unit: packets per second (PPS).  Note: The value of this parameter must be greater than 0.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[RegionId].example.com/?Action=ModifyDdosPolicy
&Distribution=****
&ExternalServiceIP=192.168.x.x/32
&FlowRate=1
&HttpRate=60
&PackageRate=1
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "CA179B61-DD6D-4FE3-A410-CC16AC705DF4"
}
```

2.16.5.3.11 DescribeBlockSwitchs

Description

You can call this operation to query the status of the traffic block switch in anti-DDoS.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBlockSwitchs.
CurrentPage	Integer	No	The current page number.
PageSize	Integer	No	The maximum number of records displayed on a page.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.
CurrentPage	Integer	The current page number.
PageSize	Integer	The maximum number of records displayed on a page.
TotalCount	Integer	The total number of pages returned.
BlockSwitchs	Array	The traffic block switch information. For more information, see the following parameter descriptions.
Code	String	The code of the block switch, which uniquely identifies a block switch.
Description	String	The brief description of the block switch.

Name	Type	Description
Id	Integer	The ID of the block switch.
Mode	Integer	The status of the block switch. Valid values: • 0: indicates disabled. • 1: indicates enabled.
ModeName	String	The status name of the block switch. Valid values: • Disabled • Enabled
Name	String	The name of the block switch.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[ RegionId].example.com/?Action=DescribeBlockSwitchs
&CurrentPage=1
&PageSize=20
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "PageSize": 10,
  "RequestId": "95F2F4C8-7623-48B7-A976-30B48F3A25EB",
  "CurrentPage": 1,
  "BlockSwitchs": [
    {
      "Description": "test",
      "Mode": 0,
      "ModeName": "Disabled",
      "id": 1,
      "Code": "UPGRADE_SWITCH",
      "Name": "Upgrade channel switch"
    },
    {
      "Description": "Automatic upgrade switch",
      "Mode": 1,
      "ModeName": "Enabled",
      "Id": 2,
      "Code": "AUTO_UPGRADE_SWITH",
      "Name": "Automatic upgrade switch"
    }
  ]
}
```

```
}
```

2.16.5.3.12 ModifyBlockSwitchs

Description

You can call this operation to change the status of the block switch in DDoS settings.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyBlockSwitch.
Id	Integer	Yes	The ID of the block switch.
Mode	Integer	Yes	The status of the block switch. Valid values: 0: indicates disabled. 1: indicates enabled.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[ RegionId].example.com/?Action=ModifyBlockSwitch
&Id=1
&Mode=1
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "B7FA97F0-082D-4611-A3C4-867011E2A106"
```

```
}
```

2.16.5.3.13 DescribeDdosEvents

Description

You can call this operation to query distributed denial of service (DDoS) events that meet the specified search criteria.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeDdosEvents.
CurrentPage	Integer	No	The number of the page to return.
PageSize	Integer	No	The number of records to return on each page.
StartRow	Integer	No	The sequence number of the first record to return on the current page.
Distribution	String	No	The ID of the region. For example, a value of DXJF indicates the region where the Daxing IDC is located.
VmIP	String	No	The IP address of the victim server.
StartDay	Long	No	The beginning of the time range where data is queried.
EndDay	Long	No	The end of the time range where data is queried.

Parameter	Type	Required	Description
SearchReason	String	No	The reason why the DDoS event is triggered. Valid values: bps, pps, and qps. You can query events triggered by multiple reasons. For example, you can enter "bps,pps" to query the DDoS events that are triggered when the traffic rate threshold or the packet transmission rate threshold is exceeded.
SelectStatus	String	No	The status of the DDoS event. Valid values: - Scrubbing - Scrubbing completed

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
TotalCount	Integer	The total number of returned pages.
DdosEvents	Array	The DDoS events. For more information, see the following descriptions.
Id	Long	The ID of the event.
GmtCreate	Long	The time when the event was created.
GmtModified	Long	The time when the event was updated.
Aliuid	Long	The AliUid of the asset owner.
AttackType	String	The type of the attack.  Note: In the current version, only the value of defence is supported.

Parameter	Type	Description
Caller	String	The name of the system that calls the operation.  Note: Currently, the fixed value is beaver_dj , indicating Network Traffic Monitoring System.
Category	Integer	The number of the security event category.
CategoryName	String	The name of the security event category.
VmIp	String	The IP address of the victim server.
Code	String	The scrubbing status of the event. Valid values: - Scrubbing - Scrubbing completed
Bps	Long	The traffic rate threshold. Unit: Mbit/s.
Pps	Long	The packet rate threshold. Unit: packets per second (PPS).
Qps	Long	The HTTP request rate threshold. Unit: queries per second (QPS).
Conn	Integer	The threshold of concurrent connections.  Note: This response parameter has been deprecated.
NewConn	Integer	The threshold of new connections.  Note: This response parameter has been deprecated.
Reason	String	The reason why the event was reported.
Distribution	String	The ID of the region.
DistributionDisplay	String	The name of the region.

Parameter	Type	Description
IsFinished	Boolean	Indicates whether the attack has finished. Valid values: • true: indicates that the attack has finished. • false: indicates that the attack has not finished.
OccurrenceTime	Long	The time when the event occurred.
EndTime	Long	The time when the attack finished.
LocationAdd	String	The location where the event was added.  Note: This response parameter is invalid in Apsara Stack.
LocationDel	String	The location where the event was canceled.  Note: This response parameter is invalid in Apsara Stack.
Status	Integer	The status of the IP address where the DDoS event occurred. Valid values: • 0: indicates that the IP address has not expired. • 1: indicates that the IP address has expired.
Successful	Integer	Indicates whether the attack succeeds. Valid values: • 0: indicates that the attack has failed. • 1: indicates that the attack succeeded.
NeedIgnore	Integer	Indicates whether you need to ignore the event. Valid values: • 0: indicates that you do not need to ignore the event. • 1: indicates that the event has been reported repeatedly and you need to ignore the event.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=DescribeDdosEvents
&CurrentPage=1
&Distribution=DXJF
$StartDay=1381079107176
$EndDay=1481079107176
&PageSize=10
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TotalCount":1,
  "RequestId":"AD525B06-F5F7-4319-94F4-45154D5B0750",
  "DdosEvents":[
    {
      "NewConn":0,
      "Status":0,
      "LocationDel":"nulllocal",
      "Category":21,
      "Bps":5,
      "EndTime":1573233588000,
      "Zone":"default",
      "GmtModified":1484372333000,
      "AttackType":"0",
      "Conn":0,
      "Code":"Scrubbing",
      "DistributionDisplay":"Daxing IDC",
      "Reason":"bps",
      "OccurrenceTime":1473233588000,
      "GmtCreate":1484369068000,
      "Pps":450,
      "Caller":"beaver_dj",
      "Qps":0,
      "Distribution":"am1",
      "LocationAdd":"local",
      "CategoryName":"DDOS_DEFENSE",
      "Id":3,
      "IsFinished":false,
      "NeedIgnore":0
    }
  ],
  "CurrentPage":1
}
```

2.16.5.3.14 DescribeFlowAnalysisResult

Description

You can call this operation to query the analysis result of the traffic sent to an IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeFlowAnalysisResult.
Distribution	String	Yes	The ID of the region. For example, a value of DXJF indicates the region where the Daxing IDC is located.
VmIP	String	Yes	The IP address of the victim server.
StartDate	Long	Yes	The beginning of the time range where traffic is analyzed.
SearchReason	String	No	The reason why the distributed denial of service (DDoS) event is triggered. Valid values: bps, pps, and qps. You can query events triggered by multiple reasons. For example, you can enter "bps,pps" to query the DDoS events that are triggered when the traffic rate threshold or the packet transmission rate threshold is exceeded.
SelectStatus	String	No	The status of the DDoS event. Valid values: • Scrubbing • Scrubbing completed

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TopAttackers	Array	The analysis on the top 10 attackers. For more information, see the following descriptions.

Parameter	Type	Description
Ip	String	The IP address of the attacker.
Count	Float	The percentage of attacks launched to the IP address compared to the total attacks.
TopProtocols	Array	The analysis on the composition of the attack traffic. For more information, see the following descriptions.  Note: The traffic composition analysis shows traffic of different protocols, including TCP, ICMP, and UDP.
Protocol	String	The protocol.
Count	Float	The percentage of the traffic of the specified protocol compared to the total amount of traffic.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=DescribeFlowAnalysisResult
&Distribution=DD_DXJF
&startDate=123123312000
&Vmlp=x.x.x.x
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "TopAttackers":["Ip":"x.x.x.x","Count":"1.00"],
  "RequestId":"B2488F1F-930D-4906-AC76-61045B4F1EF2",
  "TopProtocols":["Protocol":"tcp","Count":"1.00"]
}
```

2.16.5.3.15 DescribeFlowDetails

Description

You can call this operation to query the detailed traffic information for a specified IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeFlowDetails.
Distribution	String	Yes	The ID of the region. For example, a value of DXJF indicates the region where the Daxing IDC is located.
VmIP	String	Yes	The IP address of the victim server.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
HttpStatusCode	Integer	The HTTP status code.
FlowDetail	Struct	The detailed traffic information. For more information, see the following descriptions.
AliUid	Long	The ID of the Alibaba Cloud account.
Distribution	String	The ID of the region.
DistributionDisplay	String	The name of the region.
ExternalServiceIp	String	The IP address or Classless Inter-Domain Routing (CIDR) block.
FlowRate	Integer	The flow rate. Unit: Mbit/s.
HttpRate	Integer	The HTTP request rate. Unit: queries per second (QPS).
PackageRate	Integer	The packet rate. Unit: packets per second (PPS).

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[RegionId].example.com/?Action=DescribeFlowDetails&Distribution=****
```

```
&Vmlp=10.0.x.x  
&<Common request parameters>
```

- Sample response (JSON format)

```
{  
  "RequestId":"8491DBFD-48C0-4E11-B6FC-6F38921244A9",  
  "FlowDetail":{  
    "PackageRate":200,  
    "HttpRate":0,  
    "ExternalServiceIP":"10.0.x.x/32",  
    "Distribution":"DXJF",  
    "DistributionDisplay":"Daxing IDC",  
    "FlowRate":900,  
    "AliUid":0  
  },  
  "HttpStatusCode":200  
}
```

2.16.5.3.16 CancelCleanStatus

Description

You can call this operation to disable DDoS traffic scrubbing for a specified IP address.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CancelCleanStatus.
Distribution	String	Yes	The ID of the region. For example, a value of DXJF indicates the region where the Daxing IDC is located.
Vmlp	String	Yes	The IP address of the instance, in x.x.x.x format.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=CancelCleanStatus
&Distribution=DXJF
&SourceIp=10.0.x.x
&Vmlp=172.16.x.x
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

2.16.5.3.17 CreateWhiteList

Description

You can call this operation to add a whitelist of trusted IP addresses that are exempt from traffic security monitoring.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to CreateWhiteList.
Type	Integer	Yes	The type of the whitelist. Valid values: 6: indicates a server brute-force attack whitelist. 12: indicates a BWAf source IP address whitelist. 15: indicates an application attack whitelist.
Username	String	No	The username used to add the whitelist.

Parameter	Type	Required	Description
DestinationIp	String	No	The destination IP address.  Note: When you add a BWAf source IP address whitelist (that is, the Type parameter is set to 12), the DestinationIp parameter must be set to the default value 0.0.0.0.
SourceIpStr	String	No	The source IP address.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[ RegionId].example.com/?Action=CreateWhiteList
&Type=15
&DestinationIp=192.168.xx.xx
&SourceIpStr=192.168.xx.xx
&Username=test
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

2.16.5.3.18 DescribeWhiteList

Description

You can call this operation to query the IP addresses that have been added to a whitelist.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeWhiteList.
DestinationIp	String	No	The destination IP address.
SourceIpStr	String	No	The source IP address.
Type	Integer	No	The type of the whitelist. Valid values: • 6: indicates a server brute-force attack whitelist. • 12: indicates a BWAf source IP address whitelist. • 15: indicates an application attack whitelist.
Username	String	No	The username.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
TotalCount	Integer	The total number of returned pages.
WhiteLists	List	The whitelist records. For more information, see the following descriptions.
SourceIp	String	The source IP address.
Id	Integer	The ID of the whitelist record.

Parameter	Type	Description
Type	Integer	The type of the whitelist. Valid values: • 6: indicates a server brute-force attack whitelist. • 12: indicates a BWAf source IP address whitelist. • 15: indicates an application attack whitelist.
Username	String	The username.
DestinationIp	String	The destination IP address.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[RegionId].example.com/?Action=DescribeWhiteList
&Type=15
&DestinationIp=172.16.xx.xx
&SourceIpStr=172.17.xx.xx
&Username=test
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "CurrentPage":1,
  "PageSize":20,
  "RequestId":"430A3687-B9EC-4F71-B472-EE24ED609863",
  "Success":true,
  "TotalCount":0,
  "WhiteLists":[{
    "DestinationIp":"172.16.xx.xx",
    "Id":6,
    "SourceIp":"172.17.xx.xx",
    "Type":15,
    "Username":"*****"
  }]
}
```

2.16.5.3.19 DeleteWhiteList

Description

You can call this operation to delete a specified whitelist entry.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteWhiteList.
Id	Integer	Yes	The ID of the whitelist entry.

Response parameters

Name	Type	Description
RequestId	String	The GUID generated by Alibaba Cloud for the request.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample requests

```
https://ddosprivate.[ RegionId].example.com/?Action=DeleteWhiteList
&Id=15
&<Common request parameters>
```

- Sample responses (JSON format)

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

2.16.5.3.20 DescribeConsoleDdosPolicies

Description

You can call this operation to obtain the records of anti-DDoS policies, including the system default policies.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set this parameter to DescribeConsoleDdosPolicies.
AliUid	Long	Yes	The ID of the Alibaba Cloud account.
CurrentPage	Integer	No	The number of the page to return.
PageSize	Integer	No	The number of records to return on each page.
StartRow	Integer	No	The start row to return.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The number of the current page returned.
PageSize	Integer	The number of records returned on each page.
TotalCount	Integer	The total number of returned pages.
ThresholdList	List	The anti-DDoS policies. For more information, see the following descriptions.
DepartmentName	String	The department name of the current user.
ExternalServiceIP	String	The IP address or Classless Inter-Domain Routing (CIDR) block.  Note: A value of default is returned if the system default policy is used.
Code	String	The IDC ID corresponding to the CIDR block.
CodeName	String	The IDC name corresponding to the CIDR block.

Parameter	Type	Description
FlowRate	Integer	The threshold for the traffic rate. Unit: Mbit/s.
HttpRate	Integer	The threshold for the HTTP request rate. Unit : queries per second (QPS).
PackageRate	Integer	The threshold for the packet rate. Unit: packets per second (PPS).
AliUid	Long	The Alibaba Cloud account ID corresponding to the policy.

Error codes

For more information about the error codes that this operation can return, see [Error codes](#).

Examples

- Sample request

```
https://ddosprivate.[RegionId].example.com/?Action=DescribeConsoleDdosPolicies
&AliUid=****
&CurrentPage=1
&PageSize=10
&SourceIp=xx.xx.xx.xx
&<Common request parameters>
```

- Sample response (JSON format)

```
{
  "CurrentPage":1,
  "HttpStatusCode":200,
  "PageSize":20,
  "RequestId":"7C3AC882-E5A8-4855-BE77-B6837B695EF1",
  "ThresholdList":[
    {
      "AliUid":151971404963****,
      "Code":"DD_DXJF",
      "CodeName":"DD_DXJF",
      "DepartmentName":"****Cloud",
      "ExternalServiceIP":"1.1.xx.xx/32",
      "FlowRate":1,
      "HttpRate":52,
      "PackageRate":1
    },
    {
      "AliUid":151971404963****,
      "Code":"DD_DXJF",
      "CodeName":"DD_DXJF",
      "DepartmentName":"****Cloud",
      "ExternalServiceIP":"2.2.xx.xx/32",
      "FlowRate":1,
      "HttpRate":51,
      "PackageRate":1
    }
  ]
}
```

```

    "AliUid":-1,
    "Code":"DD_DXJF",
    "CodeName":"DD_DXJF",
    "ExternalServiceIP":"default",
    "FlowRate":900,
    "HttpRate":0,
    "PackageRate":200
  },
  "TotalCount":3
}

```

2.16.6 Sensitive Data Discovery and Protection

2.16.6.1 List of operations by function

The following table lists API operations available for use in Sensitive Data Discovery and Protection (SDDP). For more information, see the corresponding operation description.

Operation	Description
DescribeDataAssets	Queries data assets globally based on the specified conditions.
DescribeInstances	Queries instances, databases, projects, or buckets based on the specified conditions.
DescribeTables	Queries tables of MaxCompute, Relational Database Service (RDS), and Table Store.
DescribePackages	Queries MaxCompute packages based on the specified conditions.
DescribeColumns	Queries columns in tables of MaxCompute, Relational Database Service (RDS), and Table Store.
DescribeOssObjects	Queries Object Storage Service (OSS) objects based on the specified conditions.
DescribeOssObjectDetail	Queries the details of an OSS object based on its ID.
DescribeDeparts	Queries departments based on the specified conditions.
DescribeAccounts	Queries accounts based on the specified conditions.
DescribeAccountDetail	Queries the details of an account based on the account ID and account type.
DescribePrivileges	Queries permissions of an account based on the account ID and other specified conditions.
DescribeEventTypes	Queries types of anomalous activities based on the specified conditions.

Operation	Description
DescribeEvents	Queries anomalous activities based on the specified conditions.
DescribeEventDetail	Queries the details of an anomalous activity based on the specified ID.
ModifyEventStatus	Processes an anomalous activity.
ModifyEventTypeStatus	Enables one or more subtypes of anomalous activities.
ModifyDefaultLevel	Sets the default risk level or modifies the risk levels of sensitive data.
DescribeRules	Queries rules based on the specified conditions.
CreateRule	Creates a custom rule.
ModifyRule	Modifies a custom rule.
ModifyRuleStatus	Enables or disables a rule.
DeleteRule	Deletes a custom rule.
DescribeDataLimitSet	Queries the instances, databases, or buckets of a specified service that SDDP is authorized to scan.
CreateDataLimit	Grants the permission of scanning the instances, databases, or buckets of a specified service.
DeleteDataLimit	Revokes the permission of scanning the instances, databases, or buckets of a specified service.

2.16.6.2 Make API requests

2.16.6.2.1 Request structure

Apsara Stack Security API operations use the Remote Procedure Call (RPC) protocol. This topic describes the API request syntax.

Description

You can call API operations by sending HTTP requests. The request syntax is as follows:

```
http://endpoint/?Action=xx&parameters
```

Where:

- `endpoint`: the endpoint of the Sensitive Data Discovery and Protection (SDDP) API is `sddp-api.[RegionId].example.com`.

- **Action:** the name of the operation being performed.

For example, to query data assets, you must set the Action parameter to

DescribeDataAssets.

- **parameters:** the request parameters for the operation. Separate multiple parameters with ampersands (&). Request parameters include both common parameters and operation-specific parameters.
 - Common parameters include information such as the API version and authentication information.
 - For more information about operation-specific parameters, see the corresponding operation description.

Example

The following example demonstrates how to call the **DescribeDataAssets** operation to query data assets:

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeDataAssets&CurrentPage=1
&PageSize=10&AccessKeyId=key-test&Format=JSON&SecureTransport=true&SignatureM
ethod=HMAC-SHA1&SignatureNonce=15215528852396&SignatureVersion=1.0&SourceIp=
1xxx6&Timestamp=2019-04-19Txxxxxx&Version=2019-01-03&Signature=xxxx%xxxx%3D
```

API requests are presented in the following easy-to-read format in this document:

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeDataAssets
&CurrentPage=1
&PageSize=10
&Format=JSON
&Version=2019-01-03
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=15215528852396
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2019-04-19T12:00:00Z
```

2.16.6.2.2 Request signatures

Apsara Stack Security authenticates each access request. Therefore, each request must contain signature information, regardless of whether it is sent through HTTP or HTTPS.

API authorization

To ensure the security of your account, we recommend that you use a Resource Access Management (RAM) user to call API operations. Before using a RAM user to call an API operation, you must grant the RAM user the corresponding permission to call the operation by creating an authorization policy and attaching the policy to the RAM user.

API signature

To ensure security, Apsara Stack authenticates each API request through the signature. When you manually make an API request, you must use the AccessKey secret to calculate the signature, that is, the hash-based message authentication code (HMAC) value, based on the encoded request string. For more information, see the definition in [RFC 2104](#).

This topic uses the raw access parameters in the following table to describe how to create an API signature.

Parameter	Description
Endpoint	http://yundunprivate.[RegionId].example.com/?
Operation-specific parameters	Action=DescribeFeatures
Common parameters except Signature	&Timestamp=2016-02-23T12:46:24Z &Format=JSON &AccessKeyId=<yourAccessKeyId> &SignatureMethod=HMAC-SHA1 &SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf &Version=2018-01-16 &SignatureVersion=1.0
AccessKey secret	<yourAccessKeySecret>

1. Create a canonicalized query string by arranging the request parameters.

**Note:**

The request parameters include all common and operation-specific parameters except Signature.

a. Arrange the parameters.

Arrange the request parameters in alphabetical order.

b. Encode the parameters.

Parameter names and values in the request URL must be encoded in UTF-8. The encoding rules are as follows:

- Uppercase letters, lowercase letters, digits, and some special characters such as ampersands (&), hyphens (-), underscores (_), periods (.), and tildes (~) do not need to be encoded.
- Other characters must be percent encoded in %XY format. XY represents the ASCII code of the characters in hexadecimal notation. For example, double quotation marks (") are encoded as %22.
- Extended UTF-8 characters are encoded in %XY%ZA... format.
- Spaces must be encoded as %20. Do not encode spaces as plus signs (+).

c. Connect the encoded parameter names and values with equal signs (=).

d. Arrange the parameter name and value pairs connected by equal signs in alphabetical order, and connect them with ampersands (&) to produce the canonicalized query string.

2. Create a string-to-sign from the encoded canonicalized query string.

```
StringToSign=HTTPMethod + "&" + percentEncode("/") + "&" +  
percentEncode(CanonicalizedQueryString)
```

3. Calculate the HMAC value of the string-to-sign according to the definition in [RFC 2104](#).

Note:

The key used for signature calculation is your AccessKey secret plus the ampersand (&) (ASCII 38). Secure Hash Algorithm 1 (SHA1) is used as the hash algorithm.

4. Encode the HMAC value in Base64 to obtain the signature string.

```
LEW8N4y7Uasop*****
```

5. Add the signature string to the request as the Signature parameter.

2.16.6.2.3 Common parameters

Common request parameters, such as the API version number and authentication information, must be included in all API requests.

Parameter	Type	Required	Description
Version	String	Yes	The version number of the API, in the format of YYYY-MM-DD. Set the value to 2019-01-03.
AccessKeyId	String	Yes	The AccessKey ID provided to you by Apsara Stack.
Signature	String	Yes	The signature string of the current request.
SignatureMethod	String	Yes	The encryption method of the signature string. Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard. The time must be in UTC. Format: YYYY-MM-DDThh:mm:ssZ. For example, 2014-05-26T12:00:00Z indicates 20:00:00 on May 26, 2014 (UTC+8).
SignatureVersion	String	Yes	The version of the signature encryption algorithm. Set the value to 1.0.
SignatureNonce	String	Yes	A unique, random number used to prevent replay attacks. You must use different numbers for different requests.
ResourceOwnerAccount	String	No	The name of the account that owns the resource to be accessed through this API request.

Parameter	Type	Required	Description
Format	String	No	The format of the response. Set the value to JSON or XML.  Note: Default value: XML.

2.16.6.2.4 Responses

Apsara Stack Security APIs can return responses in XML or JSON format. The system returns a unique identifier specified by **RequestId** each time you send a request to call an API operation, no matter whether the call is successful or not.

Sample response in XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<!--Root node of the response -->
<Operation name+Response>
  <!--Returned request ID-->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!--Returned results-->
</Operation name+Response>
```

Sample response in JSON format

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /* Returned results */
}
```

2.16.6.3 APIs

2.16.6.3.1 DescribeDataAssets

Description

You can call this operation to query data assets globally based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDataAssets.

Parameter	Type	Required	Description
Rangeld	Integer	Yes	The type of the assets to query. Valid values: 1: MaxCompute project. 2: MaxCompute table. 3: MaxCompute package. 21: Object Storage Service (OSS) bucket. 22: OSS object. 31: Table Store instance. 32: Table Store table. 51: Relational Database Service (RDS) database. 52: RDS table.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Name	String	No	The search keyword. Fuzzy match is supported.
RuleId	Long	No	The ID of the rule.
RiskLevels	String	No	The ID of the risk level. Separate multiple IDs with commas (,).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of returned pages.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
Items	Array	The list of assets.
Owner	String	The account of the asset owner.
ProductCode	String	The code of the big data service, for example, RDS or OSS.
Acl	String	The access control list (ACL) for the OSS bucket.

Parameter	Type	Description
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
DepartName	String	The name of the department.
Name	String	The name of the asset.
Labelsec	Boolean	The label security flag of the MaxCompute asset.
CreationTime	Long	The time when the asset was created. Unit: milliseconds.
Id	Long	The ID of the primary key.
Protection	Boolean	The protection flag of the MaxCompute asset.
RuleName	String	The name of the hit rule.
ObjectKey	String	The key of the OSS object.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeDataAssets
&Rangeld=1
&CurrentPage=1
&PageSize=10
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "71064826-726F-4ADA-B879-05D8055476FB"
  "TotalCount": 4,
  "PageSize": 10,
  "CurrentPage": 1,
  "Items": [
    {
      "Owner": "dtdep-239-153536994****",
      "ProductCode": "ODPS",
      "ProductId": 1,
      "Acl": "",
      "RiskLevelId": 2,
      "RiskLevelName": "Internal",
      "DepartName": "DemoCenter",
      "Name": "****data",
      "Labelsec": false,
      "CreationTime": 1536751124000,

```

```
"Sensitive":true,
"Id":268,
"Protection":false,
"RuleName":"Hit rule"
"ObjectKey":"Internal"
}
]
}
```

2.16.6.3.2 DescribeInstances

Description

You can call this operation to query instances, databases, projects, or buckets based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeInstances.
ProductCode	String	Yes	The code of the big data service, for example, RDS or OSS.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Name	String	No	The search keyword. Fuzzy match is supported.
RuleId	Long	No	The ID of the rule.
RiskLevelId	Long	No	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of returned pages.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
Items	Array	The list of instances.
Owner	String	The account of the instance owner.

Parameter	Type	Description
ProductCode	String	The code of the big data service, for example, RDS or OSS.
Acl	String	The access control list (ACL) for the OSS bucket.
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
DepartName	String	The name of the department.
Name	String	The name of the asset.
Labelsec	Boolean	The label security flag of the MaxCompute asset.
CreationTime	Long	The time when the instance was created. Unit: milliseconds.
Id	Long	The ID of the primary key.
Protection	Boolean	The protection flag of the MaxCompute asset.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeInstances
&CurrentPage=1
&PageSize=10
&ProductCode=ODPS
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "71064826-726F-4ADA-B879-05D8055476FB",
  "TotalCount": 4,
  "PageSize": 10,
  "CurrentPage": 1,
  "Items": [
    {
      "Owner": "dtdep-239-153536994****",
      "ProductCode": "ODPS",
      "ProductId": 1,
      "Acl": "",
      "RiskLevelId": 2,
      "RiskLevelName": "Internal",
      "DepartName": "DemoCenter",

```

```

    "Name": "****data",
    "Labelsec": false,
    "CreationTime": 1536751124000,
    "Sensitive": true,
    "Id": 268,
    "Protection": false
  }
]
}

```

2.16.6.3.3 DescribeTables

Description

You can call this operation to query tables of MaxCompute, Relational Database Service (RDS), and Table Store.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTables.
InstanceId	Long	Yes	The ID of the instance.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Name	String	No	The search keyword. Fuzzy match is supported.
RuleId	Long	No	The ID of the rule.
RiskLevelId	Long	No	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of returned pages.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
Items	Array	The list of instances.
Owner	String	The account of the instance owner.

Parameter	Type	Description
ProductCode	String	The code of the big data service, for example, RDS or OSS.
Acl	String	The access control list (ACL) for the OSS bucket.
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
DepartName	String	The name of the department.
Name	String	The name of the asset.
Labelsec	Boolean	The label security flag of the MaxCompute asset.
CreationTime	Long	The time when the table was created. Unit: milliseconds.
Id	Long	The ID of the primary key.
Protection	Boolean	The protection flag of the MaxCompute asset.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeInstances
&CurrentPage=1
&PageSize=10
&ProductCode=ODPS
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "71064826-726F-4ADA-B879-05D8055476FB",
  "TotalCount": 4,
  "PageSize": 10,
  "CurrentPage": 1,
  "Items": [
    {
      "Owner": "dtdep-239-153536994****",
      "ProductCode": "ODPS",
      "ProductId": 1,
      "Acl": "",
      "RiskLevelId": 2,
      "RiskLevelName": "Internal",
      "DepartName": "DemoCenter",

```

```
"Name": "****data",
"Labelsec": false,
"CreationTime": 1536751124000,
"Sensitive": true,
"Id": 268,
"Protection": false
}
]
```

2.16.6.3.4 DescribePackages

Description

You can call this operation to query MaxCompute packages based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePackages.
InstanceId	Long	Yes	The ID of the instance.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Name	String	No	The search keyword. Fuzzy match is supported.
RuleId	Long	No	The ID of the rule.
RiskLevelId	Long	No	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of returned pages.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
Items	Array	The list of packages.
Owner	String	The account of the package owner.

Parameter	Type	Description
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
DepartName	String	The name of the department.
Name	String	The name of the asset.
CreationTime	Long	The time when the package was created. Unit: milliseconds.
Id	Long	The ID of the primary key.
InstanceId	Long	The ID of the instance.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```

}

2.16.6.3.5 DescribeColumns

Description

You can call this operation to query columns in tables of MaxCompute, Relational Database Service (RDS), and Table Store.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeColumns.
InstanceId	Long	Yes	The ID of the instance.
TableId	Long	Yes	The ID of the table.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Name	String	No	The search keyword. Fuzzy match is supported.
RuleId	Long	No	The ID of the rule.
RiskLevelId	Long	No	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of returned pages.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
Items	Array	The list of packages.
Owner	String	The account of the package owner.
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
DepartName	String	The name of the department.

Parameter	Type	Description
Name	String	The name of the asset.
CreationTime	Long	The time when the column was created. Unit : milliseconds.
Id	Long	The ID of the primary key.
RuleId	Long	The ID of the hit rule.
RuleName	String	The name of the hit rule.
TableId	Long	The ID of the table.
InstanceId	Long	The ID of the instance.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeColumns
&CurrentPage=1
&PageSize=20
&InstanceId=1
&TableId=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId":"769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "TotalCount":4,
  "PageSize":10,
  "CurrentPage":1,
  "Items":[
    {
      "Owner":"dtdep-239-153536994****",
      "ProductCode":"ODPS",
      "ProductId":1,
      "Acl": "",
      "RiskLevelId":2,
      "RiskLevelName":"Internal",
      "DepartName":"DemoCenter",
      "Name":"****data",
      "CreationTime":1536751124000,
      "Sensitive":true,
      "Id":268,
      "RuleId":1,
      "RuleName":"Hit rule",
      "InstanceId":1,
      "TableId":1
    }
  ]
}
```

}

2.16.6.3.6 DescribeOssObjects

Description

You can call this operation to query Object Storage Service (OSS) objects based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeOssObjects.
InstanceId	Long	Yes	The ID of the instance.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Name	String	No	The search keyword. Fuzzy match is supported.
RuleId	Long	No	The ID of the rule.
RiskLevelId	Long	No	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
TotalCount	Integer	The total number of returned pages.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
Items	Array	The list of packages.
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
DepartName	String	The name of the department.
Name	String	The name of the asset.

Parameter	Type	Description
Id	Long	The ID of the primary key.
RegionId	String	The ID of the region.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribeOssObjects
&CurrentPage=1
&PageSize=20
&InstanceId=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "TotalCount": 4,
  "PageSize": 10,
  "CurrentPage": 1,
  "Items": [
    {
      "RiskLevelName": "Internal",
      "Id": 17383,
      "RiskLevelId": 2,
      "RegionId": "cn-hangzhou",
      "Name": "obj****"
    }
  ]
}
```

2.16.6.3.7 DescribeOssObjectDetail

Description

You can call this operation to query the details of an Object Storage Service (OSS) object based on its ID.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeOssObjectDetail.

Parameter	Type	Required	Description
Id	Long	Yes	The ID of the OSS object.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
OssObjectDetail	Object	The details of the OSS object.
RiskLevelId	Long	The ID of the risk level.
RiskLevelName	String	The name of the risk level.
Name	String	The name of the asset.
Id	Long	The ID of the primary key.
RegionId	String	The ID of the region.
CategoryName	String	The type of the file.
RuleList	Array	The list of the hit rules.
RuleName	String	The name of the hit rule.
Count	Integer	The number of times that the rule is hit.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeOssObjectDetail
&Id=12
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "OssObjectDetail": {
    "RegionId": "cn-hangzhou",
    "BucketName": "",
    "RiskLevelName": "Internal",
    "Id": 17383,
    "RiskLevelId": 2,
    "CategoryName": "MAC address",
    "Name": "obj_id",
    "RuleList": [
      {
        "RuleName": "ID card number",
        "Count": 10
      }
    ]
  }
}
```

```
}  
  }  
}
```

2.16.6.3.8 DescribeDeparts

Description

You can call this operation to query departments based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDeparts.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Key	String	No	The search keyword. Fuzzy match is supported.
AccountType	Integer	No	The type of the query. Valid values: 1: department query. 2: account query.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
TotalCount	Integer	The total number of returned pages.
Items	Array	The list of departments.
Id	Long	The ID of the primary key.
DepartName	String	The name of the department.
DepartId	Long	The ID of the department.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeDeparts
&CurrentPage=1
&PageSize=10
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId":"769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "PageSize":10,
  "CurrentPage":1
  "TotalCount":1,
  "Items":[
    {
      "Id":283,
      "DepartId":2,
      "DepartName":"Development"
    }
  ]
}
```

2.16.6.3.9 DescribeAccounts

Description

You can call this operation to query accounts based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccounts.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
Key	String	No	The search keyword. Fuzzy match is supported.
DepartId	Long	No	The ID of the department.

Parameter	Type	Required	Description
QueryType	Integer	No	The type of the resource. Valid values: 1: instance. 2: table. 3: package. 4: column. 5: table in a package.
ProductCode	String	No	The code of the service. Valid values: - MaxCompute - RDS - OTS
OperationId	Integer	No	The type of the operation. For more information, see Operation type definition .
InstanceId	Long	No	The ID of the instance.
TableId	Long	No	The ID of the table.
PackageId	Long	No	The ID of the package.
ColumnId	Long	No	The ID of the column.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
TotalCount	Integer	The total number of returned pages.
Items	Array	The list of accounts.
Id	Long	The ID of the primary key.
LongName	String	The name of the account.
Email	String	The email address.
CreateTime	Long	The time when the account was created. Unit: milliseconds.

Parameter	Type	Description
LoginDataTime	Long	The last logon time of the account. Unit: milliseconds.
UserId	Long	The ID of the account.
FullName	String	The display name.
CellphoneNum	String	The mobile phone number.
TelephoneNum	String	The landline phone number.
AccountTypeId	Integer	The type of the account. Valid values: • 2: Apsara Stack Console account. • 3: Resource Access Management (RAM) account.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeAccounts
&CurrentPage=1
&PageSize=10
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "PageSize": 10,
  "CurrentPage": 1,
  "TotalCount": 1,
  "Items": [
    {
      "LoginName": "sddp_****",
      "Email": "test@example.com",
      "CreateTime": 1543300900000,
      "LoginDataTime": 1544493748000,
      "UserId": 10****,
      "FullName": "sddp****",
      "Id": 1091,
      "CellphoneNum": "1300000****",
      "TelephoneNum": "0571-6000****",
      "AccountTypeId": 1
    }
  ]
}
```

}

2.16.6.3.10 DescribeAccountDetail

Description

You can call this operation to query the details of an account based on the account ID and account type.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccountDetail.
UserId	Long	Yes	The ID of the account.
AccountTypeId	Integer	Yes	The type of the account. Valid values: 2: Apsara Stack Console account. 3: Resource Access Management (RAM) account.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Account	Object	The details of the account.
Id	Long	The ID of the primary key.
LongName	String	The name of the account.
Email	String	The email address.
CreateTime	Long	The time when the account was created. Unit: milliseconds.
LoginDataTime	Long	The last logon time of the account. Unit: milliseconds.
UserId	Long	The ID of the account.
FullName	String	The display name.

Parameter	Type	Description
CellphoneNum	String	The mobile phone number.
TelephoneNum	String	The landline phone number.
PrivilegeList	Array	The list of available accounts.
ProdcutName	String	The service that the account can operate . Separate multiple services with forward slashes (/).
UseAccountName	String	The name of the used account.
UseAccountId	Long	The ID of the used account.
UseAccountType	Integer	The type of the used account.
UseAccountCreateTime	Long	The time when the used account was created. Unit: milliseconds.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[ RegionId].example.com/?Action=DescribeAccountDetail
&UserId=1
&AccountTypeId=2
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "Account": {
    "LoginName": "yundun****",
    "Email": "kf@example.com",
    "CreateTime": 1543384996000,
    "LoginDataTime": 1543385065000,
    "UserId": 1045,
    "FullName": "yundun****",
    "Id": 882,
    "CellphoneNum": "1300000****",
    "TelephoneNum": "0571-6000****",
    "PrivilegeList": [
      {
        "UseAccountType": 2,
        "ProductName": "OSS/ODPS",
        "UseAccountCreateTime": 1546413235000,
        "UseAccountName": "ram_****",
        "UseAccountId": 259
      }
    ]
  }
}
```

}

2.16.6.3.11 DescribePrivileges

Description

You can call this operation to query permissions of an account based on the account ID and other specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribePrivileges.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
AccountId	Long	Yes	The ID of the account.
UseAccountId	Long	No	The ID of the used account.
Key	String	No	The search keyword. Fuzzy match is supported.
DataTypeId	String	No	The type of the resource. For more information, see Resource type definition .

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
TotalCount	Integer	The total number of returned pages.
Items	Array	The list of permissions.
Id	Long	The ID of the primary key.
AccountId	Long	The ID of the account.

Parameter	Type	Description
AccountType	Integer	The type of the account. Valid values: • 2: Apsara Stack Console account. • 3: Resource Access Management (RAM) account.
UseAccountId	Long	The ID of the used account.
UseAccountType	Long	The type of the used account. Valid values: • 2: Apsara Stack Console account. • 3: RAM account.
DataType	String	The type of the resource. For more information, see Resource type definition
DataTypeId	Integer	The ID of the resource type. For more information, see Resource type definition
DataInstance	String	The instance. A value of * indicates all instances.
DataTable	String	The table. A value of * indicates all tables.
DataColumn	String	The column. A value of * indicates all columns.
DataPackage	String	The package. A value of * indicates all packages.
ResourceName	String	The name of the resource.
ResourcePath	String	The path of the resource.
Operation	String	The operation permission. Separate multiple permissions with semicolons (;).
PolicyCondition	String	The usage conditions.
Sensitive	Boolean	Indicates whether the permission is sensitive.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribePrivileges
&CurrentPage=1
&PageSize=20
```

```
&AccountId=1  
&<Common request parameters>
```

- Sample success response in JSON format

```
{  
  "RequestId":"769FB3C1-F4C9-42DF-9B72-7077A8989C13",  
  "PageSize":10,  
  "CurrentPage":1,  
  "TotalCount":1,  
  "Items":[  
    {  
      "UseAccountType":2,  
      "DataInstance":"341",  
      "AccountId":259,  
      "ResourceName":"bucket****",  
      "Operation":"GET;OPEARETE",  
      "AccountType":2,  
      "ResourcePath":"kf",  
      "DataTypeId":21,  
      "Sensitive":false,  
      "DataType":"OSS_BUCKET",  
      "Id":1,  
      "UseAccountId":259  
    }  
  ]  
}
```

2.16.6.3.12 DescribeEventTypes

Description

You can call this operation to query types of anomalous activities based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEventTypes.
ParentTypeId	Long	No	The ID of the type.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Parameter	Type	Description
EventTypeList	Array	The list of types.  Note: If you do not set the ParentTypeId parameter, the system returns the type list. Otherwise, the system returns the list of subtypes under the specified type.
Id	Long	The ID of the type.
Code	String	The code of the type.
Name	String	The name of the type.
SubTypeList	Array	The list of subtypes.
Id	Long	The ID of the subtype.
Code	String	The code of the subtype.
Name	String	The name of the subtype.
Status	String	The status of the subtype. Valid values: 1: enabled. 2: disabled.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribeEventTypes
&ParentTypeId=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "EventTypeList": [
    {
      "SubTypeList": [
        {
          "Id": 1,
          "Code": "010001",
          "Name": "Incorrect configuration - Sensitive MaxCompute projects are not protected",
          "Status": 1
        }
      ]
    }
  ],
}
```

```

    "Id":1,
    "Code":"01",
    "Name":"Anomalous permission access"
  }
]
}

```

2.16.6.3.13 DescribeEvents

Description

You can call this operation to query anomalous activities based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEvents.
CurrentPage	Integer	Yes	The number of the page to return.
PageSize	Integer	Yes	The number of entries to return on each page.
TypeCode	String	No	The ID of the type of the anomalous activity.
UserId	Long	No	The account ID of the operator of the anomalous activity.
DealUserId	Long	No	The account ID of the handler of the anomalous activity.
Status	Integer	No	The status of the anomalous activity. Valid values: 0: unprocessed. 1: confirmed as a violation. 2: excluded as a false positive.
SubTypeCode	String	No	The ID of the subtype of the anomalous activity.
StartTime	Long	No	The beginning of the time range to query. Unit: milliseconds.
EndTime	Long	No	The end of the time range to query. Unit: milliseconds.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
TotalCount	Integer	The total number of returned pages.
Items	Array	The list of anomalous activities.
Id	Long	The ID of the anomalous activity.
UserId	Long	The account ID of the operator.
LoginName	String	The account name of the operator.
DisplayName	String	The account display name of the operator.
ProductCode	String	The code of the service where the anomalous activity occurred.
TypeCode	String	The ID of the type.
TypeName	String	The name of the type.
SubTypeCode	String	The ID of the subtype.
SubTypeName	String	The name of the subtype.
AlertTime	Long	The time when the anomalous activity occurred.
EventTime	Long	The time when the alert was reported.
Status	Integer	The status of the anomalous activity. Valid values: 0: unprocessed. 1: confirmed as a violation. 2: excluded as a false positive.
DealUserId	Long	The account ID of the handler.
DealLoginName	String	The account name of the handler.
DealDisplayName	String	The account display name of the handler.
DealTime	Long	The time when the anomalous activity was processed. Unit: milliseconds.
Backed	Boolean	Indicates whether the processing result of the anomalous activity was returned as a feedback to the detection algorithm.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribeEvents
&CurrentPage=1
&TypeCode=01
&PageSize=10
&<Common request parameters>
```

- Sample success response in JSON format

```

    }
  ]
}
```

2.16.6.3.14 DescribeEventDetail

Description

You can call this operation to query the details of an anomalous activity based on the specified ID.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeEventDetail.
Id	Long	Yes	The ID of the anomalous activity.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
Event	Object	The details of the anomalous activity.
Id	Long	The ID of the anomalous activity.
UserId	Long	The account ID of the operator.
LoginName	String	The account name of the operator.
DisplayName	String	The account display name of the operator.
ProductCode	String	The code of the service where the anomalous activity occurred.
TypeCode	String	The ID of the type.
TypeName	String	The name of the type.
SubTypeCode	String	The ID of the subtype.
SubTypeName	String	The name of the subtype.
AlertTime	Long	The time when the anomalous activity occurred.
EventTime	Long	The time when the alert was reported.
Status	Integer	The status of the anomalous activity. Valid values: 0: unprocessed. 1: confirmed as a violation. 2: excluded as a false positive.
DealUserId	Long	The account ID of the handler.
DealLoginName	String	The account name of the handler.

Parameter	Type	Description
DealDisplayName	String	The account display name of the handler.
DealTime	Long	The time when the anomalous activity was processed. Unit: milliseconds.
Backed	Boolean	Indicates whether the processing result of the anomalous activity was returned as a feedback to the detection algorithm.
Detail	Object	The detailed content of the anomalous activity.
Content	Array	The content.
Label	String	The title.
Value	String	The description.
Chart	Array	The baseline.
XLabel	String	The X-axis title.
YLabel	String	The Y-axis title.
Data	Object	The content of the baseline.
X	Array	The array of data along the X-axis.
Y	Array	The array of data along the Y-axis.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribeEventDetail
&Id=1
&<Common request parameters>

```

2.16.6.3.15 ModifyEventStatus

Description

You can call this operation to process an anomalous activity.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyEventStatus.
Id	Long	Yes	The ID of the anomalous activity.
Status	Integer	Yes	The status of the anomalous activity. Valid values: • 1: confirmed as a violation. • 2: excluded as a false positive.
DealReason	String	Yes	The processing comments.
Backed	Boolean	No	Specifies whether to return the processing result of the anomalous activity as a feedback to the detection algorithm.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=ModifyEventStatus
&Id=1
&Status=1
&DealReason=Confirmed violation
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "8491DBFD-48C0-4E11-B6FC-6F38921244A9"
```

```
}
```

2.16.6.3.16 ModifyEventTypeStatus

Description

You can call this operation to enable one or more subtypes of anomalous activities.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyEven tTypeStatus.
SubTypeIds	String	Yes	The ID of the subtype of anomalous activities. Separate multiple IDs with commas (,).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=ModifyEventTypeStatus  
&SubTypeIds=1,2,3,4  
&<Common request parameters>
```

- Sample success response in JSON format

```
{  
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
```

```
}
```

2.16.6.3.17 ModifyDefaultLevel

Description

You can call this operation to set the default risk level or modify the risk levels of sensitive data.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDefaultLevel.
DefaultId	Long	No	The ID of the default risk level.
SensitiveIds	String	No	The ID of the risk level of sensitive data. Separate multiple IDs with commas (,).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=ModifyDefaultLevel
&Type=15
&DefaultId=2
&SensitiveIds=3,4
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
```

```
}
```

2.16.6.3.18 DescribeRules

Description

You can call this operation to query rules based on the specified conditions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRules.
Name	String	No	The search keyword. Fuzzy match is supported.
RiskLevelId	Long	No	The ID of the risk level.
Category	Integer	No	The type of the rule. Valid values: 0: keyword. 2: regular expression.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
CurrentPage	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
TotalCount	Integer	The total number of returned pages.
Items	Array	The list of rules.
Id	Long	The ID of the rule.
Name	String	The name of the rule.
Content	String	The content of the rule.
Description	String	The description of the rule.
RiskLevelId	Long	The ID of the risk level.
Status	Integer	The status of the rule. Valid values: 0: disabled. 1: enabled.

Parameter	Type	Description
Category	Integer	The type of the rule. Valid values: 0: keyword. 2: regular expression.
CategoryName	String	The name of the rule type.
UserId	Long	The account ID of the rule creator.
LoginName	String	The account name of the rule creator.
DisplayName	String	The account display name of the rule creator.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribeRules
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "Items": [
    {
      "Description": "IP address",
      "Category": 2,
      "GmtModified": 1545277010000,
      "RiskLevelId": 2,
      "Name": "IP address",
      "GmtCreate": 1545277010000,
      "UserId": 0,
      "Status": 1, //0: disabled. 1: enabled.
      "Content": "(?\\D|^)((?:25[0-4]|2[0-4]\\d|1\\d{2}|[1-9]\\d{1})\\.)(?:25[0-5]|2[0-4]\\d|[01]?\\d?\\d\\.){2}(?:25[0-5]|2[0-4]\\d|1[0-9]\\d|[1-9]\\d{1-9})(?\\D|$)",
      "CategoryName": "Regular expression",
      "RiskLevelName": "Internal",
      "DepartName": "KF",
      "LoginName": "det****",
      "Id": 2000
    }
  ],
  "TotalCount": 18,
  "PageSize": 10,
  "CurrentPage": 1
}
```

2.16.6.3.19 CreateRule

Description

You can call this operation to create a custom rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateRule.
Name	String	Yes	The name of the rule.
Content	String	Yes	The content of the rule.
Category	Integer	Yes	The type of the rule. Valid values: 0: keyword. 2: regular expression.
RiskLevelId	Long	Yes	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].aliyuncs.com/?Action=CreateRule
&Name=Mobile phone number
&Category=0
&Content=1300000****
&RiskLevelId=4
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
```

```
}
```

2.16.6.3.20 ModifyRule

Description

You can call this operation to modify a custom rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyRule.
Id	Long	Yes	The ID of the rule.
Name	String	Yes	The name of the rule.
Content	String	Yes	The content of the rule.
Category	Integer	Yes	The type of the rule. Valid values: 0: keyword. 2: regular expression.
RiskLevelId	Long	Yes	The ID of the risk level.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=ModifyRule
&Id=1
&Name=Mobile phone number
&Category=0
&Content=1300000****
&RiskLevelId=4
```

<Common request parameters>

- Sample success response in JSON format

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

2.16.6.3.21 ModifyRuleStatus

Description

You can call this operation to enable or disable a rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyRuleStatus.
Id	Long	Yes	The ID of the rule.
Status	Integer	Yes	The status of the rule. Valid values: • 0: disabled. • 1: enabled.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=ModifyRuleStatus
&Id=1
&Status=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

```
}
```

2.16.6.3.22 DeleteRule

Description

You can call this operation to delete a custom rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteRule.
Id	Long	Yes	The ID of the rule.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DeleteRule
&Id=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

2.16.6.3.23 DescribeDataLimitSet

Description

You can call this operation to query the instances, databases, or buckets of a specified service that Sensitive Data Discovery and Protection (SDDP) is authorized to scan.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDataLimitSet.
ResourceType	Integer	Yes	The ID of the service. Valid values: 1: MaxCompute. 2: Object Storage Service (OSS). 5: Relational Database Service (RDS).

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.
DataLimitList	Array	The list of instances that SDDP is authorized to scan.
Id	Long	The ID of the primary key.
RegionId	String	The ID of the region.
LocalName	String	The name of the region.
ParentId	String	The name of the instance.
UserName	String	The username.
Password	String	The password.
Connector	String	The connection string of the database.
OssBucketList	Array	The list of existing OSS buckets.
RegionId	String	The ID of the region.
BucketName	String	The name of the OSS bucket.
RegionList	Array	The list of regions.
RegionId	String	The ID of the region.
LocalName	String	The name of the region.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DescribeDataLimitSet
&ResourceType=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "769FB3C1-F4C9-42DF-9B72-7077A8989C13",
  "DataLimitSet": {
    "ResourceType": 1,
    "DataLimitList": [
      {
        "Id": 1,
        "RegionId": "cn-hangzhou",
        "LocalName": "China (Hangzhou)",
        "ParentId": "oss-bucket",
        "UserName": "Username",
        "Password": "Password",
        "Connector": "Connection string"
      }
    ],
    "OssBucketList": [
      {
        "RegionId": "cn-hangzhou",
        "BucketName": "oss-bucket"
      }
    ],
    "RegionList": [
      {
        "RegionId": "cn-hangzhou",
        "LocalName": "Hangzhou"
      }
    ]
  }
}
```

2.16.6.3.24 CreateDataLimit

Description

You can call this operation to grant the permission of scanning the instances, databases, or buckets of a specified service.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateDataLimit.

Parameter	Type	Required	Description
ResourceType	Integer	Yes	The ID of the service. Valid values: 1: MaxCompute. 2: Object Storage Service (OSS). 5: Relational Database Service (RDS).
ResourceType	String	Yes	The ID of the region.
ParentId	String	Yes	The name of the instance.
UserName	String	Yes	The username.
Password	String	Yes	The password.
Connector	String	Yes	The connection string of the database.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=CreateDataLimit
&ResourceType=1
&ServiceRegionId=cn-hangzhou
&ParentId=test
&UserName=<userName>
&Password=<passWord>
@Connector=jdbc:mysql://localhost:3306/test
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "7C3AC882-E5A8-4855-BE77-B6837B695EF1"
```

```
}
```

2.16.6.3.25 DeleteDataLimit

Description

You can call this operation to revoke the permission of scanning the instances, databases, or buckets of a specified service.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteDataLimit.
Id	Long	Yes	The authorization ID.

Response parameters

Parameter	Type	Description
RequestId	String	The ID of the request.

Error codes

For a list of error codes, see [Error codes](#).

Examples

- Sample request

```
https://sddp-api.[RegionId].example.com/?Action=DeleteDataLimit
&Id=1
&<Common request parameters>
```

- Sample success response in JSON format

```
{
  "RequestId": "208B016D-4CB9-4A85-96A5-0B8ED1EBF271"
}
```

2.16.6.4 Data dictionaries

2.16.6.4.1 Operation type definition

ID	Description
1	Get

ID	Description
2	CreateDelete
3	Operate
4	Read
5	Write
6	List
7	CreateTable
8	CreateInstance
9	CreateFunction
10	CreateResource

17	Select
18	Alter
19	Update
20	Drop
21	Create
22	Delete
23	Modify
24	Insert
201	CreateBucket
202	ModifyBucket
203	GetBucket
204	DeleteBucket
205	CreateObject
206	ModifyObject
207	GetObject

ID	Description
208	DeleteObject
301	LoadData
302	DumpData
303	Show

2.16.6.4.2 Resource type definition

ID	Name	Description
1	ODPS_PROJECT	MaxCompute project
2	ODPS_TABLE	MaxCompute table
3	ODPS_PACKAGE	MaxCompute package
4	ODPS_PACKAGE_TABLE	Table in a MaxCompute package
5	ODPS_COLUMN	MaxCompute column
21	OSS_BUCKET	OSS bucket
31	OTS_INSTANCE	Table Store instance
32	OTS_TABLE	Table Store table

2.16.6.4.3 Risk level definition

ID	Name	Description
1	S1	Weak risk level
2	S2	Medium risk level
3	S3	High risk level
4	S4	Highest risk level

2.16.7 Error codes

Module	Error code	Error message	Description
Threat Detection Service	yd.error.sas.1	The specified field has not been found in the metadata.	The error message returned because the field you queried does not exist in the metadata. Check the request and try again.

Module	Error code	Error message	Description
Threat Detection Service	yd.error.sas.2	An error occurred while invoking the task engine. Try again later.	The error message returned because the system has failed to call the task engine. Try again later.
Threat Detection Service	yd.error.sas.3	An error occurred while starting the task. Try again later.	The error message returned because the system has failed to start the task. Try again later.
Threat Detection Service	yd.error.sas.4	An error occurred while stopping the task. Try again later.	The error message returned because the system has failed to stop the task. Try again later.
Threat Detection Service	yd.error.sas.5	An error occurred while restarting the task. Try again later.	The error message returned because the system has failed to restart the task. Try again later.
Threat Detection Service	yd.error.sas.6	An error occurred while obtaining the task status. Try again later.	The error message returned because the system has failed to obtain the task status. Try again later.
Threat Detection Service	yd.error.sas.7	An error occurred while deleting the task. Try again later.	The error message returned because the system has failed to delete the task. Try again later.
Threat Detection Service	yd.error.sas.8	The specified table does not contain metadata.	The error message returned because the table you queried has no metadata configured. Check the request and try again.

Module	Error code	Error message	Description
Threat Detection Service	yd.error.sas.400	The specified asset is under protection. Uninstall the Server Guard client and try again.	The error message returned because the asset you want to delete is protected. Uninstall the Server Guard agent from the server and try again.
Threat Detection Service	yd.error.sas.500	A system error has occurred.	The error message returned because a system error has occurred. Contact Alibaba Cloud technical support.
Threat Detection Service	yd.error.sas.101	The parameter is invalid .	The error message returned because a parameter error has occurred. Check the request and try again.
Threat Detection Service	yd.error.sas.103	Request failed.	The error message returned because the request has failed. Try again later.
Threat Detection Service	yd.error.sas.502	You are not authorized to access the instance.	The error message returned because you are not authorized to operate the server.
Threat Detection Service	yd.error.sas.100	Request failed. Refresh the page and try again.	The error message returned because the request has failed. Try again later.
Threat Detection Service	yd.error.sas.501	The function is not available in the current version.	The error message returned because the version you are using does not support this feature.

Module	Error code	Error message	Description
Anti-DDoS	yd.error.ddos.400	An error occurred while accessing the server. Try again later.	The error message returned because the system has failed to access the server. Check the request and try again.
Anti-DDoS	yd.error.ddos.500	An error occurred on the server.	The error message returned because a server error has occurred. Contact Alibaba Cloud technical support.
Anti-DDoS	yd.error.ddos.UNKNOWN_EXCEPTION	An internal error occurred.	The error message returned because an unknown error has occurred. Contact Alibaba Cloud technical support.
Anti-DDoS	yd.error.ddos.REQUEST_TIMEOUT	The request has timed out.	The error message returned because the request has timed out. Try again later.
Anti-DDoS	yd.error.ddos.SERVER_FAILED	An operation error occurred.	The error message returned because the operation has failed. Contact Alibaba Cloud technical support.
Anti-DDoS	yd.error.ddos.NOT_AUTHORIZED	You are not authorized to perform this operation.	The error message returned because you are not authorized to perform the action . Check the account permission.
Anti-DDoS	yd.error.ddos.PARAMETER_INVALID	The specified parameter is invalid or missing.	The error message returned because the specified request parameter is invalid . Check the request parameter and try again.

Module	Error code	Error message	Description
Anti-DDoS	yd.error.ddos. IP_SEGMENT_INVALID	The specified CIDR block is invalid.	The error message returned because the specified CIDR block is invalid. Check the CIDR block specified in the request parameter.
Anti-DDoS	yd.error.ddos. IP_SEGMENT_REPEAT	One CIDR block cannot be used in different regions. Enter another CIDR block.	The error message returned because one CIDR block belongs to different regions. Check the CIDR block specified in the request parameter.
Anti-DDoS	yd.error.ddos. IP_SEGMENT_ALREADY	The specified CIDR block already exists.	The error message returned because the specified CIDR block already exists. Check the CIDR block specified in the request parameter.
Anti-DDoS	yd.error.ddos .IP_SEGMENT _MASK_LENGTH_ERR	The prefix length must be less than 24 bits.	The error message returned because the mask contains more than 24 characters. Check the CIDR block mask specified in the request parameter.
Anti-DDoS	yd.error.ddos. QUERY_REGION_LIST_ER R	An error occurred while obtaining the region list .	The error message returned because the system has failed to read the list of regions. Try again later.
Anti-DDoS	yd.error.ddos .IP_SEGMENT _OPERATION_ERR	An error occurred while performing the operation on the CIDR block.	The error message returned because the system has failed to process the CIDR block. Try again later.

Module	Error code	Error message	Description
Anti-DDoS	yd.error.ddos. .QUERY_IP_SEGMENT_ERR	An error occurred while obtaining the CIDR block.	The error message returned because the system has failed to read the CIDR block information. Try again later.
Anti-DDoS	yd.error.ddos. .MODIFY_IP_SEGMENT_ERR	An error occurred while modifying the CIDR block.	The error message returned because the system has failed to modify the CIDR block information. Try again later.
Anti-DDoS	yd.error.ddos. IP_SEGMENT_TYPE_ERR	Check whether the type of the CIDR block (internal or external) is specified.	The error message returned because the CIDR block type is not specified. Check the CIDR block type and try again.
Anti-DDoS	yd.error.ddos. .CANCEL_FLOW_CLEAN_ERR	An error occurred while canceling traffic scrubbing. Check the network connection to Beaver.	The error message returned because the system has failed to cancel traffic scrubbing. Check the network connection with Network Traffic Monitoring System and try again.
Anti-DDoS	yd.error.ddos. .QUERY_FLOW_ANALYSIS_ERR	An error occurred while obtaining the traffic analysis result. Check the network connection to Beaver.	The error message returned because the system has failed to obtain the traffic analysis result. Check the network connection with Network Traffic Monitoring System and try again.

Module	Error code	Error message	Description
Anti-DDoS	yd.error.ddos. .QUERY_BEAV ER_URL_ERR	An error occurred while obtaining the Beaver URL.	The error message returned because the system has failed to obtain the URL of Network Traffic Monitoring System . Check the network connection with Network Traffic Monitoring System and try again.
Anti-DDoS	yd.error.ddos. SET_VALVE_INVALID	The specified thresholds are invalid.	The error message returned because the threshold validation has failed. Check the thresholds and try again.
Anti-DDoS	yd.error.ddos. .VALVE_DEFA ULT_ALREADY	You cannot add the default threshold again .	The error message returned because the system has failed to add the default threshold, which can only be modified.
Anti-DDoS	yd.error.ddos .NOT_BELONG _BEAVER_IP_SEGMENT	Check whether the specified CIDR block belongs to the internal network of Beaver.	The error message returned because the CIDR block you entered is not in the internal CIDR block of Network Traffic Monitoring System. Check the CIDR block.
Anti-DDoS	yd.error.ddos. VALVE_DELETE_ERR	Do not delete the threshold.	The error message returned because the system has failed to delete the default threshold or the threshold of 128.0.0.0/1, which cannot be deleted.

Module	Error code	Error message	Description
Anti-DDoS	yd.error.ddos.QUERY_CODE_ERR	An error occurred while obtaining the product configuration.	The error message returned because the system has failed to read the dictionary. Try again later.
Anti-DDoS	yd.error.ddos.IS_OPENED	Enabled.	The error message returned because the specified switch has been turned on and cannot be turned on repeatedly.
Anti-DDoS	yd.error.ddos.IS_CLOSED	Disabled.	The error message returned because the specified switch has been turned off and cannot be turned off repeatedly.
Server Guard	yd.error.aqs.REQUEST_FAILED	Request failed. Try again later.	The error message returned because the request has failed. Try again later.
Common errors of Apsara Stack Security	yd.error.all.10001	Authorization required.	The error message returned because you are not authorized to perform the action . Check the account permission.
Common errors of Apsara Stack Security	yd.error.all.10002	A system error has occurred. Try again later.	The error message returned because a system error has occurred. Try again later.
Common errors of Apsara Stack Security	yd.error.all.10003	The parameter is invalid .	The error message returned because the specified request parameter is invalid . Check the request parameter and try again.

Module	Error code	Error message	Description
Common errors of Apsara Stack Security	yd.error.all.other	A system error has occurred.	The error message returned because a system exception has occurred. Try again later.
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1001	An internal error has occurred.	The error message returned because a system error has occurred. Try again later.
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1007	The specified API is unavailable.	The error message returned because the API has been brought offline. Contact Alibaba Cloud technical support .
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1008	An error occurred while verifying postOnly.	The error message returned because the validation has failed . Check the common request parameters and try again.
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1009	csrfToken must not be empty.	The error message returned because the csrfToken field is left blank. Check the common request parameters and try again.
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1010	An error occurred while verifying csrfToken.	The error message returned because the validation has failed . Check the common request parameters and try again.
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1011	The Region ID must not be empty.	The error message returned because RegionId is left blank . Check the RegionId parameter.

Module	Error code	Error message	Description
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1012	The specified region ID format is invalid.	The error message returned because the specified region ID format is invalid. Check the RegionId parameter .
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1013	The parameter is null.	The error message returned because the specified request parameter is left blank . Check the request parameter and try again.
Common errors of Apsara Stack Security	yd.error.all.ConsoleSystemError_1014	The specified parameter format is invalid.	The error message returned because the specified parameter format is invalid. Check the request parameter and try again.
Common errors of Apsara Stack Security	yd.error.all.ConsoleNeedLogin	You are not logged on.	The error message returned because you are not authorized to perform the action . Check the account permission.
Common errors of Apsara Stack Security	yd.error.all.InvalidApi	The API is invalid.	The error message returned because an API exception has occurred. Try again later.
Common errors of Apsara Stack Security	yd.error.all.InvalidParameter	The parameter is invalid .	The error message returned because the specified request parameter is invalid . Check the request parameter and try again.

Module	Error code	Error message	Description
Common errors of Apsara Stack Security	yd.error.all.InvalidResult	The return value is invalid.	The error message returned because the return value is invalid. Try again later.
Common errors of Apsara Stack Security	yd.error.all.PropertyConversionFailed	An error occurred during conversion.	The error message returned because property conversion has failed. Try again later.
Common errors of Apsara Stack Security	yd.error.all.NoPermission	Authorization required.	The error message returned because you are not authorized to perform the action . Check the account permission.
Common errors of Apsara Stack Security	yd.error.all.ServerError	A server error has occurred.	The error message returned because a server exception has occurred. Try again later or contact Alibaba Cloud technical support.
Common errors of Apsara Stack Security	yd.error.all.UnknownError	An internal error has occurred.	The error message returned because a system error has occurred. Try again later or contact Alibaba Cloud technical support.

2.17 Key Management Service (KMS)

2.17.1 API reference

2.17.1.1 Make API requests

2.17.1.1.1 Overview

Make API requests

You can call KMS APIs by sending HTTP POST and GET requests to the KMS API server address with the corresponding API request parameters included in the request. The system will then return the request processing results.

1. [Request structure.](#)
2. [Common parameters.](#)
3. [Request signatures.](#)
4. [Responses.](#)

2.17.1.1.2 Request structure

Endpoints

The endpoint of the KMS API is kms.example.com.

Protocols

In KMS, requests can be sent only through the HTTPS channel.

SSL V2 and SSL V3 are not supported. TLS V1.0 and later are supported.

Methods

HTTP method POST or GET requests are URL encoded with the parameter values required by the API that is being called.

Parameters

For each request, you must specify the Action parameter indicating the API you want to call (such as `CreateKey`), the common request parameters required by all APIs, and the parameters specific to the API being called.

Encoding

Requests and responses are encoded in UTF-8.

2.17.1.1.3 Common parameters

Common request parameters

Common request parameters must be included in the request of each operation.

Parameter	Type	Required	Description
Format	String	No	The format of the response. Valid values: JSON and XML. Default value: XML.
Version	String	Yes	The version number of the API. The format is YYYY-MM-DD. The current version is 2016-01-20.
AccessKeyId	String	Yes	The AccessKey ID provided to you by Alibaba Cloud.
Signature	String	Yes	The signature string. For more information about how to calculate the signature value, see Request signatures .
SignatureMethod	String	Yes	The signature method. HMAC-SHA1 is supported.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC. For example, 20:00:00 (UTC+8) on December 1, 2015 must be written as 2015-12-01T12:00:00Z.

Parameter	Type	Required	Description
SignatureVersion	String	Yes	The algorithm version of the signature. The current version is 1.0.

Examples

```
https://kms.cn-hangzhou.example.com/?
Format=json
&Version=2016-01-20
&AccessKeyId=testid
&Signature=YlrFhyqDZQ1ThNYARrv3Ptaxqf****
&SignatureMethod=HMAC-SHA1
&Timestamp=2016-03-25T09:36:58Z
&SignatureVersion=1.0
```

Common response parameters

The system returns a unique identifier (RequestId) for each API request, regardless of whether the request is successful.

Examples

XML format

```
<KMS>
<RequestId>348d9445-e39a-4d80-907d-298cc6c94447</RequestId>
<!--Response-->
</KMS>
```

JSON format

```
{
  "RequestId": "284b2b80-9b17-4546-a093-adfbae512a54"
}
```

2.17.1.1.4 Request signatures

KMS authenticates each access request. Therefore, a request must contain signature information whether submitted using HTTP or HTTPS. KMS performs symmetric encryption using the AccessKey ID and AccessKey Secret to verify the identity of a request sender. The AccessKey ID and AccessKey Secret are issued to visitors by Alibaba Cloud. The AccessKey ID indicates the identity of the visitor. The AccessKey Secret is used to encrypt signature strings and verify signature strings on the server. It must be kept strictly confidential.

Perform the following steps to sign an access request:

1. Use request parameters to construct the canonicalized query string.
 - a. Sort parameters. Sort all request parameters by name in alphabetic order. These parameters include **common request parameters** and customized API request parameters , but do not include the **Signature parameter** in the **common request parameters**.

**Note:**

When you use the GET method to submit requests, specify these parameters in the request URI following the question mark (?) and connect the remaining parameters with ampersands (&).

- b. Encode parameters. The parameter names and values must be encoded using UTF-8. The URL encoding rules are described as follows:
 - Uppercase letters (A to Z), lowercase letters (a to z), digits (0 to 9), hyphens (-), underscores (_), periods (.), and tildes (~) are not encoded.
 - Other characters are encoded in the %XY format, where XY is the hexadecimal representation of the character in ASCII. For example, double quotation marks (") are encoded as %22.
 - Extended UTF-8 characters are encoded in the %XY%ZA... format.
 - A space is encoded as %20, instead of the plus sign (+).

**Note:**

This encoding method is similar to but different from the application/x-www-form-urlencoded MIME encoding algorithm (such as the java.net.URLEncoder class provided by the Java standard library). You can encode the names and values following the method for the standard library, then replace the plus signs (+) in the encoded strings with %20, the asterisks (*) with %2A, and change %7E back to the tilde (~) to conform to the encoding rules described above. You can implement this algorithm by using the following percentEncode() method:

```
private static final String ENCODING = "UTF-8";

private static String percentEncode(String value) throws UnsupportedEncodingException {
    return value != null ? URLEncoder.encode(value, ENCODING).replace("+", "%20")
        .replace("*", "%2A").replace("%7E", "~") : null;
}
```

- c. Connect the encoded parameter names and values with equal signs (=).
 - d. Sort the equal sign-connected parameter pairs in alphabetical order, and connect them with ampersands (&) to produce a canonicalized query string.
2. Use the created canonicalized query string to construct a string for signature calculation based on the following rule:

```
StringToSign=
  HTTPMethod + "&" +
  percentEncode( "/" ) + "&" +
  percentEncode(CanonicalizedQueryString)
```

- In the preceding example, HTTPMethod indicates that an HTTP-style request such as GET is submitted.
 - percentEncode("/") is the encoded value (%2F) of a forward slash (/). The encoding follows the URL encoding rules described in the previous step. percentEncode (CanonicalizedQueryString) is the encoded string of the canonicalized query string. The encoding follows the URL encoding rules described in the preceding step.
3. Use the signature string to calculate the HMAC value of the signature as defined by [RFC 2104](#).

**Note:**

The key used for signature calculation is your **AccessKey Secret**. An ampersand (&, ASCII: 38) is added to the end of the key. The SHA-1 hashing algorithm is used.

4. Encode the HMAC value into a string based on Base64 encoding rules to obtain the signature value.
5. Add the obtained signature value to the request as the **Signature** parameter to sign the request.

**Note:**

When the signature value is submitted to the KMS server as the final request parameter value, the value will be URL encoded like other parameters based on [RFC 3986](#).

Taking DescribeRegions as an example, the **AccessKey ID**testid and**AccessKey Secret** testsecretare used. The request URL before being signed is: `http://kms.example.com/?TimeStamp=2016-02-23T12:46:24Z&Format=XML&AccessKeyId=testid&Action=`

```
DescribeRegions&SignatureMethod=HMAC-SHA1&SignatureNonce=3ee8c1b8-83d3-44af-
-a94f-4e0ad82fd6cf&Version=2014-05-26&SignatureVersion=1.0
```

The corresponding **StringToSign** is:

```
GET&%2F&AccessKeyId%3Dtestid%26Action%3DDescribeRegions%26Format%3DXML
%26SignatureMethod%3DHMAC-SHA1%26SignatureNonce%3D3ee8c1b8-83d3-44af-
a94f-4e0ad82fd6cf%26SignatureVersion%3D1.0%26TimeStamp%3D2016-02-23T12%
253A46%253A24Z%26Version%3D2014-05-26
```

Because **AccessKey Secret** is testsecret, the Key used for HMAC calculation is testsecret&. The calculated signature value is: CT9X0VtwR86fNWSnsc6v8YGOju****.

Add the signature value to the URL request as the Signature parameter. The URL is:
http://kms.example.com/?SignatureVersion=1.0&Action=DescribeRegions&Format=XML&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf&Version=2014-05-26&AccessKeyId=testid&Signature=CT9X0VtwR86fNWSnsc6v8YGOju****&SignatureMethod=HMAC-SHA1&TimeStamp=2016-02-23T12%3A46%3A24Z.

2.17.1.1.5 Responses

After you make an API request, the system will return an HTTP status code. If the request is successful, the system returns a 2xx error code. If the request has failed, the system returns a 4xx or 5xx error code. For a successful request, the response is in JSON format. If you make an API request by using third-party tools, you can customize the response format in the request parameters. In this reference, line breaks are used in the response examples for readability.

Sample success responses

XML format

```
<? xml version="1.0" encoding="UTF-8"? >
<!--The root node of the response -->
<Operation name+Response>
  <!--Returned request ID-->
  <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
  <!--Returned results-->
</Operation name+response>
```

JSON format

```
{
  "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
  /*Returned results*/
}
```

```
}
```

Sample error responses

If an error occurs during an API call, the system will not return any results. You can troubleshoot the error based on the error code returned. Error codes can be divided into API-specific and common error codes.

When an error occurs on an HTTP request, the system returns HTTP status code 4xx or 5xx. The response body includes the error code and error message. It also includes a globally unique request ID (RequestId), and the ID of the site accessed by the request (HostId). If the cause of the error cannot be identified, you can contact Alibaba Cloud technical support personnel and provide the HostId and RequestId returned in the error.

XML format

```
<KMS>
<HttpStatus>400</HttpStatus>
<Code>IllegalTimestamp</Code>
<Message>The input parameter "Timestamp" that is mandatory for processing this request is not supplied. </Message>
<RequestId>3b237773-bc2c-4bea-95fc-319a1a5baa68</RequestId>
</KMS>
```

JSON format

```
{
  "HttpStatus": 400
  "Code": "IllegalTimestamp"
  "Message": "The input parameter "Timestamp" that is mandatory for processing this request is not supplied."
  "RequestId": "e85db688-a2d3-44ca-9790-4259f59e90d8"
}
```

Common error codes

Error code	Error message	HTTP status code
InternalFailure	Internal Failure	500
ServiceUnavailableTemporary	Service Unavailable Temporary	503
InvalidAccessKeyId.NotFound	The AccessKey ID provided does not exist in our records.	404
Forbidden.KeyNotFound	The specified Key is not found.	404
Forbidden.AliasNotFound	The specified Alias is not found.	404

Error code	Error message	HTTP status code
Forbidden.NoPermission	This operation is forbidden by permission system.	403
Forbidden.AccessKey	This AccessKey is not enabled.	403
UnsupportedHTTPMethod	This http method is not supported.	403
Forbidden.UbsmsInvalidUserid	Userid Invalid For Ubsms	403
Forbidden.UbsmsInvalidBid	Your account partner does not have KMS Service	403
Forbidden.KmsServiceNotEnabled	Kms service is not Enabled for current user. Please get access permission first	403
Forbidden.ProhibitedByRiskControl	Current user is Prohibited By Risk Control	403
Forbidden.InDebtOverdue	Current user is indebted Overdue	403
Forbidden.InDebt	Current user is indebted	403
ParseRequestParameterException	Server parse parameters exception. Please check your input params.	400
MissingParameter	The parameter "< parameter name >" is needed but not provided.	400
InvalidParameter	The specified parameter "< parameter name >" is not valid.	400
IncompleteSignature	The request signature does not conform to Alibaba Cloud standards.	400
IllegalTimestamp	The input parameter "Timestamp" that is required for processing this request is not supplied.	400
Rejected.LimitExceeded	The request was rejected because user create resource limit was exceeded.	400

Error code	Error message	HTTP status code
AliasAlreadyExists	AliasName Already Exists	400
InvalidKeyMaterial	key material is invalid	400
InvalidImportToken	import token is invalid	400
ExpiredImportToken	import token is expired	400
Unsupported.Origin	This key origin is not valid for this api	400
Unsupported.Alias	Alias is not valid for this api	400
Rejected.StateModifiedFailed	Keystate modified failed	409
Rejected.Disabled	The request was rejected because the key state is Disabled	409
Rejected.PendingDeletion	The request was rejected because the key state is PendingDeletion	409
Rejected.PendingImport	The request was rejected because the key state is PendingImport	409

2.17.1.2 Use RAM to authorize KMS resources

A Customer Master Key (CMK) that you create is your own resource.

You have full operation permissions on resources that you own, and can use APIs to perform operations on them by default.

You can use an Apsara Stack tenant account to create RAM users. Unauthorized RAM users cannot operate on resources owned by an Apsara Stack tenant account. RAM users must be granted permission to access resources owned by an Apsara Stack tenant account through RAM authorization.

Before you authorize a RAM user to access a CMK, be sure to read and understand the RAM and API documentation.

KMS resource types that can be authorized in RAM

The ARN formats for the two types of KMS key resources are as follows:

```
acs:kms:${region-id}:${resource-owner-id}:key/${key-uuid}
```

```
acs:kms:${region-id}:${resource-owner-id}:key
```

KMS operations

Operations available in KMS are as follows:

- Create a secret

CreateKey

- Generate a DEK

GenerateDataKey

- Encrypt data

Encrypt

- Decrypt data

Decrypt

- View key details

DescribeKey

- List keys

ListKeys

Mapping of actions and resources in the RAM authorization

[Table 2-536: Mapping of actions and resources in RAM authorization](#) lists the actions and resources.

Table 2-536: Mapping of actions and resources in RAM authorization

API	Action	Resource
CreateKey	kms:CreateKey	acs:kms:\$regionid:\${resource-owner-id}:key
ListKeys	kms:ListKeys	acs:kms:\$regionid:\${resource-owner-id}:key
GenerateDataKey	kms:GenerateDataKey	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}
Encrypt	kms:Encrypt	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}
Decrypt	kms:Decrypt	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}

API	Action	Resource
DescribeKey	kms:DescribeKey	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}
EnableKey	kms:EnableKey	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}
DisableKey	kms:DisableKey	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}
ScheduleKeyDeletion	kms:ScheduleKeyDeletion	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}
CancelKeyDeletion	kms:CancelKeyDeletion	acs:kms:\$regionid:\${resource-owner-id}:key/\${keyid}

2.17.1.3 Encryption Context

Functions of Encryption Context

Encryption Context is a JSON string in the string-string format that may be used to protect data integrity in KMS APIs, such as Encrypt, GenerateDataKey, and Decrypt).

If this parameter is specified during encryption operations (Encrypt and GenerateDataKey), an equivalent parameter is also required to decrypt the ciphertext.

Encryption Context is related to decryption but it is not included in the encrypted CipherBlob

.

Valid value of Encryption Context

The Encryption Context can be a JSON string up to 8,192 characters in the string-string format.

Note:

When you call the preceding APIs to fill in Encryption Context, notice the escape character.

Examples:

- Valid Encryption Context

```
1. {"ValidKey": "ValidValue"}
2. {"Key1": "Value1", "Key2": "Value2"}
```

- Invalid Encryption Context

```
1. [{"Key": "Value"}] // json array
2. {"Key": 12345} //String-int
```

```
3. {"Key": ["value1", "value2"]} // String-array
```

Equivalent Encryption Context

In essence, Encryption Context is a hashtable map in the string-string format. Therefore, you only need to ensure that the key-value pairs indicated by the JSON string has the same meaning when Encryption Context is used as a parameter. In these cases, the Encryption Context is considered equivalent. You can use an equivalent Encryption Context to decrypt a ciphertext instead of the original string used for encryption.

Equivalent Encryption Context example:

```
{"Key1": "Value1", "Key2": "Value2"} is equivalent to {"Key2": "Value2", "Key1": "Value1"}
```

2.17.1.4 Impact of CMK states on API calls

In Key Management Service (KMS), each Customer Master Key (CMK) has three states: Enabled, Disabled, and PendingDeletion.

A new CMK is in the Enabled state by default. Only CMKs in the Enabled state can be used to encrypt and decrypt data. The expected responses of API calls vary depending on different key states.

[Table 2-537: Key status codes and the expected responses of API calls](#) lists the status codes and expected responses.

Table 2-537: Key status codes and the expected responses of API calls

Expected response	HTTP status code
Success	200
Rejected.Enabled	409
Rejected.Disabled	409
Rejected.PendingDeletion	409
Rejected.StateModifiedFailed	409

CMKs in the PendingDeletion state are permanently deleted after the scheduled period expires.

[Table 2-538: Key states and the expected responses of API calls](#) lists the states and expected responses.

Table 2-538: Key states and the expected responses of API calls

API	Enabled	Disabled	PendingDeletion
CreateKey	Success	Success	Success
GenerateDataKey	Success	Rejected.Disabled	Rejected.PendingDeletion
Encrypt	Success	Rejected.Disabled	Rejected.PendingDeletion
Decrypt	Success	Rejected.Disabled	Rejected.PendingDeletion
ListKeys	Success	Success	Success
DescribeKey	Success	Success	Success
EnableKey	Success	Success	Rejected.StateModifiedFailed
DisableKey	Success	Success	Rejected.StateModifiedFailed
ScheduleKeyDeletion	Success	Success	Rejected.StateModifiedFailed
CancelKeyDeletion	Rejected.StateModifiedFailed	Rejected.StateModifiedFailed	Success

2.17.1.5 API list

2.17.1.5.1 CancelKeyDeletion

You can call this operation to cancel the scheduled deletion of a CMK.

When the scheduled deletion of a CMK is canceled, the key returns to the Enabled state.

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK.

Response parameters

Name	Type	Description
RequestId	String	The ID of the request.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=CancelKeyDeletion
&KeyId=<cmkid>
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "RequestId": "3da5b8cc-8107-40ac-a170-793cd181d7b7"
}
```

XML format

```
//xml response
<KMS>
  <RequestId>3da5b8cc-8107-40ac-a170-793cd181d7b7</RequestId>
</KMS>
```

2.17.1.5.2 CreateKey

You can call this operation to create a CMK.

CMKs can be used to encrypt small strings of data, under 4 KB. Though these CMKs can be used to manually encrypt a DEK, in most cases you can call the **GenerateDataKey** API to generate DEKs. For more information about how to generate a DEK, see [GenerateDataKey](#).

Request parameters

Name	Type	Required	Description
Origin	String	Yes	The source of the CMK material. If it is set to External, you must import the CMK material.
Description	String	No	The description of the CMK. It must be 0 to 8,192 characters in length.
KeyUsage	String	No	The intended use of the CMK. Default value: ENCRYPT/DECRYPT.

Response parameters

Name	Type	Description
KeyMetadata	KeyMetadata	The metadata associated with the CMK.

KeyMetadata

Name	Type	Description
CreationDate	Timestamp	The date and time when the CMK is created, in the UTC format.
Description	String	The description of the CMK.
KeyId	String	The globally unique ID of the CMK.
KeyState	String	The state of the CMK.
KeyUsage	String	The intended use of the CMK . Default value: ENCRYPT/DECRYPT.
DeleteDate	Timestamp	The scheduled period before the CMK is deleted. - If this value is null, there is no deletion scheduled for the CMK. - This parameter is present only when KeyState is PendingDeletion.
Creator	String	The creator of the CMK.
Arn	String	The Alibaba Cloud resource name of the CMK.
Origin	String	The source of the CMK material.
MaterialExpireTime	String	The date and time when the key expires, in the UTC format. If this value is null, there is no expiration time for the CMK material.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=CreateKey
&Description=test
&KeyUsage=ENCRYPT/DECRYPT
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "KeyMetadata": {
    "CreationDate": "2016-03-25T10:42:40Z",
    "Description": "test",
    "KeyId": "*****",
    "KeyState": "Enabled",
    "KeyUsage": "ENCRYPT/DECRYPT",
    "DeleteDate": ""
  },
  "RequestId": "3455b9b4-95c1-419d-b310-db6a53b09a39"
}
```

XML format

```
//xml response
<KMS>
  <KeyMetadata>
    <CreationDate>2016-03-25T10:40:47Z</CreationDate>
    <Description>test</Description>
    <KeyId>*****</KeyId>
    <KeyState>Enabled</KeyState>
    <KeyUsage>ENCRYPT/DECRYPT</KeyUsage>
  </KeyMetadata>
  <RequestId>6cb4bf6b-d9c9-4660-af5f-2328378e7257</RequestId>
</KMS>
```

2.17.1.5.3 Decrypt

You can call this operation to decrypt the encrypted `CiphertextBlob` that is generated by the following APIs:

- [GenerateDataKey](#)
- [Encrypt](#)

Request parameters

Name	Type	Required	Description
CiphertextBlob	String	Yes	The ciphertext to be decrypted.
EncryptionContext	String	No	The JSON string of the key-value pair. If you specify this parameter in the <code>Encrypt</code> or <code>GenerateDataKey</code> API, you need to provide the same parameter before you can decrypt the ciphertext. For more information, see Encryption Context .

Response parameters

Name	Type	Description
KeyId	String	The globally unique ID of the CMK. It is the CMK ID used by the encrypted ciphertext.
Plaintext	String	The decrypted plaintext.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=Decrypt
&CiphertextBlob=<your ciphertextblob>
&EncryptionContext = <json string>
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "KeyId": "KeyId"
  "Plaintext": "Plaintext"
  "RequestId": "207596a2-36d3-4840-b1bd-f87044699bd7"
```

```
}
```

XML format

```
//xml response
<KMS>
  <KeyId>KeyId</KeyId>
  <Plaintext>Plaintext</Plaintext>
  <RequestId>4bd560a1-729e-45f1-a3d9-b2a33d61046b</RequestId>
</KMS>
```

2.17.1.5.4 DescribeKey

You can call this operation to return and view detailed information about a specified CMK.

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK. The API supports aliases.

Response parameters

Name	Type	Description
KeyMetadata	KeyMetadata	The metadata of the CMK.

KeyMetadata

Name	Type	Description
CreationDate	Timestamp	The date and time when the CMK is created, in the UTC format.
Description	String	The description of the CMK.
KeyId	String	The globally unique ID of the CMK.
KeyState	String	The state of the CMK.
KeyUsage	String	The intended use of the CMK.

Name	Type	Description
DeleteDate	Timestamp	The scheduled period before the CMK is deleted. For more information, see ScheduleKeyDeletion . This parameter is present only when KeyState is PendingDeletion.
Creator	String	The creator of the CMK.
Arn	String	The Alibaba Cloud resource name of the CMK.
Origin	String	The source of the CMK material.
MaterialExpireTime	String	The date and time when the key expires, in the UTC format. If this value is null, there is no expiration time for the CMK material.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=DescribeKey
&KeyId=<your-key-id>
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "KeyMetadata": {
    "CreationDate": "2016-03-25T10:42:40Z",
    "Description": "test",
    "KeyId": "*****",
    "KeyState": "Enabled",
    "KeyUsage": "ENCRYPT/DECRYPT",
    "DeleteDate": "",
    "Creator": "*****"
  },
  "RequestId": "3455b9b4-95c1-419d-b310-db6a53b09a39"
}
```

```

2.17.1.5.5 DescribeRegions

You can call this operation to view the list of regions.

Response parameters

Name	Type	Description
RegionId	String	The ID of the region.

Examples

Sample responses

JSON format

```
//json response
{
  "Regions": {
    "Region": [
      {
        "RegionId": "cn-beijing"
      },
      {
        "RegionId": "cn-zhangjiakou"
      },
      {
        "RegionId": "cn-hangzhou"
      }
    ]
  },
  "RequestId": "815240e2-aa37-4c26-9cca-05d4df3e8fe6"
}
```

XML format

```
//xml response
<KMS>
  <Regions>
    <Region>
      <RegionId>cn-beijing</RegionId>
    </Region>
    <Region>
      <RegionId>cn-zhangjiakou</RegionId>
    </Region>
  </Regions>
</KMS>
```

```
</Region>
<Region>
  <RegionId>cn-hangzhou</RegionId>
</Region>
</Regions>
<RequestId>f7f4f9d2-11f5-4710-bbdb-08ba27deb4b8</RequestId>
</KMS>
```

2.17.1.5.6 DisableKey

You can all this operation to disable a specified CMK. A disabled CMK cannot be used for encryption or decryption. A ciphertext key that was encrypted by a disabled CMK cannot be decrypted until the CMK is enabled again.

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK.

Response parameters

Name	Type	Description
RequestId	String	The ID of the request.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=DisableKey
&KeyId=<cmkid>
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "RequestId": "2fe70ce2-3303-4fd6-b3ac-472fb2705c62"
}
```

XML format

```
//xml response
<KMS>
  <RequestId>2fe70ce2-3303-4fd6-b3ac-472fb2705c62</RequestId>
```

</KMS>

2.17.1.5.7 EnableKey

You can call this operation to enable a specified CMK.

Request format

```
KeyId="string"
```

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK.

Response parameters

Name	Type	Description
RequestId	String	The ID of the request.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=EnableKey
&KeyId=<cmkid>
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "RequestId": "efb1cbbd-a093-4278-bc03-639dd4fcc207"
}
```

XML format

```
//xml response
<KMS>
  <RequestId>efb1cbbd-a093-4278-bc03-639dd4fcc207</RequestId>
</KMS>
```

2.17.1.5.8 Encrypt

You can call this operation to create a ciphertext DEK by encrypting a plaintext DEK using your CMK.

- Only data keys which do not exceed 4 KB in size can be encrypted, such as RSA keys, database keys, or other sensitive customer data.
- If you migrate encrypted data from one region to another, you can use this API to encrypt the DataKey plaintext to be used for encrypting data in the previous region. By doing this, you can provide an encrypted CiphertextBlob that is recognized by the new region and can be decrypted by calling the Decrypt API in the new region.

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK. The API supports aliases.
Plaintext	String	Yes	The plaintext key to be encrypted.
EncryptionContext	String to string map	No	The JSON string of the key-value pair. If you specify this parameter, you need to provide the same parameter when you call the Decrypt API. For more information, see Encryption Context .

Response parameters

Name	Type	Description
KeyId	String	The globally unique ID of the CMK. If you use an alias in the request, the CMK ID of the alias is returned.
CiphertextBlob	String	The encrypted ciphertext.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=Encrypt
&KeyId=<your-key-id>
&Plaintext=<data need encrypt>
&EncryptionContext=<json string>
```

&<Common request parameters>

Sample responses

JSON format

```
//json response
{
  "KeyId": "your-key-id",
  "CiphertextBlob": "CiphertextBlob",
  "RequestId": "475f1620-b9d3-4d35-b5c6-3fbdd941423d"
}
```

XML format

```
//xml response
<KMS>
  <KeyId>your-key-id</KeyId>
  <CiphertextBlob>CiphertextBlob</CiphertextBlob>
  <RequestId>475f1620-b9d3-4d35-b5c6-3fbdd941423d</RequestId>
</KMS>
```

2.17.1.5.9 GenerateDataKey

You can call this operation to create a DEK. You can then use this DEK to encrypt data locally

.

A Plaintext (the plaintext DEK) and a CiphertextBlob (the ciphertext DEK) are returned.

The DEK is encrypted by using the CMK that corresponds to the ID specified in the request.

You can call the `Decrypt` API to decrypt the DEK.

Notice:

We recommend that you encrypt data locally by using the following method:

- Call the `GenerateDataKey` API. Use the Plaintext to encrypt data locally and then delete the Plaintext from memory. Store the CiphertextBlob and the encrypted data.
- To decrypt data, call the `Decrypt` API and use the CiphertextBlob as a parameter. If the call is successful, the Plaintext is returned. Use the Plaintext to decrypt data locally.

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK. The API supports aliases. For more information, see Alias instructions .
KeySpec	String	No	The length and type of the DEK: AES_256 refers to a 256-bit symmetric key. AES_128 refers to a 128-bit symmetric key.
NumberOfBytes	Integer	No	The length of the data key in bytes. Valid values: 1 to 1,024.
EncryptionContext	String to string map	No	The JSON string of the key-value pair. If you specify this parameter, you need to provide the same parameter when you call the Decrypt API. For more information, see Encryption Context .

Response parameters

Name	Type	Description
KeyId	String	The globally unique ID of the CMK. If you use an alias in the request, the CMK ID of the alias is returned.
Plaintext	String	The plaintext DEK.
CiphertextBlob	String	The encrypted DEK.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=GenerateDataKey
&KeyId=<your-key-id>
&KeySpec=AES_256
&EncryptionContext={"Example":"Example"}
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "CiphertextBlob": "CiphertextBlob",
  "KeyId": "KeyId",
  "Plaintext": "Plaintext",
  "RequestId": "7021b6ec-4be7-4d3c-8a68-1e85d4d515a0"
}
```

XML format

```
//xml response
<KMS>
  <CiphertextBlob>CiphertextBlob</CiphertextBlob>
  <KeyId>KeyId</KeyId>
  <Plaintext>Plaintext</Plaintext>
  <RequestId>7021b6ec-4be7-4d3c-8a68-1e85d4d515a0</RequestId>
</KMS>
```

2.17.1.5.10 ListKeys

You can call this operation to list the IDs of all CMKs in your region.

Request parameters

Name	Type	Required	Description
PageNumber	Integer	No	The current page number. It must be an integer greater than 0. Default value : 1.
PageSize	Integer	No	The number of items on each page. It must be an integer greater than 0 but less than 101. Default value: 10.

Response parameters

Name	Type	Description
KeyId	String	The globally unique ID of the CMK.
TotalCount	Integer	The total number of CMKs.
PageNumber	Integer	The current page number.
PageSize	Integer	The number of items on each page.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=ListKeys
&PageNumber=1
&PageSize=10
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "Keys": {
    "Key": [
      {
        "KeyId": "key1"
      },
      {
        "KeyId": "key2"
      },
      {
        "KeyId": "key3"
      }
    ]
  },
  "TotalCount": 3,
  "PageNumber": 1,
  "PageSize": 10,
  "RequestId": "1fbcd12a-1b7f-468f-84a3-1ff3444dfd8b"
}
```

XML format

```
//xml response
<KMS>
  <Keys>
    <Key>
      <KeyId>key1</KeyId>
    </Key>
    <Key>
```

```

    <KeyId>key2</KeyId>
  </Key>
  <Key>
    <KeyId>key3</KeyId>
  </Key>
</Keys>
<TotalCount>3</TotalCount>
<PageNumber>1</PageNumber>
<PageSize>10</PageSize>
<RequestId>1050b8f1-b264-496d-a782-6299cbaf15f8</RequestId>
</KMS>

```

2.17.1.5.11 ScheduleKeyDeletion

You can call this operation to schedule CMK deletion.

- Before the scheduled period has expired,
 - the CMK is in the PendingDeletion state and cannot be used for encryption, decryption, or DEK generation.
 - We recommend that you use [DisableKey](#).
 - A deleted CMK cannot be restored, and the content encrypted and the DEK generated by using the CMK cannot be decrypted. Because of these risks, CMKs cannot be deleted directly and their deletion must be scheduled in advance.
- You must specify a scheduled period for CMK deletion. The period can range from 7 to 30 days, and the CMK will be deleted when the scheduled period expires. You can call the [CancelKeyDeletion](#) API to cancel the request after submission but before the end of the scheduled period.
- The key is guaranteed to be deleted within 24 hours after the scheduled period.

For example, suppose User A sends a request to delete a CMK at 14:00, September 10, 2016 with a scheduled period of seven days. KMS will delete the CMK within 24 hours after 14:00, September 17.

Request parameters

Name	Type	Required	Description
KeyId	String	Yes	The globally unique ID of the CMK.

Name	Type	Required	Description
PendingWindowInDays	Integer	Yes	The scheduled period, specified in number of days. During this period, the CMK is in the PendingDeletion state and the scheduled deletion can be canceled. After the period expires, the deletion cannot be canceled. Valid values: 7 to 30.

Response parameters

Name	Type	Description
RequestId	String	The ID of the request.

Examples

Sample request

```
https://kms.cn-hangzhou.example.com/?Action=ScheduleKeyDeletion
&KeyId=<your-key-id>
&PendingWindowInDays=[7~30]
&<Common request parameters>
```

Sample responses

JSON format

```
//json response
{
  "RequestId": "52ac67cb-3d3d-4ada-b4e2-7047660d3ce9"
}
```

XML format

```
//xml response
<KMS>
  <RequestId>52ac67cb-3d3d-4ada-b4e2-7047660d3ce9</RequestId>
```

</KMS>

2.17.2 SDK reference

2.17.2.1 Create an AccessKey pair

You can create an AccessKey pair in the Apsara Stack console.

2.17.2.2 SDK

Alibaba Cloud provides SDKs in the following four languages:

- [Java](#)
- [Python](#)
- [PHP](#)
- [C#](#)

For SDKs in other languages, go to [Third-party SDK services](#).

2.17.2.3 JAVA SDK sample code

Sample code

```

package com.alibaba.samples;

        System.out.println("Error message: " + eResponse.getErrMsg());
    }
    /**
     * Decrypt the cipher text and verify result with original plain text.
     */
    try {
        DecryptResponse decResponse = Decrypt(cipherBlob);
        System.out.println("Plaintext: " + decResponse.getPlaintext());
        String verifyPlainText = decResponse.getPlaintext();
        int isMatch = verifyPlainText.compareTo(plainText);
        System.out.println("KeyId: " + decResponse.getKeyId());
        System.out.println("=====");
        System.out.printf("Decrypt the cipher text success, result " + (isMatch == 0 ? "match"
            " : \"mismatch\" + \"\n\");
        System.out.println("=====\\n");
    } catch (ClientException eResponse) {
        System.out.println("Failed.");
        System.out.println("Error code: " + eResponse.getErrCode());
        System.out.println("Error message: " + eResponse.getErrMsg());
    }
}
}

```

Access KMS in a VPC environment

You must add a custom endpoint directing to a domain name in the VPC. You must also specify to use this endpoint when accessing KMS later.

```
DefaultProfile.addEndpoint("cn-hangzhou-vpc", "cn-hangzhou-vpc", "Kms", "kms-vpc.cn-hangzhou.aliyuncs.com"); //Add a custom endpoint.
```

2.17.2.4 Create an AccessKey pair

You can create an AccessKey pair in the Apsara Stack console.

2.17.2.5 SDK

Alibaba Cloud provides SDKs in the following four languages:

- [Java](#)
- [Python](#)
- [PHP](#)
- [C#](#)

For SDKs in other languages, go to [Third-party SDK services](#).

2.17.2.6 JAVA SDK sample code

Sample code

```

package com.alibaba.samples;
import java.util.*;
import java.util.List;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.exceptions.ClientException;

```

```

import com.aliyuncs.http.FormatType;
import com.aliyuncs.http.MethodType;
import com.aliyuncs.http.ProtocolType;
//Current KMS SDK version:2016-01-20

Access KMS in a VPC environment

You must add a custom endpoint directing to a domain name in the VPC. You must also specify to use this endpoint when accessing KMS later.

```
DefaultProfile.addEndpoint("cn-hangzhou-vpc", "cn-hangzhou-vpc", "Kms", "kms-vpc.cn-hangzhou.aliyuncs.com"); //Add a custom endpoint.
```

2.18 Apsara Stack DNS

2.18.1 Overview

2.18.1.1 Calling methods

You can use a pair of AccessKey ID and AccessKey Secret to call API operations. You can use SDKs of different languages, or create a client based on the signature description provided by the POP gateway.

2.18.1.2 Supported formats

- AccessKey ID and AccessKey Secret of an Apsara Stack tenant account
- Temporary AccessKey ID and AccessKey Secret of an Apsara Stack tenant account
- AccessKey ID and AccessKey Secret of a RAM user account
- Temporary AccessKey ID and AccessKey Secret of a RAM user account

2.18.1.3 Instructions

- The AccessKey ID is used to identify users.
- The AccessKey Secret is used to compute the request signature.

2.18.1.4 Time format

Unless otherwise specified, the time string is a UTC+0 time in the format of YYYY-MM-DDTHH:mm:ssZ. For example, 2018-01-16T09:00:01Z indicates 17:00:01 on January 16, 2018, in China Standard Time (UTC+8).

2.18.2 List of operations by function

DNS V2.0 provides the following API operations.

API	Description
ObtainGlobalAuthZoneList	Obtains global authoritative zones

API	Description
ObtainGlobalAuthRecordList	Obtains global authoritative RRsets
AddGlobalRrSet	Adds global RRsets
DeleteGlobalRrSet	Deletes global RRsets
UpdateGlobalRrSet	Updates global RRsets
RemarkGlobalRrSet	Configures descriptions for global RRsets

2.18.3 Prerequisites

2.18.3.1 Obtain an AccessKey pair

You can obtain an AccessKey pair in the Apsara Stack console.

Obtain an AccessKey pair of a department

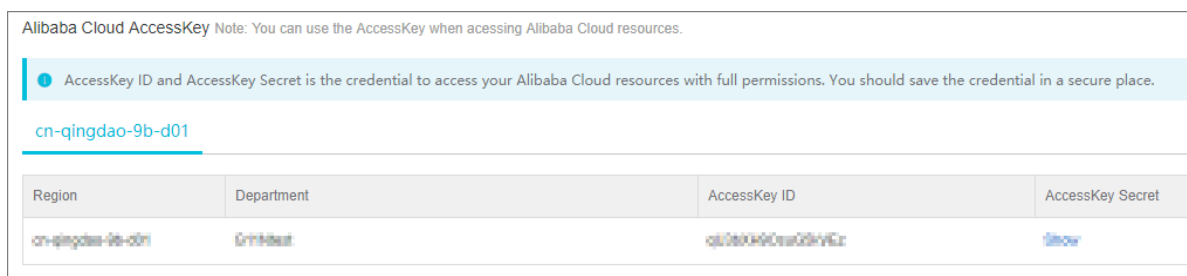

To obtain an AccessKey pair of a department, follow these steps:

1. Log on to the Apsara Stack console as an administrator.
2. In the top navigation bar, click  and choose **User Center > Department Management**.
3. On the Department Management page that appears, select a department for which you want to obtain an AccessKey pair, and click **Get AccessKey**.

Obtain an AccessKey pair of a personal account

To obtain an AccessKey pair of a personal account, follow these steps:

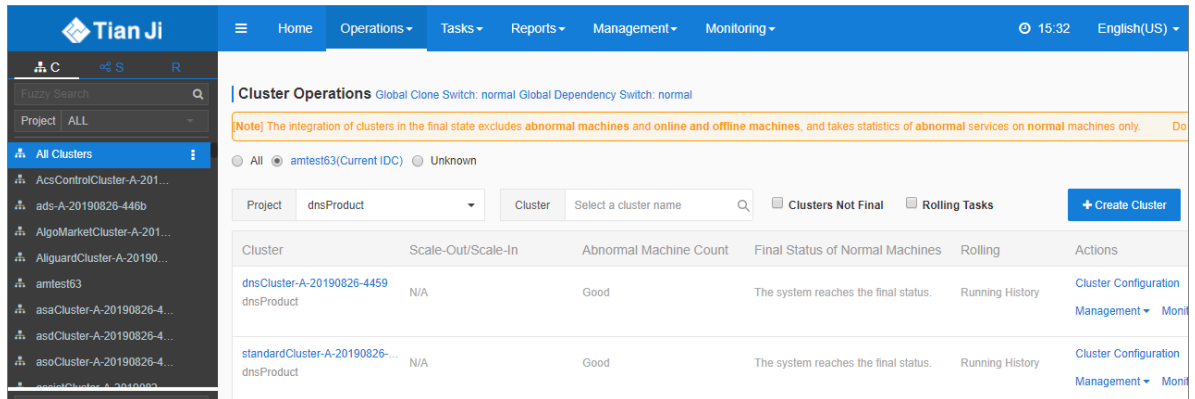

1. Log on to the Apsara Stack console as an administrator.
2. In the upper-right corner of the home page, move the pointer over the profile image and click **Personal Information**.
3. On the Personal Information page, locate the AccessKey ID in the **Alibaba Cloud AccessKey** section.

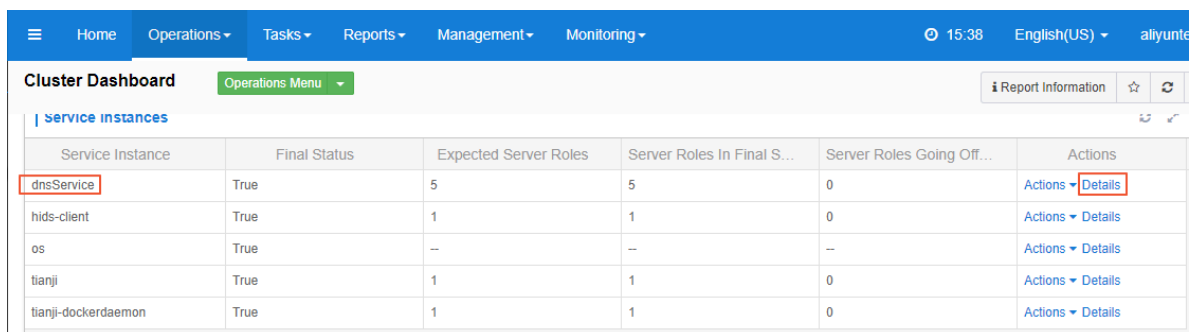

2.18.3.2 Obtain an endpoint

Procedure

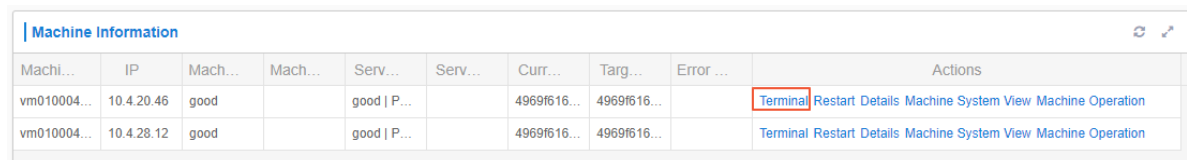

1. Log on to the Apsara Infrastructure Management Framework console as an administrator.
2. In the top navigation bar, choose Operations > Cluster Operations. On the Cluster Operations page, select **dnsProduct** from the Project drop-down list. Click a cluster name in the Cluster column to go to the Cluster Dashboard page.

3. In the Service Instances section, click **Details** in the Actions column of dnsService. The Service Instance Information Dashboard page opens. In the Server Role List section, click Details in the Actions column of dnsServerRole#.

4. On the Server Role Dashboard page, click **Terminal** in the Actions column of a machine to go to the console.

5. Run the `sudo docker ps -l` command to obtain the ID of the current container.
6. Run the `sudo docker inspect ${container id} | grep env` command to obtain the endpoint of the current environment.

The endpoint is the value corresponding to `pop_out_endpoint` (the character string starting with "api.").

2.18.4 SDK example

2.18.4.1 Create a client

You need to specify a region ID, AccessKey ID, and AccessKey Secret to create a client.

Go SDK

```
1. if client, err := genesisdns.NewClientWithAccessKey(RegionId, AccessKey, AccessSecret); err == nil {
2.     //Write your code for processing normal requests.
3. } else {
4.     //Write your code for processing creation failures.
5. }
```

Python SDK

```
1. from aliyunsdkcore.client import AcsClient
2. from aliyunsdkcore.acs_exception.exceptions import ClientException
3. from aliyunsdkcore.acs_exception.exceptions import ServerException
4.
5.
6. client = AcsClient("<access-key-id>",
7.     "<access-key-secret>",
8.     "<region-id>");
```

Java SDK

```
1. public static void main(String[] args) {
2.     DefaultProfile profile = DefaultProfile.getProfile("{regionid}","{ak}", "{secret}");
3.     IAcsClient client = new DefaultAcsClient(profile);
4. }
```

2.18.4.2 Obtain global authoritative zones

Go SDK

```
1. if client, err := genesisdns.NewClientWithAccessKey("{regionid}","{ak}", "{secret}"); err == nil {
2.     request := genesisdns.CreateObtainGlobalAuthZoneListRequest()
3.     request.SetDomain("{endpoint}")
4.     if response, err := client.ObtainGlobalAuthZoneList(request); err == nil {
5.         fmt.Println(response.ZoneList)
6.     }
7. }
```

Python SDK

```
1. client = AcsClient("{ak}", "{secret}", "{regionid}");
2.
3. request = ObtainGlobalAuthZoneListRequest.ObtainGlobalAuthZoneListRequest()
4. request.set_PageSize(10)
5. region_provider.modify_point("GenesisDns", "{regionid}","{endpoint}")
6. try:
7.     response = client.do_action_with_exception(request)
8.     print(response)
9. except ServerException as e:
```

```

10. print(e)
11. except ClientException as e:
12.     print(e)

```

Java SDK

```

1. public static void main(String[] args) {
2.     DefaultProfile profile = DefaultProfile.getProfile("{regionid}", "{ak}", "{secret}");
3.     IAcsClient client = new DefaultAcsClient(profile);
4.     ObtainGlobalAuthZoneListRequest request = new ObtainGlobalAuthZoneListRequest();
5.     try {
6.         request.setEndpoint("{endpoint}");
7.         request.setConnectTimeout(1000);
8.         request.setReadTimeout(1000);
9.         request.setPageSize(10);
10.        ObtainGlobalAuthZoneListResponse response = client.getAcsResponse(request);
11.        System.out.println(JSON.toJSONString(response.getZoneList()));
12.    } catch (Exception ex) {
13.        System.out.println(ex.getMessage());
14.    }
15. }

```

2.18.4.3 Obtain global authoritative RRsets

Go SDK

```

1. if client, err := genesisdns.NewClientWithAccessKey("{regionid}", "{ak}", "{secret}"); err == nil {
2.     request := genesisdns.CreateObtainGlobalAuthRecordListRequest()
3.     request.SetDomain("{endpoint}")
4.     request.Id = requests.Integer("{zone id}")
5.     if response, err := client.ObtainGlobalAuthRecordList(request); err == nil {
6.         fmt.Println(response.Records)
7.     }
8. }

```

Python SDK

```

1. from aliyunsdkcore.client import AcsClient
2. from aliyunsdkcore.profile import region_provider
3. from aliyunsdkcore.acs_exception.exceptions import ClientException
4. from aliyunsdkcore.acs_exception.exceptions import ServerException
5. from aliyunsdkgenesisdns.request.v20180925 import ObtainGlobalAuthRecordListRequest
6.
7. client = AcsClient("{ak}", "{secret}", "{regionid}")
8.
9. request = ObtainGlobalAuthRecordListRequest.ObtainGlobalAuthRecordListRequest()
10. request.set_PageSize(10)
11. request.set_Id("{zone id}")
12. region_provider.modify_point("GenesisDns", "{regionid}", "{endpoint}")
13. try:
14.     response = client.do_action_with_exception(request)
15.     print(response)
16. except ServerException as e:
17.     print(e)
18. except ClientException as e:

```

```
19. print(e)
```

Java SDK

```
1. public static void main(String[] args) {
2.     DefaultProfile profile = DefaultProfile.getProfile("{regionid}", "{ak}", "{secret}");
3.     IAcsClient client = new DefaultAcsClient(profile);
4.     ObtainGlobalAuthRecordListRequest request = new ObtainGlobalAuthRecordListRequest();
5.     try {
6.         request.setEndpoint("{endpoint}");
7.         request.setConnectTimeout(1000);
8.         request.setReadTimeout(1000);
9.         request.setPageSize(10);
10.        request.setId(Long.parseLong("{zone id}"));
11.        ObtainGlobalAuthRecordListResponse response = client.getAcsResponse(request);
12.        System.out.println(JSON.toJSONString(response.getRecords()));
13.    } catch (Exception ex) {
14.        System.out.println(ex.getMessage());
15.    }
16. }
```

2.18.4.4 Add global RRsets

The following examples describe how a Resource Record Set (RRSet) is defined.

```
1. request.RrSet = "[\"2001:0:0:0:0:0:0:1\"]" //A RRSet with an AAAA record
2. request.RrSet = "[\"2001:0:0:0:0:0:0:1\", \"2001::2\"]" //A RRSet with two AAAA records
3. request.RrSet = "[\"2001:0:0:0:0:0:0:1 10\", \"2001::2 10\"]" //A RRSet with two weighted AAAA records
4. request.Type = "AAAA"
5.
6. request.RrSet = "[\"www.aliyun.com. \"]" //A RRSet with a CNAME record
7. request.RrSet = "[\"www.aliyun.com. 10\", \"www.taobao.com 30\"]" //A RRSet with two weighted CNAME records
8. request.Type = "CNAME"
9.
10. request.RrSet = "[\"10 mailserver1.example.com. \"]" //A RRSet with an MX record
11. request.Type = "MX"
12.
13. request.RrSet = "[\"10 mailserver1.example.com.\", \"20 mailserver2.example.com. \"]" //A RRSet with two MX records
14. request.RrSet = "[\"v=spf1 ip4:192.168.0.1/16 ip6:2001::1/96 ~all\"]" //A RRSet with a TXT record
15. request.Type = "TXT"
16.
17. request.RrSet = "[\"1 10 8080 www1.example.com.\", \"2 20 8081 www2.example.com. \"]" //A RRSet with two SRV records
18. request.Type = "SRV"
19.
20. request.RrSet = "[\"100 50 \\\"S\\\" \\\"Z3950+I2L+I2C\\\" \\\"_z3950._tcp.example.com. \"]" //A RRSet with a NAPTR record
21. request.Type = "NAPTR"
22.
